Motivation and Inspiration

The main motivation for development of the FEI system, comprised of these lecture notes and accompanying modeling tools, computational libraries and visualization tools, is to help research and teach modeling and simulation for civil engineering mechanics problems. Focus is on development and use of methods that reduce Kolmogorov complexity and modeling uncertainty. In other words, focus is on development and use of methods that predict and inform rather than fit. These lecture notes, in particular, are being developed to document research, teaching and practical problem solving work for Real-ESSI problems (Realistic modeling and simulation of Earthquakes, Soils, Structures and their Interaction). Almost all of the theories, formulations and algorithms described here can be directly analyzed using Real-ESSI Simulator system (`http://real-essi.info/` ; `http://real-essi.us/`) on local computers or on Cloud Computers (Amazon Web Services, AWS, on Marketplace, search for ESSI). A number of theories and formulations, related to Real-ESSI problems, developed by us and others, as referenced, are collected within these Lecture Notes in order to have one location, one write-up, with all/most necessary material for the analysis of ESSI problems. These Lecture Notes are in perpetual development, and chapters and sections are being edited and added as you read this. In that sense, these Lecture Notes are not "polished" and there are some rough edges, however improvement work is underway.

Work on these lecture notes was inspired by a number of books and lecture notes that I have enjoyed over many years, (Bathe, 1982), (Bathe and Wilson, 1976), (Felippa, 1992b, 1989, 1993; Felippa and Park, 1995), (Willam, 1993), (Sture, 1993), (Lubliner, 1990), (Crisfield, 1991), (Chen and Han, 1988a), (Zienkiewicz and Taylor, 1991a,b), (Argyris and Mlejnek, 1991), (Malvern, 1969), (Saouma, 1992-2013), (Dunica and Kolundžija, 1986), (Kojić, 1997), (Hjelmstad, 1997), (Oberkampf et al., 2002). I particularly enjoyed book by Bathe (1982), the only one I had partial access to in the late '80s, with all the examples that could be worked out on paper. In '89 I managed to purchase a used book by Zienkiewicz (1977) for US$50, from my first salary as a young engineer in Energoprojekt Company, from a colleague. In the early '90s, I was lucky to get exposed to early, draft versions of books by Kojić (1993); Kojić (1997). Few years later, I enjoyed lectures and lecture notes by Felippa (1992b, 1989, 1993); Felippa and Park (1995), Willam (1993), and Sture (1993).

Current version of lecture notes, the one in front of you, aims to extend concepts described by my Teachers and Professors. Presented formulations and implementations are available within the Real-ESSI Simulator `http://real-essi.info/`, `http://real-essi.us/`. A number of available, provided models, some very simple, some more sophisticated, and some very sophisticated, can be analyzed and results visualized using Real-ESSI Simulator on local computers or on Cloud Computers (Amazon Web Services, AWS).

Dedication

This book is dedicated to friends, colleagues, supporters, promoters that I had a privilege to know and work with over last many years, and that are not with us anymore.
May they rest in peace!

Robert P. Kennedy, 1939-2018

"Response of a soil structure system is nonlinear, and I would really like to know what that response is!"
"There are engineers and then there are Engineers!"

Nebojša Orbović, Небојша Орбовић, 1962-2021

"As an engineer, I have to know, with good accuracy, what will happen to the structure during loading, and will use modeling and analysis to find out, hence verification and validation for modeling and analysis is really important"
"As an engineer, I have to know what are response sensitivities to modeling parameters."

Contributions

Useful contributions were also made by the following students, colleagues and collaborators (other than those listed on the front page): Mr. Babak Kamranimoghadam (بابک کامرانی), Mr. Chang-Gyun Jeong (정창균), Mr. Chao Luo (罗超), Mr. Max Sieber, Mr. Antonio Felipe Salazar, and Mr. Borko Miladinović (Борко Миладиновић).

Comments

Comments, corrections, edits &c. are much appreciated! Special thanks to (in chronological order): Miroslav Živković (Мирослав Живковић), Dmitry J. Nicolsky, Andrzej Niemunis, Robbie Jaeger, Yiorgos Perikleous (Γιώργος Περικλέους), Robert Roche, Viktor Vlaski, Edison Lam, Dr. Sukumar Baishya, Marco Andreini, Francisco "Paco" Beltran.

The best way to send a comment on these lecture notes is by email, however please read the following NOTE about sending an email to me. It would be great if you can place the following in the subject line of your email: `Draft CompMech Lecture Notes`. This will be much appreciated as it will help me filter your email and place it in Draft_CompMech_Lecture_Notes email-box that I regularly read.

Acknowledgement

Many developments described in these lecture notes, developed over many years, were made possible in collaborators with, and with financial support from the: US-DOE, US-NRC, CNSC/CCSN, US-NSF, CalTrans, CH-ENSI/IFSN, ATC/US-FEMA, UN-IAEA, US-ACE, and NASA. Their support and collaboration is much appreciated!

Software

Theoretical and computational developments described in these lecture notes are implemented in a program Real-ESSI Simulator (`http://real-essi.info/`; (`http://real-essi.us/`; `http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/`). The Real ESSI Simulator (Realistic Modeling and Simulation of Earthquakes, Soils, Structures and their Interaction), (pronunciation of ESSI is similar to easy, as in "as easy as pie") is a software, hardware and documentation system for select level of fidelity (high, low, intermediate), high performance, time domain, nonlinear/inelastic, deterministic or probabilistic, 3D, finite element modeling and simulation of

- statics and dynamics of soil,
- statics and dynamics of rock,
- statics and dynamics of structures,
- statics of soil-structure systems, and
- dynamics of earthquake-soil-structure system interaction.

The Real-ESSI Simulator systems is used for the analysis, design and assessment of static and dynamic behavior of infrastructure objects, including buildings, bridges, dams, nuclear energy installations, tunnels, etc. The Real-ESSI Simulator develops modeling and simulations that inform and predict.

The Real-ESSI Simulator program is available in source, in executable form and as debian package at `http://real-essi.info/`, `http://real-essi.us/`. The Real ESSI Simulator system is also available for use on Amazon Web Services Market Place, search for "Real ESSI" or "MS ESSI".

The name Real-ESSI, is explained in some detail in section 201.2.6 on page 710.

Distribution?

These Lecture Notes can be downloaded and distributed worldwide. If you use these Lecture Notes, please cite them as:

101.1 Chapter Summary and Highlights

101.2 On Modeling

Modeling of mechanical behaviour of civil engineering problems is performed using models. It is important to note that everything we do for design or assessment is based on models. Models can range from very simple to very sophisticated.

Simple Model Example. For example, simple model for the strength of a beam, as developed by Leonardo da Vinci and noted by Timoshenko (1953), states: "In every article that is supported, but is free to bend, and is of uniform cross section and material, the part that is farthest from the support will bend the most." Leonardo da Vinci suggested a number of tests with variation in beam length and keeping the same cross section, and record what loads could these beams carry. He concluded that strength of beams supported on both ends, simple beams, varies inversely proportional to teh beam length and directly to the beam width.

This simple model for beam bending, as stated, is based directly on observations of experiments. These experiments represent the physics discovery experiments.

Sophisticated Model Example. The same simple beam problem can be analyzed using a sophisticated Bernoulli or Timoshenko beam finite elements, or even using 3D solid brick elements.

The importance of computer analysis for design and performance assessment of civil engineering systems has recently dramatically increased. With availability of fast, inexpensive computers, and availability of numerical analysis programs, computer analysis of civil engineering systems for design and for assessment of performance is commonly used. It is important to note that failure of civil engineering systems has high consequences. For safe and economical design and for assessment of performance (reliability, robustness and safety) of civil engineering systems, engineers have to perform proper analysis, usually a numerical, computer analysis.

Developers of computer analysis software, computational analysts/engineers and users of numerical analysis face a critical question: How should confidence in analysis results be critically assessed?

Verification and Validation (V&V) of computational analysis is the major process for assessing and quantifying this confidence. Verification is the assessment of the software correctness and numerical accuracy of the solution to a given computational model. Validation is the assessment of physical accuracy of a computational model based on comparisons between computation simulation and experimental data. For verification, the association or relationship of the simulation to the real world is not an issue while for validation the relationship between computation and real world external data is the issue. Verification and validation are covered in much more detail in part 300 of this book, on pages after page 1436.

101.2.1 The Performance Challenge

Computational science challenges (Post, 2004):

- The Performance Challenge
- The Programming Challenge
- The Prediction Challenge

Parallel computing, development of portable Distributed Memory Parallel (DMP) applications, spedifically Architecture Aware Plastic Domain Decomposition (AAPDD) Method (Feng et al., 2024) that addresses the challenge of multiple CPUs, multiple cores, multiple GPUs, multiple networks, etc.

The Programming Challenge.

Quality controlled, managed program development...

The Prediction Challenge

Epistemic, modeling uncertainties

Aliatory, parametric uncertainties

Development of numerical modeling tools for engineers to develop a hierarchy of models, to explore, try, different levels of modeling sophistication in order to understand, gain insight into the influence of epistemic/modeling uncertainty on analysis and to propagate aleatory/parametric uncertainty through models...

101.2.2 Analysis Governance

Analysis governance, sometimes also called simulations governance[1] (Szabó and Actis, 2011, 2012), is a very important components of numerical analysis in civil engineering.

Analysis governance is a process of increasing confidence in numerical analysis results. Analysis governance covers both

- Numerical analysis tools, the program that is used for analysis

---

[1] Analysis consists of modeling, the physics component, and simulation, the numerics component, hence analysis covers both modeling and simulation components (Analysis = Modeling + Simulation).

- Numerical analyst, expert engineer that is performing the analysis

The numerical analysis program has to be extensively verified and validated.

Numerical analyst, expert engineer has to have required level of expertise, knowledge, experience and, if possible, has to be certified to perform required analysis.

101.3 Specialization to Computational Mechanics

In this section we start from general mechanics and specialize our interest toward the field of computational mechanics (this is based on great lecture notes by Prof. Carlos Felippa (Felippa, 1993)):

101.3.1 Mechanics

- Theoretical
- Applied
- Computational
    - Nanomechanics
    - Micromechanics
    - Continuum Mechanics
        - Solids and Structures
        - Fluids
        - Multiphysics
    - Systems
- Experimental

101.3.2 Continuum Mechanics

- Statics
    - Time invariant
    - Transient (quasi-statics)
- Dynamics

101.3.3 Statics and Dynamics

- Linear
- Nonlinear
    - Elastic
    - Inelastic

101.3.4 Discretization Methods

- Finite Element Method (FEM)
  - FEM Formulation
    - Displacement
    - Equilibrium
    - Mixed
    - Hybrid
  - FEM Solution
    - Stiffness
    - Flexibility
    - Mixed
- Boundary Element Method
- Finite Difference Method
- Finite Volume Method
- Spectral Method
- Mesh-Free Method

101.3.5 The Solution Morass

A system of 1000 linear equations has one solution.

A system of 1000 cubic equations has $3^{1000} \approx 10^{477}$ solutions.

It is worth putting this number in prospective: number of atoms in the earth is about 10^{50}, and a number of atoms in the universe is about 10^{78} (Niemunis, 2015 –).

Solution: Continuation or Incremental analysis!

101.3.6 Smooth Nonlinearities

- Finite deflections
- Nonlinear elasticity
- Follower forces

101.3.7 Rough Nonlinearities

- Elasto-plasticity
- Contact/Interface/Joint
- Interface/joint Friction

101.4 Tour of Computational Mechanics

In this section we describe various examples of equilibrium path and set up basic terminology.

101.4.1 Equilibrium Path

101.4.2 Special Equilibrium Points

101.4.2.1 Critical Points

Limit Points

Bifurcation Points

101.4.2.2 Turning Points

101.4.2.3 Failure Points

101.4.3 Generalized Response

101.4.4 Sources of Nonlinearities

Tonti Diagrams

101.4.5 Simulation Process: Loading Stages, Increments and Iterations

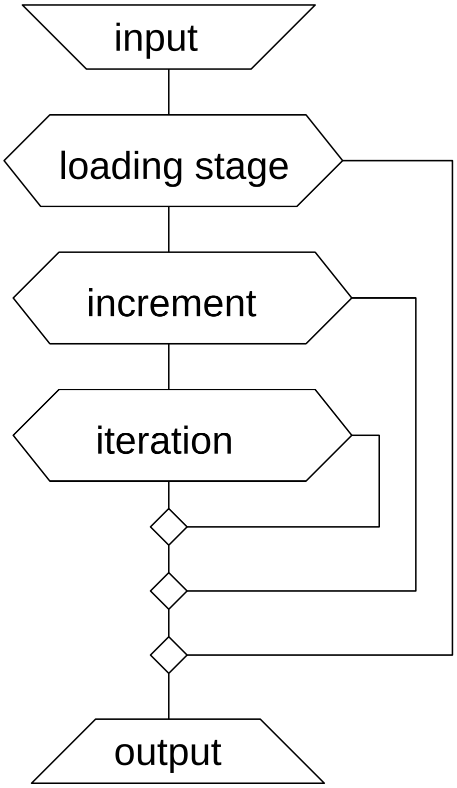

Figure 101.1: Nonlinear analysis loading stages, loading increments, equilibrium iterations.

Chapter 102

Finite Elements Formulation

(1989-1994-1999-2005-2010-2011-2012-2013-2015-2016-2017-2018-2019-2020-2021-)

(In collaboration with Dr. Zhao Cheng, Dr. Nima Tafazzoli, Prof. José Abell, Dr. Yuan Feng. Prof. Han Yang)

102.1 Chapter Summary and Highlights

This section uses basic principles of mechanics to derive finite element equations. We start with general setup, assuming large deformation in section 102.2, and then proceed to develop finite element formulation for small deformations in section 102.3 on page 104 . Further investigation of large deformation formulation is given in chapter 106 on page 482.

102.2 Formulation of the Continuum Mechanics Incremental Equations of Motion

This section follows Bathe (1982), Felippa (1989) and Felippa (1993).

Assume that a 3D solid is analyzed in a fixed Cartesian coordinate system, Figure (102.1). Also, assume that the solid can undergo large displacements and rotations, large strains, and nonlinear or inelastic constitutive response. The main aim is to evaluate the equilibrium of solid at discrete times $0, \Delta t, 2\Delta t, \ldots$, where Δt is an increment in time. To do that, a continuation strategy is used. That is, assume that the solution for all the variables (generalized displacements, strain, stress, forces, etc.) is available, was solved for, for all time steps from 0 to time t. Solution for the next time step $t + \Delta t$ will be based on already obtained solution from the previous time step, at time t, (Felippa, 1993). This approach will be applied for each time step, repetitively until the solution for all time steps is obtained.

In following all parts of the solid, as they undergo displacements and rotations, from the original configuration to the final configuration, adopted is a Lagrangian (or material) formulation of the problem. This approach is contrasting Eulerian (or spatial) formulation , usually used in the analysis of fluid mechanics problems.

In the Lagrangian incremental analysis approach the equilibrium of the solid at time $t+\Delta t$ is expressed using the principle of virtual displacements. Using tensorial notation[1] this principle requires that:

$$\int_{{}^{t+\Delta t}V} {}^{t+\Delta t}\sigma_{ij} \; \delta \; {}_{t+\Delta t}\epsilon_{ij} \; {}^{t+\Delta t}dV = {}^{t+\Delta t}\mathcal{R} \tag{102.1}$$

where the ${}^{t+\Delta t}\sigma_{ij}$ are Cartesian components of the Cauchy stress tensor, see section 701.2.1 on page 2860, the ${}_{t+\Delta t}\epsilon_{ij}$ are the Cartesian components of an infinitesimal strain tensor, see section 701.2.2 on page 2863, and the δ means "variation in" i.e.:

---

[1] Einstein's summation rule is implied unless stated differently, all lower case indices $(i, j, p, q, m, n, o, r, s, t, \ldots\ )$ can have values of 1, 2, 3, and values for capital letter indices will be specified where need be.

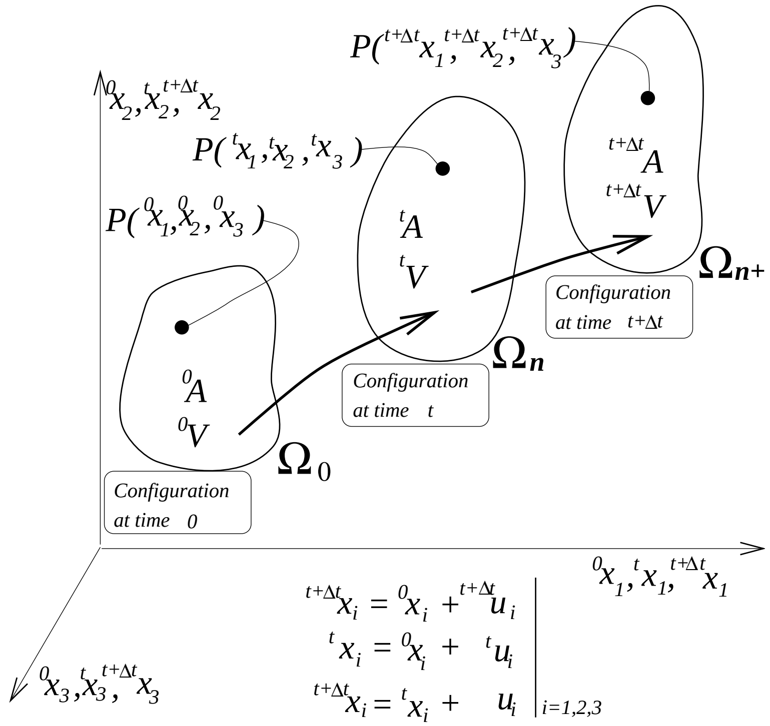

Figure 102.1: Motion of solid in a Cartesian coordinate system.

$$\delta\ {}_{t+\Delta t}\epsilon_{ij} = \delta\frac{1}{2}\left(\frac{\partial u_i}{\partial\ {}^{t+\Delta t}x_j}+\frac{\partial u_j}{\partial\ {}^{t+\Delta t}x_i}\right) = \frac{1}{2}\left(\frac{\partial\delta u_i}{\partial\ {}^{t+\Delta t}x_j}+\frac{\partial\delta u_j}{\partial\ {}^{t+\Delta t}x_i}\right) \qquad (102.2)$$

It should be noted that Cauchy stresses are "body forces per unit area" in the configuration at time $t+\Delta t$, and the infinitesimal strain components are also referred to this as yet unknown configuration. The right hand side of equation (102.1), i.e. ${}^{t+\Delta t}\mathcal{R}$ is the virtual work performed when the solid is subjected to a virtual displacement at time $t+\Delta t$:

$${}^{t+\Delta t}\mathcal{R} = \int_{{}^{t+\Delta t}V}\left({}^{t+\Delta t}f_i^B - \rho\ddot{u}_i^{t+\Delta t}\right)\ \delta u_i^{t+\Delta t}\ {}^{t+\Delta t}dV + \int_{{}^{t+\Delta t}S} {}^{t+\Delta t}f_i^S\ \delta u_i^{t+\Delta t}\ {}^{t+\Delta t}dS$$

where ${}^{t+\Delta t}f_i^B$ and ${}^{t+\Delta t}f_i^S$ are the components of the externally applied body and surface force vectors, respectively, and $-\rho\ddot{u}_i{}^{t+\Delta t}$ is the inertial body force that is present if accelerations are present[2], δu_i is the ith component of the virtual displacement vector.

The main problem in applying equation (102.1) is that the configuration of the solid at a time $t+\Delta t$ is unknown. The continuous change in the configuration, deformation of the solid needs to be properly

---

[2] This is based on D'Alembert's principle (D'Alembert, 1758).

modeled. As an example, consider, for example, Cauchy stress at time $t + \Delta t$. This stress cannot be obtained by adding to the Cauchy stresses at time t, a stress increment that is due only to material deformation. The reason is that material might rotate, and stress state is a function of tractions (loads) and size and orientation of differentially small faces on which stress components act. For material only nonlinear analysis, the of large displacements, large rotations and large strain will be neglected. Large displacements, rotations and large strains will be addressed in more detail in Chapter 106 on page 482.

The continuous change in the configuration of the solid is dealt with by using appropriate stress and strain measures and constitutive relations. When solving the general problem[3] one possible approach is given in Simo (1988). The previous discussion was oriented toward small deformation, small-displacement analysis leading to the use of Cauchy stress tensor σ_{ij} and small strain tensor ϵ_{ij}.

In the following, covered briefly are other stress and strain measures particularly useful in large strain and large displacement analysis. More detailed description of large displacements, large rotations and large strains problems is addressed in Chapter 106 on page 482.

The solution is sought for equation 102.1, which expresses the equilibrium and compatibility requirements of the general solid considered in the configuration corresponding to time $t + \Delta t$. The nonlinear or inelastic behavior of material enters equation 102.1 through the stress-strain constitutive equations. In general, the solid can undergo large displacements, large rotations large strains, and since constitutive relations are nonlinear, the relation in equation 102.1 cannot be solved directly. However, an approximate solution can be obtained by referring all variables to a previously calculated known equilibrium configuration, and linearizing the resulting equations. Iterations can then improve this solution.

To develop the governing equations for the approximate solution obtained by linearization, recall that the solutions for time $0, \Delta t, 2\Delta t, \ldots, t$ have already been calculated and that the Piola–Kirchhoff stress tensor is energy conjugate to the Green–Lagrange strain tensor:

$$\int_{{}^0V} {}^t_0S_{ij}\; \delta^t_0\epsilon_{ij}\; {}^0dV = \int_{{}^0V} \left(\frac{{}^0\rho}{{}^t\rho}\; {}^0_t x_{i,m}\; {}^t\sigma_{mn}\; {}^0_t x_{j,n} \right) \left({}^t_0 x_{k,i}\; \delta^t_t\epsilon_{kl}\; {}^t_0\, x_{l,j} \right)\; {}^0dV = \int_{{}^0V} \frac{{}^0\rho}{{}^t\rho}\; {}^t\sigma_{mn}\; \delta^t_0\epsilon_{mn}\; {}^0dV \tag{102.3}$$

since

$${}^t_0x_{k,l}\,{}^0_t x_{l,m} = \delta_{km}$$

and

---

[3] That is, large displacements, large rotations, large deformations and material nonlinear and/or inelastic.

$$ {}_{0}\rho \; {}^{0}dV = {}^{t}\rho \, {}^{t}dV $$

one obtains

$$ \int_{^{0}V} {}^{t}_{0}S_{ij} \; \delta^{t}_{0}\epsilon_{ij} \; {}^{0}dV = \int_{^{0}V} {}^{t}\sigma_{mn} \; \delta^{t}_{t}\epsilon_{mn} \; {}^{t}dV \tag{102.4} $$

where 2nd Piola–Kirchhoff stress tensor is defined as:

$$ {}^{t}_{0}S_{ij} = \frac{{}^{0}\rho}{{}^{t}\rho} \; {}^{0}_{t}x_{i,m} \; {}^{t}\sigma_{mn} \; {}^{0}_{t}x_{j,n} \tag{102.5} $$

and ${}^{0}_{t}x_{j,n} = \frac{\partial^{0}x_i}{\partial^{t}x_m}$, and $\frac{{}^{0}\rho}{{}^{t}\rho}$ represents the ratio of the mass density at time 0 and time t, and the Green–Lagrange strain is defined as:

$$ {}^{t}_{0}\epsilon_{ij} = \frac{1}{2}\left({}^{t}_{0}u_{i,j} + {}^{t}_{0}u_{j,i} + {}^{t}_{0}u_{k,i} \; {}^{t}_{0}u_{k,j} \right) \tag{102.6} $$

By employing equation 102.4 stresses and strains are referenced to the known equilibrium configuration. The choice lies between two formulations, named (a)total Lagrangian and (b) updated Lagrangian formulations.

For the total Lagrangian formulations, all static and kinematic variables are referenced to the initial configuration at time 0. On the other hand, for the updated Lagrangian formulation, all static and kinematic variables are referenced to the previous step equilibrium configuration at time t. Both the total Lagrangian and updated Lagrangian formulations include all kinematic nonlinear effects due to large displacement, large rotations, and large strains. Whether the large strain behavior is modeled appropriately depends on the constitutive relations specified. The only advantage of using one over the other formulation lies in numerical efficiency.

Using equation 102.4 in the total Lagrangian formulation, considered is this equation:

$$ \int_{^{0}V} {}^{t+\Delta t}_{0}S_{ij} \; \delta^{t+\Delta t}_{0}\epsilon_{ij} \; {}^{0}dV = {}^{t+\Delta t}\mathcal{R} \tag{102.7} $$

while in the updated Lagrangian formulation considered is this equation:

$$ \int_{^{t}V} {}^{t+\Delta t}_{t}S_{ij} \; \delta^{t+\Delta t}_{t}\epsilon_{ij} \; {}^{t}dV = {}^{t+\Delta t}\mathcal{R} \tag{102.8} $$

where ${}^{t+\Delta t}\mathcal{R}$ is the external virtual work as defined in equation ??. Approximate solution to the equation 102.7 and equation 102.8 can be obtained by linearization. Comparison of the total Lagrangian and updated Lagrangian formulations reveal that they are quite similar, with the difference in the choice of different reference configurations for kinematic and static variables. If in the numerical solution the appropriate constitutive tensors are employed, identical results should be obtained.

102.3 Finite Element Discretization

Consider the equilibrium of a general three–dimensional solid such as in Figure (102.2) (Bathe, 1996). The external forces acting on a solid are surface tractions f_i^S and body forces f_i^B. Displacements are u_i and strain tensor[4] is ϵ_{ij} and the stress tensor corresponding to strain tensor is σ_{ij}.

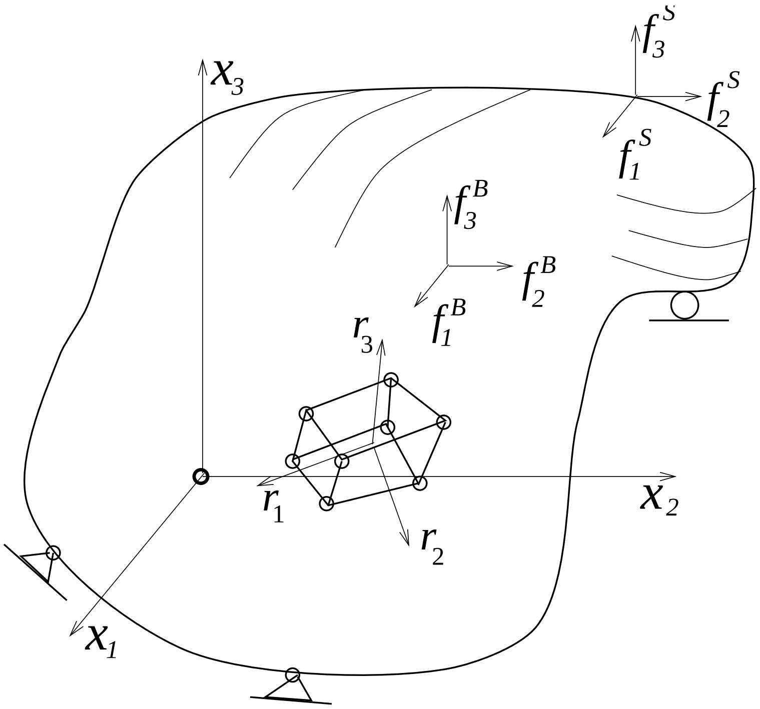

Figure 102.2: General three dimensional solid.

Dynamic equilibrium equation is given as

$$\sigma_{ij,j} = f_i - \rho \ddot{u}_i \tag{102.9}$$

where $\sigma_{ij,j}$ is a small deformation (Cauchy) stress tensor, f_i are external (body (f_i^B) and surface (f_i^S)) forces, ρ is material density and $\ddot{u}_i$ are accelerations. Inertial forces $\rho \ddot{u}_i$ follow from D'Alembert's principle

---

[4] small strain tensor as defined in equation: $\epsilon_{ij} = \frac{1}{2}\left(u_{i,j} + u_{j,i}\right)$.

(D'Alembert, 1758). The above equation can be premultiplied with virtual displacements δu_i and then integrated by parts to obtain the weak form, as further elaborated below.

For a given solid, loaded with external forces, with prescribed supports solution for displacements, strains and stresses are sought. The principle of virtual displacements (PVD) can be used to find a solution. Using PVD, equilibrium is achieved if the total internal virtual work is equal to the total external virtual work, for any compatible, small virtual displacements, that satisfy the essential boundary conditions.

Mathematically this is expressed using equation 102.10 for the solid at time $t + \Delta t$. Since the incremental approach is used, a time dimension is dropped so that all the equations are applied for the given increment[5], at time $t + \Delta t$. The equation is now, using tensorial notation[6]:

$$\int_V \sigma_{ij} \; \delta\epsilon_{ij} \; dV = \int_V \left(f_i^B - \rho \ddot{u}_i \right) \; \delta u_i \; dV + \int_S f_i^S \; \delta u_i \; dS \tag{102.10}$$

The internal work given on the left side of (102.10) is equal to the actual stresses σ_{ij} going through the virtual strains $\delta\epsilon_{ij}$ that corresponds to the imposed virtual displacements. The external work is on the right side of (102.10) and is equal to the actual surface forces f_i^S and body forces $f_i^B - \rho\ddot{u}_i$ going through the virtual displacements δu_i.

It is noted virtual strains used in equationi 102.10 correspond to the imposed virtual displacements that can be represented by any compatible set of displacements that satisfy the geometric boundary conditions. The equation 102.10 is an expression of equilibrium, and for different virtual displacements, correspondingly, different equations of equilibrium are obtained. Equation 102.10 also contains the compatibility and constitutive requirements. Displacements should be continuous and compatible and should satisfy the displacement boundary conditions, and the stresses should be evaluated from the strains using appropriate constitutive relations. Thus, the principle of virtual displacements contains all requirements that need to be fulfilled to analyze a problem in solid and structural mechanics. The principle of virtual displacements can be directly related to the principle that the total potential Π of the system must be stationary.

In the finite element analysis, approximation for the solid in Figure 102.2 is done by creating an assemblage of discrete finite elements with the elements connected at nodal points. The displacements measured in a local coordinate system r_1, r_2 and r_3 within each element are assumed to be a function of the displacements at the N finite element nodal points:

---

[5] $t + \Delta t$ will be dropped from now one in this chapter.

[6] Einstein's summation rule is implied unless stated differently, all lower case indices $(i, j, p, q, m, n, o, r, s, t, \dots)$ can have values of 1, 2, 3, and values for capital letter indices will be specified where need be.

$$u_i \approx \hat{u}_a = H_I \bar{u}_{Ia} \tag{102.11}$$

where $I = 1, 2, 3, \ldots, n$ and n is number of nodes in a specific element, $a = 1, 2, 3$ represents a number of dimensions (can be 1 or 2 or 3). Real displacement field u_i is approximated with approximate displacement field $\hat{u}_a$, and H_I represent displacement interpolation functions, $\bar{u}_{Ia}$ is the tensor of global approximate generalized displacement components at all element nodes. The term generalized displacements mean that both translations, rotations, or any other nodal unknown are modeled independently. Here specifically, only translational degrees of freedom are considered. The strain tensor is defined as:

$$\epsilon_{ab} = \frac{1}{2}\left(u_{a,b} + u_{b,a}\right) \tag{102.12}$$

and by using equation 102.11, approximate strain tensor can be defined as:

$$\begin{aligned} \epsilon_{ab} \;\approx\; \hat{e}_{ab} \;&=\; \frac{1}{2}\left(\hat{u}_{a,b} + \hat{u}_{b,a}\right) = \\ &=\; \frac{1}{2}\left((H_I\ \bar{u}_{Ia})_{,b} + (H_I\ \bar{u}_{Ib})_{,a}\right) = \\ &=\; \frac{1}{2}\left(\left(H_{I,b}\ \bar{u}_{Ia}\right) + \left(H_{I,a}\ \bar{u}_{Ib}\right)\right) \end{aligned} \tag{102.13}$$

The most general stress-strain relationship[7] for an isotropic material is:

$$\hat{\sigma}_{ab} = E_{abcd}\left(\hat{e}_{cd} - \epsilon^0_{cd}\right) + \sigma^0_{ab} \tag{102.14}$$

where $\hat{\sigma}_{ab}$ is the approximate Cauchy stress tensor, E_{abcd} is the constitutive tensor[8], $\hat{e}_{cd}$ is the infinitesimal approximate strain tensor, ϵ^0_{cd} is the infinitesimal initial strain tensor and σ^0_{ab} is the initial Cauchy stress tensor.

Using the assumption of the displacements within each finite element, as expressed in equation 102.11, equilibrium equations that correspond to nodal point displacements of the assemblage of finite elements can be derived. Equation 102.10 can be rewritten as a sum[9] of integrations over the volume and areas of all finite elements:

$$\bigcup_m \int_{V^m} \hat{\sigma}_{ab}\ \delta\hat{e}_{ab}\ dV^m = \bigcup_m \int_{V^m} \left(f^B_a - \rho\ddot{u}_a\right)\ \delta\hat{u}_a\ dV^m + \bigcup_m \int_{S^m} f^S_a\ \delta\hat{u}^S_a\ dS^m$$

---

[7] in terms of exact stress and strain fields, but it holds for approximate fields as well.

[8] This tensor can be elastic or elastoplastic constitutive tensor.

[9] Or, more correctly as a union $\bigcup_m$ since we are integrating over the union of elements.

where $m = 1, 2, 3, \ldots, k$ and k is the number of elements. It is important to note that the integrations in (??) are performed over the element volumes and surfaces, and that for convenience different element coordinate systems may be used in the calculations. If we substitute equations 102.11, 102.12, 102.13 and 102.14 in ??, it follows:

$$\bigcup_m \int_{V^m} \left(E_{abcd} \left(\hat{e}_{cd} - \epsilon^0_{cd} \right) + \sigma^0_{ab} \right) \; \delta \left(\frac{1}{2} \left(H_{I,b} \; \bar{u}_{Ia} + H_{I,a} \; \bar{u}_{Ib} \right) \right) \; dV^m = \\ \bigcup_m \int_{V^m} f^B_a \; \delta \left(H_I \bar{u}_{Ia} \right) \; dV^m - \bigcup_m \int_{V^m} H_J \; \ddot{u}_{Ja} \; \rho \; \delta \left(H_I \bar{u}_{Ia} \right) \; dV^m + \bigcup_m \int_{S^m} f^S_a \; \delta \left(H_I \bar{u}_{Ia} \right) \; dS^m \tag{102.15}$$

or:

$$\bigcup_m \int_{V^m} \left(E_{abcd} \left(\left(\frac{1}{2} \left(H_{J,d} \; \bar{u}_{Jc} + H_{J,c} \; \bar{u}_{Jd} \right) \right) - \epsilon^0_{cd} \right) + \sigma^0_{ab} \right) \; \delta \left(\frac{1}{2} \left(H_{I,b} \; \bar{u}_{Ia} + H_{I,a} \; \bar{u}_{Ib} \right) \right) \; dV^m = \\ = \bigcup_m \int_{V^m} f^B_a \; \delta \left(H_I \bar{u}_{Ia} \right) \; dV^m - \bigcup_m \int_{V^m} H_J \; \ddot{u}_{Ja} \; \rho \; \delta \left(H_I \bar{u}_{Ia} \right) \; dV^m + \bigcup_m \int_{S^m} f^S_a \; \delta \left(H_I \bar{u}_{Ia} \right) \; dS^m \tag{102.16}$$

We can observe that δ in the previous equations represents a virtual quantity, but the rules for δ are quite similar to regular differentiation so that δ can enter the brackets and "virtualize" the nodal displacement[10]. It thus follows:

$$\bigcup_m \int_{V^m} \left(E_{abcd} \left(\left(\frac{1}{2} \left(H_{J,d} \; \bar{u}_{Jc} + H_{J,c} \; \bar{u}_{Jd} \right) \right) - \epsilon^0_{cd} \right) + \sigma^0_{ab} \right) \; \left(\frac{1}{2} \left(H_{I,b} \; \delta\bar{u}_{Ia} + H_{I,a} \; \delta\bar{u}_{Ib} \right) \right) \; dV^m = \\ = \bigcup_m \int_{V^m} f^B_a \; \left(H_I \delta\bar{u}_{Ia} \right) \; dV^m - \bigcup_m \int_{V^m} H_J \; \ddot{u}_{Ja} \; \rho \; \left(H_I \delta\bar{u}_{Ia} \right) \; dV^m + \bigcup_m \int_{S^m} f^S_a \; \left(H_I \delta\bar{u}_{Ia} \right) \; dS^m \tag{102.17}$$

Let us now work out some algebra on the left-hand side of the equation (102.17):

$$\bigcup_m \int_{V^m} \left(E_{abcd} \left(\frac{\left(H_{J,d} \; \bar{u}_{Jc} + H_{J,c} \; \bar{u}_{Jd} \right)}{2} \right) - E_{abcd} \epsilon^0_{cd} + \sigma^0_{ab} \right) \; \left(\frac{\left(H_{I,b} \; \delta\bar{u}_{Ia} + H_{I,a} \; \delta\bar{u}_{Ib} \right)}{2} \right) \; dV^m = \\ = \bigcup_m \int_{V^m} f^B_a \; \left(H_I \delta\bar{u}_{Ia} \right) \; dV^m - \bigcup_m \int_{V^m} H_J \; \ddot{u}_{Ja} \; \rho \; H_I \delta\bar{u}_{Ia} \; dV^m + \bigcup_m \int_{S^m} f^S_a \; \left(H_I \delta\bar{u}_{Ia} \right) \; dS^m \tag{102.18}$$

and further:

---

[10] since they are driving variables that define the overall displacement field through interpolation functions

$$
\begin{aligned}
\bigcup_m \int_{V^m} \left(\left(\frac{1}{2} \left(H_{J,d}\; \bar{u}_{Jc} + H_{J,c}\; \bar{u}_{Jd} \right) \right)\; E_{abcd}\; \left(\frac{1}{2} \left(H_{I,b}\; \delta\bar{u}_{Ia} + H_{I,a}\; \delta\bar{u}_{Ib} \right) \right) \right)\; dV^m + \\
+ \bigcup_m \int_{V^m} \left(-E_{abcd}\; \epsilon^0_{cd}\; \left(\frac{1}{2} \left(H_{I,b}\; \delta\bar{u}_{Ia} + H_{I,a}\; \delta\bar{u}_{Ib} \right) \right) \right)\; dV^m + \\
+ \bigcup_m \int_{V^m} \left(\sigma^0_{ab} \right)\; \left(\frac{1}{2} \left(H_{I,b}\; \delta\bar{u}_{Ia} + H_{I,a}\; \delta\bar{u}_{Ib} \right) \right)\; dV^m = \\
\bigcup_m \int_{V^m} f^B_a\; \left(H_I \delta\bar{u}_{Ia} \right)\; dV^m \\
- \bigcup_m \int_{V^m} H_J\; \ddot{\bar{u}}_{Ja}\; \rho\; H_I \delta\bar{u}_{Ia}\; dV^m \\
+ \bigcup_m \int_{S^m} f^S_a\; \left(H_I \delta\bar{u}_{Ia} \right)\; dS^m
\end{aligned}
\qquad (102.19)
$$

Several things should be observed in the equation (102.19). Namely, the first three lines in the equation can be simplified if one takes into account symmetries of E_{ijkl} and σ_{ij}. In the case of the elastic stiffness tensor E_{ijkl} major and both minor symmetries exist. In the case of the elastoplastic stiffness tensor, such symmetries exist if a flow rule is associated. If the flow rule is non–associated, only minor symmetries exist while major symmetry is destroyed[11]. As a matter of fact, both minor symmetries in E_{ijkl} are the only symmetries needed, and the first line of (102.19) can be rewritten as:

$$
\begin{aligned}
& \bigcup_m \int_{V^m} \left(\left(\frac{1}{2} \left(H_{J,d}\; \bar{u}_{Jc} + H_{J,c}\; \bar{u}_{jd} \right) \right)\; E_{abcd}\; \left(\frac{1}{2} \left(H_{I,b}\; \delta\bar{u}_{Ia} + H_{I,a}\; \delta\bar{u}_{Ib} \right) \right) \right)\; dV^m = \\
= & \bigcup_m \int_{V^m} \left(H_{J,d}\; \bar{u}_{Jc} \right)\; E_{abcd}\; \left(H_{I,b}\; \delta\bar{u}_{Ia} \right)\; dV^m = \\
= & \bigcup_m \int_{V^m} \left(H_{I,b}\; \delta\bar{u}_{Ia} \right)\; E_{abcd}\; \left(H_{J,d}\; \bar{u}_{Jc} \right)\; dV^m
\end{aligned}
\qquad (102.20)
$$

Similar simplifications are possible in the second and third line of the equation (102.19). Namely, in the second line both minor symmetries of E_{ijkl} can be used so that:

---

[11] for more on stiffness tensor symmetries, see sections (104.6.1, 104.3 and 104.4)

$$\begin{aligned} & \bigcup_m \int_{V^m} \left(-E_{abcd}\;\epsilon^0_{cd}\;\left(\frac{1}{2}\left(H_{I,b}\;\delta\bar{u}_{Ia} + H_{I,a}\;\delta\bar{u}_{Ib}\right)\right)\right)\;dV^m = \\ = \;& \bigcup_m \int_{V^m} \left(-E_{abcd}\;\epsilon^0_{cd}\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\right)\;dV^m \end{aligned} \tag{102.21}$$

and the third line can be simplified due to the symmetry in Cauchy stress tensor σ_{ij} as:

$$\begin{aligned} & \bigcup_m \int_{V^m} \left(\sigma^0_{ab}\right)\;\left(\frac{1}{2}\left(H_{I,b}\;\delta\bar{u}_{Ia} + H_{I,a}\;\delta\bar{u}_{Ib}\right)\right)\;dV^m = \\ = \;& \bigcup_m \int_{V^m} \left(\sigma^0_{ab}\right)\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\;dV^m \end{aligned} \tag{102.22}$$

After these simplifications, equation (102.19) looks like this:

$$\begin{aligned} & \bigcup_m \int_{V^m} \left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\;E_{abcd}\;\left(H_{J,d}\;\bar{u}_{Jc}\right)\;dV^m + \\ + \;& \bigcup_m \int_{V^m} \left(-E_{abcd}\;\epsilon^0_{cd}\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\right)\;dV^m + \bigcup_m \int_{V^m} \left(\sigma^0_{ab}\right)\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\;dV^m = \\ = \;& \bigcup_m \int_{V^m} f^B_a\;\left(H_I\delta\bar{u}_{Ia}\right)\;dV^m - \bigcup_m \int_{V^m} H_J\;\ddot{\bar{u}}_{Ja}\;\rho\;H_I\delta\bar{u}_{Ia}\;dV^m + \bigcup_m \int_{S^m} f^S_a\;\left(H_I\delta\bar{u}_{Ia}\right)\;dS^m \end{aligned} \tag{102.23}$$

or if unknown nodal accelerations[12] $\ddot{\bar{u}}_{Jc}$ and displacements $\bar{u}_{Jc}$ are left on the left hand side and all known quantities are moved to the right hand side:

$$\begin{aligned} & \bigcup_m \int_{V^m} H_J\;\delta_{ac}\;\ddot{\bar{u}}_{Jc}\;\rho\;H_I\delta\bar{u}_{Ia}\;dV^m + \bigcup_m \int_{V^m} \left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\;E_{abcd}\;\left(H_{J,d}\;\bar{u}_{Jc}\right)\;dV^m = \\ = \;& \bigcup_m \int_{V^m} f^B_a\;\left(H_I\delta\bar{u}_{Ia}\right)\;dV^m + \bigcup_m \int_{S^m} f^S_a\;\left(H_I\delta\bar{u}_{Ia}\right)\;dS^m + \\ + \;& \bigcup_m \int_{V^m} \left(E_{abcd}\;\epsilon^0_{cd}\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\right)\;dV^m - \bigcup_m \int_{V^m} \left(\sigma^0_{ab}\right)\;\left(H_{I,b}\;\delta\bar{u}_{Ia}\right)\;dV^m \end{aligned} \tag{102.24}$$

To obtain the equation for the unknown nodal generalized displacements from equation 102.24, invoke the virtual displacement theorem. This theorem states that virtual displacements are any, non

---

[12] It is noted that $\ddot{\bar{u}}_{Jc} = \delta_{ac}\ddot{\bar{u}}_{Ja}$ relationship was used here, where δ_{ac} is the Kronecker delta.

zero, kinematically admissible displacements. In that case, we can factor out nodal virtual displacements $\delta\bar{u}_{Ia}$ so that equation 102.24 becomes:

$$\begin{aligned}
&\left[\bigcup_m \int_{V^m} H_J\ \delta_{ac}\ \ddot{\bar{u}}_{Jc}\ \rho\ H_I\ dV^m + \bigcup_m \int_{V^m} \left(H_{I,b}\right)\ E_{abcd}\ \left(H_{J,d}\ \bar{u}_{Jc}\right)\ dV^m\right]\ \delta\bar{u}_{Ia} = \\
= &\bigcup_m \left[\int_{V^m} f_a^B\ H_I\ dV^m\right] \delta\bar{u}_{Ia} + \bigcup_m \left[\int_{S^m} f_a^S\ H_I\ dS^m\right] \delta\bar{u}_{Ia} + \\
+ &\bigcup_m \left[\int_{V^m} \left(E_{abcd}\ \epsilon_{cd}^0\ H_{I,b}\right)\ dV^m\right] \delta\bar{u}_{Ia} - \bigcup_m \left[\int_{V^m} \left(\sigma_{ab}^0\right)\ H_{I,b}\ dV^m\right] \delta\bar{u}_{Ia}
\end{aligned} \tag{102.25}$$

and now just cancel $\delta\bar{u}_{Ia}$ on both sides:

$$\begin{aligned}
&\bigcup_m \int_{V^m} H_J\ \ \delta_{ac}\ \rho\ H_I\ \ddot{\bar{u}}_{Jc} dV^m + \\
&\bigcup_m \int_{V^m} \left(H_{I,b}\right)\ E_{abcd}\ \left(H_{J,d}\ \bar{u}_{Jc}\right)\ dV^m = \\
= &\bigcup_m \int_{V^m} f_a^B\ H_I\ dV^m + \bigcup_m \int_{S^m} f_a^S\ H_I\ dS^m + \\
+ &\bigcup_m \int_{V^m} \left(E_{abcd}\ \epsilon_{cd}^0\ H_{I,b}\right)\ dV^m - \bigcup_m \int_{V^m} \left(\sigma_{ab}^0\right)\ H_{I,b}\ dV^m
\end{aligned} \tag{102.26}$$

One should also observe that in the first line of equation (102.26) generalized nodal accelerations $\ddot{\bar{u}}_{Jc}$ and generalized nodal displacements $\bar{u}_{Jc}$ are unknowns that are not subjected to integration so they can be factored out of the integral:

$$\begin{aligned}
&\bigcup_m \int_{V^m} H_J\ \delta_{ac}\ \rho\ H_I\ dV^m\ \ddot{\bar{u}}_{Jc} \\
+ &\bigcup_m \int_{V^m} H_{I,b}\ E_{abcd}\ H_{J,d}\ dV^m\ \bar{u}_{Jc} \\
= &\bigcup_m \int_{V^m} f_a^B\ H_I\ dV^m + \bigcup_m \int_{S^m} f_a^S\ H_I\ dS^m + \\
+ &\bigcup_m \int_{V^m} \left(E_{abcd}\ \epsilon_{cd}^0\ H_{I,b}\right)\ dV^m - \bigcup_m \int_{V^m} \left(\sigma_{ab}^0\right)\ H_{I,b}\ dV^m
\end{aligned} \tag{102.27}$$

We can now define several tensors from equation (102.27):

$$^{(m)}M_{IacJ} = \int_{V^m} H_J \; \delta_{ac} \; \rho \; H_I \; dV^m \tag{102.28}$$

$$^{(m)}K_{IacJ} = \int_{V^m} H_{I,b} \; E_{abcd} \; H_{J,d} \; dV^m \tag{102.29}$$

$$^{(m)}F^B_{Ia} = \int_{V^m} f^B_a \; H_I \; dV^m \tag{102.30}$$

$$^{(m)}F^S_{Ia} = \int_{S^m} f^S_a \; H_I \; dS^m \tag{102.31}$$

$$^{(m)}F^{\epsilon^0_{mn}}_{Ia} = \int_{V^m} E_{abcd} \; \epsilon^0_{cd} \; H_{I,b} \; dV^m \tag{102.32}$$

$$^{(m)}F^{\sigma^0_{mn}}_{Ia} = \int_{V^m} \sigma^0_{ab} \; H_{I,b} \; dV^m \tag{102.33}$$

where $^{(m)}M_{IacJ}$ is the element mass tensor, $^{(m)}K_{IacJ}$ is the element stiffness tensor, $^{(m)}F^B_{Ia}$ is the tensor of element body forces, $^{(m)}F^S_{Ia}$ is the tensor of element surface forces, $^{(m)}F^{\epsilon^0_{mn}}_{Ia}$ is the tensor of element initial strain effects, $^{(m)}F^{\sigma^0_{mn}}_{Ia}$ is the tensor of element initial stress effects. Now equation (102.27) becomes:

$$\bigcup_{(m)} {}^{(m)}M_{IacJ} \; \ddot{\bar{u}}_{Jc} + \bigcup_{(m)} {}^{(m)}K_{IacJ} \; \bar{u}_{Jc} = \bigcup_{m} {}^{(m)}F^B_{Ia} + \bigcup_{m} {}^{(m)}F^S_{Ia} + \bigcup_{m} {}^{(m)}F^{\epsilon^0_{mn}}_{Ia} - \bigcup_{m} {}^{(m)}F^{\sigma^0_{mn}}_{Ia} \tag{102.34}$$

By summing[13] all the relevant tensors, a well known equation is obtained:

$$\begin{aligned} M_{AacB} \; \ddot{\bar{u}}_{Bc} + K_{AacB} \; \bar{u}_{Bc} &= F_{Aa} \\ A, B &= 1, 2, \ldots, \# \text{ of nodes} \\ a, c &= 1, \ldots, \# \text{ of dimensions (1, 2 or 3)} \end{aligned} \tag{102.35}$$

where:

---

[13] Summation of the element volume integrals expresses the direct addition of the element tensors to obtain global, system tensors. This method of direct addition is usually referred to as the direct stiffness method.

$$M_{AacB} = \bigcup_m {}^{(m)}M_{IacJ} \quad ; \quad K_{AacB} = \bigcup_m {}^{(m)}K_{IacJ} \tag{102.36}$$

are the system mass and stiffness tensors, respectively, $\ddot{u}_{Bc}$ is the tensor of unknown nodal accelerations, and $\bar{u}_{Bc}$ is the tensor of unknown generalized nodal displacements, while the load tensor is given as:

$$F_{Aa} = \bigcup_m {}^{(m)}F^{B}_{Ia} + \bigcup_m {}^{(m)}F^{S}_{Ia} + \bigcup_m {}^{(m)}F^{\epsilon^0_{mn}}_{Ia} - \bigcup_m {}^{(m)}F^{\sigma^0_{mn}}_{Ia} \tag{102.37}$$

After assembling the system of equations in (102.36), it is relatively easy to solve for the unknown displacements $\bar{u}_{Lc}$ either for static or fully dynamic case. It is also very important to note that in all previous equations, omissions of inertial force term (all terms with ρ) will yield static equilibrium equations. Description of solutions procedures for static linear and nonlinear problems are described in some detail in chapter 107. In addition to that, solution procedures for dynamic, linear and nonlinear problems are described in some detail in chapter 108.

A note on the final form of the tensors used is in order. In order to use readily available system of equation solvers equation (102.36) will be rewritten in the following form:

$$M_{PQ}\,\ddot{u}_P + K_{PQ}\,\bar{u}_P = F_Q \quad P, Q = 1, 2, \ldots, (\#ofDOFs)N \tag{102.38}$$

where M_{PQ} is system mass matrix, K_{PQ} is system stiffness matrix and F_Q is the loading vector. Matrix form of equation 102.36, presented as equation 102.38 is obtained flattening the system mass tensor M_{AacB}, system stiffness tensor K_{AacB}, unknown acceleration tensor $\ddot{u}_{Bc}$, unknown displacement tensor $\bar{u}_{Bc}$ and the system loading tensor F_{Aa}. Flattening from the fourth order mass/stiffness tensors to two-dimensional mass/stiffness matrix is done by simply performing appropriate (re–) numbering of nodal DOFs in each dimension. A similar approach is used for unknown accelerations/displacements and loadings.

102.3.1 Static Analysis: Internal and External Loads.

Internal and external loading tensors is defined as:

$$(f_{Ia})_{int} = \bigcup_{(m)} {}^{(m)}K_{IacJ}\ \bar{u}_{Jc} = \bigcup_{m} \int_{V^m} \sigma_{ab}\ H_{I,b}\ dV^m \tag{102.39}$$

$$(f_{Ia})_{ext} = \bigcup_{m} {}^{(m)}F^{B}_{Ia} + \bigcup_{m} {}^{(m)}F^{S}_{Ia} + \bigcup_{m} {}^{(m)}F^{\epsilon^0_{mn}}_{Ia} - \bigcup_{m} {}^{(m)}F^{\sigma^0_{mn}}_{Ia} \tag{102.40}$$

where $(f_{Ia})_{int}$ is the internal force tensor and $(f_{Ia})_{ext}$ is the external force tensor. Equilibrium is obtained when residual:

$$r_{Ia}(\bar{u}_{Jc}, \lambda) = (f_{Ia}\,(\bar{u}_{Jc}))_{int} - \lambda\,(f_{Ia})_{ext} \tag{102.41}$$

is equal to zero, $\mathbf{r}(\mathbf{u}, \lambda) = 0$. The same equation in flattened form yields:

$$\mathbf{r}(\mathbf{u}, \lambda) = \mathbf{f}_{int}(\mathbf{u}) - \lambda \mathbf{f}_{ext} = 0 \tag{102.42}$$

102.4 Isoparametric Solid Finite Elements

102.4.1 8 Node Brick

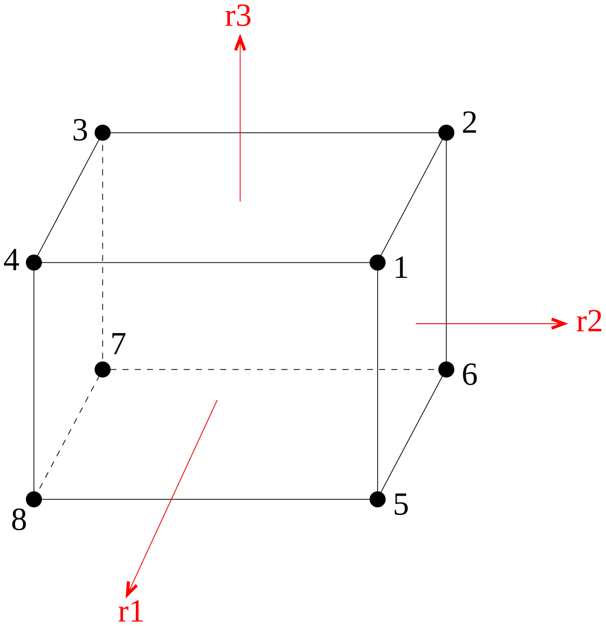

Figure 102.3: 8 node brick element

Table 102.1: Values of r_1, r_2, and r_3 at each of the eight nodes

Node	r_1	r_2	r_3
1	+1	+1	+1
2	-1	+1	+1
3	-1	-1	+1
4	+1	-1	+1
5	+1	+1	-1
6	-1	+1	-1
7	-1	-1	-1
8	+1	-1	-1

Shape function of the nodes which i indicates the node number:

$$N_i^{(e)} = \frac{1}{8}(1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i) \tag{102.43}$$

102.4.2 Collapsed 8 Node Brick

It is sometimes required to mesh finite element models using collapsed brick elements. Collapsed brick elements are finite elements that do not feature all 8 nodes, rather some nodes are merged. This is done to help generate meshes for complicated geometries where it is impossible to rely on solid bricks with eight (8) nodes only. For example, SASSI2000 (System for Analysis of Soil-Structure Interaction) program (Ostadan, 2007) uses such elements. For example, solid elements with 7, 6, and 5 nodes are used extensively and are created by collapsing/combining nodes of 8 node brick into solid elements with 7, 6 or 5 nodes. There are three types of collapsed SASSI 8 node brick element, as shown in Figure 102.4.

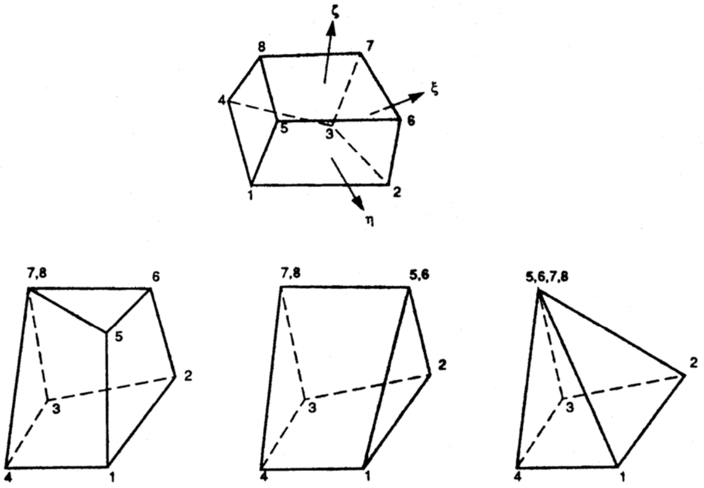

Figure 102.4: Three types of collapsed brick elements in SASSI (Ostadan, 2007).

Verification tests for collapsed brick finite elements are provided in verification section ?? on page 1547.

102.4.3 20 Node Brick

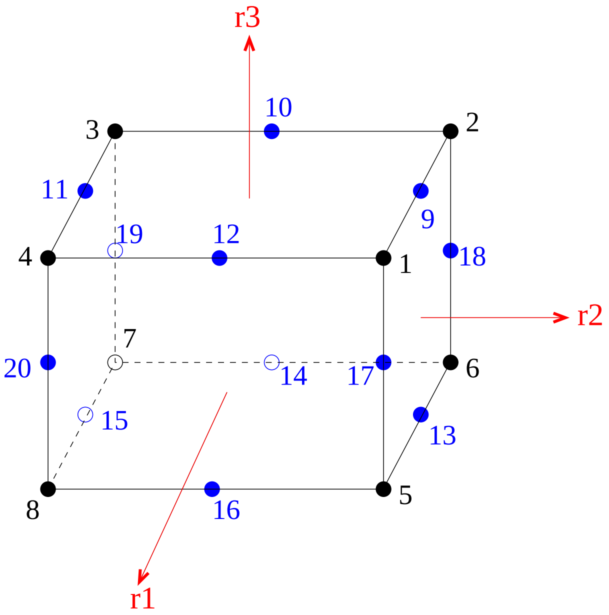

Figure 102.5: 20 node brick element

Table 102.2: Values of r_1, r_2, and r_3 at each of the 9^{th} to 20^{th} nodes

Node	r_1	r_2	r_3
9	0	+1	+1
10	-1	0	+1
11	0	-1	+1
12	+1	0	+1
13	0	+1	-1
14	-1	0	-1
15	0	-1	-1
16	+1	0	-1
17	+1	+1	0
18	-1	+1	0
19	-1	-1	0
20	+1	-1	0

Shape function of the 8 corner nodes (1 to 8) which i indicates the node number:

$$N_i^{(e)} = \frac{1}{8}(1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i)(r_1(r_1)_i + r_2(r_2)_i + r_3(r_3)_i - 2) \tag{102.44}$$

Shape function of the node numbers 9, 11, 13, and 15 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 - r_1^2)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i) \tag{102.45}$$

Shape function of the node numbers 10, 12, 14, and 16 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 - r_2^2)(1 + r_1(r_1)_i)(1 + r_3(r_3)_i) \tag{102.46}$$

Shape function of the node numbers 17, 18, 19, and 20 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 - r_3^2)(1 + r_1(r_1)_i)(1 + r_2(r_2)_i) \tag{102.47}$$

102.4.4 27 Node Brick

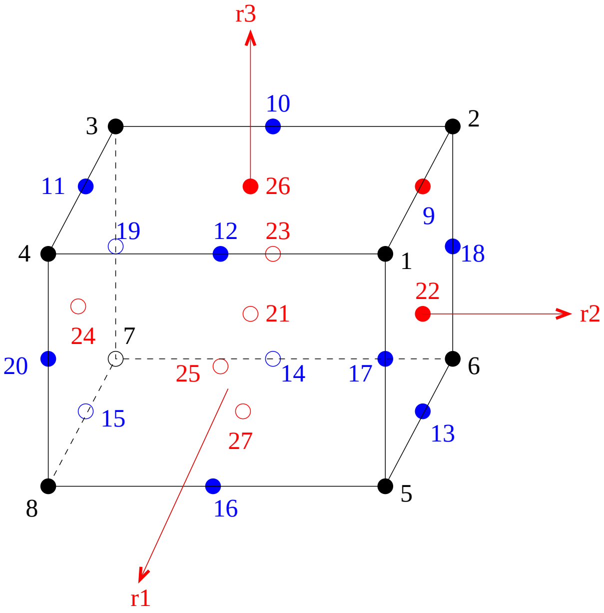

Figure 102.6: 27 node brick element

Table 102.3: Values of r_1, r_2, and r_3 at each of the 21^{th} to 27^{th} nodes

Node	r_1	r_2	r_3
21	0	0	0
22	0	$+1$	0
23	-1	0	0
24	0	-1	0
25	$+1$	0	0
26	0	0	$+1$
27	0	0	-1

Shape function of the 8 corner nodes (1 to 8) which i indicates the node number:

$$N_i^{(e)} = \frac{1}{8}(1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i)(r_1(r_1)_i)(r_2(r_2)_i)(r_3(r_3)_i) \tag{102.48}$$

Shape function of the node numbers 9, 11, 13, and 15 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 - r_1^2)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i)(r_2(r_2)_i)(r_3(r_3)_i) \tag{102.49}$$

Shape function of the node numbers 10, 12, 14, and 16 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 + r_1(r_1)_i)(1 - r_2^2)(1 + r_3(r_3)_i)(r_1(r_1)_i)(r_3(r_3)_i) \tag{102.50}$$

Shape function of the node numbers 17, 18, 19, and 20 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{4}(1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(1 - r_3^2)(r_1(r_1)_i)(r_2(r_2)_i) \tag{102.51}$$

Shape function of the node number 21:

$$N_{21}^{(e)} = (1 - r_1^2)(1 - r_2^2)(1 - r_3^2) \tag{102.52}$$

Shape function of the node numbers 22 and 24 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{2}(1 - r_1^2)(1 + r_2(r_2)_i)(1 - r_3^2)(r_2(r_2)_i) \tag{102.53}$$

Shape function of the node numbers 23 and 25 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{2}(1 + r_1(r_1)_i)(1 - r_2^2)(1 - r_3^2)(r_1(r_1)_i) \tag{102.54}$$

Shape function of the node numbers 26 and 27 which i indicates the node number:

$$N_i^{(e)} = \frac{1}{2}(1 - r_1^2)(1 - r_2^2)(1 + r_3(r_3)_i)(r_3(r_3)_i) \tag{102.55}$$

102.4.5 Isoparametric 8 – 20 Node Finite Element

The basic procedure in the isoparametric[14] finite element formulation is to express the element coordinates and element displacements in the form of interpolations using the local three dimensional[15] coordinate system of the element. Considering the general 3D element, the coordinate interpolations, using indicial notation[16] are:

---

[14] name isoparametric comes from the fact that both displacements and coordinates are defined in terms of nodal values. Superparametric and subparametric finite elements exists also.

[15] in the case of element presented here, that is isoparametric 8 – 20 node finite element.

[16] Einstein's summation rule is implied unless stated differently, all lower case indices $(i, j, p, q, m, n, o, r, s, t, \ldots)$ can have values of 1, 2, 3, and values for capital letter indices will be specified where need be.

$$x_i = H_A\left(r_k\right)\,\bar{x}_{Ai} \tag{102.56}$$

where $A = 1, 2, \ldots, n$ and n is the total number of nodes associated with that specific element, $\bar{x}_{Ai}$ is the i-th coordinate of node A, $i = 1, 2, 3$, $k = 1, 2, 3$ and H_A are the interpolation functions defined in local coordinate system of the element, with variables r_1, r_2 and r_3 varying from -1 to $+1$.

The interpolation functions H_A for the isoparametric 8–20 node are the so called serendipity interpolation functions mainly because they were derived by inspection. For the finite element with nodes numbered as in Figure (102.7) they are given[17] in the following set of formulae:

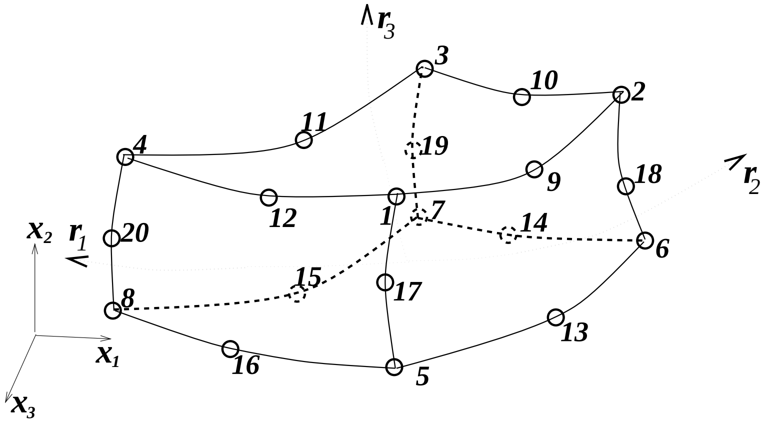

Figure 102.7: Isoparametric 8–20 node brick element in global and local coordinate systems

$$H_{20} = \frac{isp\,(20)\,\left(1+r_1\right)\left(1-r_2\right)\left(1-r_3^2\right)}{4} \qquad H_{19} = \frac{isp\,(19)\,\left(1-r_1\right)\left(1-r_2\right)\left(1-r_3^2\right)}{4}$$

$$H_{18} = \frac{isp\,(18)\,\left(1-r_1\right)\left(1+r_2\right)\left(1-r_3^2\right)}{4} \qquad H_{17} = \frac{isp\,(17)\,\left(1+r_1\right)\left(1+r_2\right)\left(1-r_3^2\right)}{4}$$

$$H_{16} = \frac{isp\,(16)\,\left(1+r_1\right)\left(1-r_2^2\right)\left(1-r_3\right)}{4} \qquad H_{15} = \frac{isp\,(15)\,\left(1-r_1^2\right)\left(1-r_2\right)\left(1-r_3\right)}{4}$$

$$H_{14} = \frac{isp\,(14)\,\left(1-r_1\right)\left(1-r_2^2\right)\left(1-r_3\right)}{4} \qquad H_{13} = \frac{isp\,(13)\,\left(1-r_1^2\right)\left(1+r_2\right)\left(1-r_3\right)}{4}$$

$$H_{12} = \frac{isp\,(12)\,\left(1+r_1\right)\left(1-r_2^2\right)\left(1+r_3\right)}{4} \qquad H_{11} = \frac{isp\,(11)\,\left(1-r_1^2\right)\left(1-r_2\right)\left(1+r_3\right)}{4}$$

$$H_{10} = \frac{isp\,(10)\,\left(1-r_1\right)\left(1-r_2^2\right)\left(1+r_3\right)}{4} \qquad H_{9} = \frac{isp\,(9)\,\left(1-r_1^2\right)\left(1+r_2\right)\left(1+r_3\right)}{4}$$

---

[17] for more details see Bathe (1982).

$$
\begin{aligned}
H_8 &= \frac{(1+r_1)\,(1-r_2)\,(1-r_3)}{8} + \frac{-H_{15}-H_{16}-H_{20}}{2} \\
H_7 &= \frac{(1-r_1)\,(1-r_2)\,(1-r_3)}{8} + \frac{-H_{14}-H_{15}-H_{19}}{2} \\
H_6 &= \frac{(1-r_1)\,(1+r_2)\,(1-r_3)}{8} + \frac{-H_{13}-H_{14}-H_{18}}{2} \\
H_5 &= \frac{(1+r_1)\,(1+r_2)\,(1-r_3)}{8} + \frac{-H_{13}-H_{16}-H_{17}}{2} \\
H_4 &= \frac{(1+r_1)\,(1-r_2)\,(1+r_3)}{8} + \frac{-H_{11}-H_{12}-H_{20}}{2} \\
H_3 &= \frac{(1-r_1)\,(1-r_2)\,(1+r_3)}{8} + \frac{-H_{10}-H_{11}-H_{19}}{2} \\
H_2 &= \frac{(1-r_1)\,(1+r_2)\,(1+r_3)}{8} + \frac{-H_{10}-H_{18}-H_{9}}{2} \\
H_1 &= \frac{(1+r_1)\,(1+r_2)\,(1+r_3)}{8} + \frac{-H_{12}-H_{17}-H_{9}}{2}
\end{aligned}
$$

where r_1, r_2 and r_3 are the axes of natural, local, curvilinear coordinate system and $isp\,(nod\_num)$ is boolean function that returns +1 if node number (nod_num) is present and 0 if node number (nod_num) is not present.

To be able to evaluate various important element tensors[18], to calculate the strain–displacement transformation tensor[19] is needed. The element strains are obtained in terms of derivatives of element displacements with respect to the local coordinate system. Because the element displacements are defined in the local coordinate system, there is a need to relate global x_1, x_2 and x_3 derivatives to the r_1, r_2 and r_3 derivatives. In order to obtain derivatives with respect to global coordinate system, i.e. $\frac{\partial}{\partial x_a}$, use chain rule for differentiation in the following form:

$$
\frac{\partial}{\partial x_k} = \frac{\partial r_a}{\partial x_k}\frac{\partial}{\partial r_a} = J^{-1}_{ak}\,\frac{\partial}{\partial r_a} \tag{102.57}
$$

while the inverse relation is:

$$
\frac{\partial}{\partial r_k} = \frac{\partial x_a}{\partial r_k}\frac{\partial}{\partial x_a} = J_{ak}\,\frac{\partial}{\partial x_a} \tag{102.58}
$$

where J_{ak} is the Jacobian operator relating local coordinate derivatives to the global coordinate derivatives:

---

[18] i.e. ${}^{(m)}K_{IacJ}$, ${}^{(m)}F^{B}_{Ia}$, ${}^{(m)}F^{S}_{Ia}$, ${}^{(m)}F^{\epsilon^0_{mn}}_{Ia}$, ${}^{(m)}F^{\sigma^0_{mn}}_{Ia}$, that are defined in chapter (102.3).

[19] from the equation $\hat{\epsilon}_{ab} = \frac{1}{2}\left(\left(H_{I,b}\,\bar{u}_{Ia}\right) + \left(H_{I,a}\,\bar{u}_{Ib}\right)\right)$

$$J_{ak} = \frac{\partial x_a}{\partial r_k} = \begin{bmatrix} \frac{\partial x_1}{\partial r_1} & \frac{\partial x_2}{\partial r_1} & \frac{\partial x_3}{\partial r_1} \\ \\ \frac{\partial x_1}{\partial r_2} & \frac{\partial x_2}{\partial r_2} & \frac{\partial x_3}{\partial r_2} \\ \\ \frac{\partial x_1}{\partial r_3} & \frac{\partial x_2}{\partial r_3} & \frac{\partial x_3}{\partial r_3} \end{bmatrix} \tag{102.59}$$

The existence of equation (102.57) requires that the inverse of J_{ak} exists and that inverse exists provided that there is a one–to–one[20] correspondence between the local and the global coordinates of element.

It should be pointed out that except for the very simple cases, volume and surface element tensor[21] integrals are evaluated by means of numerical integration[22] Numerical integration rules is quite a broad subject and will not be covered here[23].

102.4.6 Isoparametric 8 - 27 Node Finite Element

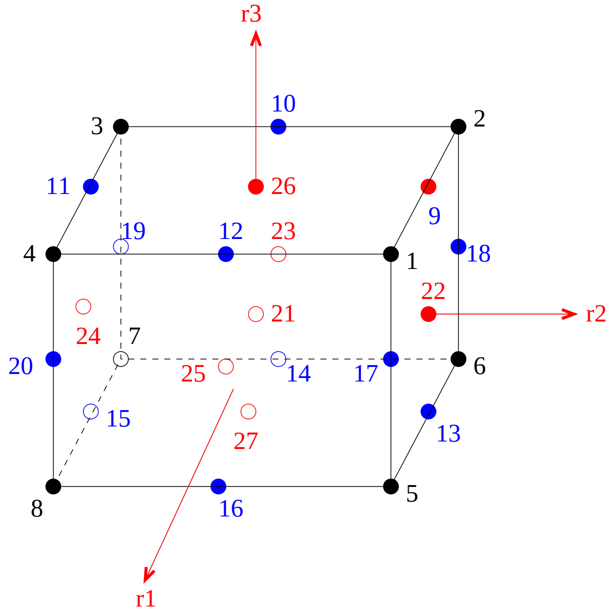

Figure 102.8: 8-27 variable node brick element

---

[20] unique.

[21] as defined in chapter (102.3) by equations (102.29), (102.30), (102.31), (102.32) and (102.33).

[22] Gauss–Legendre, Newton–Coates, Lobatto are among the most used integration rules.

[23] nice explanation with examples is given in Bathe (1982).

$$
\begin{aligned}
H_1 &= \frac{(1+r_1)(1+r_2)(1+r_3)}{8} - \frac{H_9+H_{12}+H_{17}}{2} - \frac{H_{22}+H_{25}+H_{26}}{4} - \frac{H_{21}}{8}\\

H_{24} &= -\frac{1}{2}(1-r_1^2)(1-r_2)(1-r_3^2)r_2 \\
H_{25} &= \frac{1}{2}(1+r_1)(1-r_2^2)(1-r_3^2)r_1 \\
H_{26} &= \frac{1}{2}(1-r_1^2)(1-r_2^2)(1+r_3)r_3 \\
H_{27} &= -\frac{1}{2}(1-r_1^2)(1-r_2^2)(1-r_3)r_3
\end{aligned}
$$

102.4.7 Surface Loads for Solid Bricks

To apply surface load on brick elements, equivalent nodal forces have to be applied instead of the surface load. The equivalent force of the i-th node F_i is given by the following equation with shape function H_i and load distribution function f .

$$F_i = \int_S f H_i ds \tag{102.60}$$

Assuming that the load distribution is uniform

$$F_i = f \int_S H_i ds \tag{102.61}$$

Furthermore, when the magnitude of the load per unit area is 1, and the size of the element is $1 \times 1 \times 1$, equivalent nodal forces are given as shown in Figure 102.9 for 8 node brick element, 20 brick element, and 27 nodes brick element.

Figure 102.9 shows cases of normal loads on vertical upper surface (with nodes: 1, 2, 3, 4 for 8 node brick; 1, 2, 3, 4, 9, 10, 11, and 12 for 20 node brick; and 1, 2, 3, 4, 9, 10, 11, 12 and 26 for the 27 node brick).

Nodal loads from uniform surface loads for 27 node brick are obtained as:

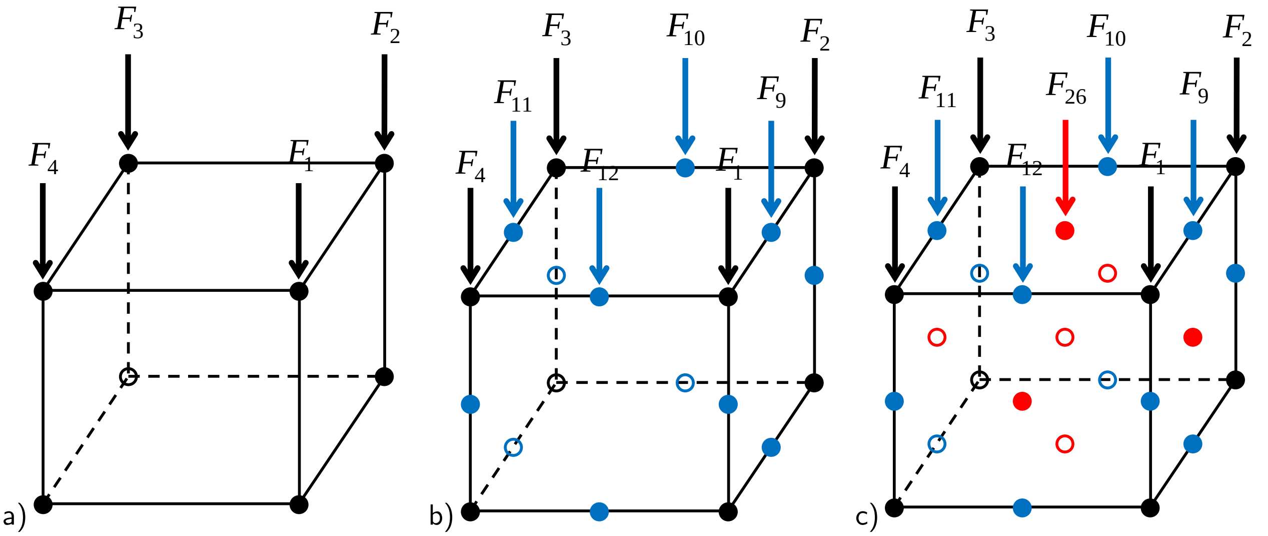

Figure 102.9: Nodal loads for brick elements: (a) $F_1 = F_2 = F_3 = F_4 = +1/4$; (b) $F_1 = F_2 = F_3 = F_4 = -\frac{1}{12}$, $F_9 = F_{10} = F_{11} = F_{12} == +\frac{1}{3}$; (c) $F_1 = F_2 = F_3 = F_4 = +\frac{1}{36}$, $F_9 = F_{10} = F_{11} = F_{12} == +\frac{1}{9}, F_{36} = \frac{4}{9}$.

- for nodes 1, 2, 3, and 4, $N_i^{(e)} = \frac{1}{8}(1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i)(r_1(r_1)_i)(r_2(r_2)_i)(r_3(r_3)_i)$

$$\begin{aligned}
\int_{-1}^{+1} H_i dS &= \\
&= \frac{1}{8}(1 + r_3(r_3)_i)(r_3(r_3)_i) \int_{-1}^{+1}\int_{-1}^{+1} (1 + r_1(r_1)_i)(1 + r_2(r_2)_i)(r_1(r_1)_i)(r_2(r_2)_i)(r_2(r_2)_i) dr_1 dr_2 \\
&= \frac{1}{8}(1 + r_3(r_3)_i)(r_3(r_3)_i)((r_1)_i)^2((r_2)_i)^2(\frac{2}{3})^2 \\
&= \frac{1}{18}(1 + r_3(r_3)_i)(r_3(r_3)_i)((r_1)_i)^2((r_2)_i)^2 \qquad (102.62)
\end{aligned}$$

- for nodes 9, 10, 11 and 12, $N_i^{(e)} = \frac{1}{4}(1 - r_1^2)(1 + r_2(r_2)_i)(1 + r_3(r_3)_i)(r_2(r_2)_i)(r_3(r_3)_i)$

$$\begin{aligned}
\int_{-1}^{+1} H_i dS &= \\
&= \frac{1}{4}(1 + r_3(r_3)_i)(r_3(r_3)_i) \int_{-1}^{+1} (1 - r_1^2)(1 + r_2(r_2)_i)(r_2(r_2)_i) dr_1 dr_2 \\
&= \frac{1}{8}(1 + r_3(r_3)_i)(r_3(r_3)_i)((r_2)_i)^2(\frac{4}{3})(\frac{2}{3}) \\
&= \frac{2}{9}(1 + r_3(r_3)_i)(r_3(r_3)_i)((r_2)_i)^2 \qquad (102.63)
\end{aligned}$$

- for nodes 26 $N_i^{(e)} = \frac{1}{2}(1-r_1^2)(1-r_2^2)(1+r_3(r_3)_i)(r_3(r_3)_i)$

$$
\begin{aligned}
\int_{-1}^{+1} H_i dS &= \\
&= \frac{1}{4}(1+r_3(r_3)_i)(r_3(r_3)_i)\int_{-1}^{+1}\int_{-1}^{+1}(1-r_1^2)(1-r_2^2)dr_1dr_2 \\
&= \frac{1}{8}(1+r_3(r_3)_i)(r_3(r_3)_i)(\frac{4}{3})(\frac{4}{3}) \\
&= \frac{8}{9}(1+r_3(r_3)_i)(r_3(r_3)_i) \qquad (102.64)
\end{aligned}
$$

102.5 Numerical Integration for Solid Brick Elements

Gauss integration rule, see Bathe (1996), section 5.5.3. While using the regular Newton-Coates integration formula, one uses $(n+1)$ equally spaced points to integrate exactly polynomial of order n. On the other hand, while using the Gauss integration formula, one uses n unequally spaced points to integrate exactly polynomial of order $(2n-1)$.

102.9 Shear Beam Finite Element

102.10 Quadrilateral Shell Finite Element with 6DOFs per Node

Based on works by Bergan and Felippa (1985); Alvin et al. (1992); Felippa and Militello (1992); Felippa and Alexander (1992); Militello and Felippa (1991). The stiffness matrix for this element is obtained by averaging two quad shells made up of two ANDES triangular shells (with an alternating orientation of diagonals, Stošić (1984-2022))

102.11 Seismic Isolator and Dissipator Finite Elements

Base isolation system are used to change dynamic characteristics of seismic motions that excite structure and also to dissipate seismic energy before it excites structure. Therefore there are two main types of devices:

- Base Isolators (Kelly, 1991a,b; Toopchi-Nezhad et al., 2008; Huang et al., 2010; Vassiliou et al., 2013) are usually made of low damping (energy dissipation) elastomers and are primarily meant to change (reduce) frequencies of input motions. They are not designed nor modeled as energy dissipators.
- Base Dissipators Kelly and Hodder (1982); Fadi and Constantinou (2010); Kumar et al. (2014) are developed to dissipate seismic energy before it excites the structure. There two main types of such dissipators:
  - Elastomers made of high dissipation rubber, and
  - Frictional pendulum dissipators

Both isolators and dissipators are usually developed to work in two horizontal dimensions, while motions in vertical direction are not isolated or dissipated. This can create potential problems and need to be carefully modeled.

Modeling of base isolation and dissipation system is done using two-node finite elements of relatively short length.

102.11.1 Base Isolation Systems

Base isolation systems are modeled using linear or nonlinear elastic elements. Stiffness is provided from either tests on a full-sized base isolators, or from material characterization of rubber (and steel plates if used in a sandwich isolator construction). Depending on rubber used, a number of models can be used to develop stiffness of the device Ogden (1984); Simo and Miehe (1992); Simo and Pister (1984).

Particularly important is to properly account for vertical stiffness as vertical motions can be amplified depending on characteristics of seismic motions, structure and stiffness of the isolators Hijikata et al. (2012); Araki et al. (2009). It is also important to note that assumption of small deformation is used in most cases. In other words, the stability of the isolator, for example, overturning or rolling is not modeled. It is assumed that elastic stiffness will not suddenly change if the isolator becomes unstable (rolls or overturns).

102.11.2 Base Dissipator Systems

Base dissipator systems are modeled using inelastic (nonlinear) two node elements. There are three basic types of dissipator models used:

- High damping rubber dissipators
- Rubber dissipators with lead core
- Frictional pendulum (double or triple) dissipators

Each one is calibrated using tests done on a full dissipator. It is important to be able to take into account the influence of (an increase in) temperature on resulting behavior. Energy dissipation results in heating of devices, and an increase in temperature influences material properties of dissipators.

102.11.3 Two Node, 3D, Rubber Isolator Finite Element

Kelly (1991a,b)

Behavior of rubber (Ogden, 1984; Simo and Miehe, 1992; Simo and Pister, 1984)

102.11.4 Two Node, 3D, Frictional Pendulum Finite Element

102.12 Fully Coupled, Porous Solid – Pore Fluid Finite Elements

102.12.1 u-p-U Formulation

102.12.1.1 Background

This section follows developments by Zienkiewicz and Shiomi (1984).

The relationship between effective stress, total stress and pore pressure is given as:

$$\sigma''_{ij} = \sigma_{ij} - \alpha\delta_{ij}p \tag{102.83}$$

where σ''_{ij} is effective stress tensor, σ_{ij} is total stress tensor, δ_{ij} is Kronecker delta. $\delta_{ij} = 1$, when i=j, and $\delta_{ij} = 0$, when $i \neq j$. It is assumed that tensile components of effective and total stress are positive, and the pore fluid pressure p is also positive in tension, hence for compressions (usual case) pore fluid pressure is negative ($p < 0$) (Zienkiewicz et al., 1999a). For isotropic materials, $\alpha = 1 - K_T/K_S$. K_T is the total bulk modulus of the solid matrix, K_S is the bulk modulus of the solid particle. For most of the soil mechanics problems, as the bulk modulus K_S of the solid particles is much larger than that of the whole material, $\alpha \approx 1$ can be assumed. Equation (102.83) becomes

$$\sigma''_{ij} = \sigma_{ij} - \delta_{ij}p \tag{102.84}$$

In the next sections, a detailed derivation of formulation and numerical implementation for a fully coupled (pore fluid and porous soil) solid mechanics problem is given. Derivations are based in part on earlier work by Zienkiewicz et al. (1999a).

102.12.1.2 Governing Equations of Porous Media

The following notation is used:

- σ_{ij}, the total Cauchy stress in the mixture,
- u_i, the displacement of the solid skeleton,
- w_i, the displacement of the fluid phase relative to the skeleton of solid,
- p, the pore water pressure,
- $\varepsilon_{ij} = \frac{1}{2}(u_{i,j} + u_{j,i})$, the strain increment of the solid phase,
- $\omega_{ij} = \frac{1}{2}(u_{i,j} - u_{j,i})$, the rotation increment of the solid phase,
- ρ, ρ_s, ρ_f, the densities of the mixture, solid phase and water respectively,
- n the porosity,
- $\theta = -\dot{w}_{i,i}$, the rate of change of volume of water per unit total volume of mixture.

The Equilibrium Equation of the Mixture. The overall equilibrium or momentum balance equation for the soil-fluid mixture is written as

$$\sigma_{ij,j} - \rho \ddot{u}_i - \rho_f [\ddot{w}_i + \underline{\dot{w}_j \dot{w}_{i,j}}] + \rho b_i = 0 \tag{102.85}$$

here $\ddot{u}_i$ is the acceleration of the solid part, b_i is the body force per unit mass, $\ddot{w}_i + \underline{\dot{w}_j \dot{w}_{i,j}}$ is the fluid acceleration relative to the solid part, $\ddot{w}_i$ is local acceleration, $\underline{\dot{w}_j \dot{w}_{i,j}}$ is convective acceleration.

The underlined terms in the above equation represent the fluid acceleration relative to the solid and convective terms of this acceleration. Generally, this acceleration is so small that it is frequently omitted. For static problems, equation 102.85 only consists of the first and last terms.

For fully saturated porous media (no air inside), from definition

$$
\begin{aligned}
\rho &= \frac{M_t}{V_t} \\
&= \frac{M_s + M_f}{V_t} \\
&= \frac{V_s\rho_s + V_f\rho_f}{V_t} \\
&= \frac{V_f}{V_t}\rho_f + \frac{V_t - V_f}{V_t}\rho_s \\
&= n\rho_f + (1-n)\rho_s \\
\rho &= n\rho_f + (1-n)\rho_s \qquad (102.86)
\end{aligned}
$$

where M_t, M_s and M_f are the mass of total, solid part and fluid part respectively. V_t, V_s and V_f are the volume of total, solid part and fluid part respectively.

The Equilibrium Equation of the Fluid. For the pore fluid, the equation of momentum balance is written as

$$
-p_{,i} - R_i - \rho_f\ddot{u}_i - \rho_f[\ddot{w}_i + \underline{\dot{w}_j\dot{w}_{i,j}}]/n + \rho_f b_i = 0 \qquad (102.87)
$$

where R is the viscous drag forces. It is noted that the underlined terms in equation 102.87 represent the convective fluid acceleration again and are generally small. Also note that the permeability $\mathbf{k}$ is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e., $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured. Assuming the Darcy seepage law: $n\dot{w} = Ki$, here i is the head gradient. Seepage force is then $R = \rho_f gi$. R can be written as

$$
R_i = k_{ij}^{-1}\dot{w}_j \qquad \text{or} \qquad R_i = k^{-1}\dot{w}_i \qquad (102.88)
$$

where k_{ij} or k are Darcy permeability coefficients for anisotropic and isotropic conditions respectively.

Flow Conservation Equation. The final equation is supplied by the mass conservation of the fluid flow

$$
\dot{w}_{i,i} + \alpha\dot{\varepsilon}_{ii} + \frac{\dot{p}}{Q} + \underline{n\frac{\dot{\rho}_f}{\rho_f}} + \dot{s}_0 = 0 \qquad (102.89)
$$

The first term of equation(102.89) is the flow divergence of a unit volume of mixture. The second term is the volume change of the mixture. In the third term, Q is relative to the compressibility of the solid and fluid. The underlined terms represent change of density and rate of volume expansion of the solid in case of thermal changes. They are generally negligible.

$$\frac{1}{Q} \equiv \frac{n}{K_f} + \frac{\alpha - n}{K_s} \cong \frac{n}{K_f} + \frac{1-n}{K_s} \tag{102.90}$$

where K_s and K_f are the bulk moduli of the solid and fluid phases respectively. Note that the bulk modulus of the solid phase K_s is the actual bulk modulus of the solid particle.

Obtained are the total mixture equilibrium equation (102.85), fluid equilibrium equation (102.87) and the flow conservation equation (102.89) for saturated soil. By omitting the convective acceleration (the underline terms in (102.85) and (102.87)), density variation and the volume expansion due to the thermal change (the underline terms in (102.89)), the equations of coupled system can be further simplified, as summarized below

$$\sigma_{ij,j} - \rho \ddot{u}_i - \rho_f \ddot{w}_i + \rho b_i = 0 \tag{102.91}$$

$$-p_{,i} - R_i - \rho_f \ddot{u}_i - \frac{\rho_f \ddot{w}_i}{n} + \rho_f b_i = 0 \tag{102.92}$$

$$\dot{w}_{i,i} + \alpha \dot{\varepsilon}_{ii} + \frac{\dot{p}}{Q} = 0 \tag{102.93}$$

Bulk Modulus of Fluid (see Verruijt (2012) page 97... compressibility of water and with air bubbles)...

102.12.1.3 Modified Governing Equations.

Solid Part Equilibrium Equation. A new variable U_i is introduced in place of the relative pseudo-displacement w_i

$$U_i = u_i + U_i^R = u_i + \frac{w_i}{n} \tag{102.94}$$

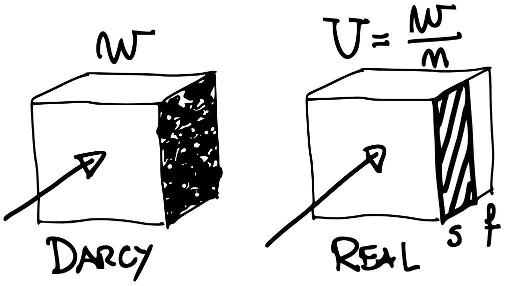

Figure 102.10: Fluid mechanics of Darcy's flow (w_i) versus real flow ($U_i = w_i/n$).

Change of variables is finalized by insertion of equation 102.94 into equations 102.91 and 102.92, and then by subtraction of term ($[n \times \mathit{equation}$ 102.92]) from equation 102.91, which leads to the equation of skeleton equilibrium

$$\sigma_{ij,j} - \rho\ddot{u}_i + \rho b_i + np_{,i} + nR_i + n\rho_f\ddot{u}_i - n\rho_f b_i = 0 \tag{102.95}$$

By substituting $\rho = (1-n)\rho_s + n\rho_f$

$$\sigma_{ij,j} - (1-n)\rho_s\ddot{u}_i - n\rho_f\ddot{u}_i + (1-n)\rho_s b_i + n\rho_f b_i + np_{,i} + nR_i + n\rho_f\ddot{u}_i - n\rho_f b_i = 0$$

$$\sigma_{ij,j} + np_{,i} + (1-n)\rho_s b_i - (1-n)\rho_s\ddot{u}_i + nR_i = 0 \tag{102.96}$$

By using the definition of effective stress, equation 102.83, equation 102.95 becomes

$$\sigma''_{ij,j} - (\alpha - n)p_{,i} + (1-n)\rho_s b_i - (1-n)\rho_s\ddot{u}_i + nR_i = 0 \tag{102.97}$$

Fluid Part Equilibrium Equation. The fluid part equilibrium equation can be obtained simply by $[n \times$ (102.92],i.e.

$$-np_{,i} - nR_i - n\rho_f\ddot{u}_i - \rho_f\ddot{w}_i + n\rho_f b_i = 0$$

$$-np_{,i} - nR_i - n\rho_f(\ddot{u}_i + \frac{\ddot{w}_i}{n}) + n\rho_f b_i = 0 \tag{102.98}$$

From equation (102.94),

$$\ddot{U}_i = \ddot{u}_i + \frac{\ddot{w}_i}{n} \tag{102.99}$$

so that equation (102.98) becomes:

$$-np_{,i} + n\rho_f b_i - n\rho_f\ddot{U}_i - nR_i = 0 \tag{102.100}$$

Mixture Balance of Mass. By differentiating equation (102.94) in time and space

$$\dot{w}_{i,i} = n\dot{U}_{i,i} - n\dot{u}_{i,i} \tag{102.101}$$

Notice that $\dot{\varepsilon}_{ii} = \dot{u}_{i,i}$, so that equation (102.101) becomes

$$\dot{w}_{i,i} = n\dot{U}_{i,i} - n\dot{\varepsilon}_{ii} \tag{102.102}$$

By substituting (102.102) to (102.93)

$$n\dot{U}_{i,i} - n\dot{\varepsilon}_{ii} + \alpha\dot{\varepsilon}_{ii} + \frac{\dot{p}}{Q} = 0 \tag{102.103}$$

or:

$$-n\dot{U}_{i,i} = (\alpha - n)\dot{\varepsilon}_{ii} + \frac{1}{Q}\dot{p} \tag{102.104}$$

Developed is a set of modified governing equations (102.97), (102.100) and (102.104). They are summarized below

$$\sigma^{''}_{ij,j} - (\alpha - n)p_{,i} + (1-n)\rho_s b_i - (1-n)\rho_s \ddot{u}_i + nR_i = 0 \tag{102.105}$$

$$-np_{,i} + n\rho_f b_i - n\rho_f \ddot{U}_i - nR_i = 0 \tag{102.106}$$

$$-n\dot{U}_{i,i} = (\alpha - n)\dot{\varepsilon}_{ii} + \frac{1}{Q}\dot{p} \tag{102.107}$$

From the modified equation set (102.105), (102.106) and (102.107), it is noted that only $\ddot{u}_i$ occurs in the first equation, and only $\ddot{U}_i$ in the second, thus leading to a convenient diagonal form in discretization.

Obtained is a a complete equation system given by (102.105), (102.106) and (102.107). With the basic definitions introduced earlier, there are three essential unknowns:

1. three solid displacement u_i
2. pore pressure p
3. three fluid displacement U_i

The boundary conditions imposed on these variables will complete the problem. These boundary conditions are:

- For the momentum balance part,
  - on boundary Γ_t, traction $t_i(t)$(or $\sigma_{ij}n_j$), where n_i is the i-th component of the normal to the boundary.
  - On boundary Γ_u, the displacement u_i is given.
- For the fluid part, again the boundary is divided into two parts:
  - On Γ_p, the pressure p is specified,
  - on Γ_w, the normal outflow $\dot{w}_n$ is specified. For impermeable boundary a zero value for the outflow should be specified.

The boundary conditions can be summarized below

$$\begin{aligned}
\Gamma &= \Gamma_t \cup \Gamma_u \\
t_i &= \sigma_{ij} n_j = \bar{t}_i \qquad \text{on} \qquad \Gamma = \Gamma_t \\
u_i &= \bar{u}_i \qquad \text{on} \qquad \Gamma = \Gamma_u
\end{aligned} \tag{102.108}$$

and

$$\begin{aligned}
\Gamma &= \Gamma_p \cup \Gamma_w \\
p &= \bar{p} \qquad \text{on} \qquad \Gamma = \Gamma_p \\
n^T w &= w_n \qquad \text{on} \qquad \Gamma = \Gamma_w
\end{aligned} \tag{102.109}$$

102.12.1.4 Numerical Solution of the u-p-U Governing Equations

The solutions to the problems governed by the modified governing equation set (102.105), (102.106) and (102.107) can be found by solving partial differential equations, which can be written as

$$A\ddot{\Phi} + B\dot{\Phi} + L(\Phi) = 0 \tag{102.110}$$

where A, B are constant matrices, and L is an operator involving spatial differentials. The dot notation represents the time differentiation. Vector of dependent variables, Φ represents the displacement u or the pore fluid pressure p.

The finite element solution of a problem proceeds as follows.

1. Discretize or approximate the unknown functions Φ by a finite set of parameters $\overline{\Phi}_k$ and shape function H_k. They are specified in space dimensions. Thus

$$\Phi \cong \Phi^h = \sum_{k=1}^{n} H_k \overline{\Phi}_k \tag{102.111}$$

2. Insert the value of the approximating function $\hat{\Phi}$ into the differential equations to obtain a residual, then a set of weighted residual equations can be written in the form

$$\int^{\Omega} W_j^T (A\ddot{\Phi}^h + B\dot{\Phi}^h + L(\Phi^h)) d\Omega = 0 \tag{102.112}$$

In the finite element method, the weighting functions W_j are usually identical to the shape functions.

The solid displacement u_i, the pore pressure p, and the absolute fluid displacement U_i can be approximated using shape functions and nodal values.

$$\begin{aligned} u_i &= H^u_K \bar{u}_{Ki} \\ p &= H^p_K \bar{p}_K \\ U_i &= H^U_K \bar{U}_{Ki} \end{aligned} \tag{102.113}$$

where H^u_K, H^p_K, and H^U_K are shape functions for solid displacement, pore pressure and fluid displacement, respectively, $\bar{u}_{Ki}$,$\bar{p}_K$,$\bar{U}_{Ki}$ are nodal values of solid displacement, pore pressure and fluid displacement, respectively.

Numerical Solution of solid part equilibrium equation. To obtain the numerical solution of the first equation, premultiply equation 102.105 by H^u_K and integrate over the domain.

First term of (102.105) becomes

$$\begin{aligned} \int_\Omega H^u_K \sigma''_{ij,j} d\Omega &= \int_{\Gamma_t} H^u_K n_j \sigma''_{ij} d\Gamma - \int_\Omega H^u_{K,j} \sigma''_{ij} d\Omega \\ &= \int_{\Gamma_t} H^u_K (\bar{t}_i + n_i \alpha p) d\Gamma - \int_\Omega H^u_{K,j} \sigma''_{ij} d\Omega \\ &= (f^u_1)_{Ki} - \int_\Omega H^u_{K,j} D_{ijml} \varepsilon_{ml} d\Omega \\ &= (f^u_1)_{Ki} - [\int_\Omega H^u_{K,j} D_{ijml} H^u_{P,l} d\Omega] \bar{u}_{Pm} \\ &= (f^u_1)_{Ki} - K^{EP}_{KimP} \bar{u}_{Pm} \\ &= (f^u_1)_{Ki} - K^{EP}_{KijL} \bar{u}_{Lj} \\ &= (\boldsymbol{f^u_1}) - \boldsymbol{K^{EP}} \bar{\boldsymbol{u}} \end{aligned} \tag{102.114}$$

where K^{EP} is the stiffness matrix of the solid part,n_i is the direction of the normal on the boundary.

Second term of (102.105) becomes

$$\begin{aligned} -\int_\Omega H^u_K (\alpha - n) p_{,i} d\Omega &= -\int_{\Gamma_p} H^u_K (\alpha - n) n_i p d\Gamma + \int_\Omega H^u_{K,i} (\alpha - n) p d\Omega \\ &= -\int_{\Gamma_p} H^u_K (\alpha - n) n_i p d\Gamma + [\int_\Omega H^u_{K,i} (\alpha - n) H^p_M d\Omega] \bar{p}_M \\ &= -(f^u_4)_{Ki} + (G_1)_{KiM} \bar{p}_M \\ &= -\boldsymbol{f^u_4} + (\boldsymbol{G_1}) \bar{\boldsymbol{p}} \end{aligned} \tag{102.115}$$

Third term of (102.105) (solid body force) is then

$$\int_\Omega H_K^u (1-n)\rho_s b_i d\Omega = (f_5^u)_{Ki} \tag{102.116}$$

Fourth term of (102.105) can be written as

$$\begin{aligned}
-\int_\Omega H_K^u (1-n)\rho_s \delta_{ij}\ddot{u}_j d\Omega &= -[\int_\Omega H_K^u (1-n)\rho_s \delta_{ij} H_L^u d\Omega]\ddot{\bar{u}}_{Lj} \\
&= -(M_s)_{KijL}\ddot{\bar{u}}_{Lj} \\
&= \boldsymbol{-M_s\ddot{\bar{u}}}
\end{aligned} \tag{102.117}$$

where M_s is the mass matrix of solid part. By substituting equations (102.88) and (102.94), last term of (102.105) (Damping Matrix) becomes

$$\begin{aligned}
\int_\Omega H_K^u n R_i d\Omega &= \int_\Omega H_K^u n k_{ij}^{-1}\dot{w}_j d\Omega \\
&= \int_\Omega H_K^u n^2 k_{ij}^{-1}\dot{U}_j d\Omega - \int_\Omega H_K^u n^2 k_{ij}^{-1}\dot{u}_j d\Omega \\
&= [\int_\Omega H_K^u n^2 k_{ij}^{-1} H_L^U d\Omega]\dot{\bar{U}}_{Lj} - [\int_\Omega H_K^u n^2 k_{ij}^{-1} H_L^U d\Omega]\dot{\bar{u}}_{Lj} \\
&= (C_2)_{KijL}\dot{\bar{U}}_{Lj} - (C_1)_{KijL}\dot{\bar{u}}_{Lj} \\
&= \boldsymbol{C_2\dot{\bar{U}} - C_1\dot{\bar{u}}}
\end{aligned} \tag{102.118}$$

Equation (102.105) becomes

$$\boldsymbol{-K^{EP}\bar{u} + f_1^u - f_4^u + G_1\bar{p} + f_5^u + M_s\ddot{\bar{u}} + C_2\dot{\bar{U}} - C_1\dot{\bar{u}}} = 0 \tag{102.119}$$

or

$$\boldsymbol{K^{EP}\bar{u} - G_1\bar{p} - C_2\dot{\bar{U}} + C_1\dot{\bar{u}} + M_s\ddot{\bar{u}} = \bar{f}_s} \tag{102.120}$$

where

$$\bar{f}_s = f_1^u - f_4^u + f_5^u \tag{102.121}$$

and in index form

$$K_{KijL}^{EP} - (G_1)_{KiL}\bar{p}_L + (C_2)_{KijL}\dot{\bar{U}}_{Lj} - (C_1)_{KijL}\dot{\bar{u}}_{Lj} + (M_s)_{KijL}\ddot{\bar{u}}_{Ki} = (\bar{f}_s)_{Ki} \tag{102.122}$$

where

$$\begin{aligned}
\boldsymbol{K^{EP}} = (K^{EP})_{KimP} &= \int_{\Omega} H^u_{K,j} D_{ijml} H^u_{P,l} d\Omega \\
\boldsymbol{G_1} = (G_1)_{KiM} &= \int_{\Omega} H^u_{K,i} (\alpha - n) H^p_M d\Omega \\
\boldsymbol{C_2} = (C_2)_{KijL} &= \int_{\Omega} H^u_K n^2 k^{-1}_{ij} H^U_L d\Omega \\
\boldsymbol{C_1} = (C_1)_{KijL} &= \int_{\Omega} H^u_K n^2 k^{-1}_{ij} H^u_L d\Omega \\
\boldsymbol{M_s} = (M_s)_{KijL} &= \int_{\Omega} H^u_K (1-n) \rho_s \delta_{ij} H^u_L d\Omega \\
\boldsymbol{\bar{f}} = (\bar{f}_s)_{Ki} &= (f^u_1)_{Ki} - (f^u_4)_{Ki} + (f^u_5)_{Ki}
\end{aligned} \tag{102.123}$$

Numerical Solution of fluid part equilibrium equation. From equations (102.88) and (102.94),

$$R_i = n k^{-1}_{ij} (\dot{U}_j - \dot{u}_j) \tag{102.124}$$

By substituting (102.124) into equation (102.106),

$$-n p_{,i} + n \rho_f b_i - n \rho_f \ddot{U}_i - n^2 k^{-1}_{ij} (\dot{U}_j - \dot{u}_j) = 0 \tag{102.125}$$

By premultiplying (102.125) by H^U_K and integrating over the domain, first term of (102.125) becomes

$$\begin{aligned}
-\int_{\Omega} n H^U_K p_{,i} d\Omega &= -\int_{\Gamma_p} n H^U_K n_i p d\Gamma + \int_{\Omega} n H^U_{K,i} p d\Omega \\
&= -(f_1)_{Ki} + [\int_{\Omega} n H^U_{K,i} H^p_M d\Omega] \bar{p}_M \\
&= -(f_1)_{Ki} + (G_2)_{KiM} \bar{p}_M \\
&= \boldsymbol{-(f_1)_{Ki} + (G_2)\bar{p}}
\end{aligned} \tag{102.126}$$

Second term of (102.125) is then

$$\int_{\Omega} H^U_K \rho_f b_i d\Omega = (f_2)_{Ki} \tag{102.127}$$

Third term of (102.125) (Lumped mass matrix obtained by multiplying δ_{ij}) becomes

$$\begin{aligned}
-\int_{\Omega} H^U_K n \rho_f \delta_{ij} \ddot{U}_j d\Omega &= -[\int_{\Omega} H^U_K n \rho_f \delta_{ij} H^U_L d\Omega] \ddot{\bar{U}}_{Lj} \\
&= -(M_f)_{KijL} \ddot{\bar{U}}_{Lj} \\
&= \boldsymbol{-M_f \ddot{\bar{U}}}
\end{aligned} \tag{102.128}$$

Forth term of (102.125) becomes

$$\begin{aligned}
-\int_\Omega H^U_K n^2 k^{-1}_{ij} \dot{U}_j d\Omega + \int_\Omega H^U_K n^2 k^{-1}_{ij} \dot{u}_j d\Omega &= -[\int_\Omega H^U_K n^2 k^{-1}_{ij} H^U_L d\Omega]\dot{\overline{U}}_{Lj} \qquad (102.129)\\
+[\int_\Omega H^U_K n^2 k^{-1}_{ij} H^u_L d\Omega]\dot{\overline{u}}_{Lj} & \\
&= -(C_3)_{KijL}\dot{\overline{U}}_{Lj} + (C_2)^T_{LjiK}\dot{\overline{u}}_{Lj} \\
&= \boldsymbol{C_3}\dot{\overline{\boldsymbol{U}}} + \boldsymbol{C_2^T}\dot{\overline{\boldsymbol{u}}} \qquad (102.130)
\end{aligned}$$

Equation (102.125) becomes

$$-\boldsymbol{f_1} + \boldsymbol{G_2}\overline{\boldsymbol{p}} + \boldsymbol{f_2} - \boldsymbol{M_f}\ddot{\overline{\boldsymbol{U}}} - \boldsymbol{C_3}\dot{\overline{\boldsymbol{U}}} + \boldsymbol{C_2^T}\dot{\overline{\boldsymbol{u}}} = \boldsymbol{0} \qquad (102.131)$$

or

$$-\boldsymbol{G_2}\overline{\boldsymbol{p}} - \boldsymbol{C_2^T}\dot{\overline{\boldsymbol{u}}} + \boldsymbol{C_3}\dot{\overline{\boldsymbol{U}}} + \boldsymbol{M_f}\ddot{\overline{\boldsymbol{U}}} = \overline{\boldsymbol{f}}_{\boldsymbol{f}} \qquad (102.132)$$

where

$$\overline{f}_f = f_2 - f_1 \qquad (102.133)$$

and in index form

$$-(G_2)_{KiM}\overline{p}_M - (C_2)^T_{LjiK}\dot{\overline{u}}_{Lj} + (C_3)_{KijL}\dot{\overline{U}}_{Lj} + (M_f)_{KijL}\ddot{U}_{Lj} = (f_f)_{Ki} \qquad (102.134)$$

where

$$\begin{aligned}
\boldsymbol{(f_f)_{Ki}} &= (f_1)_{Ki} - (f_2)_{Ki} \\
\boldsymbol{G_2} &= (G_2)_{KiN} = \int_\Omega n H^U_{K,i} H^p_M d\Omega \\
\boldsymbol{C_2^T} &= (C_2^T)_{KijL} = \int_\Omega H^U_K n^2 k^{-1}_{ij} H^u_L d\Omega \\
\boldsymbol{C_3} &= (C_3)_{KijL} = \int_\Omega H^U_K n^2 k^{-1}_{ij} H^U_L d\Omega \\
\boldsymbol{M_f} &= (M_f)_{KijL} = \int_\Omega H^U_K n \rho_f \delta_{ij} H^U_L d\Omega \qquad (102.135)
\end{aligned}$$

Numerical Solution of flow conservation equation. By integrating (102.107) in time and noticing that $\varepsilon_{ii} = u_{i,i}$,

$$-nU_{i,i} = (\alpha - n)\varepsilon_{ii} + \frac{1}{Q}p \qquad (102.136)$$

By multiplying (102.136) by H^p_M and integrating over domain, first term of (102.136) becomes

$$-[\int_\Omega H^p_M n H^U_{L,j} d\Omega]\overline{U}_{Lj} = -(G_2)_{MLj}\overline{U}_{Li} = -\boldsymbol{G_2^T}\overline{\boldsymbol{U}} \qquad (102.137)$$

Second term of (102.136) is

$$\begin{aligned}\int_{\Omega} H^p_M(\alpha - n)u_{i,i}d\Omega &= [\int_{\Omega} H^p_M(\alpha - n)H^u_{L,j}d\Omega]\bar{u}_{Lj} \\ &= (G_1)_{LjM}\bar{u}_{Lj} \\ &= \boldsymbol{G_1^T}\bar{\boldsymbol{u}} \end{aligned} \tag{102.138}$$

Third term of (102.136) becomes

$$[\int_{\Omega} H^p_N \frac{1}{Q} H^p_M d\Omega]p_N = P_{NM}p_M = \boldsymbol{P}\bar{\boldsymbol{p}} \tag{102.139}$$

The equation (102.136) becomes

$$\boldsymbol{G_2^T}\bar{\boldsymbol{U}} + \boldsymbol{G_1^T}\bar{\boldsymbol{u}} + \boldsymbol{P}\bar{\boldsymbol{p}} = \boldsymbol{0} \tag{102.140}$$

in index form

$$(G_2)_{LiK}\bar{U}_{Li} + (G_1)_{LiK}\bar{u}_{Li} + P_{KL}\bar{p}_L = 0 \tag{102.141}$$

102.12.1.5 Matrix form of the governing equations.

The numerical forms of governing equations (102.120),(102.132) and (102.140) can be written together in the matrix form as

$$\begin{bmatrix} M_s & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & M_f \end{bmatrix} \begin{bmatrix} \ddot{\bar{u}} \\ \ddot{\bar{p}} \\ \ddot{\bar{U}} \end{bmatrix} + \begin{bmatrix} C_1 & 0 & -C_2 \\ 0 & 0 & 0 \\ -C_2^T & 0 & C_3 \end{bmatrix} \begin{bmatrix} \dot{\bar{u}} \\ \dot{\bar{p}} \\ \dot{\bar{U}} \end{bmatrix} + \begin{bmatrix} K^{EP} & -G_1 & 0 \\ -G_1^T & -P & -G_2^T \\ 0 & -G_2 & 0 \end{bmatrix} \begin{bmatrix} \bar{u} \\ \bar{p} \\ \bar{U} \end{bmatrix} = \begin{bmatrix} \bar{f}_s \\ 0 \\ \bar{f}_f \end{bmatrix} \tag{102.142}$$

or in index form

$$\begin{bmatrix} (M_s)_{KijL} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & (M_f)_{KijL} \end{bmatrix} \begin{bmatrix} \ddot{\bar{u}}_{Lj} \\ \ddot{\bar{p}}_N \\ \ddot{\bar{U}}_{Lj} \end{bmatrix} + \begin{bmatrix} (C_1)_{KijL} & 0 & -(C_2)_{KijL} \\ 0 & 0 & 0 \\ -(C_2)_{LjiK} & 0 & (C_3)_{KijL} \end{bmatrix} \begin{bmatrix} \dot{\bar{u}}_{Lj} \\ \dot{\bar{p}}_N \\ \dot{\bar{U}}_{Lj} \end{bmatrix}$$
$$+ \begin{bmatrix} (K^{EP})_{KijL} & -(G_1)_{KiM} & 0 \\ -(G_1)_{LjM} & -P_{MN} & -(G_2)_{LjM} \\ 0 & -(G_2)_{KiL} & 0 \end{bmatrix} \begin{bmatrix} \bar{u}_{Lj} \\ \bar{p}_M \\ \bar{U}_{Lj} \end{bmatrix} = \begin{bmatrix} \bar{f}^{solid}_{Ki} \\ 0 \\ \bar{f}^{fluid}_{Ki} \end{bmatrix} \tag{102.143}$$

where

$$
\begin{aligned}
\boldsymbol{M_s} &= (M_s)_{KijL} = \int_\Omega H_K^u (1-n)\rho_s \delta_{ij} H_L^u d\Omega \\
\boldsymbol{M_f} &= (M_f)_{KijL} = \int_\Omega H_K^U n\rho_f \delta_{ij} H_L^U d\Omega \\
\boldsymbol{C_1} &= (C_1)_{KijL} = \int_\Omega H_K^u n^2 k_{ij}^{-1} H_L^u d\Omega \\
\boldsymbol{C_2} &= (C_2)_{KijL} = \int_\Omega H_K^u n^2 k_{ij}^{-1} H_L^U d\Omega \\
\boldsymbol{C_3} &= (C_3)_{KijL} = \int_\Omega H_K^U n^2 k_{ij}^{-1} H_L^U d\Omega \\
\boldsymbol{K^{EP}} &= (K^{EP})_{KijL} = \int_\Omega H_{K,m}^u D_{imjn} H_{L,n}^u d\Omega \\
\boldsymbol{G_1} &= (G_1)_{KiM} = \int_\Omega H_{K,i}^u (\alpha - n) H_M^p d\Omega \\
\boldsymbol{G_2} &= (G_2)_{KiM} = \int_\Omega n H_{K,i}^U H_M^p d\Omega \\
\boldsymbol{P} &= P_{NM} = \int_\Omega H_N^p \frac{1}{Q} H_M^p d\Omega
\end{aligned}
\tag{102.144}
$$

$$
\begin{aligned}
\bar{f}_{Ki}^{solid} &= (f_1^u)_{Ki} - (f_4^u)_{Ki} + (f_5^u)_{Ki} \\
\bar{f}_{Ki}^{fluid} &= -(f_1^U)_{Ki} + (f_2^U)_{Ki} \\

\end{aligned}
\tag{102.145}
$$

Functions N^u,N^p,N^U are shape functions for unknown field of skeleton dispalacements, pore fluid pressures and fluid displacements, respectively, while ρ, ρ_s, ρ_f are the density of the total, solid and fluid phases, respectively, n is the porosity, and by its definition $\rho = (1-n)\rho_s + n\rho_f$, the symbol n_i is the direction of the normal on the boundary, u_i is the displacement of the solid part, p is pore fluid pressure and U_i is the absolute displacement of the fluid part. Equation (102.142) represents the general form $(u-p-U)$ for coupled system which can be written in a familiar form as

$$
\boldsymbol{M\ddot{x} + C\dot{x} + Kx = f}
\tag{102.146}
$$

where x represents the generalized unknown variable. The solution of this equation for each time step will render an unknown field for given initial and boundary conditions.

102.12.1.6 Choice of shape functions

Isoparametric elements are used in previous sections, where the coordinates are interpolated using the same shape functions as for the unknown. This mapping allows using elements of more arbitrary shape than simple forms such as rectangles and triangles. But in static or dynamic undrained analysis the permeability (and compressibility) matrices are zero, i.e.($Q \rightarrow \infty$,and $P \rightarrow 0$),resulting in a zero-matrix diagonal term in the equation(102.143).

The matrix to be solved is the same as that in the solutions of problems of incompressible elasticity or fluid mechanics. Actually, a wide choice of shape functions is available if the limiting(undrained) condition is never imposed. Due to the presence of first derivatives in space in all the equations, it is necessary to use "C_0-continuous" interpolation functions and the suitable element forms are shown in Fig.102.11.

102.12.2 u-p-U Formulation for Partially Saturated, Unsaturated Material

Coming SOON, by end of Winter 2020

102.12.3 u-p Formulation

102.12.3.1 Governing Equations of Porous Media

The formulation given here is based on Zienkiewicz et al. (1999b).

The first governing equation of porous media is total momentum balance equation:

$$\sigma_{ij,j} - \rho \ddot{u}_i + \rho b_i = 0 \tag{102.147}$$

where $\sigma_{ij} = \sigma''_{ij} - \alpha p \delta_{ij}$ and $\rho = (1-n)\rho_s + n\rho_f$.

The second governing equation is the fluid mass balance equation:

$$\left(k_{ij}(-p_{,j} + \rho_f b_j)\right)_{,i} + \alpha \dot{u}_{i,i} + \frac{\dot{p}}{Q_{sf}} = 0 \tag{102.148}$$

where

$$k_{ij} = \frac{k'_{ij}}{g\rho_f} = \frac{k'_{ij}}{\gamma_f} \tag{102.149}$$

and k'_{ij} is the permeability in Darcy's law with the same unit as velocity.

$$Q_{sf} = \frac{K_s K_f}{K_s + K_f} \tag{102.150}$$

is the total compression modulus, K_s and K_f are solid and fluid compression modulus, respectively.

The boundary conditions are

$$\sigma_{ij} n_j = \bar{t}_i \quad \text{on} \quad \Gamma = \Gamma_t \tag{102.151}$$

$$u_i = \bar{u}_i \quad \text{on} \quad \Gamma = \Gamma_u \tag{102.152}$$

$$n_i w_i = n_i k_{ij}(-p_{,j} + \rho_f b_j) = \bar{w} = -\bar{q} \quad \text{on} \quad \Gamma = \Gamma_w \tag{102.153}$$

$$p = \bar{p} \quad \text{on} \quad \Gamma = \Gamma_p \tag{102.154}$$

where $\bar{w}$ is the outflow and $\bar{q}$ is the influx.

102.12.3.2 Numerical Solutions of the Governing Equations

The solid displacement u_i and the pore pressure p can be approximated using shape functions and nodal values:

$$u_i = N^u_K \bar{u}_{Ki} \tag{102.155}$$

$$p = N^p_L \bar{p}_L \tag{102.156}$$

Similar approximations are applied to $\dot{u}_i$, $\ddot{u}_i$, $\dot{p}$ and $\ddot{p}$.

Numerical solution of the total momentum balance The numerical solution of the total momentum balance is

$$\int_\Omega N^u_K \left(\sigma_{ij,j} - \rho \ddot{u}_i + \rho b_i \right) \mathrm{d}\Omega = 0 \tag{102.157}$$

First-term of (102.157) becomes

$$
\begin{aligned}
\int_{\Omega} N^u_K \sigma_{ij,j} \mathrm{d}\Omega &= \int_{\Gamma_t} N^u_K \sigma_{ij,j} n_j \mathrm{d}\Omega - \int_{\Omega} N^u_{K,j} \sigma_{ij} \mathrm{d}\Omega \\
&= \int_{\Gamma_t} N^u_K \bar{t}_i \mathrm{d}\Omega - \int_{\Omega} N^u_{K,j} (\sigma''_{ij} - \alpha p \delta_{ij}) \mathrm{d}\Omega \\
&= (f^u_1)_{Ki} - \int_{\Omega} N^u_{K,j} \sigma''_{ij} \mathrm{d}\Omega + \int_{\Omega} N^u_{K,i} \alpha p \mathrm{d}\Omega \\
&= (f^u_1)_{Ki} - \int_{\Omega} N^u_{K,j} D_{ijml} \varepsilon_{ml} \mathrm{d}\Omega + [\int_{\Omega} \alpha N^u_{K,i} N^p_N \mathrm{d}\Omega] \bar{p}_N \\
&= (f^u_1)_{Ki} - [\int_{\Omega} N^u_{K,j} D_{ijml} N^u_{P,m} \mathrm{d}\Omega] \bar{u}_{Pm} + [\int_{\Omega} \alpha N^u_{K,i} N^p_N \mathrm{d}\Omega] \bar{p}_N \\
&= (f^u_1)_{Ki} - (K^{ep}_{KimP}) \bar{u}_{Pm} + (Q_{KiN}) \bar{p}_N \\
&= \boldsymbol{f^u_1 - (K^{ep}) \bar{u} + Q \bar{p}}
\end{aligned}
\tag{102.158}
$$

Second term of (102.157) becomes

$$
\begin{aligned}
-\int_{\Omega} N^u_K \rho \ddot{u}_i \mathrm{d}\Omega &= -\int_{\Omega} N^u_K \rho N^u_L \mathrm{d}\Omega \ddot{u}_{Li} \\
&= -[\int_{\Omega} N^u_K \rho N^u_L \mathrm{d}\Omega] \ddot{\bar{u}}_{Li} \\
&= -[\delta_{ij} \int_{\Omega} N^u_K \rho N^u_L \mathrm{d}\Omega] \ddot{\bar{u}}_{Lj} \\
&= -(M_{KijL}) \ddot{\bar{u}}_{Lj} \\
&= \boldsymbol{-M \ddot{\bar{u}}}
\end{aligned}
\tag{102.159}
$$

The third term of (102.157) becomes

$$
\begin{aligned}
\int_{\Omega} N^u_K \rho b_i \mathrm{d}\Omega &= (f^u_2)_{Ki} \\
&= \boldsymbol{f^u_2}
\end{aligned}
\tag{102.160}
$$

The equation (102.157) thus becomes

$$
(M_{KijL}) \ddot{\bar{u}}_{Lj} - (Q_{KiN}) \bar{p}_N + (K^{ep}_{KijL}) \bar{u}_{Lj} = (f^u_1)_{Ki} + (f^u_2)_{Ki} = (f^u)_{Ki}
\tag{102.161}
$$

or

$$
\boldsymbol{M \ddot{\bar{u}} - Q \bar{p} + (K^{ep}) \bar{u} = f^u_1 + f^u_2 = f^u}
\tag{102.162}
$$

Numerical solution of the fluid mass balance The numerical solution of the fluid mass balance is

$$
\int_{\Omega} N^p_M \left(k_{ij} (-p_{,j} + \rho_f b_j)_{,j} + \alpha \dot{u}_{i,i} + \frac{\dot{p}}{Q_{sf}} \right) \mathrm{d}\Omega = 0
\tag{102.163}
$$

First term of (102.163) becomes

$$\begin{aligned}
& \int_{\Omega} N_M^p \left(k_{ij}(-p_{,j} + \rho_f b_j)\right)_{,i} \mathrm{d}\Omega \qquad (102.164)\\
= & \int_{\gamma_w} N_M^p w_i n_i \mathrm{d}\Omega - \int_{\Omega} N_{M,i}^p k_{ij}(-p_{,j} + \rho_f b_j)\mathrm{d}\Omega \\
= & \int_{\gamma_w} N_M^p \bar{w}\mathrm{d}\Omega + \int_{\Omega} N_{M,i}^p k_{ij} p_{,j}\mathrm{d}\Omega - \int_{\Omega} N_{M,i}^p k_{ij}\rho_f b_j \mathrm{d}\Omega \\
= & (f_1^p)_M + \int_{\Omega} N_{M,i}^p k_{ij} p_{,j}\mathrm{d}\Omega - \int_{\Omega} N_{M,i}^p k_{ij}\rho_f b_j \mathrm{d}\Omega \\
= & (f_1^p)_M + [\int_{\Omega} N_{M,i}^p k_{ij} N_{N,j}^p \mathrm{d}\Omega]\bar{p}_N - (f_2^p)_M \\
= & (f_1^p)_M + (H_{MN})\bar{p}_N - (f_2^p)_M \\
= & \boldsymbol{f_1^p} + \boldsymbol{H}\bar{\boldsymbol{p}} - \boldsymbol{f_2^p} \qquad (102.165)
\end{aligned}$$

Second term of (102.163) becomes

$$\begin{aligned}
\int_{\Omega} N_M^p \alpha \dot{u}_{i,i}\mathrm{d}\Omega &= [\int_{\Omega} N_M^p \alpha N_{L,j}^u \mathrm{d}\Omega]\dot{\bar{u}}_{Lj} \\
&= (Q_{LjM})\dot{\bar{u}}_{Lj} \\
&= \boldsymbol{Q}^{\boldsymbol{T}}\dot{\bar{\boldsymbol{u}}} \qquad (102.166)
\end{aligned}$$

The third term of (102.163) becomes

$$\begin{aligned}
\int_{\Omega} N_M^p \frac{\dot{p}}{Q_{sf}}\mathrm{d}\Omega &= [\int_{\Omega} N_M^p \frac{1}{Q_{sf}} N_N^p \mathrm{d}\Omega]\dot{\bar{p}}_N \\
&= (S_{MN})\dot{\bar{p}}_N \\
&= \boldsymbol{S}\dot{\bar{\boldsymbol{p}}} \qquad (102.167)
\end{aligned}$$

The equation (102.163) thus becomes

$$(H_{MN})\bar{p}_N + (Q_{LjM})\dot{\bar{u}}_{Lj} + (S_{MN})\dot{\bar{p}}_N = -(f_1^p)_M + (f_2^p)_M = (f^p)_M \tag{102.168}$$

or

$$\boldsymbol{H}\bar{\boldsymbol{p}} + \boldsymbol{Q}^{\boldsymbol{T}}\dot{\bar{\boldsymbol{u}}} + \boldsymbol{S}\dot{\bar{\boldsymbol{p}}} = -\boldsymbol{f_1^p} + \boldsymbol{f_2^p} = \boldsymbol{f^p} \tag{102.169}$$

Matrix form of the governing equations Combine equation (102.161) and (102.168), to obtain

$$\begin{aligned}
&\begin{bmatrix} M_{KiLj} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \ddot{u}_{Lj} \\ \ddot{p}_N \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ Q_{LjM} & S_{MN} \end{bmatrix} \begin{bmatrix} \dot{u}_{Lj} \\ \dot{p}_N \end{bmatrix} \\
&\quad + \begin{bmatrix} (K^{ep})_{KiLj} & -Q_{KiN} \\ 0 & H_{MN} \end{bmatrix} \begin{bmatrix} u_{Lj} \\ p_N \end{bmatrix} = \begin{bmatrix} f_{Ki}^u \\ f_M^p \end{bmatrix}
\end{aligned} \tag{102.170}$$

or, by combining equations (102.162) and (102.169), obtain

$$\begin{bmatrix} \boldsymbol{M} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} \end{bmatrix} \begin{bmatrix} \ddot{\boldsymbol{u}} \\ \ddot{\boldsymbol{p}} \end{bmatrix} + \begin{bmatrix} \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{Q}^T & \boldsymbol{S} \end{bmatrix} \begin{bmatrix} \dot{\boldsymbol{u}} \\ \dot{\boldsymbol{p}} \end{bmatrix} + \begin{bmatrix} \boldsymbol{K}^{ep} & \boldsymbol{Q} \\ \boldsymbol{0} & \boldsymbol{H} \end{bmatrix} \begin{bmatrix} \boldsymbol{u} \\ \boldsymbol{p} \end{bmatrix} = \begin{bmatrix} \boldsymbol{f}^u \\ \boldsymbol{f}^p \end{bmatrix} \tag{102.171}$$

where

$$\boldsymbol{f}^u \quad \leftrightarrow \quad f^u_{Ki} = (f^u_1)_{Ki} + (f^u_2)_{Ki} \tag{102.172}$$

$$\boldsymbol{f}^p \quad \leftrightarrow \quad f^p_M = -(f^p_1)_M + (f^p_2)_M \tag{102.173}$$

and

$$\boldsymbol{f}^u_1 \quad \leftrightarrow \quad (f^u_1)_{Ki} = \int_{\Gamma_t} N^u_K \bar{t}_i \mathrm{d}\Gamma \tag{102.174}$$

$$\boldsymbol{f}^u_2 \quad \leftrightarrow \quad (f^u_2)_{Ki} = \int_{\Omega} N^u_K \rho b_i \mathrm{d}\Omega \tag{102.175}$$

$$\boldsymbol{f}^p_1 \quad \leftrightarrow \quad (f^p_1)_M = \int_{\Gamma_w} N^p_M \bar{w} \mathrm{d}\Gamma \tag{102.176}$$

$$\boldsymbol{f}^p_2 \quad \leftrightarrow \quad (f^p_2)_M = \int_{\Omega} N^p_{M,i} k_{ij} \rho_f b_j \mathrm{d}\Omega \tag{102.177}$$

$$\boldsymbol{M} \quad \leftrightarrow \quad M_{KiLj} = \delta_{ij} \int_{\Omega} N^u_K \rho N^u_L \mathrm{d}\Omega \tag{102.178}$$

$$\boldsymbol{Q} \quad \leftrightarrow \quad Q_{KiN} = \int_{\Omega} \alpha N^u_{K,i} N^p_N \mathrm{d}\Omega \tag{102.179}$$

$$\boldsymbol{S} \quad \leftrightarrow \quad S_{MN} = \int_{\Omega} N^p_M \frac{1}{Q_{sf}} N^p_N \mathrm{d}\Omega \tag{102.180}$$

$$\boldsymbol{H} \quad \leftrightarrow \quad H_{MN} = \int_{\Omega} N^p_{M,i} k_{ij} N^p_{N,j} \mathrm{d}\Omega \tag{102.181}$$

102.12.3.3 8 Node $u-p$ Brick

102.13 Material and Geometric Non–Linear Finite Element Formulation

102.13.1 Introduction

Presented here is a detailed formulation of material and geometric non–linear static finite element system of equations. The configuration of choice is material or Lagrangian. Eulerian and mixed Eulerian-Lagrangian configuration will be mentioned as need be.

102.13.2 Equilibrium Equations

The local form of equilibrium equations in material format (Lagrangian) for static case can be written as:

$$P_{iJ,J} - \rho_0 b_i = 0 \tag{102.182}$$

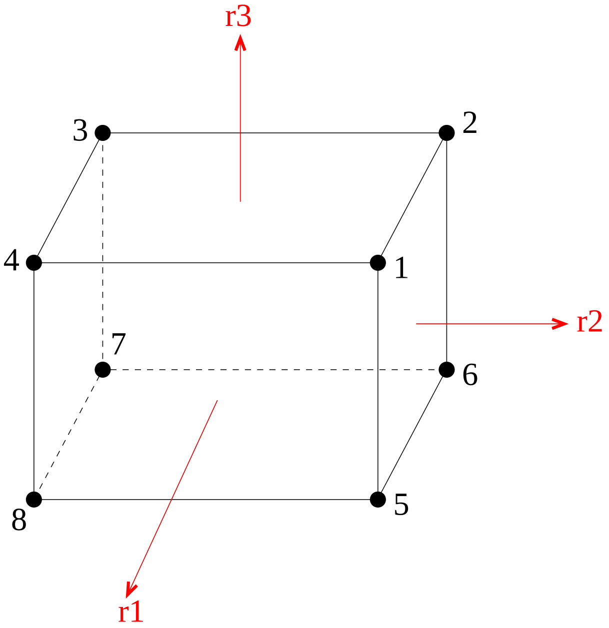

Figure 102.15: 8 node $u-p$ brick element. Note that all four DOFs (three porous solid displacements u_i and a pore fluid pressure p are defined at each node.

where $P_{iJ} = S_{IJ}(F_{iI})^t$ and S_{IJ} are first and second Piola–Kirchhoff stress tensors, respectively and b_I are body forces.

Weak form of equilibrium equations is obtained by premultiplying 102.182 with virtual displacements δu_i and integrating by parts on the initial configuration B_0 (initial volume V_0):

$$\int_{V_0} \delta u_{i,j} P_{ij} dV = \int_{V_0} \rho_0 \delta u_i b_i dV - \int_{S_0} \delta u_i \bar{t}_i dS \tag{102.183}$$

It proves beneficial to rewrite Lagrangian format of weak form of equilibrium equilibrium by using symmetric second Piola–Kirchhoff stress tensor S_{ij}:

$$\begin{aligned}
\int_{V_0} \delta u_{i,j} F_{jl} S_{il} dV &= \\
\int_{V_0} \frac{1}{2} \left(\delta u_{i,j} F_{jl} + F_{lj} \delta u_{j,i} + \right) S_{il} dV &= \\
\int_{V_0} \frac{1}{2} \left(\delta u_{i,j} \left(\delta_{jl} + u_{j,l} \right) + \left(\delta_{lj} + u_{l,j} \right) \delta u_{j,i} \right) S_{il} dV &= \\
\int_{V_0} \frac{1}{2} \left(\delta u_{i,l} + \delta ui, ju_{j,l} \right) + \left(\delta u_{l,i} + u_{l,j} \delta u_{j,i} \right) S_{il} dV &= \\
\int_{V_0} \frac{1}{2} \left(\left(\delta u_{i,l} + \delta u_{l,i} \right) + \left(\delta u_{i,j} u_{j,l} + u_{l,j} \delta u_{j,i} \right) \right) S_{il} dV &=
\end{aligned} \tag{102.184}$$

where symmetry of S_{il} was used, definition for deformation gradient $F_{ki} = \delta_{ki} + u_{k,i}$. In addition, conveniently defined was differential operator $\hat{E}_{il}(\delta u_i, u_i)$ as

$$\hat{E}_{il}(\delta u_i, u_i) = \frac{1}{2}\left(\delta u_{l,i} + \delta u_{i,l}\right) + \frac{1}{2}\left(u_{l,j}\delta u_{j,i} + \delta u_{i,j}u_{j,l}\right) \tag{102.185}$$

102.13.3 Formulation of Non–Linear Finite Element Equations

Consider the motion of a general solid in a fixed, non-moving Cartesian coordinate system, as shown in Figure (102.16), and assume that the solid can experience large displacements, large strains, and nonlinear constitutive response. The aim is to evaluate the equilibrium positions of the complete solid at discrete time points $0, \Delta t, 2\Delta t, \ldots,$ where Δt is an increment in time. To develop the solution strategy, assume that the solutions for the static and kinematic variables for all time steps from 0 to time t inclusive, have been obtained. The solution process for the next required equilibrium position corresponding to time $t + \Delta t$ is typical and would be applied repetitively until a complete solution path has been found. Hence, in the analysis one follows all particles of the solid in their motion, from the original to the final configuration of the solid. In so doing, a Lagrangian (or material) formulation of the problem was adopted.

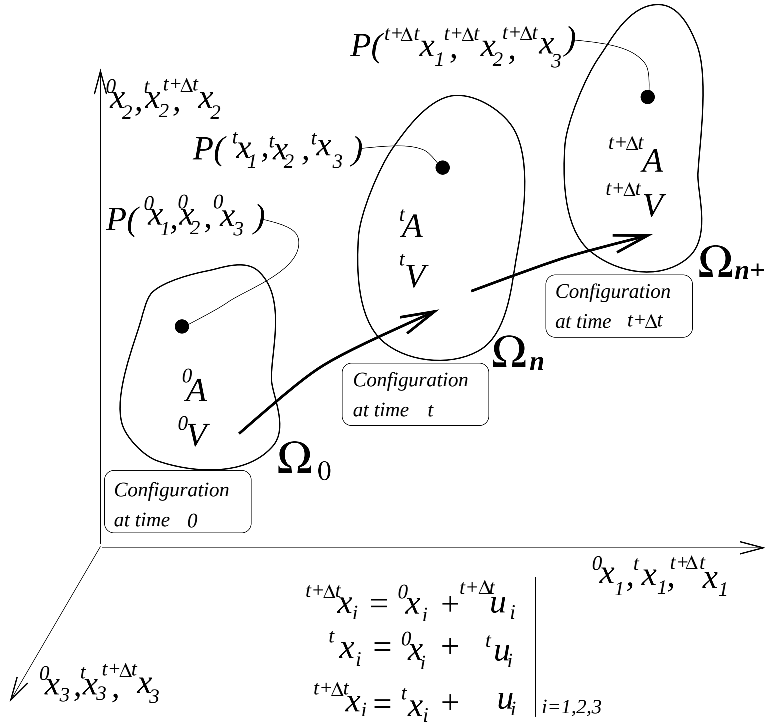

Figure 102.16: Motion of a solid in non-moving Cartesian coordinate system.

Weak format of the equilibrium equations can be obtained by premultiplying 102.182 with virtual displacements δu_i and integrating by parts. We obtain the virtual work equations in the Lagrangian format:

$$\int_{V_0} \delta u_{i,j} P_{ij} dV = \int_{V_0} \rho_0 \delta u_i b_i dV - \int_{S_0} \delta u_i \bar{t}_i dV \tag{102.186}$$

Virtual work equations can also be written in terms of second Piola–Kirchhoff stress tensor S_{IJ} as:

$$\int_{V_0} \delta u_{i,j} F_{jl} S_{il} dV = \int_{V_0} \rho_0 \delta u_i b_i dV + \int_{S_0} \delta u_i \bar{t}_i dV \tag{102.187}$$

which after some algebraic manipulations, and after observing that $S_{IJ} = S_{JI}$ yields (SEE ABOVE!) By introducing a differential operator $\hat{E}(u_1, u_2)$ as:

$$\hat{E}_{il}({}^1u_i, {}^2u_i) = \frac{1}{2}\,\left({}^1u_{i,l} + {}^1u_{l,i}\right) + \frac{1}{2}\,\left({}^1u_{l,j}\ {}^2u_{j,i} + {}^2u_{i,j}\ {}^1u_{j.l}\right) \tag{102.188}$$

virtual work equation 102.185 can be written as:

$$\int_{V_0} \hat{E}_{il}(\delta u_i, u_i) S_{il} dV \quad = \quad \int_{V_0} \rho_0 \delta u_i b_i dV + \int_{S_0} \delta u_i \bar{t}_i dV \tag{102.189}$$

or as:

$$W(\delta u_i, u_i^{(k)})^{int} + W^{ext}(\delta u_i) = 0 \tag{102.190}$$

with:

$$\begin{aligned} W^{int}(\delta u_i, {}^{n+1}_{\ \ 0}u_i^{(k)}) \quad &= \quad \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, {}^{n+1}_{\ \ 0}u_i^{(k)})\ {}^{n+1}_{\ \ 0}S_{ij}^{(k)}\ dV \\ &= \quad \int_{\Omega_c} \left(\left(\delta u_{j,i} + \delta u_{i,j}\right) + \left(u_{j,r}\delta u_{r,i} + \delta u_{i,r} u_{r,j}\right)\right)\ S_{ij}^{(k)}\ dV \end{aligned} \tag{102.191}$$

$$W^{ext}(\delta u_i) \quad = \quad -\int_{\Omega_c} \rho_0\ \delta u_i\ {}^{n+1}_{\ \ 0}b_i\ dV - \int_{\partial\Omega_c} \delta u_i\ {}^{n+1}_{\ \ 0}t_i\ dS \tag{102.192}$$

102.13.4 Computational Domain in Incremental Analysis

This chapter elaborates on the choice of Total Lagrangian (TL) formulations as a computational domain. In addition, a Newton-type procedure is chosen for satisfying equilibrium, i.e., virtual work for a given computational domain. Given the displacement field $u_i^{(k)}(X_j)$, in iteration k, the iterative change δu_i

$$u_i^{(k+1)} = u_i^{(k)} + \Delta u_i \tag{102.193}$$

is obtained from the linearized virtual work expression

$$W(\delta u_i, u_i^{(k+1)}) \simeq W(\delta u_i, u_i^{(k)}) + \Delta W(\delta u_i, \Delta u_i; u_i^{(k)}) \tag{102.194}$$

Here, $W(\delta u_i, u_i^{(k)})$ is the virtual work expression

$$W(\delta u_i, u_i^{(k)}) = W(\delta u_i, u_i^{(k)})^{int} + W^{ext}(\delta u_i) \tag{102.195}$$

with

$$W^{int}(\delta u_i, {}^{n+1}_{\;\;0}u_i^{(k)}) = \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, {}^{n+1}_{\;\;0}u_i^{(k)})\; {}^{n+1}_{\;\;0}S_{ij}^{(k)}\; dV \tag{102.196}$$

$$W^{ext}(\delta u_i) = -\int_{\Omega_c} \rho_0\; \delta u_i\; {}^{n+1}_{\;\;0}b_i\; dV - \int_{\partial\Omega_c} \delta u_i\; {}^{n+1}_{\;\;0}t_i\; dS \tag{102.197}$$

and the $\Delta W(\delta u_i, \Delta u_i; u_i^{(k)})$ is the linearization of virtual work

$$\begin{aligned} \Delta W(\delta u_i, \Delta u_i; u_i^{(k)}) &= \lim_{\epsilon \to 0} \frac{\partial W(\delta u_i, u_i + \epsilon \Delta u_i)}{\partial \epsilon} \\ &= \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, u_i)\; dS_{ij}\; dV + \int_{\Omega_c} \Delta\hat{E}_{ij}(\delta u_i, u_i)\; S_{ij} dV \\ &= \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, u_i)\; \mathcal{L}_{ijkl}\; \hat{E}_{kl}(\Delta u_i, u_i)\; dV + \int_{\Omega_c} \Delta\hat{E}_{ij}(\delta u_i, u_i)\; S_{ij}\; dV \end{aligned} \tag{102.198}$$

Here it was used that $dS_{ij} = 1/2\; \mathcal{L}_{ijkl} dC_{kl} = \mathcal{L}_{ijkl}\hat{E}_{kl}(\Delta u_i, u_i)$.

In order to obtain expressions for stiffness matrix, work is done on equation 102.198 in some more details. To this end, equation 102.198 can be rewritten by expanding definitions for $\hat{E}$ as

$$\begin{aligned} &\Delta W(\delta u_i, \Delta u_i; u_i^{(k)}) = \\ &\frac{1}{4}\int_{\Omega_c} \left(\left(\delta u_{j,i} + \delta u_{i,j}\right) + \left(u_{j,r}\delta u_{r,i} + \delta u_{i,r}u_{r,j}\right)\right)\; \mathcal{L}_{ijkl}\; \left(\left(\Delta u_{k,l} + \Delta u_{l,k}\right) + \left(u_{k,s}\Delta u_{s,l} + \Delta u_{l,s}u_{s,k}\right)\right)\; dV + \\ &+ \int_{\Omega_c} \frac{1}{2}\left(\Delta u_{j,l}\delta u_{l,i} + \delta u_{i,l}\Delta u_{l,j}\right) S_{ij}\; dV \end{aligned} \tag{102.199}$$

Or, by conveniently splitting the above equation

$$\begin{aligned} &\Delta^1 W(\delta u_i, \Delta u_i; u_i^{(k)}) = \\ &\frac{1}{4}\int_{\Omega_c} \left(\left(\delta u_{j,i} + \delta u_{i,j}\right) + \left(u_{j,r}\delta u_{r,i} + \delta u_{i,r}u_{r,j}\right)\right)\; \mathcal{L}_{ijkl}\; \left(\left(\Delta u_{k,l} + \Delta u_{l,k}\right) + \left(u_{k,s}\Delta u_{s,l} + \Delta u_{l,s}u_{s,k}\right)\right)\; dV \end{aligned} \tag{102.200}$$

$$\Delta^2 W(\delta u_i, \Delta u_i; u_i^{(k)}) = \int_{\Omega_c} \frac{1}{2}\left(\Delta u_{j,l}\delta u_{l,i} + \delta u_{i,l}\Delta u_{l,j}\right) S_{ij}\; dV \tag{102.201}$$

By further working on equation 102.200

$$\begin{aligned} \Delta^1 W(\delta u_i, \Delta u_i; u_i^{(k)}) = \quad & \int_{\Omega_c} \left(\frac{1}{2}\left(\delta u_{j,i} + \delta u_{i,j}\right)\right)\; \mathcal{L}_{ijkl}\; \left(\frac{1}{2}\left(\Delta u_{k,l} + \Delta u_{l,k}\right)\right)\; dV \\ + \quad & \int_{\Omega_c} \left(\frac{1}{2}\left(\delta u_{j,i} + \delta u_{i,j}\right)\right)\; \mathcal{L}_{ijkl}\; \left(\frac{1}{2}\left(u_{k,s}\Delta u_{s,l} + \Delta u_{l,s}u_{s,k}\right)\right) dV \\ + \quad & \int_{\Omega_c} \frac{1}{2}\left(u_{j,r}\delta u_{r,i} + \delta u_{i,r}u_{r,j}\right) \mathcal{L}_{ijkl}\; \frac{1}{2}\left(u_{k,s}\Delta u_{s,l} + \Delta u_{l,s}u_{s,k}\right) dV \\ + \quad & \int_{\Omega_c} \frac{1}{2}\left(u_{j,r}\delta u_{r,i} + \delta u_{i,r}u_{r,j}\right) \mathcal{L}_{ijkl}\; \left(\frac{1}{2}\left(\Delta u_{k,l} + \Delta u_{l,k}\right)\right)\; dV \end{aligned} \tag{102.202}$$

It should be noted that the Algorithmic Tangent Stiffness (ATS) tensor $\mathcal{L}_{ijkl}$ poses both minor symmetries ($\mathcal{L}_{ijkl} = \mathcal{L}_{jikl} = \mathcal{L}_{ijlk}$). However, Major symmetry cannot be guaranteed. Non–associated flow rules in elastoplasticity lead to the loss of major symmetry ($\mathcal{L}_{ijkl} \neq \mathcal{L}_{klij}$). Moreover, it can be shown (i.e., Jeremić and Sture (1997)) that there is algorithmic induced symmetry loss even for associated flow rules.

With the minor symmetry of $\mathcal{L}_{ijkl}$ one can write (102.202) as:

$$\begin{aligned}\Delta^1 W(\delta u_i, \Delta u_i; u_i^{(k)}) = & \int_{\Omega_c} \delta u_{i,j} \; \mathcal{L}_{ijkl} \; \Delta u_{l,k} dV \\ + & \int_{\Omega_c} \delta u_{i,j} \; \mathcal{L}_{ijkl} \; u_{k,s} \Delta u_{l,s} dV \\ + & \int_{\Omega_c} \delta u_{i,r} u_{r,j} \; \mathcal{L}_{ijkl} \; u_{k,s} \Delta u_{l,s} dV \\ + & \int_{\Omega_c} \delta u_{i,r} u_{r,j} \; \mathcal{L}_{ijkl} \; \Delta u_{l,k} dV \end{aligned} \tag{102.203}$$

Similarly, by observing symmetry of second Piola–Kirchhoff stress tensor S_{ij}

$$\Delta^2 W(\delta u_i, \Delta u_i; u_i^{(k)}) = \int_{\Omega_c} \delta u_{i,l} \Delta u_{l,j} \; S_{ij} dV \tag{102.204}$$

Weak form of equilibrium expressions (i.e. (102.192) and (102.192)) for internal (W^{int}) and external (W^{ext}) virtual work, with the above mentioned symmetry of S_{ij} can be written as

$$W^{int}(\delta u_i, {}^{n+1}_{\;\;0}u_i^{(k)}) = \int_{\Omega_c} \delta u_{i,j} \; S_{ij} dV + \int_{\Omega_c} \delta u_{i,r} u_{r,j} \; S_{ij} dV \tag{102.205}$$

$$W^{ext}(\delta u_i) \;\; = \;\; - \int_{\Omega_c} \rho_0 \; \delta u_i b_i \; dV - \int_{\partial\Omega_c} \delta u_i \; t_i \; dS \tag{102.206}$$

Standard finite element discretization of displacement field yields:

$$u_i \approx \hat{u}_i = H_I \bar{u}_{Ii} \tag{102.207}$$

where $\hat{u}_i$ is the approximation to exact, analytic (if it exists) displacement field u_i, H_I are standard FEM shape functions and $\bar{u}_{Ii}$ are nodal displacements. With this approximation

$$\begin{aligned}\Delta^1 W(\delta u_i, \Delta u_i; u_i^{(k)}) = & \int_{\Omega_c} \left(H_{I,j} \delta \bar{u}_{Ii}\right) \; \mathcal{L}_{ijkl} \; \left(H_{Q,k} \Delta \bar{u}_{Ql}\right) dV \\ + & \int_{\Omega_c} \left(H_{I,j} \delta \bar{u}_{Ii}\right) \; \mathcal{L}_{ijkl} \; \left(H_{J,k} \bar{u}_{Js}\right) \left(H_{Q,s} \Delta \bar{u}_{Ql}\right) dV \\ + & \int_{\Omega_c} \left(H_{I,r} \delta \bar{u}_{Ii}\right) \left(H_{J,j} \bar{u}_{Jr}\right) \mathcal{L}_{ijkl} \; \left(H_{J,k} \bar{u}_{Js}\right) \left(H_{Q,s} \Delta \bar{u}_{Ql}\right) dV \\ + & \int_{\Omega_c} \left(H_{I,r} \delta \bar{u}_{Ii}\right) \left(H_{J,j} \bar{u}_{Jr}\right) \mathcal{L}_{ijkl} \; \left(H_{Q,k} \Delta \bar{u}_{Ql}\right) dV \end{aligned} \tag{102.208}$$

$$\Delta^2 W(\delta u_i, \Delta u_i; u_i^{(k)}) = \int_{\Omega_c} \left(H_{I,l}\delta \bar{u}_{Ii}\right) \left(H_{Q,j}\Delta \bar{u}_{Ql}\right) S_{ij} dV \tag{102.209}$$

$$W^{int}(\delta u_i, {}^{n+1}_{\ \ 0}u_i^{(k)}) = \int_{\Omega_c} \left(H_{I,j}\delta \bar{u}_{Ii}\right)\ S_{ij} dV + \int_{\Omega_c} \left(H_{I,r}\delta \bar{u}_{Ii}\right)\ \left(H_{J,j}\bar{u}_{Jr}\right)\ S_{ij} dV \tag{102.210}$$

$$W^{ext}(\delta u_i) \ = \ -\int_{\Omega_c} \rho_0\ \left(H_I \delta \bar{u}_{Ii}\right)\ b_i\ dV - \int_{\partial\Omega_c} \left(H_I \delta \bar{u}_{Ii}\right)\ t_i\ dS \tag{102.211}$$

Upon noting that virtual nodal displacements δu_{Ii} are any non–zero, continuous displacements, and since they occur in all expressions for linearized virtual work (from Equations (102.194), (102.195), (102.196), (102.197) and (102.198)) they can be factored out so that (while remembering that $\Delta W^1 + \Delta W^2 + W^{ext} + W^{int} = 0$):

$$\begin{aligned}
& \int_{\Omega_c} \left(H_{I,j}\right)\ \mathcal{L}_{ijkl}\ \left(H_{Q,k}\Delta \bar{u}_{Ql}\right) dV \\
+ & \int_{\Omega_c} \left(H_{I,j}\right)\ \mathcal{L}_{ijkl}\ \left(H_{J,k}\bar{u}_{Js}\right) \left(H_{Q,s}\Delta \bar{u}_{Ql}\right) dV \\
+ & \int_{\Omega_c} \left(H_{I,r}\right) \left(H_{J,j}\bar{u}_{Jr}\right) \mathcal{L}_{ijkl}\ \left(H_{J,k}\bar{u}_{Js}\right) \left(H_{Q,s}\Delta \bar{u}_{Ql}\right) dV \\
+ & \int_{\Omega_c} \left(H_{I,r}\right) \left(H_{J,j}\bar{u}_{Jr}\right) \mathcal{L}_{ijkl}\ \left(H_{Q,k}\Delta \bar{u}_{Ql}\right) dV \\
+ & \int_{\Omega_c} \left(H_{I,l}\right) \left(H_{Q,j}\Delta \bar{u}_{Ql}\right) S_{ij} dV \\
+ & \int_{\Omega_c} \left(H_{I,j}\right)\ S_{ij} dV + \int_{\Omega_c} \left(H_{I,r}\right)\ \left(H_{J,j}\bar{u}_{Jr}\right)\ S_{ij} dV \\
= & \int_{\Omega_c} \rho_0\ \left(H_I\right)\ b_i\ dV + \int_{\partial\Omega_c} \left(H_I\right)\ t_i\ dS
\end{aligned} \tag{102.212}$$

By rearranging previous equations, one can write:

$$\begin{aligned}
& \left(\int_{\Omega_c} H_{I,j}\mathcal{L}_{ijkl}H_{Q,k} dV + \int_{\Omega_c} H_{I,j}\mathcal{L}_{ijkl}H_{J,k}\bar{u}_{Js}H_{Q,s} dV + \int_{\Omega_c} H_{I,r}H_{J,j}\bar{u}_{Jr}\mathcal{L}_{ijkl}H_{J,k}\bar{u}_{Js}H_{Q,s} dV\right. \\
+ & \left.\int_{\Omega_c} H_{I,r}H_{J,j}\bar{u}_{Jr}\mathcal{L}_{ijkl}H_{Q,k} dV + \int_{\Omega_c} H_{I,l}H_{Q,j}S_{ij} dV\right) \Delta \bar{u}_{Ql} \\
+ & \int_{\Omega_c} \left(H_{I,j}\right)\ S_{ij} dV + \int_{\Omega_c} \left(H_{I,r}\right)\ \left(H_{J,j}\bar{u}_{Jr}\right)\ S_{ij} dV \\
= & \int_{\Omega_c} \rho_0\ \left(H_I\right)\ b_i\ dV + \int_{\partial\Omega_c} \left(H_I\right)\ t_i\ dS
\end{aligned} \tag{102.213}$$

The vectors of external and internal forces are

$$\mathbf{f}_{int} \ = \ \frac{\partial(W^{int}(\delta u_i, {}^{n+1}_{\ \ 0}u_i^{(k)}))}{\partial(\delta u_i)} \tag{102.214}$$

$$\mathbf{f}_{ext} \ = \ \frac{\partial(W^{ext}(\delta u_i))}{\partial(\delta u_i)} \tag{102.215}$$

The Algorithmic Tangent Stiffness (ATS) tensor $\mathcal{L}^{ATS}_{ijkl}$ is defined as a linearization of second Piola–Kirchhoff stress tensor S_{ij} with respect to the right deformation tensor C_{kl}

$$dS_{ij} = \frac{1}{2}\,\mathcal{L}_{ijkl}\,dC_{kl} \quad \text{with} \quad dC_{kl} = 2\,\hat{E}_{kl}(du_i, u_i) \tag{102.216}$$

Then, the global algorithmic tangent stiffness matrix (tensor) is given as

$$\mathbf{K}_t = \frac{\partial(\Delta W(\delta u_i, \Delta u_i; u_i^{(k)}))}{\partial(\delta u_i)} \tag{102.217}$$

The iterative change in displacement vector Δu_i is obtained by setting a linearized virtual work to zero

$$W(\delta u_i, u_i^{(k+1)}) = 0 \quad \Rightarrow \quad W(\delta u_i, u_i^{(k)}) = -\Delta W(\delta u_i, \Delta u_i; u_i^{(k)}) \tag{102.218}$$

102.13.4.1 Total Lagrangian Format

The undeformed configuration Ω_0 is chosen as the computational domain ($\Omega_c = \Omega_0$). The iterative displacement Δu_i is obtained from the equation

$$W(\delta u_i, {}^{n+1}u_i^{(k)}) = -\Delta W(\delta u_i, \Delta u_i; {}^{n+1}u_i^{(k)}) \tag{102.219}$$

where

$$\begin{aligned} W(\delta u_i, {}^{n+1}u_i^{(k)}) \;\; &= \;\; \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, {}^{n+1}u_i^{(k)})\; {}^{n+1}S_{ij}^{(k)}\; dV \\ &\quad - \int_{\Omega_c} \rho_0\; \delta u_i\; {}^{n+1}b_i\; dV - \int_{\partial\Omega_c} \delta u_i\; {}^{n+1}t_i\; dS \end{aligned} \tag{102.220}$$

and

$$\begin{aligned} \Delta W(\delta u_i, \Delta u_i; {}^{n+1}u_i^{(k)}) \;\; &= \;\; \int_{\Omega_c} \hat{E}_{ij}(\delta u_i, {}^{n+1}u_i^{(k)})\; {}^{n+1}\mathcal{L}_{ijkl}^{(k)}\; \hat{E}_{kl}(\Delta u_i, {}^{n+1}u_i^{(k)})\; dV \\ &\quad + \int_{\Omega_c} d\hat{E}_{ij}(\delta u_i, \Delta u_i)\; {}^{n+1}S_{ij}^{(k)}\; dV \end{aligned} \tag{102.221}$$

In the case of hyperelastic–plastic response, second Piola–Kirchhoff stress ${}^{n+1}S_{ij}^{(k)}$ is obtained by integrating the constitutive law, described in Chapter 106.4. It should be noted that by integrating in the intermediate configuration, obtained is Mandel stress ${}^{n+1}\bar{T}_{ij}$ and subsequently[24] the second Piola–Kirchhoff stress $\bar{S}_{kj}$. The ATS tensor $\bar{\mathcal{L}}_{ijkl}$ is then obtained based on $\bar{S}_{kj}$. In order to obtain second Piola–Kirchhoff stress S_{kj} and ATS tensor in initial configuration, a pull-back from the intermediate configuration to the initial configuration is performed

$${}^{n+1}S_{ij} = {}^{n+1}F^p_{ip}\; {}^{n+1}F^p_{jq}\; {}^{n+1}\bar{S}_{pq} \tag{102.222}$$

$${}^{n+1}\mathcal{L}_{ijkl} = {}^{n+1}F^p_{im}\; {}^{n+1}F^p_{jn}\; {}^{n+1}F^p_{kr}\; {}^{n+1}F^p_{ls}\; {}^{n+1}\bar{\mathcal{L}}_{mnrs} \tag{102.223}$$

---

[24] $\bar{S}_{kj} = \left(\bar{C}_{ik}\right)^{-1} \bar{T}_{ij}$

102.13.5 Finite Element Formulations

Presented here is a slightly different approach to developing large deformation FEM in total Lagrangian form. Lower case indices are used for variables in current configuration, while the capital case indices are used for the reference configuration.

102.13.5.1 Strong Form

The static, strong form of momentum balance in the current configuration is

$$\frac{\partial \sigma_{ij}}{\partial x_j} + \rho b_i = 0 \tag{102.224}$$

where σ_{ij} is the Cauchy stress, rho is the material density, b_i is the material body force.

Used here was the so-called Total Lagrangian formulation that is based on the reference configuration. The strong form of momentum balance can be expressed in the reference configuration

$$\frac{\partial P_{iJ}}{\partial X_J} + \rho_0 b_i = 0 \tag{102.225}$$

where P_{iJ} is the first Pialo-Kirchhoff stress, ρ_0 is the material Lagrangian density and $\rho_0 = J\rho$.

102.13.5.2 Weak Form

The corresponding weak form of Equation 102.225 can be expressed as

$$\int_{\Omega_0} \delta u_i \left(\frac{\partial P_{iJ}}{\partial X_J} + \rho_0 b_i \right) dV = 0 \tag{102.226}$$

where δu_i is some arbitrary virtual displacement, Ω_0 is the concerned domain of the reference configuration. Using the partial integration rule, the above equation can be alternatively expressed as

$$\int_{\Omega_0} \frac{\partial}{\partial X_J} \left(P_{iJ} \delta u_i \right) dV - \int_{\Omega_0} P_{iJ} \frac{\partial \delta u_i}{\partial X_J} dV + \int_{\Omega_0} \rho_0 b_i \delta u_i dV = 0 \tag{102.227}$$

The first term of Equation 102.227 can be rewritten in terms of the surface traction

$$\int_{\Omega_0} \frac{\partial}{\partial X_J} \left(P_{iJ} \delta u_i \right) dV = \int_{\partial\Omega_0} \delta u_i P_{iJ} H_J dA = \int_{\partial\Omega_0} t_i \delta u_i dA \tag{102.228}$$

with the traction $t_i = P_{iJ} H_J$, where H_J the unit surface normal vector in the reference configuration, and $\partial\Omega_0$ is the boundary of the reference domain Ω_0.

The second term of Equation 102.227 can be rewritten as

$$\int_{\Omega_0} P_{iJ} \frac{\partial \delta u_i}{\partial X_J} dV = \int_{\Omega_0} P_{iJ} \delta F_{iJ} dV = \int_{\Omega_0} S_{IJ} \delta E_{IJ} dV \tag{102.229}$$

where S_{IJ} is the second Pialo-Kirchhoff stress and E_{IJ} is the Lagrangian-Green strain. $\delta F_{iJ} = \partial \delta u_i / \partial X_J$ is used.

The overall weak form in the reference configuration is now

$$\int_{\Omega_0} S_{IJ} \delta E_{IJ} dV = \int_{\partial \Omega_0} t_i \delta u_i dA + \int_{\Omega_0} \rho_0 b_i \delta u_i dV \tag{102.230}$$

102.13.5.3 Linearized Form

To utilize the iterative algorithm for incremental strategy, needed is the linearized form the governing equation 102.230.

The first term linearization of Equation 102.230 is

$$\begin{aligned} \Delta \int_{\Omega_0} S_{IJ} \delta E_{IJ} &= \int_{\Omega_0} \left[\Delta S_{IJ} \delta E_{IJ} + S_{IJ} \delta(\Delta E_{IJ}) \right] dV \\ &= \int_{\Omega_0} \left[\mathcal{L}_{IJKL} \Delta E_{KL} \delta E_{IJ} + S_{IJ} \delta(\Delta E_{IJ}) \right] dV \end{aligned} \tag{102.231}$$

where $\mathcal{L}_{IJKL}$ is the Lagrangian stiffness linked the second Pialo-Kirchhoff stress S_{IJ} and the Lagrangian-Green strain E_{KL} by the relation

$$S_{IJ} = \mathcal{L}_{IJKL} E_{KL} \tag{102.232}$$

The linearization of E_{KL} is

$$\Delta E_{KL} = Sym \left(F_K \frac{\partial \Delta u_b}{\partial X_L} \right) \tag{102.233}$$

where Sym is the operator of tensor symmetry, defined as $Sym(A_{ij}) := (1/2)(A_{ij} + A_{ji})$. Similarly,

$$\delta E_{IJ} = Sym \left(F_{aI} \frac{\partial \delta u_a}{\partial X_J} \right) \tag{102.234}$$

and

$$\delta(\Delta E_{IJ}) = Sym \left(\frac{\partial \delta u_c}{\partial X_I} \frac{\partial \Delta u_c}{\partial X_J} \right) \tag{102.235}$$

Note that S_{IJ} is a symmetric tensor, and L_{IJKL} is a tensor with major and minor symmetries, Equation 102.231 can be expressed as

$$\begin{aligned} \Delta \int_{\Omega_0} S_{IJ} \delta E_{IJ} &= \int_{\Omega_0} \left[\mathcal{L}_{IJKL} \left(F_{bK} \frac{\partial \Delta u_b}{\partial X_L} \right) \left(F_{aI} \frac{\partial \delta u_a}{\partial X_J} \right) + S_{IJ} \left(\frac{\partial \delta u_c}{\partial X_I} \frac{\partial \Delta u_c}{\partial X_J} \right) \right] dV \\ &= \int_{\Omega_0} \left[\frac{\partial \delta u_a}{\partial X_J} \left(F_{aI} F_{bK} \mathcal{L}_{IJKL} + \delta_{ab} S_{JL} \right) \frac{\partial \Delta u_b}{\partial X_L} \right] dV \end{aligned} \tag{102.236}$$

The overall linearization form is thus

$$\int_{\Omega_0} \left[\frac{\partial \delta u_a}{\partial X_J} \left(F_{aI} F_{bK} \mathcal{L}_{IJKL} + \delta_{ab} S_{JL} \right) \frac{\partial \Delta u_b}{\partial X_L} \right] dV = \int_{\partial \Omega_0} \Delta t_i \delta u_i dA + \int_{\Omega_0} \rho_0 \Delta b_i \delta u_i dV \tag{102.237}$$

102.13.5.4 Finite Element Form

In finite element form, the displacements u_i are interpolated from the element nodal displacements $\bar{u}_{Ai}$:

$$u_i = H_A \bar{u}_{Ai} \tag{102.238}$$

where H_A is the element shape function of the node A, $\bar{u}_{Ai}$ is the node A displacements, and

$$\frac{\partial \delta u_a}{\partial X_J} = \frac{\partial H_A}{\partial X_J}\delta \bar{u}_{Aa}, \quad \frac{\partial \Delta u_b}{\partial X_L} = \frac{\partial H_B}{\partial X_L}\Delta \bar{u}_{Bb} \tag{102.239}$$

Equation 102.237 can be expressed as

$$\left(K_{AaBb}\ \Delta \bar{u}_{Bb}\ - \Delta f^{ex}_{Aa}\right)\delta \bar{u}_{Aa} = 0 \tag{102.240}$$

where

$$K_{AaBb} = \int_{\Omega_0} \frac{\partial H_A}{\partial X_J}\left(F_{aI}F_{bK}\mathcal{L}_{IJKL} + \delta_{ab}S_{JL}\right)\frac{\partial H_B}{\partial X_L} dV \tag{102.241}$$

$$\Delta f^{ex}_{Aa} = \int_{\partial\Omega_0} H_A \Delta t_i dA + \int_{\Omega_0} \rho_0 H_A \Delta b_i dV \tag{102.242}$$

Due to the arbitrariness of the virtual nodal displacements, the expression in the parentheses should be zero in Equation 102.240, which gives the incremental finite element form:

$$K_{AaBb}\ \Delta \bar{u}_{Bb}\ = \Delta f^{ex}_{Aa} \tag{102.243}$$

102.14 Cosserat Continuum Finite Element Formulation

102.14.1 Introduction

The classical theory of elasticity describes well the behavior of metals, like steel and aluminum. But when the micro-structure of the material becomes significant, like soil and sand, the classical elasticity lacks the ability to represent the granular media properties. In 1909, Cosserat Cosserat (1909) brothers published their prominent work on the Cosserat continua to remove the shortcomings of the classical elasticity. Compared to the classical continua, Cosserat continua has the additional couple stress to reflect the free rotations on the particles.

102.14.1.1 3D Finite Element Formulation for Cosserat Continua

Pothier Pothier and Rencis (1994) proposed the three-dimensional finite element formulation for micro-polar elasticity with both classical strain and the micro-polar strain components. Riahi Dehkordi (2008) developed the finite element Cosserat formulation with the application in layered structures. This article contributes the three-dimensional finite element formulation with the micro-polar strain, which simplifies further development in the elastoplasticity algorithm. In addition, the formulation for the isoparametric brick element is provided.

102.14.1.2 Cosserat Elastoplastic Algorithm

Vardoulakis et al. Vardoulakis (1989); Papamichos et al. (1990) developed the 2D Cosserat plasticity to predict the thickness of shear bands in granular materials. De Borst de Borst (1993, 1991) applied the 2D Cosserat elastoplasticity to analyze the strain localization. Li Li and Bing Chen (2005) applied the 2D pressure-dependent Cosserat elastoplasticity to simulate the strain localization. Grammenoudis Grammenoudis and Tsakmakis (2005) implemented the micro-polar plasticity in the finite deformation framework. This article developed the implicit algorithms for 3D Cosserat plasticity. Rotational kinematic hardening is introduced to the Cosserat elastoplasticity.

102.14.2 Cosserat Elasticity

The Cosserat (micro-polar) elasticity has 6 parameters Pothier and Rencis (1994) , including λ, μ, χ, π_1, π_2, π_3.

The units of λ, μ, and χ are $Newton/(meter^2)$. The units of π_1, π_2, and π_3 are $Newton$.

102.14.2.1 Stress

The stress is the same to the classical elastic stress Riahi and Curran (2009); Dehkordi (2008),

$$\sigma = \begin{pmatrix} \sigma_{11} & \sigma_{12} & \sigma_{13} \\ \sigma_{21} & \sigma_{22} & \sigma_{23} \\ \sigma_{31} & \sigma_{32} & \sigma_{33} \end{pmatrix} \tag{102.244}$$

where the unit of σ is force per unit area ($Newton/meter^2$).

102.14.2.2 Couple Stress

The couple-stress is the couple stress of the classical elastic stress.

$$\boldsymbol{t} = \begin{pmatrix} t_{11} & t_{12} & t_{13} \\ t_{21} & t_{22} & t_{23} \\ t_{31} & t_{32} & t_{33} \end{pmatrix} \tag{102.245}$$

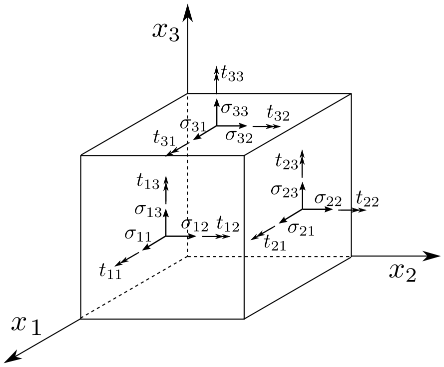

Figure 102.17: Illustration of Stress and Couple Stress

where the unit of $\boldsymbol{t}$ is torque per unit area ($Newton/meter$).

In the classical elasticity, the stress is symmetric: $\sigma_{12} = \sigma_{21}$. This is no longer true in the Cosserat materials. Namely, $\sigma_{12} \neq \sigma_{21}$ due to the couple stress.

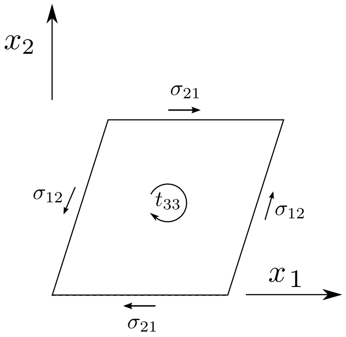

Figure 102.18: Illustration of Asymmetric Stress due to Couple Stress

102.14.2.3 Generalized Stress

In the calculation, for the purpose of simplification, the generalized stress are defined by :

$$
\begin{aligned}
&\boldsymbol{\sigma} = [\sigma \vdots t] \\
&\boldsymbol{\sigma} = [\sigma_{11}\ \sigma_{12}\ \sigma_{13}\ \sigma_{21}\ \sigma_{22}\ \sigma_{23}\ \sigma_{31}\ \sigma_{32}\ \sigma_{33} \vdots t_{11}\ t_{12}\ t_{13}\ t_{21}\ t_{22}\ t_{23}\ t_{31}\ t_{32}\ t_{33}]
\end{aligned}
\qquad (102.246)
$$

Namely, the generalized stress $\boldsymbol{\sigma}$ (18×1) is a horizontal combination of σ and t.

102.14.2.4 Cosserat Strain

$$\epsilon = u_{j,i} - e_{ijk}\phi_k = \begin{pmatrix} u_{1,1} & u_{2,1} - \phi_3 & u_{3,1} + \phi_2 \\ u_{1,2} + \phi_3 & u_{2,2} & u_{3,2} - \phi_1 \\ u_{1,3} - \phi_2 & u_{2,3} + \phi_1 & u_{3,3} \end{pmatrix} \tag{102.247}$$

where e_{ijk} is the permutation symbol.

where u and ϕ are the displacement and micro-rotation respectively.

Note that generally $\epsilon_{12} \neq \epsilon_{21}$ even when $\boldsymbol{\phi} = 0$.

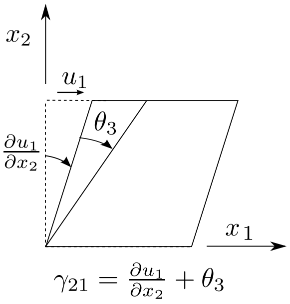

Figure 102.19: Illustration of Asymmetric Strain due to Rotations

102.14.2.5 Curvature

$$\boldsymbol{\omega} = \phi_{i,j} = \begin{pmatrix} \phi_{1,1} & \phi_{1,2} & \phi_{1,3} \\ \phi_{2,1} & \phi_{2,2} & \phi_{2,3} \\ \phi_{3,1} & \phi_{3,2} & \phi_{3,3} \end{pmatrix} \tag{102.248}$$

where ϕ is called the micro-rotation and ω is called the Cosserat rotation gradient (curvature).

102.14.2.6 Generalized Strain

In the calculation, for the purpose of simplification, the Generalized Strain are defined by :

$$\begin{aligned} \xi &= [\epsilon \vdots \omega] \\ \xi &= [\epsilon_{11}\ \epsilon_{12}\ \epsilon_{13}\ \epsilon_{21}\ \epsilon_{22}\ \epsilon_{23}\ \epsilon_{31}\ \epsilon_{32}\ \epsilon_{33} \vdots \omega_{11}\ \omega_{12}\ \omega_{13}\ \omega_{21}\ \omega_{22}\ \omega_{23}\ \omega_{31}\ \omega_{32}\ \omega_{33}] \end{aligned} \tag{102.249}$$

The generalized strain ξ (18×1) is a horizontal combination of ϵ and κ.

102.14.2.7 Constitutive Equations

Force Tangent: The relationship between the stress and strain Pothier and Rencis (1994) is

$$\sigma_{ij} = \lambda\epsilon_{kk}\delta_{ij} + \mu\epsilon_{ij} + (\mu + \chi)\epsilon_{ji} \tag{102.250}$$

Therefore, the tangent between stress and strain is

$$E_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mu \delta_{ik} \delta_{jl} + (\mu + \chi) \delta_{jk} \delta_{il} \tag{102.251}$$

Curvature Tangent: The relationship between the couple-stress and curvature is

$$t_{ij} = \pi_1 \omega_{kk} \delta_{ij} + \pi_2 \omega_{ij} + \pi_3 \omega_{ji} \tag{102.252}$$

Therefore, the tangent between couple-stress and curvature is

$$C_{ijkl} = \pi_1 \delta_{ij} \delta_{kl} + \pi_2 \delta_{ik} \delta_{jl} + \pi_3 \delta_{jk} \delta_{il} \tag{102.253}$$

102.14.2.8 Relation to the classical elasticity tangent

When $\chi = \pi_1 = \pi_2 = \pi_3 = 0$, the curvature tangent is zero, and the force tangent is the same to the classical elasticity tangent.

Full tangent matrix for one Cosserat point:

$$\mathcal{D}^{full}_{18\times 18} = \begin{pmatrix} D^{force}_{9\times 9} & [0]_{9\times 9} \\ [0]_{9\times 9} & D^{curvature}_{9\times 9} \end{pmatrix}_{18\times 18} \tag{102.254}$$

102.14.2.9 Flatten the tensor of force tangent and curvature tangent

Corresponding to the defined generalized stress and generalized strain, flatten the $3 \times 3 \times 3 \times 3$ tensor C_{ijkl} to 9×9 matrix D.

$$D_{9\times 9} = \begin{pmatrix} C_{1111} & C_{1112} & C_{1113} & C_{1121} & C_{1122} & C_{1123} & C_{1131} & C_{1132} & C_{1133} \\ C_{1211} & C_{1212} & C_{1213} & C_{1221} & C_{1222} & C_{1223} & C_{1231} & C_{1232} & C_{1233} \\ C_{1311} & C_{1312} & C_{1313} & C_{1321} & C_{1322} & C_{1323} & C_{1331} & C_{1332} & C_{1333} \\ C_{2111} & C_{2112} & C_{2113} & C_{2121} & C_{2122} & C_{2123} & C_{2131} & C_{2132} & C_{2133} \\ C_{2211} & C_{2212} & C_{2213} & C_{2221} & C_{2222} & C_{2223} & C_{2231} & C_{2232} & C_{2233} \\ C_{2311} & C_{2312} & C_{2313} & C_{2321} & C_{2322} & C_{2323} & C_{2331} & C_{2332} & C_{2333} \\ C_{3111} & C_{3112} & C_{3113} & C_{3121} & C_{3122} & C_{3123} & C_{3131} & C_{3132} & C_{3133} \\ C_{3211} & C_{3212} & C_{3213} & C_{3221} & C_{3222} & C_{3223} & C_{3231} & C_{3232} & C_{3233} \\ C_{3311} & C_{3312} & C_{3313} & C_{3321} & C_{3322} & C_{3323} & C_{3331} & C_{3332} & C_{3333} \end{pmatrix}_{9\times 9} \tag{102.255}$$

102.14.3 3D Finite Element Formulation

102.14.3.1 Force Equilibrium

$\sigma_{ji,j} + b_i = \rho \ddot{u}_i$ in dynamic problems.

$$\begin{aligned}
\frac{\partial \sigma_{xx}}{\partial x} + \frac{\partial \sigma_{yx}}{\partial y} + \frac{\partial \sigma_{zx}}{\partial z} + b_x = \rho \ddot{u}_x \\
\frac{\partial \sigma_{xy}}{\partial x} + \frac{\partial \sigma_{yy}}{\partial y} + \frac{\partial \sigma_{zy}}{\partial z} + b_y = \rho \ddot{u}_y \\
\frac{\partial \sigma_{xz}}{\partial x} + \frac{\partial \sigma_{yz}}{\partial y} + \frac{\partial \sigma_{zz}}{\partial z} + b_z = \rho \ddot{u}_z
\end{aligned} \tag{102.256}$$

where b_i is the body force, and $\ddot{u}_i$ is the acceleration of the point.

102.14.4 Momentum Equilibrium

$t_{ji,j} + e_{ijk}\sigma_{jk} + M_i = J\ddot{\theta}_i$ in dynamic problems.

$$\begin{aligned}
\frac{\partial t_{xx}}{\partial x} + \frac{\partial t_{yx}}{\partial y} + \frac{\partial t_{zx}}{\partial z} + \sigma_{xy} - \sigma_{yx} + M_x = J_x \theta_x \\
\frac{\partial t_{xy}}{\partial x} + \frac{\partial t_{yy}}{\partial y} + \frac{\partial t_{zy}}{\partial z} + \sigma_{zx} - \sigma_{xz} + M_y = J_y \theta_y \\
\frac{\partial t_{xz}}{\partial x} + \frac{\partial t_{yz}}{\partial y} + \frac{\partial t_{zz}}{\partial z} + \sigma_{yz} - \sigma_{zy} + M_z = J_z \theta_z
\end{aligned} \tag{102.257}$$

where M_i is the body rotation force per unit area ($Newton/meter^2$).

102.14.4.1 Illustration in 2D

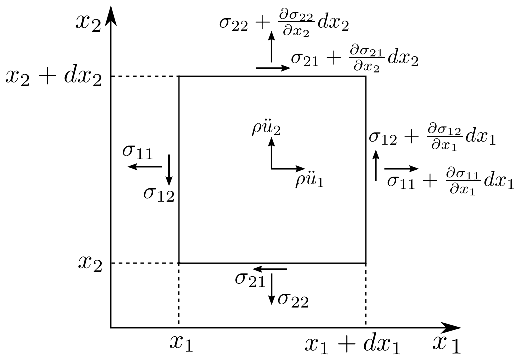

Figure 102.20: Illustration of Force Equilibrium in Cosserat Continua

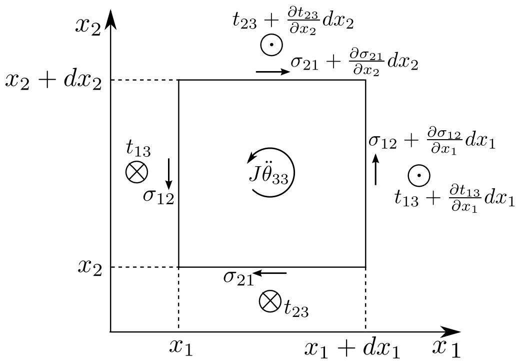

Figure 102.21: Illustration of Moment Equilibrium in Cosserat Continua

102.14.4.2 Strain-Displacement Relationship

Define the DOFs and the generalized strain. For the 8-node brick element. Each node has 6 DOFs.

The vector of nodal DOFs is defined by :

$$\mathcal{U} = [\boldsymbol{u} \;\; \phi]^T = [u_x \; u_y \; u_z \; \phi_x \; \phi_y \; \phi_z]^T_{1\times 6} \tag{102.258}$$

The vector of generalized strain ξ, (18×1) is a horizontal combination of ϵ and κ.

$$\xi = [\epsilon_{11} \; \epsilon_{12} \; \epsilon_{13} \; \epsilon_{21} \; \epsilon_{22} \; \epsilon_{23} \; \epsilon_{31} \; \epsilon_{32} \; \epsilon_{33} \vdots \omega_{11} \; \omega_{12} \; \omega_{13} \; \omega_{21} \; \omega_{22} \; \omega_{23} \; \omega_{31} \; \omega_{32} \; \omega_{33}] \tag{102.259}$$

Strain-displacement for one node. Therefore,

$$\xi_{18\times 1} = \mathcal{B}_{18\times 6} \mathcal{U}_{6\times 1} \tag{102.260}$$

So the dimension of matrix $\mathcal{B}$ (strain-displacement matrix) for 1 node is 18×6.

According to the definition of force strain (Eq 102.247) and curvature (Eq 102.248), express the matrix $\mathcal{B}$ for 1 node Riahi and Curran (2009); Padovan (1978) by

$$\mathcal{B}_N = \begin{pmatrix} \mathcal{B}_{Na} & \mathcal{B}_{Nb} \\ [0]_{9\times 3} & \mathcal{B}_{Nc} \end{pmatrix}_{18\times 6} \tag{102.261}$$

where

$$\mathcal{B}_{Na} = \begin{pmatrix} H_{N,x} & 0 & 0 \\ 0 & H_{N,x} & 0 \\ 0 & 0 & H_{N,x} \\ H_{N,y} & 0 & 0 \\ 0 & H_{N,y} & 0 \\ 0 & 0 & H_{N,y} \\ H_{N,z} & 0 & 0 \\ 0 & H_{N,z} & 0 \\ 0 & 0 & H_{N,z} \end{pmatrix}_{9\times 3}, \quad \mathcal{B}_{Nb} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -H_N \\ 0 & +H_N & 0 \\ 0 & 0 & +H_N \\ 0 & 0 & 0 \\ -H_N & 0 & 0 \\ 0 & -H_N & 0 \\ +H_N & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}_{9\times 3}, \tag{102.262}$$

$$\mathcal{B}_{Nc} = \begin{pmatrix} -H_{N,x} & 0 & 0 \\ -H_{N,y} & 0 & 0 \\ -H_{N,z} & 0 & 0 \\ 0 & -H_{N,x} & 0 \\ 0 & -H_{N,y} & 0 \\ 0 & -H_{N,z} & 0 \\ 0 & 0 & -H_{N,x} \\ 0 & 0 & -H_{N,y} \\ 0 & 0 & -H_{N,z} \end{pmatrix}_{9\times 3} \tag{102.263}$$

where H is the shape function. N is the node number, which can be 1, 2, ..., 8.

Strain-displacement for 8 node brick. So the dimension of matrix $\mathcal{B}$ (strain-displacement matrix) for 8 node brick is 18×48.

$$\mathscr{B} = [\ \mathcal{B}_1\ \ \mathcal{B}_2\ \ \mathcal{B}_3\ \ \mathcal{B}_4\ \ \mathcal{B}_5\ \ \mathcal{B}_6\ \ \mathcal{B}_7\ \ \mathcal{B}_8\ ]_{18\times 48} \tag{102.264}$$

Express the 8 node displacement by

$$\mathscr{U} = [\ \mathcal{U}_1\ \ \mathcal{U}_2\ \ \mathcal{U}_3\ \ \mathcal{U}_4\ \ \mathcal{U}_5\ \ \mathcal{U}_6\ \ \mathcal{U}_7\ \ \mathcal{U}_8\ ]^T_{48\times 1} \tag{102.265}$$

Note that matrix $\mathscr{B}$ is a field function obtained by the interpolation of the displacements at 8 nodes.

For a specified Gauss point, the Gauss coordinates should be substituted to calculate the corresponding generalized strain.

So the generalized strain at a specific Gauss coordinates is

$$\mathscr{E}|_{x_i,y_i,z_i} = \mathscr{B}|_{x_i,y_i,z_i}\mathscr{U} \tag{102.266}$$

102.14.4.3 Isoparametric 8 Node Brick

For the purpose of completeness, the shape function Bathe (1996) for the isoparametric 8 node brick is given by

$$H_i = \frac{1}{8}(1 + \xi_i \xi)(1 + \eta_i \eta)(1 + \zeta_i \zeta) \tag{102.267}$$

where the values of ξ_i, η_i, ζ_i for eight nodes are listed.

Node	ξ_i	η_i	ζ_i
1	+1	+1	+1
2	-1	+1	+1
3	-1	-1	+1
4	+1	-1	+1
5	+1	-1	+1
6	-1	+1	-1
7	-1	-1	-1
8	+1	-1	-1

In addition, the shape function is used for both the displacement interpolation in Eq (102.268) and coordinate transformation formula in Eq (102.269) from the global coordinate to the natural coordinate system.

$$\begin{aligned} u_x &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) u_x^i & u_y &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) u_y^i & u_z &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) u_z^i \\ \phi_x &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) \phi_x^i & \phi_y &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) \phi_y^i & \phi_z &= \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) \phi_z^i \end{aligned} \tag{102.268}$$

The coordinate transformation formula from the global coordinate to the natural coordinate system is

$$x = \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) x_i \qquad y = \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) y_i \qquad z = \sum_{i=1}^{8} H_i(\xi,\eta,\zeta) z_i \tag{102.269}$$

where the x_i, y_i, z_i are the nodal coordinates. Therefore, with the help of Eq (102.269), the global coordinate (x, y, z) become a function of (ξ, η, ζ), which is the natural coordinate in the isoparametric element.

To construct the strain-displacement matrix, the derivative with respect to the global coordinate (x, y, z) is required. Jacobian transformation is used to calculate the derivatives in Eq (102.262, 102.263).

$$\begin{pmatrix} \frac{\partial H_i}{\partial x} \\ \\ \frac{\partial H_i}{\partial y} \\ \\ \frac{\partial H_i}{\partial z} \end{pmatrix} = \boldsymbol{J}^{-1} \begin{pmatrix} \frac{\partial H_i}{\partial \xi} \\ \\ \frac{\partial H_i}{\partial \eta} \\ \\ \frac{\partial H_i}{\partial \zeta} \end{pmatrix} \tag{102.270}$$

where

$$\boldsymbol{J} = \begin{pmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} & \frac{\partial z}{\partial \xi} \\ \frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} & \frac{\partial z}{\partial \eta} \\ \frac{\partial x}{\partial \zeta} & \frac{\partial y}{\partial \zeta} & \frac{\partial z}{\partial \zeta} \end{pmatrix} = \begin{pmatrix} \sum_{i=1}^{8} \frac{\partial H_i}{\partial \xi} x_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \xi} y_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \xi} z_i \\ \\ \sum_{i=1}^{8} \frac{\partial H_i}{\partial \eta} x_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \eta} y_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \eta} z_i \\ \\ \sum_{i=1}^{8} \frac{\partial H_i}{\partial \zeta} x_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \zeta} y_i & \sum_{i=1}^{8} \frac{\partial H_i}{\partial \zeta} z_i \end{pmatrix} \tag{102.271}$$

Note that $\mathcal{B}_{Nb}$ in Eq (102.262) has the original shape functions. Jacobian transformation is not required on $\mathcal{B}_{Nb}$ because the interpolated rotation is used directly to construct the strain in Eq (102.247)
.

104.1 Chapter Summary and Highlights

104.2 Elasto–plasticity

104.2.1 Constitutive Relations for Infinitesimal Plasticity

A wide range of elasto–plastic materials can be characterized by means of a set of incremental constitutive relations of the general form:

$$d\epsilon_{ij} = d\epsilon^{e}_{ij} + d\epsilon^{p}_{ij} \tag{104.1}$$

$$d\sigma_{ij} = E_{ijkl} d\epsilon^{e}_{kl} \tag{104.2}$$

$$d\epsilon^{p}_{ij} = d\lambda \, \frac{\partial Q}{\partial \sigma_{ij}} = d\lambda \, m_{ij}(\sigma_{ij}, q_{*}) \tag{104.3}$$

$$dq_{*} = d\lambda \, h_{*}(\tau_{ij}, q_{*}) \tag{104.4}$$

where, following standard notation ϵ_{ij}, ϵ^{e}_{ij} and ϵ^{p}_{ij} denotes the total, elastic and plastic strain tensor, (and $d\epsilon_{ij}$ is an increment of a strain tensor ϵ_{ij}), σ_{ij} is the Cauchy stress tensor, and q_{*} signifies some suitable set of internal variables[1]. The asterisk in the place of indices in q_{*} replaces n indices[2]. Equation (104.1) expresses the commonly assumed additive decomposition of the infinitesimal strain tensor into elastic and plastic parts. Equation (104.2) represents the generalized Hooke's law[3] which linearly relates stresses and elastic strains through a stiffness modulus tensor E_{ijkl}. Equation (104.3) expresses a generally associated or non-associated flow rule for the plastic strain and (104.4) describes a suitable set of hardening laws, which govern the evolution of the plastic variables. In these equations, m_{ij} is the plastic flow direction, h_{*} the plastic moduli and $d\lambda$ is a plastic parameter to be determined with the aid of the loading—unloading criterion, which can be expressed in terms of the Karush–Kuhn–Tucker condition (Karush, 1939; Kuhn and Tucker, 1951) as:

$$F(\sigma_{ij}, q_{*}) \leq 0 \tag{104.5}$$

---

[1] In the simplest models of plasticity the internal variables are taken as either plastic strain components ϵ^{p}_{ij} or the hardening variables κ defined, for example as a function of inelastic (plastic) work, i.e. $\kappa = f\left(W^{p}\right)$. See Lubliner (1990) page 115.

[2] for example $_{ij}$ if the variable is ϵ^{p}_{ij}, or nothing if the variable is a scalar value, i.e. κ .

[3] also Eq. 104.157

$$d\lambda \geq 0 \tag{104.6}$$

$$F\ d\lambda = 0 \tag{104.7}$$

In the previous equations $F(\sigma_{ij}, q_*)$ denotes the yield function of the material and (104.5) characterizes the corresponding elastic domain, which is presumably convex. Along any process of loading, conditions (104.5), (104.6) and (104.7) must hold simultaneously. For $F < 0$, equation (104.7) yields $d\lambda = 0$, i.e. elastic behavior, while plastic flow is characterized by $d\lambda > 0$, which with (104.7) is possible only if the yield criterion is satisfied, i.e. $F = 0$. From the latter constraint, in the process of plastic loading the plastic consistency conditions[4] is obtained in the form:

$$dF = \frac{\partial F}{\partial \sigma_{ij}} d\sigma_{ij} + \frac{\partial F}{\partial q_*} dq_* = n_{ij} d\sigma_{ij} + \xi_* dq_* = 0 \tag{104.8}$$

where :

$$n_{ij} = \frac{\partial F}{\partial \sigma_{ij}} \tag{104.9}$$

$$\xi_* = \frac{\partial F}{\partial q_*} \tag{104.10}$$

Equation (104.8) has the effect of confining the stress trajectory to the yield surface[5]. It is worthwhile noting that n_{ij} and ξ_* are normals to the yield surface in stress space and the plastic variable space respectively.

An interesting alternative way of representing non–associated flow rules can be found in Runesson (1987). A fictitious plastic strain derived from associated flow rule, e^p_{ij} is introduced. This fictitious plastic strain is assumed to be related to the real plastic strain ϵ^p_{ij}, which is derived from a non–associated flow rule[6] through the linear transformation:

$$e^p_{ij} = A_{ijkl} \epsilon^p_{kl} \tag{104.11}$$

Linear transformation tensor A_{ijkl} may be state dependent in general case, and it reduces to the symmetric part of the fourth order identity tensor[7] for the case of associated plasticity.

---

[4] first order accuracy condition.

[5] Since it is only linear expansion stress trajectory is confined to the tangential plane only.

[6] as in equation 104.3.

[7] $A_{ijkl} \equiv I^{sym}_{ijkl} \equiv \frac{1}{2}\left(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}\right)$.

It is often of interest to model deviatoric strains by an associated flow rule while the volumetric part is non–associated. For this case, A_{ijkl} can be formulated as:

$$A_{ijkl} = \left(\beta \frac{1}{3} \left(\delta_{ij} \delta_{kl} \right) + \frac{1}{2} \left(\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk} \right) \right) \tag{104.12}$$

$$A^{-1}_{ijkl} = \left(- \frac{\beta}{1+\beta} \frac{1}{3} \left(\delta_{ij} \delta_{kl} \right) + \frac{1}{2} \left(\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk} \right) \right) \tag{104.13}$$

and it is obvious that the non–associated flow rule is obtained with $\beta \neq 0$ and the associated flow rule with $\beta = 0$. It is useful to choose $\beta \geq 0$ and retain nice, positive definite properties of adjusted constitutive tensors later.

Let the $\| \cdot \|$ norm, be the complementary energy norm[8]:

$$\| \sigma_{ij} \|^2 = \sigma_{ij} D_{ijkl} \sigma_{kl} \tag{104.14}$$

where D_{ijkl} is the elastic compliance tensor ($D_{ijkl} = E^{-1}_{ijkl}$), and let us introduce the adjusted complementary energy norm as:

$$^{A}\| \sigma_{ij} \|^2 = \sigma_{ij} \left(A_{ijkl} D_{klmn} \right) \sigma_{mn} = \sigma_{ij} \left({}^{A}D_{ijmn} \right) \sigma_{mn} \tag{104.15}$$

where ${}^{A}D_{ijmn}$ is the elastic compliance tensor transformed with respect to the non–associativity involved. It is clear that when $A_{ijkl} \equiv I^{sym}_{ijkl} \Longrightarrow {}^{A}\| \sigma_{ij} \|^2 \equiv \| \sigma_{ij} \|^2$

104.2.2 On Integration Algorithms

In the section Constitutive Relations for Infinitesimal Plasticity we have summarized constitutive equations that are capable of representing a wide variety of elasto–plastic materials. The problem in Computational Elasto–plasticity is to devise accurate and efficient algorithms for the integration of such constitutive relations. In the context of finite element analysis using isoparametric elements, the integration of constitutive equations is carried out at Gauss points. In each step the deformation increments are given or known, and the unknowns to be found are updated stresses and plastic variables. According to Ortiz and Popov (1985) an acceptable algorithm should satisfy:

- consistency with the constitutive relations to be integrated or first order accuracy,
- Numerical stability,

---

[8] This norm will be reintroduced later on!

- incremental plastic consistency

A non—required but desirable feature to be added to the above list is:

- higher[9] order accuracy

First two conditions are needed for attaining convergence for the numerical solution as the step or increment becomes vanishingly small. The third condition is the algorithmic counterpart of the plastic consistency condition and requires that the state of stress computed from the algorithm be contained within the elastic domain.

104.2.3 Midpoint Rule Algorithm

A class of algorithms for integrating constitutive equations with potential to satisfy the above mentioned conditions are the Generalized Midpoint rule algorithms. They are given in the following form:

$$d({}^{n+1}\sigma_{ij}) = E_{ijkl}\left(d({}^{n+1}\epsilon_{kl}) - d({}^{n+1}\epsilon^{p}_{kl})\right) \tag{104.16}$$

$$d({}^{n+1}\epsilon^{p}_{ij}) = d({}^{n}\epsilon^{p}_{ij}) + d\lambda\ {}^{n+\alpha}m_{ij} \tag{104.17}$$

$$d({}^{n+1}q_{*}) = d({}^{n}q_{*}) + d\lambda\ {}^{n+\alpha}h_{*} \tag{104.18}$$

$$F_{n+1} = 0 \tag{104.19}$$

where:

$${}^{n+\alpha}m_{ij} = m_{ij}\left((1-\alpha)\ {}^{n}\sigma_{ij} + \alpha\ \left({}^{n+1}\sigma_{ij}\right), (1-\alpha)\ {}^{n}q_{*} + \alpha\ \left({}^{n+1}q_{*}\right)\right) \tag{104.20}$$

$${}^{n+\alpha}h_{*} = h_{*}\left((1-\alpha)\ {}^{n}\sigma_{ij} + \alpha\ \left({}^{n+1}\sigma_{ij}\right), (1-\alpha)\ {}^{n}q_{*} + \alpha\ \left({}^{n+1}q_{*}\right)\right) \tag{104.21}$$

It is quite clear that the case $\alpha = 0$ corresponds to the Forward Euler approach[10], the case $\alpha = 1$ corresponds to the Backward Euler approach[11], and the case $\alpha = 1/2$ to the Crank – Nicholson scheme. Equations (104.16), (104.17), (104.18), (104.19), (104.20) and (104.21) are the nonlinear algebraic

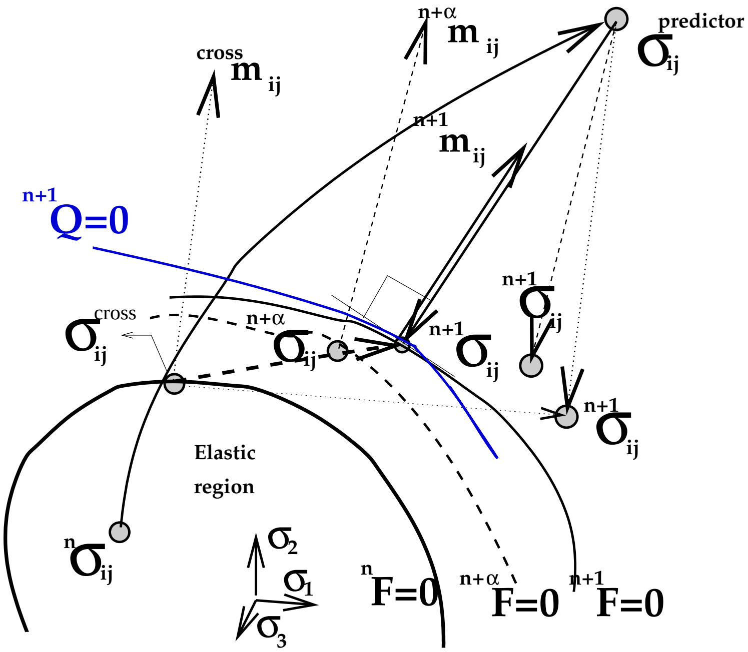

Figure 104.1: integration algorithms in elasto–plasticity

equations to be solved for the unknowns $d(^{n+1}\sigma_{ij})$, $d(^{n+1}\epsilon^p_{ij})$, $d(^{n+1}q_*)$ and $d\lambda$. From the Figure (104.1)[12] it can be seen that the Generalized Midpoint rule may be regarded as a returning mapping algorithm in which the elastic predictor $^{pred}\sigma_{ij}$ is projected on the updated yield surface along the flow direction evaluated at the midpoint $\left(^{n+\alpha}\sigma_{ij}, {}^{n+\alpha}q_*\right)$.

104.2.3.1 Accuracy Analysis

Bearing in mind the context of the displacement based finite element analysis the integration of constitutive equations is performed for the given strain increment. The updated strains $^{n+1}\epsilon_{ij} = \epsilon_{ij}\,(t_n + \Delta t)$ may be viewed as the known function of the step size Δt. The remaining updated variables $^{n+1}\sigma_{ij}$, $^{n+1}\epsilon^p_{ij}$, $^{n+1}q_*$, as well as the incremental plastic parameter λ become functions of Δt implicitly defined through equations (104.16), (104.17), (104.18) and (104.19). It should be clear from (104.16), (104.17), (104.18) and (104.19) that as $\Delta t \to 0$ than $^{n+1}\epsilon_{ij} \to {}^{n}\epsilon_{ij}$, and thus the limiting values of $^{n+1}\sigma_{ij}$, $^{n+1}\epsilon^p_{ij}$, $^{n+1}q_*$ and λ are obtained:

---

[9] at least second order accuracy.

[10] explicit scheme.

[11] implicit scheme.

[12] it should be pointed out that the vectors, as drawn on this figure, are pointing in the right direction only if we assume that $E_{ijkl} \equiv I_{ijkl}$. For any general elasticity tensor E_{ijkl} all vectors are defined in the E_{ijkl} metric, so the term "normal", as we are used to it, does not apply here.

$$
\begin{aligned}
\lim_{\Delta t \to 0} \left({}^{n+1}\sigma_{ij} \right) &= {}^{n}\sigma_{ij} \\
\lim_{\Delta t \to 0} \left({}^{n+1}\epsilon^{p}_{ij} \right) &= {}^{n}\epsilon^{p}_{ij} \\
\lim_{\Delta t \to 0} \left({}^{n+1}q_{*} \right) &= {}^{n}q_{*} \\
\lim_{\Delta t \to 0} \lambda &= 0
\end{aligned}
\tag{104.22}
$$

It can also be argued that, by virtue of the implicit function theorem ((Abraham et al., 1988) Chapter 2.5), ${}^{n+1}\sigma_{ij}$, ${}^{n+1}\epsilon^{p}_{ij}$, ${}^{n+1}q_{*}$ and λ are differentiable functions of Δt, if the functions ${}^{n+\alpha}m_{ij}$, ${}^{n+\alpha}h_{*}$ and F are sufficiently smooth. Sufficient smoothness will be assumed as needed.

First Order Accuracy. First order accuracy[13] of the algorithm, defined by the equations (104.16), (104.17), (104.18) and (104.19) with the constitutive equations given by (104.1), (104.2), (104.3) and (104.4) necessitates that the numerically integrated variables ${}^{n+1}\sigma_{ij}$, ${}^{n+1}\epsilon^{p}_{ij}$ and ${}^{n+1}q_{*}$ agree with their exact values $\sigma_{ij}(t+\Delta t)$, $\epsilon^{p}_{ij}(t+\Delta t)$ and $q_{*}(t+\Delta t)$ to within second order terms in the Taylor's expansion around the initial state ${}^{n}\sigma_{ij} = \sigma_{ij}(t)$, ${}^{n}\epsilon^{p}_{ij} = \epsilon^{p}_{ij}(t)$ and ${}^{n}q_{*} = q_{*}(t)$ in Δt. First order accuracy can be written in the following form:

$$
\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}\sigma_{ij}\right)}{d(\Delta t)} = \frac{d\left({}^{n}\sigma_{ij}\right)}{d(\Delta t)} = E_{ijkl}\left(\frac{d\left({}^{n}\epsilon_{ij}\right)}{d(\Delta t)} - \frac{d\left({}^{n}\epsilon^{p}_{ij}\right)}{d(\Delta t)} \right)
\tag{104.23}
$$

$$
\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}\epsilon^{p}_{ij}\right)}{d(\Delta t)} = \frac{d\left({}^{n}\epsilon^{p}_{ij}\right)}{d(\Delta t)} = \frac{d\left({}^{n}\lambda\right)}{d(\Delta t)} {}^{n}m_{ij}
\tag{104.24}
$$

$$
\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}q_{*}\right)}{d(\Delta t)} = \frac{d\left({}^{n}q_{*}\right)}{d(\Delta t)} = \frac{d\left({}^{n}\lambda\right)}{d(\Delta t)} {}^{n}h_{*}
\tag{104.25}
$$

$$
\lim_{\Delta t \to 0} \frac{d(\lambda)}{d(\Delta t)} = \frac{d\left({}^{n}\lambda\right)}{d(\Delta t)}
\tag{104.26}
$$

and the plastic parameter $d\left({}^{n}\lambda\right)/d(\Delta t)$ is determined with the aid of the plastic consistency condition at t:

---

[13] first order consistency.

$$\frac{d\ \left({}^{n}F\right)}{d\left(\Delta t\right)} = \frac{\partial\left({}^{n}F\right)}{\partial\sigma_{ij}}\frac{d\sigma_{ij}}{d\left(\Delta t\right)} + \frac{\partial\left({}^{n}F\right)}{\partial q_{*}}\frac{dq_{*}}{d\left(\Delta t\right)} = {}^{n}n_{ij}\frac{d\sigma_{ij}}{d\left(\Delta t\right)} + {}^{n}\xi_{*}\frac{dq_{*}}{d\left(\Delta t\right)} = 0 \tag{104.27}$$

It is now rather straightforward to check whether the Generalized Midpoint rule satisfies the consistency conditions as given by (104.23), (104.24), (104.25) and (104.26). We can proceed further on by differentiating (104.16), (104.17), (104.18) and (104.19) with respect to Δt[14]:

$$\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} = E_{ijkl}\left(\frac{d\left({}^{n+1}\epsilon_{kl}\right)}{d\left(\Delta t\right)} - \frac{d\left({}^{n+1}\epsilon^{p}_{kl}\right)}{d\left(\Delta t\right)}\right) \tag{104.28}$$

$$\begin{aligned}\frac{d\left({}^{n+1}\epsilon^{p}_{ij}\right)}{d\left(\Delta t\right)} &= \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n+\alpha}m_{ij}\right) + \lambda\,\frac{d\left({}^{n+\alpha}m_{ij}\right)}{d\left(\Delta t\right)} = \\ \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n+\alpha}m_{ij}\right) &+ \lambda\alpha\left(\left.\frac{\partial m_{ij}}{\partial\sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial m_{ij}}{\partial q_{*}}\right|_{n+1}\frac{d\left({}^{n+1}q_{*}\right)}{d\left(\Delta t\right)}\right)\end{aligned} \tag{104.29}$$

$$\begin{aligned}\frac{d\left({}^{n+1}q^{p}_{*}\right)}{d\left(\Delta t\right)} &= \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n+\alpha}h_{*}\right) + \lambda\frac{d\left({}^{n+\alpha}h_{*}\right)}{d\left(\Delta t\right)} = \\ \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n+\alpha}h_{*}\right) &+ \lambda\alpha\left(\left.\frac{\partial h_{*}}{\partial\sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial h_{*}}{\partial q_{*}}\right|_{n+1}\frac{d\left({}^{n+1}q_{*}\right)}{d\left(\Delta t\right)}\right)\end{aligned} \tag{104.30}$$

$$\frac{d\ \left({}^{n+1}F\right)}{d\left(\Delta t\right)} = \frac{\partial\left({}^{n+1}F\right)}{\partial\left({}^{n+1}\sigma_{ij}\right)}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \frac{\partial\left({}^{n+1}F\right)}{\partial\left({}^{n+1}q_{*}\right)}\frac{d\left({}^{n+1n+1}q_{*}\right)}{d\left(\Delta t\right)} = 0 \tag{104.31}$$

where ${}^{n+\alpha}m_{ij}$ and ${}^{n+\alpha}h_{*}$ are defined by the equations (104.20) and (104.21).

By taking Δt to the limit value, $\Delta t \rightarrow 0$, in the (104.28), (104.29), (104.30) and (104.31) and using the relations from (104.22) one finds:

---

[14] bearing in mind that values at t are constants and that only variables at $t + \Delta t$ are changing with respect to Δt.

$$\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} = E_{ijkl}\left(\frac{d\left({}^{n}\epsilon_{kl}\right)}{d\left(\Delta t\right)} - \frac{d\left({}^{n+1}\epsilon^{p}_{kl}\right)_{\Delta t=0}}{d\left(\Delta t\right)}\right) \tag{104.32}$$

$$\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}\epsilon^{p}_{ij}\right)}{d\left(\Delta t\right)} = \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n}m_{ij}\right) \tag{104.33}$$

$$\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}q_{*}\right)}{d\left(\Delta t\right)} = \frac{d\lambda}{d\left(\Delta t\right)}\left({}^{n}h_{*}\right) \tag{104.34}$$

$$\lim_{\Delta t \to 0} \frac{d\ \left({}^{n+1}F\right)}{d\left(\Delta t\right)} = \frac{\partial\left({}^{n}F\right)}{\partial \sigma_{ij}}\left(\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)}\right) + \frac{\partial\left({}^{n}F\right)}{\partial q_{*}}\left(\lim_{\Delta t \to 0} \frac{d\left({}^{n+1}q_{*}\right)}{d\left(\Delta t\right)}\right) = 0 \tag{104.35}$$

In the previous equations it is quite clear that since $\Delta t = 0$, then equations (104.22) hold and since the variables ${}^{n}\sigma_{ij}$, ${}^{n}\epsilon^{p}_{ij}$ and ${}^{n}q_{*}$ are constant with respect to the change in Δt, the result follows readily, i.e. the Midpoint rule satisfies first order accuracy.

Second Order Accuracy To investigate second order accuracy of the algorithm given by (104.16), (104.17), (104.18) and (104.19) together with the constitutive equations given by (104.1), (104.2), (104.3) and (104.4) we shall proceed in the following manner. Second order accuracy actually means that the numerically integrated variables ${}^{n+1}\sigma_{ij}$, ${}^{n+1}\epsilon^{p}_{ij}$ and ${}^{n+1}q_{*}$ agree with their "exact" values $\sigma_{ij}(t + \Delta t)$, $\epsilon^{p}_{ij}(t + \Delta t)$ and $q_{*}(t + \Delta t)$ to within third order terms in the Taylor's expansion around the initial state ${}^{n}\sigma_{ij} = \sigma_{ij}(t)$, ${}^{n}\epsilon^{p}_{ij} = \epsilon^{p}_{ij}(t)$ and ${}^{n}q_{*} = q_{*}(t)$ in Δt. This verbal statement can be written in the following mathematical form:

$$
\begin{gathered}
\lim_{\Delta t\to 0}\frac{d^2\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)^2} = \\
E_{ijkl}\left(\lim_{\Delta t\to 0}\frac{d^2\left({}^{n+1}\epsilon_{kl}\right)}{d\left(\Delta t\right)^2} - \lim_{\Delta t\to 0}\frac{d^2\left({}^{n}\epsilon^p_{kl}\right)}{d\left(\Delta t\right)^2}\right) = E_{ijkl}\left(\frac{d^2\left({}^{n}\epsilon_{kl}\right)}{d\left(\Delta t\right)^2} - \frac{d^2\left({}^{n}\epsilon^p_{kl}\right)}{d\left(\Delta t\right)^2}\right)
\end{gathered}
\tag{104.36}
$$

$$
\begin{gathered}
\lim_{\Delta t\to 0}\frac{d^2\left({}^{n+1}\epsilon^p_{ij}\right)}{d\left(\Delta t\right)^2} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\lim_{\Delta t\to 0}\left({}^{n+1}m_{ij}\right) + \lim_{\Delta t\to 0}\frac{d\left({}^{n+1}\lambda\right)}{d\left(\Delta t\right)}\frac{d\left({}^{n+\alpha}m_{ij}\right)}{d\left(\Delta t\right)} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n}m_{ij}\right) + \frac{d\left({}^{n}\lambda\right)}{d\left(\Delta t\right)}\frac{d\left({}^{n+\alpha}m_{ij}\right)}{d\left(\Delta t\right)} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n}m_{ij}\right) + \frac{d\left({}^{n}\lambda\right)}{d\left(\Delta t\right)}\left(\frac{\partial m_{ij}}{\partial\sigma_{ij}\,|_n}\frac{d\left({}^{n}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \frac{\partial m_{ij}}{\partial q_*\,|_n}\frac{d\left({}^{n}q_*\right)}{d\left(\Delta t\right)}\right)
\end{gathered}
\tag{104.37}
$$

$$
\begin{gathered}
\lim_{\Delta t\to 0}\frac{d^2\left({}^{n+1}q^p_*\right)}{d\left(\Delta t\right)^2} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\lim_{\Delta t\to 0}\left({}^{n+1}h_*\right) + \lim_{\Delta t\to 0}\frac{d\left({}^{n+1}\lambda\right)}{d\Delta t}\frac{d\left({}^{n+1}h_*\right)}{d\left(\Delta t\right)} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n}h_*\right) + \frac{d\left({}^{n+1}\lambda\right)}{d\Delta t}\frac{d\left({}^{n}h_*\right)}{d\left(\Delta t\right)} = \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n}h_*\right) + \frac{d\left({}^{n+1}\lambda\right)}{d\Delta t}\left(\frac{\partial h_*}{\partial\sigma_{ij}\,|_n}\frac{d\left({}^{n}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \frac{\partial h_*}{\partial q_*\,|_n}\frac{d\left({}^{n}q_*\right)}{d\left(\Delta t\right)}\right)
\end{gathered}
\tag{104.38}
$$

$$
\lim_{\Delta t\to 0}\frac{d^2\left(\lambda\right)}{d\left(\Delta t\right)^2} = \frac{d^2\left({}^{n}\lambda\right)}{d\left(\Delta t\right)^2}
\tag{104.39}
$$

and the plastic parameter $d^2\left({}^{n}\lambda\right)/d\left(\Delta t\right)^2$ is determined with the aid of the second order oscillatory satisfaction of the plastic consistency condition:

$$
\frac{d^2\ \left({}^{n}F\right)}{d\left(\Delta t\right)^2} = \left.\frac{dn_{ij}}{d\Delta t}\right|_n\frac{d\sigma_{ij}}{d\left(\Delta t\right)} + {}^{n}n_{ij}\left.\frac{d^2\left(\sigma_{ij}\right)}{d\left(\Delta t\right)^2}\right|_n + \left.\frac{d\left(\xi_*\right)}{d\Delta t}\right|_n\frac{d^n q_*}{d\left(\Delta t\right)} + {}^{n}\xi_*\frac{d^2\left({}^{n}q_*\right)}{d\left(\Delta t\right)^2} = 0
\tag{104.40}
$$

Now we can proceed by taking the second derivative of the equations (104.16), (104.17), (104.18) and (104.19) or use the already derived first derivatives from equations (104.28), (104.29), (104.30) and (104.31), and then differentiate them again so that we get:

$$\frac{d^2\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)^2} = E_{ijkl}\left(\frac{d^2\left({}^{n+1}\epsilon_{kl}\right)}{d\left(\Delta t\right)^2} - \frac{d^2\left({}^{n+1}\epsilon^p_{kl}\right)}{d\left(\Delta t\right)^2}\right) \tag{104.41}$$

$$\begin{aligned}
\frac{d^2\left({}^{n+1}\epsilon^p_{ij}\right)}{d\left(\Delta t\right)^2} &= \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n+\alpha}m_{ij}\right) &+ \\
2\frac{d\lambda}{d\left(\Delta t\right)}\alpha\left(\left.\frac{\partial m_{ij}}{\partial \sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial m_{ij}}{\partial q_*}\right|_{n+1}\frac{d\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)}\right) &+ \\
\lambda\alpha\frac{d}{d\left(\Delta t\right)}\left(\left.\frac{\partial m_{ij}}{\partial \sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial m_{ij}}{\partial q_*}\right|_{n+1}\frac{d\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)}\right) &
\end{aligned} \tag{104.42}$$

$$\begin{aligned}
\frac{d^2\left({}^{n+1}q^p_*\right)}{d\left(\Delta t\right)^2} &= \\
\frac{d^2\lambda}{d\left(\Delta t\right)^2}\left({}^{n+\alpha}h_*\right) &+ \\
2\frac{d\lambda}{d\left(\Delta t\right)}\alpha\left(\left.\frac{\partial h_*}{\partial \sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial h_*}{\partial q_*}\right|_{n+1}\frac{d\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)}\right) &+ \\
\lambda\alpha\frac{d}{d\left(\Delta t\right)}\left(\left.\frac{\partial h_*}{\partial \sigma_{ij}}\right|_{n+1}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial h_*}{\partial q_*}\right|_{n+1}\frac{d\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)}\right) &
\end{aligned} \tag{104.43}$$

$$\begin{aligned}
\frac{d^2\left({}^{n+1}F\right)}{d\left(\Delta t\right)^2} &= \\
\frac{d\left({}^{n+1}n_{ij}\right)}{d\sigma_{ij}}\frac{d\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)} + {}^{n+1}n_{ij}\frac{d^2\left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)^2} &+ \\
+\frac{d\left({}^{n+1}\xi_*\right)}{d\sigma_{ij}}\frac{d\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)} + {}^{n+1}\xi\frac{d^2\left({}^{n+1}q_*\right)}{d\left(\Delta t\right)^2} &= 0
\end{aligned} \tag{104.44}$$

If we drive Δt to the limit, namely by taking $\lim_{\Delta t \to 0}$ and keeping in mind equations (104.22) and the assumed consistency of the algorithm[15] as given by the equations (104.23), (104.24), (104.25) and (104.26) one finds:

---

[15] actually the first order accuracy that is already proven.

$$\lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)^2} = E_{ijkl} \left(\frac{d^2 \left({}^{n}\epsilon_{kl}\right)}{d\left(\Delta t\right)^2} - \lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\epsilon^{p}_{kl}\right)}{d\left(\Delta t\right)^2} \right) \tag{104.45}$$

$$\lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\epsilon^{p}_{ij}\right)}{d\left(\Delta t\right)^2} = \lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\lambda\right)}{d\left(\Delta t\right)^2} \left({}^{n+\alpha}m_{ij}\right) + 2 \frac{d\left({}^{n}\lambda\right)}{d\left(\Delta t\right)} \alpha \left(\left.\frac{\partial m_{ij}}{\partial \sigma_{ij}}\right|_{n} \frac{d\left({}^{n}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial m_{ij}}{\partial q_{*}}\right|_{n} \frac{d\left({}^{n}q_{*}\right)}{d\left(\Delta t\right)} \right) \tag{104.46}$$

$$\lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}q^{p}_{*}\right)}{d\left(\Delta t\right)^2} = \lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\lambda\right)}{d\left(\Delta t\right)^2} \left({}^{n+\alpha}h_{*}\right) + 2 \frac{d\left({}^{n}\lambda\right)}{d\left(\Delta t\right)} \alpha \left(\left.\frac{\partial h_{*}}{\partial \sigma_{ij}}\right|_{n} \frac{d\left({}^{n}\sigma_{ij}\right)}{d\left(\Delta t\right)} + \left.\frac{\partial h_{*}}{\partial q_{*}}\right|_{n} \frac{d\left({}^{n}q_{*}\right)}{d\left(\Delta t\right)} \right) \tag{104.47}$$

$$\begin{aligned} &\lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}F\right)}{d\left(\Delta t\right)^2} = \\ &\frac{d\left({}^{n}n_{ij}\right)}{d\sigma_{ij}} \frac{d\left({}^{n}\sigma_{ij}\right)}{d\left(\Delta t\right)} + {}^{n}n_{ij} \lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}\sigma_{ij}\right)}{d\left(\Delta t\right)^2} + \\ &+ \frac{d\left({}^{n}\xi_{*}\right)}{d\sigma_{ij}} \frac{d\left({}^{n}q_{*}\right)}{d\left(\Delta t\right)} + {}^{n}\xi \lim_{\Delta t \to 0} \frac{d^2 \left({}^{n+1}q_{*}\right)}{d\left(\Delta t\right)^2} = 0 \end{aligned} \tag{104.48}$$

By comparing equations (104.45), (104.46), (104.47) and (104.48) with the second order accuracy condition stated in equations (104.36), (104.37), (104.38) and (104.39) it is quite clear that the second order accuracy is obtained iff[16] $\alpha = 1/2$!

The conclusion is that the Midpoint–rule algorithm is consistent[17] for all $\alpha \in [0, 1]$ and it is second order accurate for $\alpha = 1/2$. However, one should not forget that these results are obtained for the limiting case $\Delta t \to 0$, i.e. the strain increments are small and tend to zero.

---

[16] if and only if ($\iff$).

[17] first order accurate.

104.2.3.2 Numerical Stability Analysis

Numerical stability of an algorithm plays a central role in approximation theory for initial value problems. In fact, it can be stated that consistency and stability are necessary and sufficient conditions for convergence of an algorithm as the time step tends to zero. In the approach presented by Ortiz and Popov (1985) a new methodology is proposed by which the stability properties of an integration algorithm for elasto–plastic constitutive relations can be established. Our attention is confined to perfect plasticity and a smooth yield surface.

The purpose of the following stability analysis is to determine under what conditions a finite perturbation in the initial stresses is diluted by the algorithm. In other words:

$$d\left({}^{n+1}\sigma_{ij}^{(2)}, {}^{n+1}\sigma_{ij}^{(1)}\right) \leq d\left({}^{n}\sigma_{ij}^{(2)}, {}^{n}\sigma_{ij}^{(1)}\right) \tag{104.49}$$

where $d(\cdot, \cdot)$ is some suitable distance on the yield surface and ${}^{n+1}\sigma_{ij}^{(1)}$ and ${}^{n+1}\sigma_{ij}^{(2)}$ are two sets of updated stresses corresponding to arbitrary initial stress values ${}^{n}\sigma_{ij}^{(1)}$ and ${}^{n}\sigma_{ij}^{(2)}$, respectively, and all of the previous stress values are assumed to lie on the yield surface. Stability in the sense of equation (104.49) is referred to as large scale stability. It is shown in Helgason (1978)[18] that for nonlinear initial value problems defined on Banach manifolds, consistency and large scale stability with respect to a complete metric are sufficient for convergence.

The task of directly establishing estimates of the type expressed in (104.49) is rather difficult, and so despite the conceptual appeal of large scale stability, simplified solutions are sought. It should be recognized that attention can be restricted to infinitesimal perturbation in the initial conditions of the type ${}^{n}\sigma_{ij} \rightarrow {}^{n}\sigma_{ij} + d\left({}^{n}\sigma_{ij}\right)$. This simplification is founded on the fact that the dilution or attenuation, by the algorithm of infinitesimal perturbations:

$$\|d\ {}^{n+1}\sigma_{ij}\| \leq \|d\ {}^{n}\sigma_{ij}\| \tag{104.50}$$

with respect to some suitable norm $\|\cdot\|$, of small scale stability, implies large scale stability in the sense of equation (104.49).

Let the $\|\cdot\|$ norm, be the energy norm:

$$\|\sigma_{ij}\|^2 = \sigma_{ij} D_{ijkl} \sigma_{kl} \tag{104.51}$$

---

[18] the first Chapter of Helgason's book.

where D_{ijkl} is the elastic compliance tensor $(D_{ijkl} = E^{-1}_{ijkl})$, and let the distance $d(\cdot, \cdot)$ on the yield surface be defined as

$$d\left(\sigma_{ij}^{(1)}, \sigma_{ij}^{(2)}\right) = \inf_{\gamma} \int_{\gamma} \|\sigma_{ij}^{'}(s)\| ds \tag{104.52}$$

where the infinum is taken over all possible stress paths γ on the yield surface that are joining two stress states, namely $\sigma_{ij}^{(1)}$ and $\sigma_{ij}^{(2)}$. It can be found in Helgason (1978) that for a smooth yield surface, equation (104.52) defines the geodesic distance which endows the yield surface with a complete metric structure.

Suppose that we have any two initial states of stress ${}^{n}\sigma_{ij}^{(1)}$ and ${}^{n}\sigma_{ij}^{(2)}$ and let ${}^{n+1}\sigma_{ij}^{(1)}$ and ${}^{n+1}\sigma_{ij}^{(2)}$ be the corresponding updated values, respectively, and all the previous stress states are assumed to lie on the yield surface. Then, according to Helgason (1978), there exists a unique geodesic curve that joins ${}^{n}\sigma_{ij}^{(1)}$ and ${}^{n}\sigma_{ij}^{(2)}$ for which the infinum in equation (104.52) is attained. If γ_n is such a curve, then by definition:

$$d\left({}^{n}\sigma_{ij}^{(1)}, {}^{n}\sigma_{ij}^{(2)}\right) = \int_{\gamma_n} \|\sigma_{ij}^{'}(s)\| ds \tag{104.53}$$

Let the new curve γ_{n+1} be the transform of curve γ_n by the algorithm. By definition γ_{n+1} lies on the yield surface and joins two stress states ${}^{n+1}\sigma_{ij}^{(1)}$ and ${}^{n+1}\sigma_{ij}^{(2)}$. By the definition given in (104.52), it follows that:

$$d\left({}^{n+1}\sigma_{ij}^{(1)}, {}^{n+1}\sigma_{ij}^{(2)}\right) = \int_{\gamma_{n+1}} \|\sigma_{ij}^{'}(s)\| ds \tag{104.54}$$

Under the assumption of small scale stability of the algorithm one can write:

$$\|\sigma_{ij}^{'}(s_{n+1})\| ds = \|d\sigma_{ij}(s_{n+1})\| \leq \|d\sigma_{ij}(s_n)\| = \|\sigma_{ij}^{'}(s_n)\| ds \tag{104.55}$$

for every pair of corresponding points s_n and s_{n+1} on γ_n and γ_{n+1} respectively, so it follows:

$$\int_{\gamma_{n+1}} \|\sigma_{ij}^{'}(s_{n+1})\| ds \leq \int_{\gamma_n} \|\sigma_{ij}^{'}(s_n)\| ds \tag{104.56}$$

By combining equations (104.54), (104.55) and (104.56) it is concluded that:

$$d\left({}^{n+1}\sigma_{ij}^{(1)}, {}^{n+1}\sigma_{ij}^{(2)}\right) \leq d\left({}^{n}\sigma_{ij}^{(1)}, {}^{n}\sigma_{ij}^{(2)}\right) \tag{104.57}$$

which proves large scale stability. The main conclusion of the above argument may be stated as follows: small scale stability in the energy norm is equivalent to large scale stability in the associated geodesic distance.

The previous result is of practical importance, since it shows that the stability analysis for the integration algorithm in elasto–plasticity can be carried out by the assessment of small scale stability. The small scale stability analysis of the Generalized Midpoint rule is necessary to determine how the algorithm propagates infinitesimal perturbations in the initial conditions. By differentiating equations (104.16), (104.17), (104.18) and (104.19)and considering that we are dealing with perfectly plastic case here so that $\left({}^{n+1}q_*\right) = \left({}^{n}q_*\right)$ = constants, it follows:

$$d\left({}^{n+1}\sigma_{ij}\right) = -E_{ijkl}\, d\left({}^{n+1}\epsilon^{p}_{kl}\right) \tag{104.58}$$

$$d\left({}^{n}\sigma_{ij}\right) = -E_{ijkl}\, d\left({}^{n}\epsilon^{p}_{kl}\right) \tag{104.59}$$

$$d\left({}^{n+1}\epsilon^{p}_{ij}\right) - d\left({}^{n}\epsilon^{p}_{ij}\right) = d\,\lambda\ \left({}^{n+\alpha}m_{ij}\right) + \lambda\, d\left({}^{n+\alpha}m_{ij}\right) \tag{104.60}$$

$$d\ \left({}^{n+1}F\right) = \left.\frac{\partial F}{\partial \sigma_{ij}}\right|_{n+1} d\left({}^{n+1}\sigma_{ij}\right) = {}^{n+1}n_{ij}\, d\left({}^{n+1}\sigma_{ij}\right) = 0 \tag{104.61}$$

Let us now examine the shape of $d\left({}^{n+\alpha}m_{ij}\right)$ having in mind the original definition[19] given in equation (104.20):

$${}^{n+\alpha}m_{ij} = m_{ij}\left((1-\alpha)\ {}^{n}\sigma_{ij} + \alpha\ \left({}^{n+1}\sigma_{ij}\right), (1-\alpha)\ {}^{n}q_* + \alpha\ \left({}^{n+1}q_*\right)\right)$$

and the differential of the previous equation is:

$$d\left({}^{n+\alpha}m_{ij}\right) = (1-\alpha)\left.\frac{\partial m_{ij}}{\partial \sigma_{kl}}\right|_{n+\alpha} d\left({}^{n}\sigma_{kl}\right) + \alpha\ \left.\frac{\partial m_{ij}}{\partial \sigma_{kl}}\right|_{n+\alpha} d\left({}^{n+1}\sigma_{kl}\right)$$

To ease writing let us introduce the following fourth order tensor:

---

[19] the remark about restraining analysis to perfectly plastic case still holds, so that $\left({}^{n+1}q_*\right)$ and $\left({}^{n}q_*\right)$ are constant.

$$M_{ijkl} = \frac{\partial m_{ij}}{\partial \sigma_{kl}}$$

The equation (104.60) now reads:

$$\begin{aligned} & d\left({}^{n+1}\epsilon^{p}_{ij}\right) - d\left({}^{n}\epsilon^{p}_{ij}\right) = \\ & d\lambda\ \left({}^{n+\alpha}m_{ij}\right) + \lambda\left((1-\alpha)\left({}^{n+\alpha}M_{ijkl}\right)\ d\left({}^{n}\sigma_{kl}\right) + \alpha\ \left({}^{n+\alpha}M_{ijkl}\right)\ d\left({}^{n+1}\sigma_{kl}\right)\right) \end{aligned} \tag{104.62}$$

By using equations (104.58) and (104.59) and knowing that $E^{-1}_{ijkl} = D_{ijkl}$ one can write:

$$d\left({}^{n+1}\epsilon^{p}_{ij}\right) = -D_{ijkl}\ d\left({}^{n+1}\sigma_{kl}\right)$$

$$d\left({}^{n}\epsilon^{p}_{ij}\right) = -D_{ijkl}\ d\left({}^{n}\sigma_{kl}\right)$$

so that the equation (104.62) now reads:

$$\begin{aligned} & -D_{ijkl}\ d\left({}^{n+1}\sigma_{kl}\right) + D_{ijkl}\ d\left({}^{n}\sigma_{kl}\right) = \\ & d\lambda\ \left({}^{n+\alpha}m_{ij}\right) + \lambda\left((1-\alpha)\left({}^{n+\alpha}M_{ijkl}\right) d\left({}^{n}\sigma_{kl}\right) + \alpha\ \left({}^{n+\alpha}M_{ijkl}\right) d\left({}^{n+1}\sigma_{kl}\right)\right) \end{aligned}$$

Now we are proceeding by solving the previous equation for $d\left({}^{n+1}\sigma_{kl}\right)$:

$$\begin{aligned} & \left(D_{ijkl} + \lambda\ \alpha\ \left({}^{n+\alpha}M_{ijkl}\right)\right)\ d\left({}^{n+1}\sigma_{kl}\right) = \\ & \left(D_{ijkl} - \lambda\ (1-\alpha)\left({}^{n+\alpha}M_{ijkl}\right)\right) d\left({}^{n}\sigma_{kl}\right) - d\lambda\ \left({}^{n+\alpha}m_{ij}\right) \end{aligned}$$

and by denoting :

$$\Psi_{ijkl} = D_{ijkl} - \lambda\ (1-\alpha)\left({}^{n+\alpha}M_{ijkl}\right)$$

$$\Gamma_{ijkl} = D_{ijkl} + \lambda\ \alpha\left({}^{n+\alpha}M_{ijkl}\right)$$

it follows:

$$d\left({}^{n+1}\sigma_{kl}\right) = \Gamma^{-1}_{ijkl}\left(\Psi_{ijkl}\, d\left({}^{n}\sigma_{kl}\right) - d\lambda\ \left({}^{n+\alpha}m_{ij}\right)\right) \tag{104.63}$$

Then by inserting the solution for $d\left({}^{n+1}\sigma_{kl}\right)$ in the consistency condition (104.61):

$$d\ \left({}^{n+1}F\right) = {}^{n+1}n_{kl}\ d\left({}^{n+1}\sigma_{kl}\right) = 0$$

one gets:

$$\begin{gathered} d\ \left({}^{n+1}F\right) = \\ {}^{n+1}n_{kl}\ \Gamma^{-1}_{ijkl}\left(\Psi_{ijkl}\, d\left({}^{n}\sigma_{kl}\right) - d\lambda\ \left({}^{n+\alpha}m_{ij}\right)\right) = 0 \end{gathered} \tag{104.64}$$

then if we solve for $d\lambda$:

$$d\lambda\ {}^{n+\alpha}m_{ij}{}^{n+1}n_{kl}\ \Gamma^{-1}_{ijkl} = {}^{n+1}n_{kl}\ \Gamma^{-1}_{ijkl}\Psi_{ijkl}\, d\left({}^{n}\sigma_{kl}\right) \tag{104.65}$$

or[20]:

$$d\lambda = \frac{{}^{n+1}n_{rs}\ \Gamma^{-1}_{pqrs}\Psi_{pqrs}\ d\left({}^{n}\sigma_{rs}\right)}{\left({}^{n+\alpha}m_{pq}\right)\left({}^{n+1}n_{rs}\right)\Gamma^{-1}_{pqrs}} \tag{104.66}$$

then by using the solution for $d\left({}^{n+1}\sigma_{kl}\right)$ from (104.63) and the solution for $d\lambda$ from (104.66) one can find:

$$d\left({}^{n+1}\sigma_{kl}\right) = \Gamma^{-1}_{ijkl}\Psi_{ijkl}\, d\left({}^{n}\sigma_{kl}\right) - \Gamma^{-1}_{pqrs}\ \Psi_{pqrs}\frac{{}^{n+1}n_{rs}\ \Gamma^{-1}_{ijkl}\ \left({}^{n+\alpha}m_{ij}\right)}{{}^{n+\alpha}m_{pq}{}^{n+1}n_{rs}\ \Gamma^{-1}_{pqrs}} d\left({}^{n}\sigma_{rs}\right) \tag{104.67}$$

$$d\left({}^{n+1}\sigma_{kl}\right) = \Gamma^{-1}_{ijkl}\Psi_{ijkl}\left(\delta_{ks}\delta_{rl} - \frac{{}^{n+1}n_{rs}\ \Gamma^{-1}_{ijkl}\ \left({}^{n+\alpha}m_{ij}\right)}{{}^{n+\alpha}m_{pq}{}^{n+1}n_{rs}\ \Gamma^{-1}_{pqrs}}\right) d\left({}^{n}\sigma_{rs}\right) \tag{104.68}$$

to ease the writing we can define the following notation:

---

[20] where the change in dummy indices is possible because $d\lambda$ is scalar.

$$\Phi_{klrs} = \delta_{ks}\delta_{rl} - \frac{{}^{n+1}n_{rs}\ \Gamma^{-1}_{ijkl}\ \left({}^{n+\alpha}m_{ij}\right)}{{}^{n+\alpha}m_{pq}{}^{n+1}n_{rs}\ \Gamma^{-1}_{pqrs}} \tag{104.69}$$

so that the equation (104.68) now reads:

$$d\left({}^{n+1}\sigma_{kl}\right) = \Gamma^{-1}_{ijkl}\Psi_{ijkl}\ \Phi_{klrs}\ d\left({}^{n}\sigma_{rs}\right) \tag{104.70}$$

In order to derive the estimate of the type (104.50) from (104.70) we shall proceed in the following way. The norm of a tensor is defined as:

$$\|A_{ijkl}\| = \sup_{\sigma} \frac{\|A_{ijkl}\sigma_{kl}\|}{\|\sigma_{kl}\|} \tag{104.71}$$

If we take the norm of (104.70), while recalling the inequalities:

$$\|A_{ijkl}\sigma_{kl}\| \leq \|A_{ijkl}\|\ \|\sigma_{kl}\| \quad ; \quad \|A_{ijkl}B_{ijkl}\| \leq \|A_{ijkl}\|\ \|B_{ijkl}\| \tag{104.72}$$

it follows:

$$\|d\left({}^{n+1}\sigma_{kl}\right)\| = \|\Gamma^{-1}_{ijkl}\Psi_{ijkl}\ \Phi_{klrs}\ d\left({}^{n}\sigma_{rs}\right)\| \tag{104.73}$$

then by using equations (104.72), we are able to write:

$$\|d\left({}^{n+1}\sigma_{kl}\right)\| \leq \|\Gamma^{-1}_{ijkl}\ \Psi_{ijkl}\|\ \|\Phi_{klrs}\|\ \|d\left({}^{n}\sigma_{rs}\right)\| \tag{104.74}$$

Considering the norm of $\|\Phi_{klrs}\|$ it should be noted that Φ_{klrs} defines a projection along the direction of $\Gamma^{-1}_{ijkl}\ {}^{n+\alpha}m_{ij}$ onto the hyperplane that is orthogonal to ${}^{n+1}n_{rs}$, so that the following properties hold:

$$\left(\Phi_{klrs}\right)\left(\Gamma^{-1}_{ijkl}\ {}^{n+\alpha}m_{ij}\right) = \emptyset \tag{104.75}$$

$$\left(\Phi_{klrs}\right)\left(\sigma_{rs}\right) = \sigma_{rs} \tag{104.76}$$

for every σ_{rs} that is orthogonal to ${}^{n+1}n_{rs}$. From these properties and the definition in equation (104.71) it follows that:

$$\|\Phi_{klrs}\| \equiv 1 \tag{104.77}$$

In what follows it is assumed that the fourth order tensor field

$$M_{ijkl} = \partial m_{ij} / \partial \sigma_{kl}$$

is symmetric and positive definite everywhere on the yield surface. The assumption is valid, if the flow direction m_{ij} is derived from the convex potential function, which is a rather common feature among yield criteria. It is now clear that :

$$\|\Gamma^{-1}_{ijkl}\ \Psi_{ijkl}\| = \left| \frac{{}^{max}\gamma_{ij}\ \Psi_{ijkl}\ {}^{max}\gamma_{kl}}{{}^{max}\gamma_{ij}\ \Gamma_{ijkl}\ {}^{max}\gamma_{kl}} \right| \tag{104.78}$$

where ${}^{max}\gamma_{ij}$ is the eigentensor corresponding to the maximum eigenvalue of the eigenproblem:

$$\left(\Psi_{ijkl} - \mu\ \Gamma_{ijkl}\right) \gamma_{kl} = 0 \tag{104.79}$$

which is normalized to satisfy:

$$\|{}^{max}\gamma_{ij}\|\|{}^{max}\gamma_{ij}\| = {}^{max}\gamma_{ij}\ D_{ijkl}\ {}^{max}\gamma_{kl} = 1 \tag{104.80}$$

If we denote:

$${}^{n+\alpha}\beta = {}^{max}\gamma_{ij}\ {}^{n+\alpha}M_{ijkl}\ {}^{max}\gamma_{kl} \tag{104.81}$$

as the maximum eigenvalue of the fourth order tensor ${}^{n+\alpha}M_{ijkl}$ and that value is a positive real number[21], then from equations (104.78), (104.80), (104.81) and from the definition[22] of Ψ_{ijkl} and Γ_{ijkl}, it follows:

$$\|\Gamma^{-1}_{ijkl}\ \Psi_{ijkl}\| = \left| \frac{1 - (1-\alpha)\ \lambda\ \left({}^{n+\alpha}\beta\right)}{1 + \alpha\ \lambda\ \left({}^{n+\alpha}\beta\right)} \right| \tag{104.82}$$

which, when inserted in the equation (104.74) yields:

---

[21] because ${}^{n+\alpha}M_{ijkl}$ is derived from a convex potential function.

[22] $\Psi_{ijkl} = D_{ijkl} - \lambda\ (1-\alpha)\left({}^{n+\alpha}M_{ijkl}\right)$ and $\Gamma_{ijkl} = D_{ijkl} + \lambda\ \alpha\left({}^{n+\alpha}M_{ijkl}\right)$

$$\|d\left({}^{n+1}\sigma_{kl}\right)\| \leq \left|\frac{1-(1-\alpha)\ \lambda\ \left({}^{n+\alpha}\beta\right)}{1+\alpha\ \lambda\ \left({}^{n+\alpha}\beta\right)}\right|\ \|d\left({}^{n}\sigma_{rs}\right)\| \tag{104.83}$$

Since it is said that ${}^{n+\alpha}\beta$ is a positive real number it follows that:

$$\left|\frac{1-(1-\alpha)\ \lambda\ \left({}^{n+\alpha}\beta\right)}{1+\alpha\ \lambda\ \left({}^{n+\alpha}\beta\right)}\right| \leq \left|\frac{1-\alpha}{\alpha}\right| \frac{{}^{n+\alpha}\beta}{{}^{n+\alpha}\beta} = \left|\frac{1-\alpha}{\alpha}\right| \tag{104.84}$$

and $\alpha \in [0,1]$. The new form of equation (104.83) is now:

$$\|d\left({}^{n+1}\sigma_{kl}\right)\| \leq \left|\frac{1-\alpha}{\alpha}\right|\ \|d\left({}^{n}\sigma_{rs}\right)\| \tag{104.85}$$

which in conjunction with the requirement for unconditional stability[23] yields:

$$\left|\frac{1-\alpha}{\alpha}\right| \leq 1 \tag{104.86}$$

and so it is necessary that:

$$\alpha \geq {}^{min}\alpha = \frac{1}{2} \tag{104.87}$$

The conclusion is that the Generalized Midpoint rule is unconditionally stable for $\alpha \geq 1/2$. In the case when $\alpha < 1/2$ the Generalized Midpoint rule is only conditionally stable. To obtain a stability condition for $\alpha \leq 1/2$ one has to go back to equation (104.83), and we conclude that:

$$\left|\frac{1-(1-\alpha)\ \lambda\ \left({}^{n+\alpha}\beta\right)}{1+\alpha\ \lambda\ \left({}^{n+\alpha}\beta\right)}\right| \leq 1 \quad \Rightarrow \quad \lambda \leq \frac{2}{{}^{max}\beta\ (1-2\alpha)} \quad \text{for} \quad \alpha \leq \frac{1}{2} \tag{104.88}$$

and when $\alpha = 1/2$, then ${}^{critical}\lambda \rightarrow \infty$, and thus the unconditional stability is recovered.

---

[23] that is $\|d\ {}^{n+1}\sigma_{ij}\| \leq \|d\ {}^{n}\sigma_{ij}\|$

104.2.4 Crossing the Yield Surface

Midpoint rule algorithms in computational elasto–plasticity require[24] the evaluation of the intersection[25] stress. Despite the appeal of the closed form solution, as found in Bićanić (1989), and numerical iterative procedures as found in Marques (1984) and Nayak and Zienkiewicz (1972), for some yield criteria[26] the solution is not that simple to find. Special problems arises, even with the numerical iterative methods in the area of a apex. The apex area problems are connected to the derivatives of yield a function.

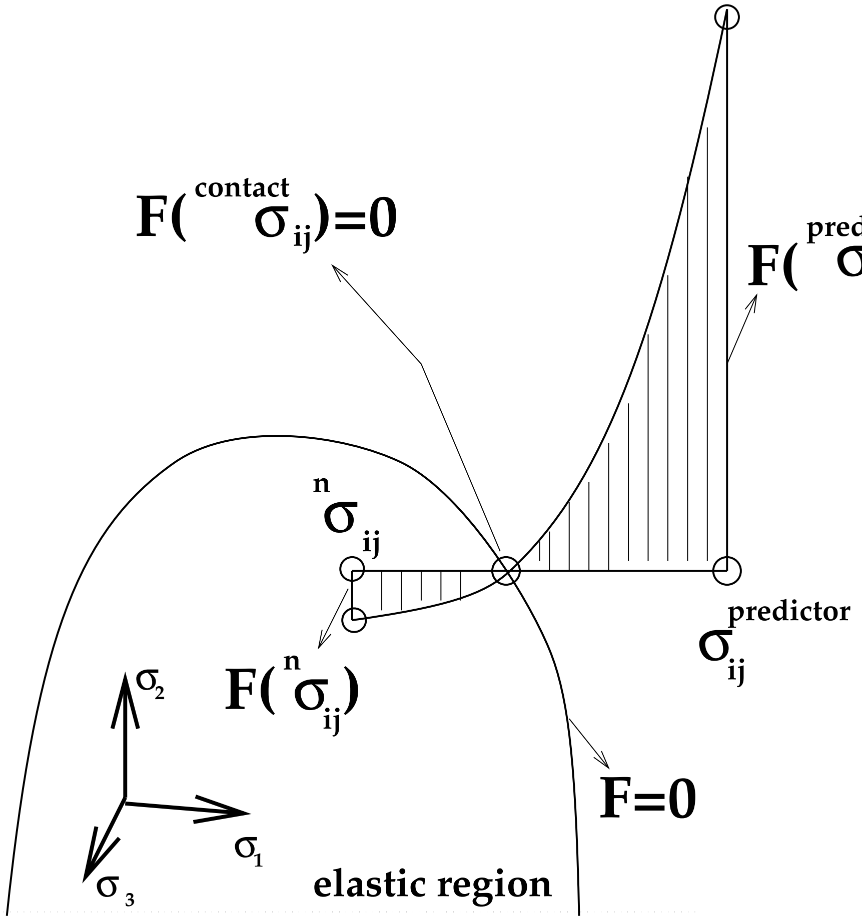

Figure 104.2: The pictorial representation of the intersection point problem in computational elasto–plasticity: which must be resolved for the Forward and Midpoint schemes

Having in mind the before mentioned problems, a different numerical scheme, that does not need derivatives, was sought for solving this problem. One possible solution was found in Press et al. (1988b)

---

[24] except for the fully implicit Backward Euler algorithm.

[25] contact, penetration point, i.e the point along the stress path where $F = 0$ or the point where stress state crosses from the elastic to the plastic region.

[26] namely for the MRS-Lade elasto–plastic model.

in the form of an excellent algorithm that combines root bracketing, bisection, and inverse quadratic interpolation to converge from a neighborhood of a zero crossing. The algorithm was developed in the 1960s by van Wijngaarden, Dekker and others at the Mathematical Center in Amsterdam. The algorithm was later improved by Brent, and so it is better known as Brent's method. The method is guaranteed to converge, so long as the function[27] can be evaluated within the initial interval known to contain a root. While the other iterative methods that do not require derivatives[28] assume approximately linear behavior between two prior estimates, inverse quadratic interpolation uses three prior points to fit an inverse quadratic function[29], whose value at $y = 0$ is taken as the next estimate of the root x. Lagrange's classical formula for interpolating the polynomial of degree $N-1$ through N points $y_1 = f(x_1)$, $y_2 = f(x_2)$, $\ldots y_3 = f(x_3)$ is given by:

$$\begin{aligned} P(x) = & \frac{(x-x_2)(x-x_3)\cdots(x-x_N)}{(x_1-x_2)(x_1-x_3)\cdots(x_1-x_N)}\, y_1 + \\ + & \frac{(x-x_1)(x-x_3)\cdots(x-x_N)}{(x_2-x_1)(x_2-x_3)\cdots(x_2-x_N)}\, y_2 + \cdots \\ \cdots + & \frac{(x-x_1)(x-x_2)\cdots(x-x_N)}{(x_N-x_1)(x_N-x_3)\cdots(x_N-x_{N-1})}\, y_N \end{aligned} \tag{104.89}$$

If the three point pairs are $[a, f(a)], [b, f(b)], [c, f(c)]$, then the interpolating formula (104.89) yields:

$$\begin{aligned} x = & \frac{(y-f(a))(y-f(b))}{(f(c)-f(a))(f(c)-f(b))}\, c + \\ + & \frac{(y-f(b))(y-f(c))}{(f(a)-f(b))(f(a)-f(c))}\, a + \\ + & \frac{(y-f(c))(y-f(a))}{(f(b)-f(a))(f(b)-f(a))}\, b \end{aligned} \tag{104.90}$$

By setting $y = 0$, we obtain a result for the next root estimate, which can be written as:

$$x = b + \frac{\frac{f(b)}{f(a)}\left(\frac{f(a)}{f(c)}\left(\frac{f(b)}{f(c)} - \frac{f(a)}{f(c)}\right)(c-b) - \left(1 - \frac{f(b)}{f(c)}\right)(b-a)\right)}{\left(\frac{f(a)}{f(c)} - 1\right)\left(\frac{f(b)}{f(c)} - 1\right)\left(\frac{f(b)}{f(a)} - 1\right)} \tag{104.91}$$

In practice b is the current best estimate of the root and the term:

---

[27] in our case yield function $F(\sigma_{ij})$.

[28] false position and secant method.

[29] x as a quadratic function of y.

$$\frac{\frac{f(b)}{f(a)}\left(\frac{f(a)}{f(c)}\left(\frac{f(b)}{f(c)}-\frac{f(a)}{f(c)}\right)(c-b)-\left(1-\frac{f(b)}{f(c)}\right)(b-a)\right)}{\left(\frac{f(a)}{f(c)}-1\right)\left(\frac{f(b)}{f(c)}-1\right)\left(\frac{f(b)}{f(a)}-1\right)}$$

is a correction. Quadratic methods[30] work well only when the function behaves smoothly. However, they run serious risk of giving bad estimates of the next root or causing floating point overflows, if divided by a small number

$$\left(\frac{f\left(a\right)}{f\left(c\right)}-1\right)\left(\frac{f\left(b\right)}{f\left(c\right)}-1\right)\left(\frac{f\left(b\right)}{f\left(a\right)}-1\right)\approx 0$$

Brent's method prevents against this problem by maintaining brackets on the root and checking where the interpolation would land before carrying out the division. When the correction of type (104.92) would not land within bounds, or when the bounds are not collapsing rapidly enough, the algorithm takes a bisection step. Thus, Brent's method combines the sureness of bisection with the speed of a higher order method when appropriate.

104.2.5 Singularities in the Yield Surface

104.2.5.1 Corner Problem

Some yield criteria are defined with more that one yield surface[31]. We will restrict our attention to a two–surface yield criterion[32]. Koiter has shown in Koiter (1960) and Koiter (1953) that in the case when two yield surfaces are active, the plastic strain rate from equation (104.3) can be derived as follows:

$$d\epsilon_{ij}^{p} = d\lambda_{cone}\ {}^{cone}m_{ij}\left(\sigma_{ij}, q_{*}\right) + d\lambda_{cap}\ {}^{cap}m_{ij}\left(\sigma_{ij}, q_{*}\right) \qquad (104.92)$$

where ${}^{cone}m_{ij}\left(\sigma_{ij}, q_{*}\right)$ and ${}^{cap}m_{ij}\left(\sigma_{ij}, q_{*}\right)$ are normals to the potential functions at a corner, which belongs to the yield functions that are active, i.e. F_{cone} and F_{cap}. We now observe that we have two non–negative plastic multipliers $d\lambda_{cone}$ and $d\lambda_{cap}$ instead of one. We must require that at the end of the loading step[33], neither of the two yield functions is violated. These multipliers $d\lambda_{cone}$ and $d\lambda_{cap}$ can be determined from the conditions:

---

[30] Newton's method for example.

[31] for example MRS-Lade yield criterion has two surfaces.

[32] having in mind MRS-Lade cone-cap yield criterion.

[33] after stress correction, i.e. return to the yield surface(s).

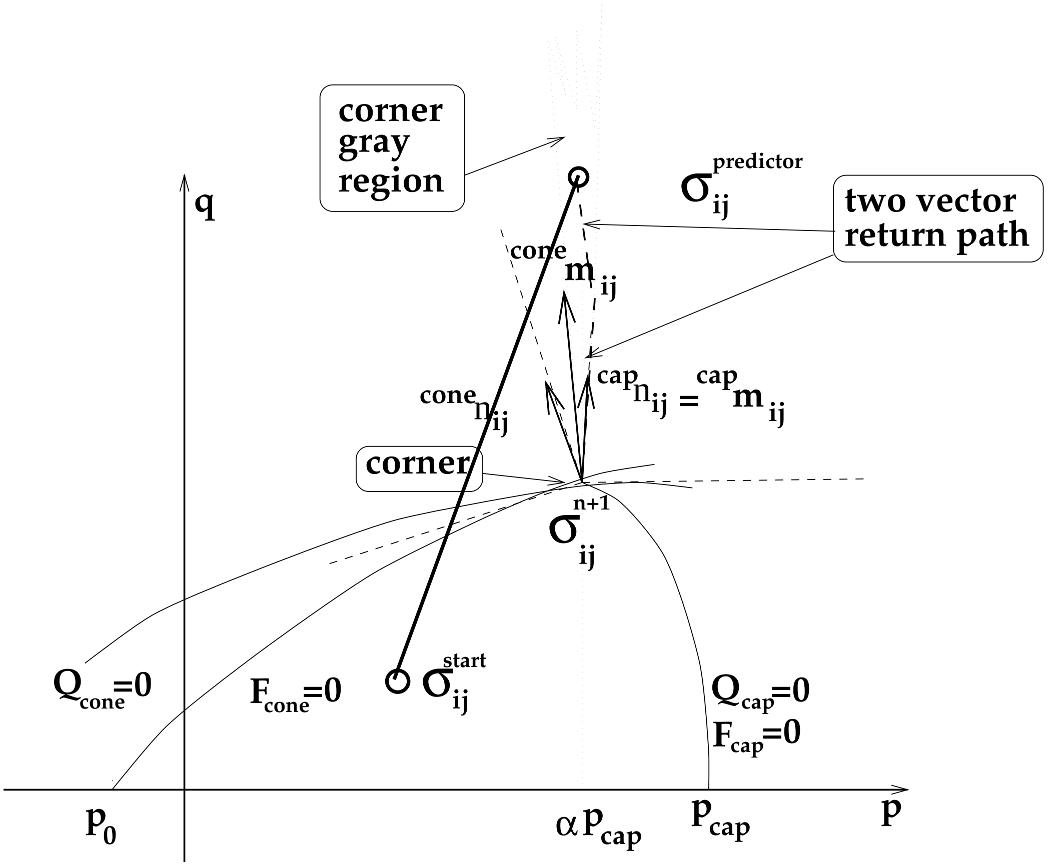

Figure 104.3: Pictorial representation of the corner point problem in computational elasto–plasticity: Yield surfaces with singular points

$$F_{cone}\left({}^{n+1}\sigma_{ij}, {}^{n+1}q_*\right) = 0 \tag{104.93}$$

$$F_{cap}\left({}^{n+1}\sigma_{ij}, {}^{n+1}q_*\right) = 0 \tag{104.94}$$

noting that by virtue of equation (104.92) we have at the corner singular point:

$${}^{n+1}\sigma_{ij} = {}^{pred}\sigma_{ij} - d\lambda_{cone}\, E_{ijkl}\, {}^{cone}m_{kl} - d\lambda_{cap}\, E_{ijkl}\, {}^{cap}m_{kl} \tag{104.95}$$

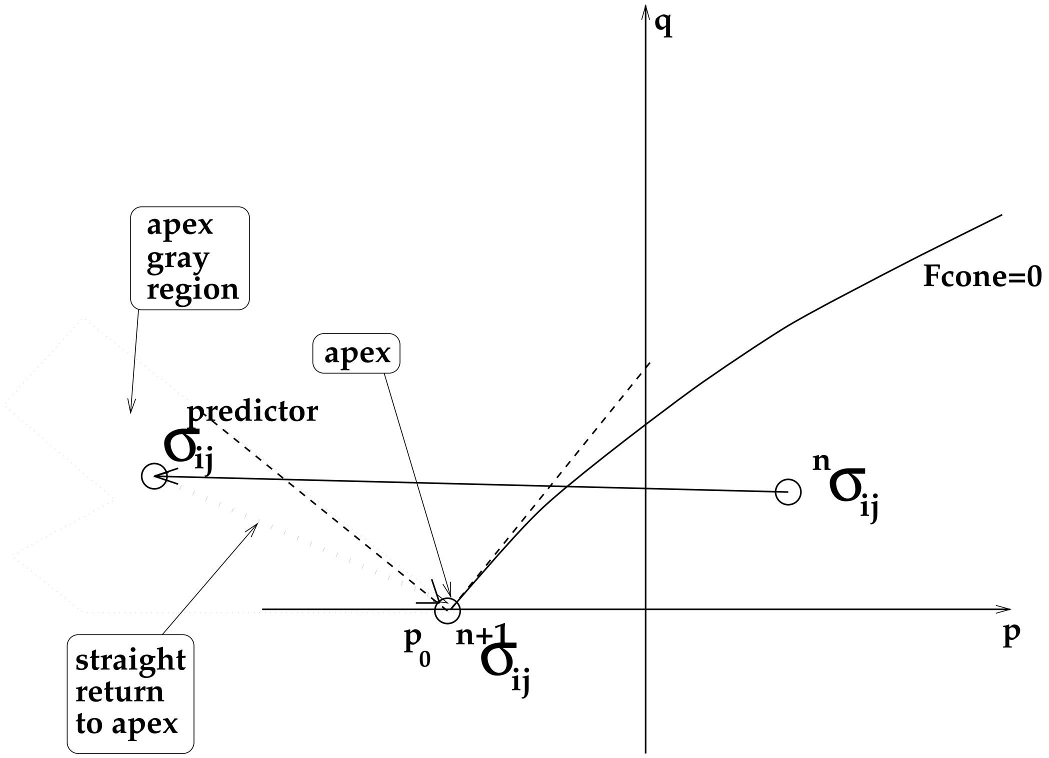

Figure 104.4: The pictorial representation of the apex point problem in computational elasto–plasticity: Yield surfaces with singular points

104.2.5.2 Apex Problem

The apex problem, as depicted in Figure (104.4) is solved in an empirical fashion. Rather than facing the complexity of solving a complex differential geometry problem[34] the stress point that is situated in the gray apex region is immediately returned to the apex point.

In the case when the hardening rule for the cone portion has developed to the stage that it affects the size of that cone portion of the yield criterion and not the position of intersection with the hydrostatic axis, then all stress returns from any part of apex gray region will be to the apex point itself. This strategy was used by Crisfield (1987). Nevertheless, the problem of integrating the rate equations in the apex gray region is readily solvable for the piecewise flat yield criteria[35] by using Koiter's conditions as found in Koiter (1960) and Koiter (1953). The apex problem for yield criteria that are smooth and differentiable everywhere except at the apex point, is solvable by means of differential geometry. Further

---

[34] using Koiter's work described in Koiter (1960) and Koiter (1953) and the fact that the sum $d\epsilon^p_{ij} = \sum_k d\lambda_k \left(\partial F_k / \partial\sigma_{ij}\right)$ can be transformed into the integral equation $d\epsilon^p_{ij} = \int d\lambda \left(\partial F / \partial\sigma_{ij}\right)\big|_{aroundapex}$ where the integration should be carried out infinitesimally close to, but in the vicinity of the apex point.

[35] Mohr - Coulomb for example.

work is needed for solving the problem, when the yield surface is not piecewise flat in the apex vicinity.

104.2.5.3 Influence Regions in Meridian Plane

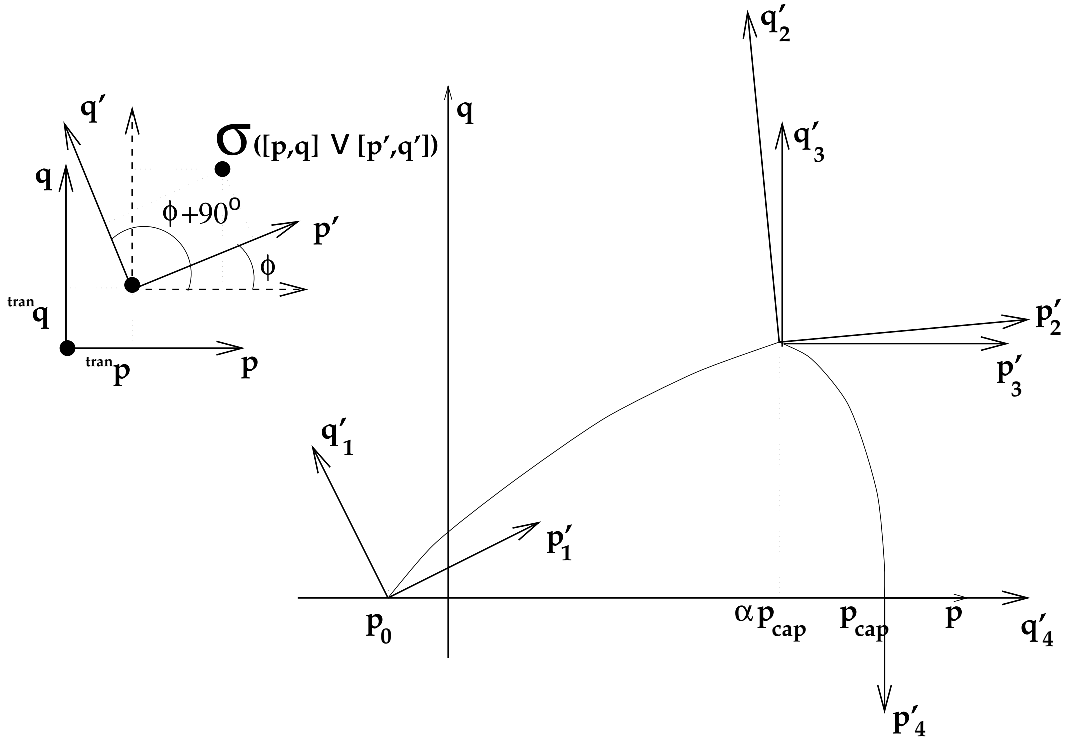

Figure 104.5: Influence regions in the meridian plane for the cone/cap surface of the MRS-Lade material model.

In order to define which surface is active and which is not for the current state of stress, a simple two dimensional analysis will be conducted. The fortunate fact for the MRS-Lade material model is that such an analysis can be conducted in the $p - q$ meridian plane, only, i.e. the value for θ can be "frozen". The concept is to calculate the stress invariants p, q and θ for the current state of stress[36], calculate the position of the apex and corner points in $p - q$ space for given the θ, calculate the two dimensional gradients at these points, perform linear transformation of the current stress state[37] to the new coordinate systems, and then check for the values of ${p'}_i$, $i = 1, 2, 3, 4$, where ${p'}_i$ is the transformed p_i axis.

The angle ψ is defined as the angle between the p axis and the tangent to the potential function.

The gradients to the cone portion of the potential surface are defined as:

---

[36] by using equations (104.138) and (104.139) as defined in section (104.4.4).

[37] now in p, q and θ space.

$$\frac{\partial Q_{cone}}{\partial p} = -n \; \eta_{cone}$$

$$\frac{\partial Q_{cone}}{\partial q} = g(\theta) \left(1 + \frac{q}{q_a}\right)^m + \frac{g(\theta) \, m \, q \left(1 + \frac{q}{q_a}\right)^{-1+m}}{q_a}$$

The gradients of the cap portion of the yield/potential surface is defined as:

$$\frac{\partial Q_{cap}}{\partial p} = \frac{2 \; (p - p_m)}{p_r^2}$$

$$\frac{\partial Q_{cap}}{\partial q} = \frac{2 \, g(\theta)^2 \, q \left(1 + \frac{q}{q_a}\right)^{2\,m}}{{f_r}^2} + \frac{2 \, g(\theta)^2 \, m \, q^2 \left(1 + \frac{q}{q_a}\right)^{-1+2\,m}}{{f_r}^2 \, q_a}$$

The vector of gradients in $p-q$ space is defined as:

$$\begin{bmatrix} \frac{\partial Q}{\partial p} \\ \frac{\partial Q}{\partial q} \end{bmatrix} \tag{104.96}$$

and the angle ϕ is calculated as:

$$\phi = \arctan \left(\frac{\left(\frac{\partial Q}{\partial p}\right)}{\left(\frac{\partial Q}{\partial q}\right)} \right) - 90^\circ \tag{104.97}$$

Care must be exercised with regard to which potential function is to be used in angle calculations. It should be mentioned that for the cap portion, the angle at the corner is $\phi = 0^\circ$, while at the tip of the cap, the angle is $\phi = -90^\circ$. If a new definition, as found in Ferrer (1992), is used for the cone potential function, where n is variable and $n \rightarrow 0$ as $p \rightarrow \alpha p_{cap}$, then the corner gray region is empty.

The linear transformation[38] between coordinate systems $p' - q'$ and $p - q$ is defined as:

$$\begin{bmatrix} p' \\ q' \end{bmatrix} = \begin{bmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} p - {}^{tran}p \\ q - {}^{tran}q \end{bmatrix} \tag{104.98}$$

and by using that linear transformation, one can check the region where our current stress state, in p, q and θ space, belongs. Figure (104.5) depicts the transformation scheme and the new coordinate systems at three important points[39].

---

[38] translation and rotation.

[39] at the apex point, corner point and the cap tip point.

104.3 A Forward Euler (Explicit) Algorithm

The explicit algorithm (Forward Euler) is based on using the starting point (the state stress σ_{ij}^{n} and internal variable space q_*^n on the yield surface) for finding all the relevant derivatives and variables.

The Explicit algorithm can be derived by starting from a first order Taylor expansion about starting point (σ_{ij}^{n}, q_*^n):

$$\begin{aligned} F^{new} &= F^{old} + \left.\frac{\partial F}{\partial \sigma_{mn}}\right|_n d\left({}^{n}\sigma_{mn}\right) + \left.\frac{\partial F}{\partial q_*}\right|_n dq_* = \\ &= {}^{n}n_{mn}\, d\sigma_{mn} + \xi_* h_* d\lambda = 0 \end{aligned} \tag{104.99}$$

From the differential form of equation (104.16) it follows:

$$d\left({}^{fE}\sigma_{mn}\right) = E_{mnpq}\left(d\left(\epsilon_{pq}\right) - d\left(\epsilon_{pq}^{p}\right)\right) =$$
$$= E_{mnpq} d\left(\epsilon_{pq}\right) - E_{mnpq}\; d\left(\epsilon_{pq}^{p}\right) = E_{mnpq} d\left(\epsilon_{pq}\right) - E_{mnpq}\; d\lambda\left({}^{cross}m_{pq}\right)$$

so that equation (104.99) becomes:

$${}^{n}n_{mn}\; E_{mnpq}\; d\epsilon_{pq} - {}^{n}n_{mn}\; E_{mnpq}\; d\lambda^{n}m_{pq} + \xi_* h_* d\lambda = 0$$

and it follows, after solving for $d\lambda$

$$d\lambda = \frac{{}^{n}n_{mn}\; E_{mnpq}\; d\epsilon_{pq}}{{}^{cros}n_{ab}\; E_{abcd}\; {}^{cros}m_{cd} - \xi_* h_*}$$

With this solution for $d\lambda$ one can obtain the increments in stress tensor and internal variables as

$$d\sigma_{mn} = E_{mnpq}\; d\epsilon_{pq} - E_{mnpq}\; \frac{{}^{n}n_{rs}\; E_{rstu}\; d\epsilon_{tu}}{{}^{n}n_{ab}\; E_{abcd}\; {}^{n}m_{cd} - \xi_A h_A}\; {}^{n}m_{pq} \tag{104.100}$$

$$dq_A = \left(\frac{{}^{n}n_{mn}\; E_{mnpq}\; d\epsilon_{pq}}{{}^{cros}n_{ab}\; E_{abcd}\; {}^{cros}m_{cd} - \xi_B h_B}\right) h_A \tag{104.101}$$

where ${}^{n}()$ denotes the starting elastic–plastic point for that increment. It should be noted that the explicit algorithm performs only one step of the computation and does not check on the equilibrium of the obtained solutions. This usually results in the slow drift of the stress–internal variable point from the yield surface for monotonic loading. It also results in spurious plastic deformations during elastic unloading for cyclic loading–unloading.

104.3.1 Continuum Tangent Stiffness Tensor.

The continuum tangent stiffness tensor (${}^{cont}E_{pqmn}^{ep}$) is obtained from the explicit (forward Euler) integration procedure (Jeremić and Sture, 1997):

$${}^{cont}E_{pqmn}^{ep} = E_{pqmn} - \frac{E_{pqkl}{}^{n}m_{kl}{}^{n}n_{ij}E_{ijmn}}{{}^{n}n_{ot}E_{otrs}\; {}^{n}m_{rs} - {}^{n}\xi_A\; h_A} \tag{104.102}$$

It is important to note that continuum tangent stiffness (${}^{cont}E_{pqmn}^{ep}$) posses minor symmetries (${}^{cont}E_{pqmn}^{ep} =$

${}^{cont}E^{ep}_{qpmn} = {}^{cont}E^{ep}_{pqnm}$), while major symmetry (${}^{cont}E^{ep}_{pqmn} = {}^{cont}E^{ep}_{mnpq}$), is only retained for associated elastic–plastic materials, when $n_{ij} \equiv m_{ij}$.

104.4 A Backward Euler (Implicit) Algorithm

In previous sections, the general theory of elasto–plasticity was presented. The accuracy and stability for the general Midpoint rule algorithm has been shown. In this chapter, the focus is on the Backward Euler algorithm, which is derived from the general Midpoint algorithm by setting $\alpha = 1$. The advantage of the Backward Euler scheme over other midpoint schemes is that the solution is sought by using the normal[40] at the final stress state. By implicitly assuming that such a stress state exists, the Backward Euler scheme is guaranteed to provide a solution, despite the size of the strain step[41]. However, it was shown in section (104.2.3.1) that the Backward Euler algorithm is only accurate to the first order.

The full implicit Backward Euler algorithm is based on the equation:

$$ {}^{n+1}\sigma_{ij} = {}^{pred}\sigma_{ij} - \Delta\lambda\; E_{ijkl}\; {}^{n+1}m_{kl} \qquad (104.103)$$

where ${}^{pred}\sigma_{ij} = E_{ijkl}\;\epsilon_{kl}$ is the elastic trial stress state, Q is the plastic potential function and ${}^{n+1}m_{kl} = \left.\frac{\partial Q}{\partial \sigma_{kl}}\right|_{n+1}$ is the gradient to the plastic potential function in the stress space at the final stress position, and

$$ {}^{pred}\sigma_{ij} = {}^{n}\sigma_{ij} + E_{ijkl}\; {}^{pred}\Delta\epsilon_{kl} \qquad (104.104)$$

is the elastic predicted (trial) stress state.

An initial estimate for the stress ${}^{n+1}\sigma_{ij}$ can be obtained using various other methods. This estimate generally does not satisfy the yield condition, so some kind of iterative scheme is necessary to return the stress to the yield surface.

104.4.1 Single Vector Return Algorithm.

If the predictor stress ${}^{pred}\sigma_{ij}$ is not in a corner or apex gray regions, a single vector return to the yield surface is possible. In order to derive such a scheme for a single vector return algorithm, a tensor of residuals r_{ij} will be defined as [42] :

$$ r_{ij} = \sigma_{ij} - \left({}^{pred}\sigma_{ij} - \Delta\lambda\; E_{ijkl}\; m_{kl} \right) \qquad (104.105)$$

---

[40] $m_{ij} = \partial Q / \partial \sigma_{ij}$

[41] large strain step increments were tested, the scheme converged to the solution even for deviatoric strain steps of 20% in magnitude.

[42] By default at increment $n+1$, and ${}^{n+1}()$ is omitted for simplicity.

This tensor represents the difference between the current stress state σ_{ij} and the Backward Euler stress state ${}^{pred}\sigma_{ij} - \Delta\lambda\ E_{ijkl}\ m_{kl}$.

The trial stress state ${}^{pred}\sigma_{ij}$ is kept fixed during the iteration process. The first order Taylor series expansion can be applied to Equation 104.105 to obtain the new residual ${}^{new}r_{ij}$ from the old one ${}^{old}r_{ij}$

$$ {}^{new}r_{ij} = {}^{old}r_{ij} + \mathrm{d}\sigma_{ij} + \mathrm{d}(\Delta\lambda)\ E_{ijkl}\ m_{kl} + \Delta\lambda\ E_{ijkl}\ \left(\frac{\partial m_{kl}}{\partial \sigma_{mn}} \mathrm{d}\sigma_{mn} + \frac{\partial m_{kl}}{\partial q_A} \mathrm{d}q_A \right) \tag{104.106} $$

where $\mathrm{d}\sigma_{ij}$ is the change in σ_{ij}, $\mathrm{d}(\Delta\lambda)$ is the change in $\Delta\lambda$, and $\frac{\partial m_{kl}}{\partial \sigma_{mn}} \mathrm{d}\sigma_{mn} + \frac{\partial m_{kl}}{\partial q_A} \mathrm{d}q_A$ is the change in m_{kl}. The goal is let ${}^{new}r_{ij} = \emptyset$, so one can write

$$ \emptyset = {}^{old}r_{ij} + \mathrm{d}\sigma_{ij} + \mathrm{d}(\Delta\lambda)\ E_{ijkl}\ m_{kl} + \Delta\lambda\ E_{ijkl}\ \left(\frac{\partial m_{kl}}{\partial \sigma_{mn}} \mathrm{d}\sigma_{mn} + \frac{\partial m_{kl}}{\partial q_A} \mathrm{d}q_A \right) \tag{104.107} $$

Similarly,

$$ q_A = {}^{n}q_A + \Delta\lambda\ h_A \tag{104.108} $$

r_A will be defined as:

$$ r_A = q_A - \left({}^{n}q_A + \Delta\lambda\ h_A \right) \tag{104.109} $$

and ${}^{n}q_A$ is kept fixed during iteration, that

$$ \emptyset = {}^{old}r_A + \mathrm{d}q_A - \mathrm{d}(\Delta\lambda)\ h_A - \Delta\lambda\ \left(\frac{\partial h_A}{\partial \sigma_{ij}} \mathrm{d}\sigma_{ij} + \frac{\partial h_A}{\partial q_B} \mathrm{d}q_B \right) \tag{104.110} $$

From equation 104.107 and 104.110, one obtains

$$ \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial \sigma_{mn}} & \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial q_A} \\ -\Delta\lambda \frac{\partial h_A}{\partial \sigma_{ij}} & \delta_{AB} - \Delta\lambda \frac{\partial h_A}{\partial q_B} \end{bmatrix} \begin{Bmatrix} \mathrm{d}\sigma_{mn} \\ \mathrm{d}q_B \end{Bmatrix} + \mathrm{d}(\Delta\lambda) \begin{Bmatrix} E_{ijkl} m_{kl} \\ -h_A \end{Bmatrix} + \begin{Bmatrix} {}^{old}r_{ij} \\ {}^{old}r_A \end{Bmatrix} = \emptyset \tag{104.111} $$

Since $f(\sigma_{ij}, q_A) = 0$, one obtains

$$ \emptyset = {}^{old}f + n_{mn} \mathrm{d}\sigma_{mn} + \xi_B \mathrm{d}q_B \tag{104.112} $$

From equations 104.111 and 104.112,

$$ \mathrm{d}(\Delta\lambda) = \frac{ {}^{old}f - \begin{Bmatrix} n_{mn} & \xi_B \end{Bmatrix} \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial \sigma_{mn}} & \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial q_A} \\ -\Delta\lambda \frac{\partial h_A}{\partial \sigma_{ij}} & \delta_{AB} - \Delta\lambda \frac{\partial h_A}{\partial q_B} \end{bmatrix}^{-1} \begin{Bmatrix} {}^{old}r_{ij} \\ {}^{old}r_A \end{Bmatrix} }{ \begin{Bmatrix} n_{mn} & \xi_B \end{Bmatrix} \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial \sigma_{mn}} & \Delta\lambda E_{ijkl} \frac{\partial m_{kl}}{\partial q_A} \\ -\Delta\lambda \frac{\partial h_A}{\partial \sigma_{ij}} & \delta_{AB} - \Delta\lambda \frac{\partial h_A}{\partial q_B} \end{bmatrix}^{-1} \begin{Bmatrix} E_{ijkl} m_{kl} \\ -h_A \end{Bmatrix} } \tag{104.113} $$

The iteration of $\Delta\lambda$ is then

$$\Delta\lambda^{k+1} = \Delta\lambda^{k} + \mathrm{d}(\Delta\lambda)^{k} \tag{104.114}$$

The iterative procedure is continued until the yield criterion $f = 0$, $\|r_{ij}\| = \emptyset$, and $\|r_A\| = \emptyset$ are satisfied within some tolerances at the final stress state [43].

In Equation 104.113, the generalized matrix $\mathbb{C}$, which is defined by

$$\mathbb{C} = \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial q_A} \\ -\Delta\lambda\frac{\partial h_A}{\partial\sigma_{ij}} & \delta_{AB} - \Delta\lambda\frac{\partial h_A}{\partial q_B} \end{bmatrix}^{-1} \tag{104.115}$$

plays an important role in the implicit algorithm. It should be mentioned here that the above definition is a simplified expression for very general model with various isotropic and kinematic hardening. Specifically, if there is no hardening,

$$\mathbb{C} = \left[\; I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} \; \right]^{-1} \tag{104.116}$$

If there is only one isotropic internal variable q,

$$\mathbb{C} = \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial q} \\ -\Delta\lambda\frac{\partial h}{\partial\sigma_{ij}} & 1 - \Delta\lambda\frac{\partial h}{\partial q} \end{bmatrix}^{-1} \tag{104.117}$$

For only one kinematic internal variable α_{ij},

$$\mathbb{C} = \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\alpha_{mn}} \\ -\Delta\lambda\frac{\partial h_{mn}}{\partial\sigma_{ij}} & I^s_{ijmn} - \Delta\lambda\frac{\partial h_{mn}}{\partial\alpha_{ij}} \end{bmatrix}^{-1} \tag{104.118}$$

For one isotropic variable q and one kinematic variable α_{ij},

$$\mathbb{C} = \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial q} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\alpha_{mn}} \\ -\Delta\lambda\frac{\partial h}{\partial\sigma_{ij}} & 1 - \Delta\lambda\frac{\partial h}{\partial q} & -\Delta\lambda\frac{\partial h}{\partial\alpha_{ij}} \\ -\Delta\lambda\frac{\partial h_{mn}}{\partial\sigma_{ij}} & -\Delta\lambda\frac{\partial h_{mn}}{\partial q} & I^s_{ijmn} - \Delta\lambda\frac{\partial h_{mn}}{\partial\alpha_{ij}} \end{bmatrix}^{-1} \tag{104.119}$$

or for two kinematic variables z_{ij} and α_{ij},

$$\mathbb{C} = \begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial z_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial\alpha_{mn}} \\ -\Delta\lambda\frac{\partial h^z}{\partial\sigma_{ij}} & I^s_{ijmn} - \Delta\lambda\frac{\partial h^z}{\partial z_{mn}} & -\Delta\lambda\frac{\partial h^z}{\partial\alpha_{ij}} \\ -\Delta\lambda\frac{\partial h^\alpha_{mn}}{\partial\sigma_{ij}} & -\Delta\lambda\frac{\partial h^\alpha_{mn}}{\partial z_{mn}} & I^s_{ijmn} - \Delta\lambda\frac{\partial h^\alpha_{mn}}{\partial\alpha_{ij}} \end{bmatrix}^{-1} \tag{104.120}$$

If we define

$$\mathbf{n} = \begin{Bmatrix} n_{mn} \\ \xi_B \end{Bmatrix} \tag{104.121}$$

---

[43] $\|\|$ is some normal of the tensor

$$\mathbf{m} = \left\{ \begin{array}{c} E_{ijkl} m_{kl} \\ -h_A \end{array} \right\} \tag{104.122}$$

$$^{old}\mathbf{r} = \left\{ \begin{array}{c} ^{old}\sigma_{ij} \\ ^{old}r_A \end{array} \right\} \tag{104.123}$$

Equation 104.114 can be simplified as

$$\mathrm{d}(\Delta\lambda) = \frac{^{old}f - \mathbf{n}^T \ \mathbb{C} \ ^{old}\mathbf{r}}{\mathbf{n}^T \ \mathbb{C} \ \mathbf{M}} \tag{104.124}$$

and

$$\left\{ \begin{array}{c} \mathrm{d}\sigma_{mn} \\ \mathrm{d}q_B \end{array} \right\} = -\mathbb{C} \left(^{old}\mathbf{r} + \mathrm{d}(\Delta\lambda)\mathbf{m} \right) \tag{104.125}$$

104.4.2 Backward Euler Algorithms: Starting Points

Some remarks are necessary in order to clarify the Backward Euler Algorithm. It is a well known fact that the rate of convergence of the Newton - Raphson Method , or even obtaining convergence at all, is closely tied to the starting point for the iterative procedure. Bad initial or starting points might lead our algorithm to an oscillating solution, i.e. the algorithm does not converge. In the following, starting points for the Newton - Raphson iterative procedure will be established for one– and two–vector return algorithms.

104.4.2.1 Single Vector Return Algorithm Starting Point.

One of the proposed starting points (Crisfield, 1991) uses the normal at the elastic trial point[44] ${}^{pred}\sigma_{ij}$. A first order Taylor expansion about point ${}^{pred}\sigma_{ij}$ yields:

$$\begin{aligned}
{}^{pred}F^{new} &= {}^{pred}F^{old} + \left.\frac{\partial F}{\partial \sigma_{mn}}\right|_{pred} d\left({}^{pred}\sigma_{mn}\right) + \left.\frac{\partial F}{\partial q_A}\right|_{pred} dq_A = \\
&= {}^{pred}F^{old} + {}^{pred}n_{mn}\, d\sigma_{mn} + \xi_A h_A d\lambda = 0
\end{aligned} \tag{104.126}$$

It is assumed that the total incremental strain ϵ_{kl} is applied in order to reach the point ${}^{pred}\sigma_{ij}$, i.e. ${}^{pred}\sigma_{ij} = E_{ijkl}\ \epsilon_{kl}$ so that any further stress "relaxation" toward the yield surface takes place under zero total strain condition $\epsilon_{kl} = \emptyset$. From the differential form of equation (104.16) it follows:

$$\begin{aligned}
d\left({}^{pred}\sigma_{mn}\right) = E_{mnpq}\left(d\left({}^{pred}\epsilon_{pq}\right) - d\left({}^{pred}\epsilon^{p}_{pq}\right)\right) = \\
= -E_{mnpq}\ d\left({}^{pred}\epsilon^{p}_{pq}\right) = -E_{mnpq}\ d\lambda\left({}^{pred}m_{pq}\right)
\end{aligned}$$

and equation (104.126) becomes:

$${}^{pred}F^{old} - {}^{pred}n_{mn}\ E_{mnpq}\ d\lambda\, {}^{pred}m_{pq} + \xi_A h_A d\lambda = 0$$

and it follows:

$$d\lambda = \frac{{}^{pred}F^{old}}{{}^{pred}n_{mn}\ E_{mnpq}\ {}^{pred}m_{pq} - \xi_A h_A}$$

With this solution for $d\lambda$ we can obtain the starting point for the Newton-Raphson iterative procedure

$${}^{start}\sigma_{mn} = E_{mnpq}\ {}^{pred}\epsilon_{pq} - E_{mnpq}\ \frac{{}^{pred}F^{old}}{{}^{pred}n_{mn}\ E_{mnpq}\ {}^{pred}m_{pq} - \xi_A h_A}\ {}^{pred}m_{pq} \tag{104.127}$$

This starting point in six dimensional stress space will in general not satisfy the yield condition $F = 0$, but it will provide a good initial guess for the upcoming Newton-Raphson iterative procedure.

It should be mentioned, however, that this scheme for returning to the yield surface is the well known Radial Return Algorithm , if the yield criterion under consideration is of the von Mises type. In the special case the normal at the elastic trial point ${}^{pred}\sigma_{ij}$ coincides with the normal at the final stress state ${}^{n+1}\sigma_{ij}$, the return is exact, i.e. the yield condition is satisfied in one step.

Another possible and readily available starting point can be obtained by applying one Forward Euler step[45]. To be able to use the Forward Euler integration scheme, an intersection point has to be found. The procedure for calculating intersection points is given in section (104.2.4).

---

[44] I have named this scheme as semi Backward Euler scheme.

[45] or more steps for really large strain increments, for example over 10% in deviatoric direction. What has actually been done is to divide the θ region into several parts and depending on the curvature of the yield surface in deviatoric plane, use different schemes and different number of subincrements (the more curved, the more subincrements) to get the first, good initial guess. In the region around $\theta = 0$, one step of the semi Backward Euler scheme is appropriate, but close to $\theta = \pi/3$ the Forward Euler subincrementation works better.

A first order Taylor expansion about intersection point ${}^{cross}\sigma_{ij}$ yields:

$$\begin{aligned} F^{new} &= F^{old} + \left.\frac{\partial F}{\partial \sigma_{mn}}\right|_{cross} d\left({}^{cross}\sigma_{mn}\right) + \left.\frac{\partial F}{\partial q_A}\right|_{cross} dq_A = \\ &= {}^{cross}n_{mn}\; d\sigma_{mn} + \xi_A h_A d\lambda = 0 \end{aligned} \tag{104.128}$$

From the differential form of equation (104.16) it follows:

$$d\left({}^{fE}\sigma_{mn}\right) = E_{mnpq}\left(d\left(\epsilon_{pq}\right) - d\left(\epsilon^{p}_{pq}\right)\right) =$$

$$= E_{mnpq} d\left(\epsilon_{pq}\right) - E_{mnpq}\; d\left(\epsilon^{p}_{pq}\right) = E_{mnpq} d\left(\epsilon_{pq}\right) - E_{mnpq}\; d\lambda\left({}^{cross}m_{pq}\right)$$

and equation (104.128) becomes:

$$-{}^{cross}n_{mn}\; E_{mnpq}\; d\epsilon_{pq} - {}^{cross}n_{mn}\; E_{mnpq}\; d\lambda\, {}^{cross}m_{pq} + \xi_A h_A d\lambda = 0$$

and it follows

$$d\lambda = \frac{{}^{cross}n_{mn}\; E_{mnpq}\; d\epsilon_{pq}}{{}^{cros}n_{mn}\; E_{mnpq}\; {}^{cros}m_{pq} - \xi_A h_A}$$

With this solution for $d\lambda$ we can obtain the starting point for the Newton-Raphson iterative procedure

$${}^{start}\sigma_{mn} = E_{mnpq}\; d\epsilon_{pq} - E_{mnpq}\; \frac{{}^{cross}n_{rs}\; E_{rstu}\; d\epsilon_{tu}}{{}^{cross}n_{ab}\; E_{abcd}\; {}^{cross}m_{cd} - \xi_A h_A}\; {}^{cross}m_{pq} \tag{104.129}$$

This starting point in six–dimensional stress space will again not satisfy the yield condition[46] $F = 0$, but will provide a good initial estimate for the upcoming Newton-Raphson iterative procedure.

104.4.3 Consistent Tangent Stiffness Tensor

The final goal in deriving the Backward Euler scheme for integration of elasto–plastic constitutive equations is to use that scheme in finite element computations. If the Newton – Raphson iterative scheme is used at the global equilibrium level then the use of the so called traditional tangent stiffness tensor[47] E^{ep}_{ijkl} destroys the quadratic rate of asymptotic convergence of the iterative scheme. In order to preserve such a quadratic rate, a consistent, also called algorithmic, tangent stiffness tensor is derived. The consistent tangent stiffness tensor make use of derivatives of direction[48] normal to the potential function, and they are derived at the final, final at each iteration, that converges to the final stress point on the yield surface, stress point. The traditional forward scheme has a constant derivative, m_{ij} that is evaluated at the intersection point.

---

[46] except for the yield criteria that have flat yield surfaces (in the stress invariant space) so that the first order Taylor linear expansion, is exact.

[47] the one obtained with the Forward Euler method, i.e. where parameter $\alpha = 0$.

[48] $m_{ij} = \partial Q / \partial \sigma_{ij}$, i.e. $\partial m_{ij} / \partial \sigma_{kl} = \partial^2 Q / \partial \sigma_{ij} \partial \sigma_{kl}$.

It appears that Simo and Taylor (1985) and Runesson and Samuelsson (1985) have first derived the consistent tangent stiffness tensor. Other interesting articles on the subject can be found in Simo and Taylor (1986), Simo and Govindjee (1988), Jetteur (1986), Braudel et al. (1986), Crisfield (1987), Ramm and Matzenmiller (1988) and Mitchell and Owen (1988). As a consequence of consistency, the use of the consistent tangent stiffness tensor significantly improves the convergence characteristics of the overall equilibrium iterations, if a Newton - Raphson scheme is used for the latter. Use of the consistent tangent stiffness tensor yields a quadratic convergence rate of Newton - Raphson equilibrium iterations. In what follows, two derivations are given, namely the consistent tangent stiffness tensor for single– and two–vector return algorithms.

The concept of consistent linearization was introduced by Hughes and Pister (1978), while detailed explanation is given by Simo and Hughes (1998). The consistent tangent stiffness leads to quadratic convergence rates at global level.

It should be mentioned that there are various 'equivalent' forms of consistent tangent stiffness depending on the specific implicit algorithm equations. For instance, Simo and Hughes (1998), and Belytschko et al. (2001) derived the consistent tangent stiffness by taking current plastic strain as unknown and seeking its derivatives in the stress space; Pérez-Foguet and Huerta (1997) and Pérez-Foguet et al. (2000) used the numerical differentiation to calculate the consistent tangent stiffness in a compact matrix-vector form; Choi (2004) adopted the compact matrix-vector form by Pérez-Foguet and Huerta (1997) and Pérez-Foguet et al. (2000) but taking current plastic strain as unknown and seeking its derivatives in the elastic strain space. Slightly different from the above strategies, in this work the implicit algorithm is adopting the traditional form but taking current stress as unknown and seeking its derivatives in the stress space. Provided these differences, the consistent tangent stiffness in this work is slightly different from those in the above work.

104.4.3.1 Single Vector Return Algorithm.

In implicit algorithm, a very important advantage is that it may lead to consistent (algorithmic) tangent stiffness (Equation 104.137). The concept of consistent linearization was introduced in Hughes and Pister (1978), more details on consistent tangent stiffness were explained in Simo and Hughes (1998). The consistent tangent stiffness leads to quadratic convergence rates at global level.

It should be mentioned that there are various 'equivalent' forms of consistent tangent stiffness depending on the specific implicit algorithm equations. For instance, Simo and Hughes (1998), and Belytschko et al. (2001) derived the consistent tangent stiffness by taking current plastic strain as unknown and seeking its derivatives in the stress space; Pérez-Foguet and Huerta (1997) and Pérez-Foguet et al. (2000) used the numerical differentiation to calculate the consistent tangent stiffness in a compact matrix-vector form; Choi (2004) adopted the compact matrix-vector form by Pérez-Foguet and Huerta (1997) and Pérez-Foguet et al. (2000) but taking current plastic strain as unknown and seeking its derivatives in the elastic strain space. Slightly different from the above strategies, in this work (section 104.4) the implicit algorithm is adopting the traditional form but taking current stress as unknown and seeking its derivatives in the stress space. Provided these differences, the consistent tangent stiffness in this work is slightly different from those in the above work. The detail derivation will be followed.

When seeking the algorithmic tangent stiffness, we look into the explicit expression of $\mathrm{d}\sigma_{ij}/\mathrm{d}\epsilon_{mn}^{pred}$. At the same time, the internal variables are initialized the values at the previous time step, in other words, they are fixed within the time step when seeking the algorithmic tangent stiffness.

Linearize Equation 104.103, one obtains

$$\mathrm{d}\sigma_{ij} = E_{ijkl}\ \mathrm{d}\epsilon_{kl}^{pred} - \mathrm{d}(\Delta\lambda)\ E_{ijkl}\ m_{kl} - \Delta\lambda\ E_{ijkl}\ \left(\frac{\partial m_{kl}}{\partial \sigma_{mn}}\mathrm{d}\sigma_{mn} + \frac{\partial m_{kl}}{\partial q_A}\mathrm{d}q_A\right) \tag{104.130}$$

Similarly, linearize Equation 104.108, one obtains

$$\mathrm{d}q_A = \mathrm{d}(\Delta\lambda)\ h_A + \Delta\lambda\ \left(\frac{\partial h_A}{\partial \sigma_{ij}}\mathrm{d}\sigma_{ij} + \frac{\partial h_A}{\partial q_B}\mathrm{d}q_B\right) \tag{104.131}$$

From equation 104.130 and 104.131, one obtains

$$\begin{bmatrix} I^s_{ijmn} + \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial \sigma_{mn}} & \Delta\lambda E_{ijkl}\frac{\partial m_{kl}}{\partial q_A} \\ -\Delta\lambda\frac{\partial h_A}{\partial \sigma_{ij}} & \delta_{AB} - \Delta\lambda\frac{\partial h_A}{\partial q_B} \end{bmatrix} \begin{Bmatrix} \mathrm{d}\sigma_{mn} \\ \mathrm{d}q_B \end{Bmatrix} + \mathrm{d}(\Delta\lambda) \begin{Bmatrix} E_{ijkl} m_{kl} \\ -h_A \end{Bmatrix} = \begin{Bmatrix} E_{ijkl}\ \mathrm{d}\epsilon_{kl}^{pred} \\ 0 \end{Bmatrix} \tag{104.132}$$

If one use the definitions of 104.115, 104.122 and 104.121, Equation 104.132 can be simplified to

$$\mathbb{C}^{-1} \begin{Bmatrix} \mathrm{d}\sigma_{mn} \\ \mathrm{d}q_B \end{Bmatrix} + \mathrm{d}(\Delta\lambda)\mathbf{m} = \begin{Bmatrix} E_{ijkl}\ \mathrm{d}\epsilon_{kl}^{pred} \\ 0 \end{Bmatrix} \tag{104.133}$$

Linearize the yield function $f(\sigma_{ij}, q_A) = 0$, one obtains

$$n_{mn}\mathrm{d}\sigma_{mn} + \xi_B \mathrm{d}q_B = 0 \tag{104.134}$$

or in a simplified form

$$\mathbf{n}^{\mathbf{T}} \begin{Bmatrix} \mathrm{d}\sigma_{mn} \\ \mathrm{d}q_B \end{Bmatrix} = \mathbf{0} \tag{104.135}$$

From Equations 104.133 and 104.135, one obtain

$$\mathrm{d}(\Delta\lambda) = \frac{\mathbf{n}^{\mathbf{T}}\mathbb{C}}{\mathbf{n}^{\mathbf{T}}\mathbb{C}\mathbf{m}} \begin{Bmatrix} E_{ijmn}\ \mathrm{d}\epsilon_{mn}^{pred} \\ 0 \end{Bmatrix} \tag{104.136}$$

Substitute expression 104.136 into 104.133, one obtains

$$\left\{ \begin{array}{c} \mathrm{d}\sigma_{ij} \\ \mathrm{d}q_A \end{array} \right\} = \left\{ \mathbb{C} - \frac{\mathbb{C}\mathbf{m}\mathbf{n}^T\mathbb{C}}{\mathbf{n}^T\ \mathbb{C}\ \mathbf{m}} \right\} \left\{ \begin{array}{c} E_{ijmn}\ \mathrm{d}\epsilon^{pred}_{mn} \\ 0 \end{array} \right\} \tag{104.137}$$

This equation gives the explicit expression of the consistent tangent stiffness $\mathrm{d}\sigma_{ij}/\mathrm{d}\epsilon^{pred}_{mn}$ for the implicit algorithm.

From section 104.4, if there are interactions between internal variables, the implicit algorithm will become very complicated. Simple models (e.g. von Mises model, or sometimes termed as J_2 model) have been proved efficient and good performance by the implicit algorithm (Simo and Hughes, 1998). Evidently, the implicit algorithm is mathematically based on the Newton-Raphson nonlinear equation solving method as well as the Eulerian backward integration method. Theoretically, the Newton-Raphson method may have quadratic convergence rate. However, Newton-Raphson method is not unconditional stable, and sometimes the iteration will diverge (Press et al., 1988a). Any bad starting point, non-continuous derivatives around solution, high nonlinearity, and interactions between internal variables, will deteriorate the implicit algorithm performance. A complicated model cannot guarantee good performance or quadratic convergence by the implicit algorithm Crisfield (1997a). The task to obtain the analytical expressions (Equations 104.116 to 104.120) may prove exceeding laborious for complicated plasticity models Simo and Hughes (1998).

104.4.4 Gradients to the Potential Function

In the derivation of the Backward Euler algorithm and the Consistent Tangent Matrix it is necessary to derive the first and the second derivatives of the potential function. The function Q is the function of the stress tensor σ_{ij} and the plastic variable tensor q_A. Derivatives with respect to the stress tensor σ_{ij} and plastic variable tensor q_A are given here. It is assumed that any stress state can be represented with the three stress invariants p, q and θ given in the following form:

$$p = -\frac{1}{3} I_1 \quad q = \sqrt{3 J_{2D}} \quad \cos 3\theta = \frac{3\sqrt{3}}{2} \frac{J_{3D}}{\sqrt{(J_{2D})^3}} \tag{104.138}$$

$$I_1 = \sigma_{kk} \quad J_{2D} = \frac{1}{2} s_{ij} s_{ij} \quad J_{3D} = \frac{1}{3} s_{ij} s_{jk} s_{ki} \quad s_{ij} = \sigma_{ij} - \frac{1}{3}\sigma_{kk}\delta_{ij} \tag{104.139}$$

Stresses are here chosen as positive in tension. The definition of Lode's angle θ in equation (104.138) implies that $\theta = 0$ defines the meridian of conventional triaxial extension (CTE), while $\theta = \pi/3$ denotes the meridian of conventional triaxial compression (CTC).

The Potential Function is given in the following form:

$$Q = Q(p, q, \theta) \tag{104.140}$$

The complete derivation of the closed form gradients is given in Appendix 703.

104.4.4.1 Analytical Gradients

The first derivative of the function Q in stress space is:

$$\frac{\partial Q}{\partial \sigma_{ij}} = \frac{\partial Q}{\partial p}\frac{\partial p}{\partial \sigma_{ij}} + \frac{\partial Q}{\partial q}\frac{\partial q}{\partial \sigma_{ij}} + \frac{\partial Q}{\partial \theta}\frac{\partial \theta}{\partial \sigma_{ij}} \tag{104.141}$$

and subsequently the first derivatives of the chosen stress invariants are

$$\frac{\partial p}{\partial \sigma_{ij}} = -\frac{1}{3}\,\delta_{ij} \tag{104.142}$$

$$\frac{\partial q}{\partial \sigma_{ij}} = \frac{3}{2}\,\frac{1}{q} s_{ij} \tag{104.143}$$

$$\frac{\partial \theta}{\partial \sigma_{ij}} = \frac{3}{2}\,\frac{\cos(3\theta)}{q^2 \sin(3\theta)} s_{ij} - \frac{9}{2}\,\frac{1}{q^3 \sin(3\theta)} t_{ij} \tag{104.144}$$

where:

$$t_{ij} = \frac{\partial J_{3D}}{\partial \sigma_{ij}}$$

The second derivative of the function Q in stress space is

$$\begin{aligned}
\frac{\partial^2 Q}{\partial \sigma_{pq}\partial \sigma_{mn}} &= \\
\left(\frac{\partial^2 Q}{\partial p^2}\frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial p \partial q}\frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial p \partial \theta}\frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial p}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial p}\frac{\partial^2 p}{\partial \sigma_{pq}\partial \sigma_{mn}} &+ \\
+ \left(\frac{\partial^2 Q}{\partial q \partial p}\frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial q^2}\frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial q \partial \theta}\frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial q}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial q}\frac{\partial^2 q}{\partial \sigma_{pq}\partial \sigma_{mn}} &+ \\
+ \left(\frac{\partial^2 Q}{\partial \theta \partial p}\frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial \theta \partial q}\frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial \theta^2}\frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial \theta}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial \theta}\frac{\partial^2 \theta}{\partial \sigma_{pq}\partial \sigma_{mn}} &
\end{aligned} \tag{104.145}$$

and the second derivatives of the stress invariants are

$$\frac{\partial^2 p}{\partial \sigma_{pq} \partial \sigma_{mn}} = \emptyset \tag{104.146}$$

$$\frac{\partial^2 q}{\partial \sigma_{pq} \partial \sigma_{mn}} = \frac{3}{2}\frac{1}{q}\left(\delta_{pm}\delta_{nq} - \frac{1}{3}\delta_{pq}\delta_{nm}\right) - \frac{9}{4}\frac{1}{q^3}\; s_{mn} s_{pq} \tag{104.147}$$

$$\begin{aligned} &\frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}} = \\ &-\left(\frac{9}{2}\frac{\cos 3\theta}{q^4 \sin(3\theta)} + \frac{27}{4}\frac{\cos 3\theta}{q^4 \sin^3 3\theta}\right)\; s_{pq}\; s_{mn} + \frac{81}{4}\frac{1}{q^5 \sin^3 3\theta}\; s_{pq}\; t_{mn} + \\ &+\left(\frac{81}{4}\frac{1}{q^5 \sin 3\theta} + \frac{81}{4}\frac{\cos^2 3\theta}{q^5 \sin^3 3\theta}\right)\; t_{pq}\; s_{mn} - \frac{243}{4}\frac{\cos 3\theta}{q^6 \sin^3 3\theta}\; t_{pq}\; t_{mn} + \\ &+\frac{3}{2}\frac{\cos(3\theta)}{q^2 \sin(3\theta)}\; p_{pqmn} - \frac{9}{2}\frac{1}{q^3 \sin(3\theta)}\; w_{pqmn} \end{aligned} \tag{104.148}$$

where:

$$w_{pqmn} = \frac{\partial t_{pq}}{\partial \sigma_{mn}} = s_{np}\delta_{qm} + s_{qm}\delta_{np} - \frac{2}{3}s_{qp}\delta_{nm} - \frac{2}{3}\delta_{pq}s_{mn}$$

and:

$$p_{pqmn} = \frac{\partial s_{pq}}{\partial \sigma_{mn}} = \left(\delta_{mp}\delta_{nq} - \frac{1}{3}\delta_{pq}\delta_{mn}\right)$$

Another important gradient is:

$$\begin{aligned} &\frac{\partial^2 Q}{\partial \sigma_{ij} \partial q_A} = \frac{\partial m_{ij}}{\partial q_A} = \\ &= \frac{\partial \frac{\partial Q}{\partial p}}{\partial q_A}\frac{\partial p}{\partial \sigma_{ij}} + \frac{\partial \frac{\partial Q}{\partial q}}{\partial q_A}\frac{\partial q}{\partial \sigma_{ij}} + \frac{\partial \frac{\partial Q}{\partial \theta}}{\partial q_A}\frac{\partial \theta}{\partial \sigma_{ij}} = \\ &= \frac{\partial^2 Q}{\partial p \partial q_A}\frac{\partial p}{\partial \sigma_{ij}} + \frac{\partial^2 Q}{\partial q \partial q_A}\frac{\partial q}{\partial \sigma_{ij}} + \frac{\partial^2 Q}{\partial \theta \partial q_A}\frac{\partial \theta}{\partial \sigma_{ij}} \end{aligned} \tag{104.149}$$

104.4.4.2 Finite Difference Gradients

After having developed the closed form, analytical derivatives[49] the author of this thesis asked himself: "is there a simpler way of finding these derivatives?" One of the proposed ways to check the analytical solution is found in Dennis and Schnabel (1983). Dennis and Schnabel proposes the finite difference method for approximating derivatives if these derivatives are not analytically available and as a tool to check your analytical derivatives if they are derived.

Another good reason for developing alternative gradients is that for $\theta = 0, \pi/3$ gradients are not defined, i.e. indefinite terms as $0/0$ are appearing. One possible solution is the use of l'Hospital's rule. This has been done in Perić (1991). The solution to the problem in this work went in a different direction, i.e. instead of aiming for the analytical form, numerical derivatives are derived.

We should recall that for a function f of a single variable, the finite difference approximation to $f'(x)$, by using forward finite difference approach, is given by:

$$a = \frac{f(x+h) - f(x)}{h} \tag{104.150}$$

where h is a vanishingly small quantity. The same definition was used in deriving the finite difference approximation for the first derivative of the yield function F and potential function Q. The first derivative of F (or Q) with respect to the stress tensor σ_{ij} for diagonal elements is[50] :

$$^{approx.}F_{,ii} = \frac{F(\sigma_{ii} + h_{ii}) - F(\sigma_{ii})}{h_{ii}} \tag{104.151}$$

and for non-diagonal elements[51]:

$$^{approx.}F_{,ij} = \frac{F(\sigma_{ij} + h_{ij} + h_{ji}) - F(\sigma_{ij})}{2h_{ij}} \tag{104.152}$$

where h_{ij} is the step size which, because of finite precision arithmetic, is a variable[52].

The accuracy of the finite difference approximation to the analytical derivatives is closely bound to the step size h_{ij}. It is suggested in Dennis and Schnabel (1983)[section 5.4.] that for functions given by the simple formula, the number h should be $h = \sqrt{macheps}$, while for more complicated functions

---

[49] see Appendix (703).

[50] no sum convention implied, just the position of the element.

[51] since the stress tensor σ_{ij} is symmetric, change in one non-diagonal element triggers the other to be changed as well.

[52] it is actually one small number, h, that is multiplied with the current stress value so that the relative order of magnitude is retained.

that number should be larger. Here $macheps$ is the so called machine epsilon. It is defined as the smallest distinguishable positive number[53], such that $1.0 + macheps > 1.0$ on the given platform. For example[54], on the Intel x86 platform[55] $macheps = 1.08E-19$ while on the SUNSparc and DEC platforms $macheps = 2.22E-16$. It has been found that in the case of yield or potential functions the best approximation of analytical gradients is obtained by using $h = \sqrt{macheps}\ 10^3$. The three order of magnitude increase in the finite difference step is due to a rather complicated[56] formula for yield and potential functions. The error in the approximation, ${}^{approx.}F_{,ij}$ is found to be after the N^{th} decimal place, where N is the order of $macheps$, i.e. $macheps = O(N)$.

Second derivative approximations for one variable function are given in the form:

$$a = \frac{\big(f(x + h_i e_i + h_j e_j) - f(x + h_i e_i)\big) - \big(f(x + h_j e_j) - f(x)\big)}{h_i h_j} \tag{104.153}$$

If the first derivatives are available in closed form, one could use equations (104.151) and (104.152) just by replacing the function values with tensor values for analytical derivatives[57].

However, if the analytic derivatives are not available, one has to devise a formula that will create a fourth order tensor from the changes in two dimensional stress tensors, σ_{ij} and σ_{kl}. Using the scheme employed in equation (104.153) the following scheme has been devised:

$$\begin{aligned} {}^{approx.}Q_{,ijkl} = \\ \frac{\big(Q(\sigma_{mn} + h_{ij} + h_{kl}) - Q(\sigma_{mn} + h_{ij})\big) - \big(Q(\sigma_{mn} + h_{kl}) - Q(\sigma_{mn})\big)}{h_{ij} h_{kl}} \end{aligned} \tag{104.154}$$

Special considerations are necessary in order to retain symmetry of the fourth order tensor. At the moment it has not been possible to figure out how to build the finite difference approximation to the second derivatives of yield/potential functions for a general stress state. The only finite difference approximation of the second derivatives that appears to have worked was the one devised in principal stress space. Namely, diagonal elements of the analytical and the approximate gradients matched exactly, but development of non-diagonal elements, and the whole scheme of symmetrizing the fourth order approximation, still remain a mystery. However, some pattern was observed in non–diagonal elements, and the work on symmetrizing it is in progress.

---

[53] in a given precision, i.e. float (real*4), double (real*8) or long double (real*10).

[54] the precision sought was double (real*8).

[55] PC computers.

[56] One should not forget that we work with six dimensional tensor formulae directly.

[57] see Dennis and Schnabel (1983), section 5.6.

For many different potential functions (or yield functions) the only task left would be the derivation of the first derivatives of F and Q and the second derivatives of Q with respect to p, q and θ, namely the first derivatives $\frac{\partial Q}{\partial p}$, $\frac{\partial Q}{\partial q}$ and $\frac{\partial Q}{\partial \theta}$ and $\frac{\partial Q}{\partial p}$, $\frac{\partial Q}{\partial q}$ and $\frac{\partial Q}{\partial \theta}$ and the second derivatives $\frac{\partial^2 Q}{\partial p^2}$, $\frac{\partial^2 Q}{\partial p \partial q}$, $\frac{\partial^2 Q}{\partial p \partial \theta}$, $\frac{\partial^2 Q}{\partial q \partial p}$, $\frac{\partial^2 Q}{\partial q^2}$, $\frac{\partial^2 Q}{\partial q \partial \theta}$, $\frac{\partial^2 Q}{\partial \theta \partial p}$, $\frac{\partial^2 Q}{\partial \theta \partial q}$ and $\frac{\partial^2 Q}{\partial \theta^2}$. If the potential function is twice differentiable with respect to the stress tensor σ_{ij}, and if it is continuous then the Hessian matrix is symmetric.

104.5 Line Search Technique for Constitutive Elastic-Plastic Integration

This section is entirely based on Jeremić (2001). There exist a repetition of some previously defined equations...

104.6 Elastic and Elastic–Plastic Material Models for Solids

In this section we present elements of general elastic and elastic–plastic material models for engineering materials. We describe various forms of the yield functions, plastic flow directions and hardening and softening laws.

104.6.1 Elasticity

DSL COMMANDS for the elastic material models are given in section 205.3 on page 827.

In linear elasticity the relationship between the stress tensor σ_{ij} and the strain tensor ϵ_{kl} can be represented in the following form:

$$\sigma_{ij} = \sigma \left(\epsilon_{ij} \right) \tag{104.155}$$

If we assume the existence of a strain energy function[58] $W \left(\epsilon_{ij} \right)$ then the stress strain relation is:

$$\sigma_{ij} = \frac{\partial W \left(\epsilon_{ij} \right)}{\partial \epsilon_{ij}} \tag{104.156}$$

The introduction of the strain energy density function into elasticity is due to Green, and elastic solids for which such a function is assumed to exist are called Green elastic or hyperelastic solids.

---

[58] per unit volume.

Linearization of an elastic continuum is carried out with respect to a reference configuration which is stress free at temperature T_0, so that ${}^0\sigma_{ij} = 0$. If we denote as E_{ijkl} an isothermal modulus tensor, then under isothermal conditions, we obtain the generalized Hooke's law:

$$\sigma_{ij} = E_{ijkl}\epsilon_{kl} \tag{104.157}$$

where E_{ijkl} is the fourth order elastic stiffness tensor with 81 independent components in total. The elastic stiffness tensor features both minor symmetry $E_{ijkl} = E_{jikl} = E_{ijlk}$ and major symmetry $E_{ijkl} = E_{klij}$ (Jeremić and Sture, 1997). The number of independent components for such elastic stiffness tensor is 21 (Spencer, 1980).

$$E_{ijkl} = \left| \frac{\partial^2 W}{\partial\epsilon_{ij}\,\partial\epsilon_{kl}} \right|_{\epsilon=0} = \left| \frac{\partial^2 W}{\partial\epsilon_{kl}\,\partial\epsilon_{ij}} \right|_{\epsilon=0} \tag{104.158}$$

We will restrain our considerations to the isotropic case. The most general form of the isotropic tensor of rank 4 has the following representation:

$$I_4 = \lambda\delta_{ij}\delta_{kl} + \mu\delta_{ik}\delta_{jl} + \nu\delta_{il}\delta_{jk} \tag{104.159}$$

If E_{ijkl} has this form then in order to satisfy the symmetry condition[59] $E_{ijkl} = E_{jikl}$ we must have $\nu = \mu$. The symmetry condition[60] $E_{ijkl} = E_{klji}$ is then automatically satisfied. The elastic constant tensor has the following form:

$$E_{ijkl} = \lambda\delta_{ij}\delta_{kl} + \mu\left(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}\right) \tag{104.160}$$

where λ and μ are the Lamé coefficients:

$$\lambda = \frac{\nu E}{(1+\nu)(1-2\nu)} \quad ; \quad \mu = \frac{E}{2(1+\nu)} \tag{104.161}$$

and E and ν are Young's Modulus and Poisson's ratio respectively. The symmetric part of the fourth order unit tensor is :

$$I^{sym}_{ijkl} = \frac{1}{2}\left(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jl}\right) \tag{104.162}$$

and can be found as multiplier of μ in equation (104.160). Equation (104.160) can be written in terms of E and ν as:

$$E_{ijkl} = \frac{E}{2(1+\nu)}\left(\frac{2\nu}{1-2\nu}\,\delta_{ij}\delta_{kl} + \delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}\right) \tag{104.163}$$

The same relation in terms of bulk modulus K and shear modulus G is:

---

[59] symmetry in stress tensor.

[60] existence of strain energy function.

$$E_{ijkl} = K\delta_{ij}\delta_{kl} + G\left(-\frac{2}{3}\delta_{ij}\delta_{kl} + \delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}\right) \tag{104.164}$$

where K and G are given as:

$$K = \lambda + \frac{2}{3}\mu \quad ; \quad G = \mu \tag{104.165}$$

The relation between the strain tensor, ϵ_{kl} and the stress tensor, σ_{ij} is:

$$\epsilon_{kl} = D_{klpq}\sigma_{pq} \tag{104.166}$$

where D_{klpq} is the elastic compliance fourth order tensor, defined as:

$$D_{klpq} = \frac{-\lambda}{2\mu\left(3\lambda + 2\mu\right)}\ \delta_{kl}\delta_{pq} + \frac{1}{4\mu}\left(\delta_{kp}\delta_{lq} + \delta_{kq}\delta_{lp}\right) \tag{104.167}$$

or in terms of E and ν:

$$D_{klpq} = \frac{1+\nu}{2E}\left(\frac{-2\nu}{1+\nu}\ \delta_{kl}\delta_{pq} + \delta_{kp}\delta_{lq} + \delta_{kq}\delta_{lp}\right) \tag{104.168}$$

of in terms of K and G:

$$D_{klpq} = \frac{1}{9K}\ \left(\delta_{kl}\delta_{pq}\right) + \frac{1}{2G}\left(-\frac{1}{3}\delta_{kl}\delta_{pq} + \frac{1}{2}\left(\delta_{kp}\delta_{lq} + \delta_{kq}\delta_{lp}\right)\right) \tag{104.169}$$

It is worthwhile noting that the part adjacent to the inverse of the bulk modulus K:

$$\left(\delta_{kl}\delta_{pq}\right)$$

controls the volumetric response and that the part adjacent to the inverse of the shear modulus G:

$$\left(-\frac{1}{3}\delta_{kl}\delta_{pq} + \frac{1}{2}\left(\delta_{kp}\delta_{lq} + \delta_{kq}\delta_{lp}\right)\right)$$

controls the shear response! This note will prove useful later on. Linear transformation of the stress tensor σ_{pq} into itself, i.e. σ_{ij} is defined as:

$$\sigma_{ij} = E_{ijkl}\epsilon_{kl} = E_{ijkl}D_{klpq}\sigma_{pq} \tag{104.170}$$

where

$$E_{ijkl}D_{klpq} = \frac{1}{2}\left(\delta_{ip}\delta_{jq} + \delta_{iq}\delta_{jp}\right) = I^{sym}_{ijpq} \tag{104.171}$$

104.6.1.1 Elastic Model

Linear elastic law is the simplest one and assumes constant Young's modulus E and constant Poisson's Ration ν.

104.6.1.2 Non–linear Elastic Model #1

This nonlinear model (Janbu, 1963), (Duncan and Chang, 1970) assumes dependence of the Young's modulus on the minor principal stress $\sigma_3 = \sigma_{min}$ in the form

$$E = K p_a \left(\frac{\sigma_3}{p_a} \right)^n \tag{104.172}$$

Here, p_a is the atmospheric pressure in the same units as E and stress. The two material constants K and n are constant for a given void ratio.

104.6.1.3 Non–linear Elastic Model #2

If Young's modulus and Poisson's ratio are replaced by the shear modulus G and bulk modulus K the non–linear elastic relationship can be expressed in terms of the normal effective mean stress p as

$$G \quad \text{and/or} \quad K = AF(e, OCR)p^n \tag{104.173}$$

where e is the void ratio, OCR is the overconsolidation ratio and $p = \sigma_{ii}/3$ is the mean effective stress (Hardin, 1978).

104.6.1.4 Lade's Non–linear Elastic Model

Lade and Nelson (1987) and Lade (1988a) proposed a nonlinear elastic model based on Hooke's law in which Poisson ratio ν is kept constant. According to this model, Young's modulus can be expressed in terms of a power law as:

$$E = M \; p_a \left(\left(\frac{I_1}{p_a} \right)^2 + \left(6 \frac{1+\nu}{1-2\nu} \right) \frac{J_{2D}}{p_a^2} \right)^\lambda \tag{104.174}$$

where $I_1 = \sigma_{ii}$ is the first invariant of the stress tensor and $J_{2D} = (s_{ij} s_{ij})/2$ is the second invariant of the deviatoric stress tensor $s_{ij} = \sigma_{ij} - \sigma_{kk}\delta_{ij}/3$. The parameter p_a is atmospheric pressure expressed in the same unit as E, I_1 and $\sqrt{J_{2D}}$ and the modulus number M and the exponent λ are constant, dimensionless numbers.

104.6.1.5 Cross Anisotropic Linear Elastic Model

104.6.2 Yield Functions

The typical plastic behavior of frictional materials is influenced by both normal and shear stresses. It is usually assumed that there exists a yield surface F in the stress space that encompasses the elastic region. States of stress inside the yield surface are assumed to be elastic (linear or non–linear). Stress states on the surface are assumed to produce plastic deformations. Yield surfaces for geomaterials are usually shaped as asymmetric tar drops with smoothly rounded triangular cross sections. In addition to that, simpler yield surfaces, based on the Drucker–Prager cone or Mohr–Coulomb hexagon can also be successfully used if matched with appropriate hardening laws. Yield surface shown in Figure 104.6 Lade (1988b) represent typical meridian plane trace for an isotropic granular material. Line BC represents stress path for conventional triaxial compression test. Figure 104.7 represents the view of the yield surface traces in the deviatoric plane.

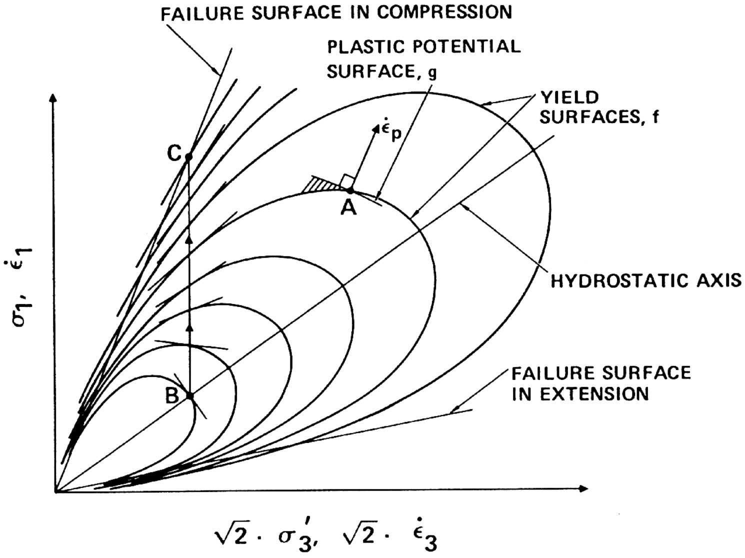

Figure 104.6: Yield surface patterns in the meridian plane for isotropic granular materials (from Lade (1988b))

104.6.3 Plastic Flow Directions

Plastic flow directions are traditionally derived from a potential surface which to some extent reassembles the yield surface. Potential surfaces for metals are the same as their yield surfaces but experimental evidence suggests that it is not the case for geomaterials. The non–associated flow rules, used in geomechanics, rely on the potential surface, which is different from the yield surface, to provide the plastic flow directions. It should be noted that the potential surface is used for convenience and there is no physical reason to assume that the plastic strain rates are related to a potential surface Q (Vardoulakis and Sulem, 1995). Instead of defining a plastic potential, one may assume that the plastic flow direction is derived from an tensor function which does not have to possess a potential function.

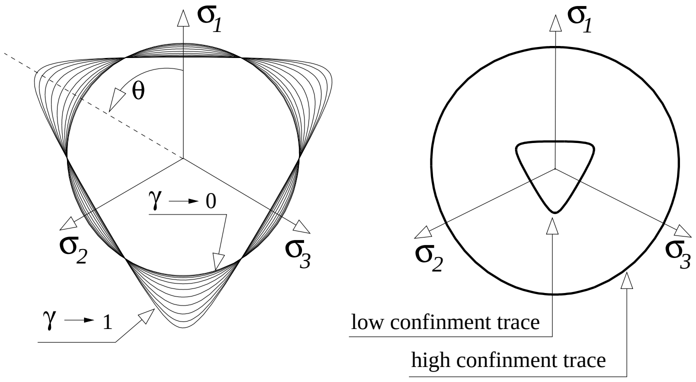

Figure 104.7: Deviatoric trace of typical yield surface for pressure sensitive materials.

104.6.4 Hardening–Softening Evolution Laws

The change in size and/or shape of the yield and potential surfaces is controlled by the hardening–softening evolution laws. Physically, these laws control the hardening and/or softening process during loading. Depending on the evolution type they control, these laws can be in general separated into isotropic and kinematic (also called anisotropic). The isotropic evolution laws control the size of the yield surface through a single scalar variable. This is usually related to the Coulomb friction or to the mean stress values at isotropic yielding. The non–isotropic evolution laws can be further specialized to rotational, translational kinematic and distortional. It should be noted that all of the kinematic evolution laws can be treated as special case of the general, distortional laws (Baltov and Sawczuk, 1965). Figure 104.8 depicts various types of evolution laws (for the control of hardening–softening) in the meridian plane[61].

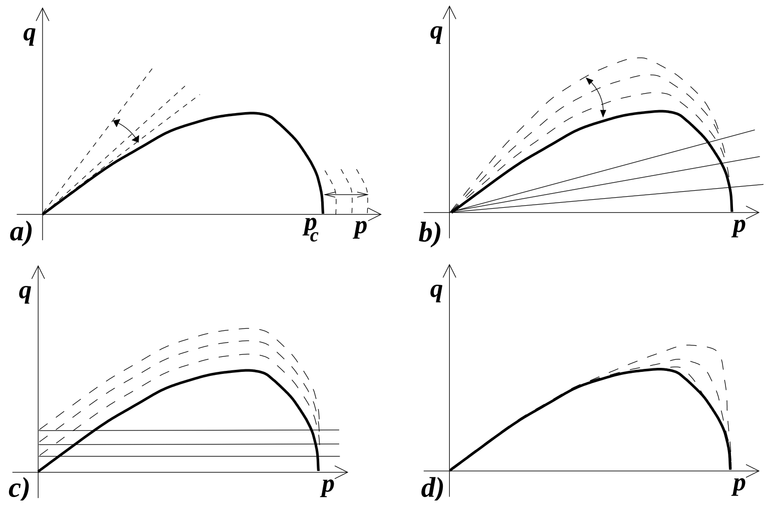

Figure 104.8: Various types of evolution laws that control hardening and/or softening of elastic–plastic material models: (a) Isotropic (scalar) controlling equivalent friction angle and isotropic yield stress. (b) Rotational kinematic hardening (second order tensor) controlling pivoting around fixed point (usually stress origin) of the yield surface. (c) Translational kinematic hardening (second order tensor) controlling translation of the yield surface. (d) Distortional (fourth order tensor) controlling the shape of the yield surface.

104.6.5 Tresca Model

The first yield criteria in the metal plasticity is Tresca yield criteria. Tresca yield criteria states that when the maximum shear stress or, the half difference of the maximum and minimum principal stresses, reaches the shear strength, τ_s, the material will begin yielding. It is can be expressed by the yield function

$$f = |\tau_{max}| - \tau_s = \frac{1}{2}|\sigma_1 - \sigma_3| - \tau_s = 0 \qquad (104.175)$$

Tresca yield surface in the principal stress space is a regular hexagonal cylinder. It is implied that the intermediate principal stress plays no role in the yielding for Tresca yield criteria.

104.6.6 von Mises Model

DSL COMMANDS for the von Mises material models are given in section 205.3 on page 827.

---

[61] The meridian plane is chosen just for illustration purposes, similar sketch can be produced in deviatoric plane as well.

Experimental data showed that for most metals, von Mises yield criteria is more accurate than Tresca criteria. von Mises yield function can be expressed by

$$f = 3J_2 - k^2 = 0 \tag{104.176}$$

or if extended to include the kinematic hardening,

$$f = \frac{3}{2}(s_{ij} - \alpha_{ij})(s_{ij} - \alpha_{ij}) - k^2 = 0 \tag{104.177}$$

where k is the scalar internal variable; its initial value is the uniaxial tension strength. α_{ij} is the tensor internal variable called the back stress. Similar to s_{ij}, α_{ij} is also a deviatoric symmetric tensor.

Although von Mises model is mainly for the metal plasticity analysis, for undrained analysis in geomechanics, von Mises model can be approximately used to simulate the undrained behaviors, (Yang and Jeremić, 2002), (Yang and Jeremić, 2003).

The stress derivative of the yield function is

$$\frac{\partial f}{\partial \sigma_{ij}} = 3(s_{ij} - \alpha_{ij}) \tag{104.178}$$

From Equation 104.178, it is easily to derive that

$$\frac{\partial f}{\partial \alpha_{ij}} = -3(s_{ij} - \alpha_{ij}) \tag{104.179}$$

and

$$\frac{\partial f}{\partial k} = -2k \tag{104.180}$$

If the associated plastic flow rule $g = f$ is assumed, then

$$m_{ij} = \frac{\partial g}{\partial \sigma_{ij}} = 3(s_{ij} - \alpha_{ij}) \tag{104.181}$$

$$\frac{\partial m_{ij}}{\partial \sigma_{mn}} = 3I^s_{ijmn} - \delta_{ij}\delta_{mn} \tag{104.182}$$

$$\frac{\partial m_{ij}}{\partial \alpha_{mn}} = -3I^s_{ijmn} \tag{104.183}$$

where I^s_{ijmn} is the symmetric unit rank-4 tensor.

It is interesting that from the Equation 104.181, von Mises model gives

$$\dot\epsilon^p_v = \dot\epsilon^p_{ii} = \dot\lambda m_{ii} = 3\dot\lambda(s_{ii} - \alpha_{ii}) = 0 \tag{104.184}$$

which accords with the phenomena that no plastic volumetric strain occurs for metals. It is implied that the isotropic stress (hydrostatic pressure) can never make the metal yield for this yield criteria. von Mises model is therefore pressure-independent.

If k is assumed a linear relation to the equivalent plastic strain ϵ_q^p, or by the equation

$$\dot{k} = H_s \dot{\epsilon}_{eq}^p = \dot{\lambda} H_s \left(\frac{2}{3} m_{ij}^{dev} m_{ij}^{dev} \right)^{0.5} \tag{104.185}$$

where H_s is the linear hardening/softening modulus to the equivalent plastic strain, the corresponding h_A is then

$$h = H_s \left(\frac{2}{3} m_{ij}^{dev} m_{ij}^{dev} \right)^{0.5} \tag{104.186}$$

where m_{ij}^{dev} is the 'deviatoric' plastic flow, and if it is associated plasticity,

$$h = 2 H_s k \tag{104.187}$$

If α_{ij} is assumed a linear relation to the plastic strain tensor ϵ_{ij}^p, or by the equation

$$\dot{\alpha}_{ij} = H_t \dot{\epsilon}_{ij}^p = \dot{\lambda} H_t m_{ij} \tag{104.188}$$

if it is associated plasticity,

$$\dot{\alpha}_{ij} = 3 \dot{\lambda} H_t (s_{ij} - \alpha_{ij}) \tag{104.189}$$

where H_t is the linear hardening/softening modulus to plastic strain tensor, the corresponding h_A is then

$$h_{ij} = H_t m_{ij} \tag{104.190}$$

if it is associated plasticity,

$$h_{ij} = 3 H_t (s_{ij} - \alpha_{ij}) \tag{104.191}$$

A saturation-type kinematic hardening rule is the Armstrong-Frederick hardening (Armstrong and Frederick, 1966),

$$\dot{\alpha}_{ij} = \frac{2}{3} h_a \dot{\epsilon}_{ij}^p - c_r \dot{\epsilon}_{eq}^p \alpha_{ij} \tag{104.192}$$

if it is associated plasticity,

$$\dot{\alpha}_{ij} = \dot{\lambda} [h_a (s_{ij} - \alpha_{ij}) - 2 c_r k \alpha_{ij}] \tag{104.193}$$

where h_a and c_r are material constants. The corresponding h_A is then

$$h_{ij} = \frac{2}{3} h_a m_{ij} - c_r m_{eq} \alpha_{ij} \tag{104.194}$$

where m_{eq} is the 'equivalent' plastic flow, and if it is associated plasticity,

$$h_{ij} = 2 h_a s_{ij} - 2 (h_a + c_r k) \alpha_{ij} \tag{104.195}$$

104.6.6.1 Yield and Plastic Potential Functions: von Mises Model (form I)

Yield function and related derivatives

$$f = \frac{3}{2}\left[\left(s_{ij}-\alpha_{ij}\right)\left(s_{ij}-\alpha_{ij}\right)\right] - k^2 = 0 \tag{104.196}$$

$$\begin{aligned}\frac{\partial f}{\partial \sigma_{ij}} &= 3\frac{\partial s_{kl}}{\partial \sigma_{ij}}\left(s_{kl}-\alpha_{kl}\right)\\ &= 3\left(\delta_{ki}\delta_{lj}-\frac{1}{3}\delta_{kl}\delta_{ij}\right)\left(s_{kl}-\alpha_{kl}\right)\\ &= 3\left(s_{ij}-\alpha_{ij}\right)\end{aligned} \tag{104.197}$$

$$\begin{aligned}\frac{\partial f}{\partial \alpha_{ij}} &= -3\frac{\partial \alpha_{kl}}{\partial \alpha_{ij}}\left(s_{kl}-\alpha_{kl}\right)\\ &= -3\delta_{ki}\delta_{lj}\left(s_{kl}-\alpha_{kl}\right)\\ &= -3\left(s_{ij}-\alpha_{ij}\right)\end{aligned} \tag{104.198}$$

$$\frac{\partial f}{\partial k} = -2k \tag{104.199}$$

Plastic flow (associated plasticity) and related derivatives

$$m_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = 3\left(s_{ij}-\alpha_{ij}\right) \tag{104.200}$$

$$\frac{\partial m_{ij}}{\partial \sigma_{mn}} = 3\delta_{im}\delta_{jn} - \delta_{ij}\delta_{mn} \tag{104.201}$$

$$\frac{\partial m_{ij}}{\partial k} = 0 \tag{104.202}$$

$$\frac{\partial m_{ij}}{\partial \alpha_{mn}} = -3\delta_{im}\delta_{jn} \tag{104.203}$$

104.6.6.2 Yield and Plastic Potential Functions: von Mises Model (form II)

Yield function and related derivatives

$$f = \left[\left(s_{ij} - \alpha_{ij}\right)\left(s_{ij} - \alpha_{ij}\right)\right]^{0.5} - \sqrt{\frac{2}{3}}k = 0 \tag{104.204}$$

$$\begin{aligned}\frac{\partial f}{\partial \sigma_{ij}} &= \frac{\partial s_{kl}}{\partial \sigma_{ij}}\left(s_{kl} - \alpha_{kl}\right)\left[\left(s_{mn} - \alpha_{mn}\right)\left(s_{mn} - \alpha_{mn}\right)\right]^{-0.5} \\ &= \left(\delta_{ki}\delta_{lj} - \frac{1}{3}\delta_{kl}\delta_{ij}\right)\left(s_{kl} - \alpha_{kl}\right)\left[\left(s_{mn} - \alpha_{mn}\right)\left(s_{mn} - \alpha_{mn}\right)\right]^{-0.5} \\ &= \left(s_{ij} - \alpha_{ij}\right)\left[\left(s_{mn} - \alpha_{mn}\right)\left(s_{mn} - \alpha_{mn}\right)\right]^{-0.5}\end{aligned} \tag{104.205}$$

$$\frac{\partial f}{\partial \alpha_{ij}} = -\left(s_{ij} - \alpha_{ij}\right)\left[\left(s_{mn} - \alpha_{mn}\right)\left(s_{mn} - \alpha_{mn}\right)\right]^{-0.5} \tag{104.206}$$

$$\frac{\partial f}{\partial k} = -\sqrt{\frac{2}{3}} \tag{104.207}$$

Plastic flow (associated plasticity) and related derivatives

$$m_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = \left(s_{ij} - \alpha_{ij}\right)\left[\left(s_{mn} - \alpha_{mn}\right)\left(s_{mn} - \alpha_{mn}\right)\right]^{-0.5} \tag{104.208}$$

$$\frac{\partial m_{ij}}{\partial \sigma_{mn}} = \left(\delta_{im}\delta_{jn} - \frac{1}{3}\delta_{ij}\delta_{mn}\right)\left[\left(s_{rs} - \alpha_{rs}\right)\left(s_{rs} - \alpha_{rs}\right)\right]^{-0.5} - \left(s_{ij} - \alpha_{ij}\right)\left(s_{mn} - \alpha_{mn}\right)\left[\left(s_{rs} - \alpha_{rs}\right)\left(s_{rs} - \alpha_{rs}\right)\right]^{-1.5} \tag{104.209}$$

$$\frac{\partial m_{ij}}{\partial k} = 0 \tag{104.210}$$

$$\frac{\partial m_{ij}}{\partial \alpha_{mn}} = -\delta_{im}\delta_{jn}\left[\left(s_{rs} - \alpha_{rs}\right)\left(s_{rs} - \alpha_{rs}\right)\right]^{-0.5} + \left(s_{ij} - \alpha_{ij}\right)\left(s_{mn} - \alpha_{mn}\right)\left[\left(s_{rs} - \alpha_{rs}\right)\left(s_{rs} - \alpha_{rs}\right)\right]^{-1.5} \tag{104.211}$$

104.6.6.3 Hardening and Softening Functions: von Mises Model

Linear isotropic hardening and related derivatives

$$\bar{k} = Hm^{equivalent} = H \left(\frac{2}{3} m_{ij} m_{ij} \right)^{0.5} \tag{104.212}$$

$$\frac{\partial \bar{k}}{\partial \sigma_{ij}} = \frac{2}{3} H m_{pq} \frac{\partial m_{pq}}{\partial \sigma_{ij}} \left(\frac{2}{3} m_{mn} m_{mn} \right)^{-0.5} \tag{104.213}$$

$$\frac{\partial \bar{k}}{\partial k} = \frac{2}{3} H m_{pq} \frac{\partial m_{pq}}{\partial k} \left(\frac{2}{3} m_{mn} m_{mn} \right)^{-0.5} \tag{104.214}$$

$$\frac{\partial \bar{k}}{\partial \alpha_{ij}} = \frac{2}{3} H m_{pq} \frac{\partial m_{pq}}{\partial \alpha_{ij}} \left(\frac{2}{3} m_{mn} m_{mn} \right)^{-0.5} \tag{104.215}$$

Linear kinematic hardening and related derivatives

$$\bar{\alpha}_{ij} = Hm^{dev}_{ij} = H \left(m_{ij} - \frac{1}{3} m_{kl} \delta_{kl} \delta_{ij} \right) \tag{104.216}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \sigma_{mn}} = H \left(\frac{\partial m_{ij}}{\partial \sigma_{mn}} - \frac{1}{3} \frac{\partial m_{kl}}{\partial \sigma_{mn}} \delta_{kl} \delta_{ij} \right) \tag{104.217}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial k} = H \left(\frac{\partial m_{ij}}{\partial k} - \frac{1}{3} \frac{\partial m_{kl}}{\partial k} \delta_{kl} \delta_{ij} \right) \tag{104.218}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \alpha_{mn}} = H \left(\frac{\partial m_{ij}}{\partial \alpha_{mn}} - \frac{1}{3} \frac{\partial m_{kl}}{\partial \alpha_{mn}} \delta_{kl} \delta_{ij} \right) \tag{104.219}$$

Armstrong-Frederick kinematic hardening for von Mises

$$\bar{\alpha}_{ij} = \frac{2}{3} h_a m^{dev}_{ij} - c_r \left(\frac{2}{3} m^{dev}_{rs} m^{dev}_{rs} \right)^{0.5} \alpha_{ij} \tag{104.220}$$

The unit of parameter h_a is Pascal. The parameter c_r is unitless. The unit of α_{ij} is Pascal.

The deviatoric component of m is employed because the backstress α_{ij} is the center of yield surface in the deviatoric stress space.

When the derivative of backstress $\bar{\alpha}_{ij} = 0$, the tensor α_{ij} reaches the tensor limit.

$$\alpha_{ij}^{lim} = \sqrt{\frac{2}{3}}\frac{h_a}{c_r}\frac{m_{ij}^{dev}}{\sqrt{m_{rs}^{dev}m_{rs}^{dev}}} \tag{104.221}$$

Some useful tensor derivatives for von Mises $\bar{\alpha}$.

$$m_{ij}^{dev} = m_{ij} - \frac{1}{3}m_{kl}\delta_{kl}\delta_{ij} \tag{104.222}$$

- Useful tensor derivatives for von Mises $\bar{\alpha}$ with respect to σ.

$$\frac{\partial\bar{\alpha}_{ij}}{\partial\sigma_{mn}} = \frac{2}{3}h_a\frac{\partial m_{ij}^{dev}}{\partial\sigma_{mn}} - \frac{2}{3}c_r m_{rs}^{dev}\frac{\partial m_{rs}^{dev}}{\partial\sigma_{mn}}\left(\frac{2}{3}m_{kl}^{dev}m_{kl}^{dev}\right)^{-0.5}\alpha_{ij} \tag{104.223}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial\sigma_{mn}} = \frac{\partial m_{ij}}{\partial\sigma_{mn}} - \frac{1}{3}\frac{\partial m_{ot}}{\partial\sigma_{mn}}\delta_{ot}\delta_{ij} \tag{104.224}$$

- Useful tensor derivatives for von Mises $\bar{\alpha}$ with respect to α.

$$\frac{\partial\bar{\alpha}_{ij}}{\partial\alpha_{mn}} = \frac{2}{3}h_a\frac{\partial m_{ij}^{dev}}{\partial\alpha_{mn}} - \frac{2}{3}c_r m_{rs}^{dev}\frac{\partial m_{rs}^{dev}}{\partial\alpha_{mn}}\left(\frac{2}{3}m_{kl}^{dev}m_{kl}^{dev}\right)^{-0.5}\alpha_{ij} - c_r\left(\frac{2}{3}m_{pq}^{dev}m_{pq}^{dev}\right)^{0.5}\delta_{im}\delta_{jn} \tag{104.225}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial\alpha_{mn}} = \frac{\partial m_{ij}}{\partial\alpha_{mn}} - \frac{1}{3}\frac{\partial m_{ot}}{\partial\alpha_{mn}}\delta_{ot}\delta_{ij} \tag{104.226}$$

- Useful tensor derivatives for von Mises $\bar{\alpha}$ with respect to k.

$$\frac{\partial\bar{\alpha}_{ij}}{\partial k} = \frac{2}{3}h_a\frac{\partial m_{ij}^{dev}}{\partial k} - \sqrt{\frac{2}{3}}c_r\alpha_{ij}(m_{rs}^{dev}m_{rs}^{dev})^{-0.5}\frac{\partial m_{pq}^{dev}}{\partial k}m_{pq}^{dev} \tag{104.227}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial k} = \frac{\partial m_{ij}}{\partial k} - \frac{1}{3}\frac{\partial m_{ot}}{\partial k}\delta_{ot}\delta_{ij} \tag{104.228}$$

104.6.7 Drucker-Prager Model

DSL COMMANDS for the Drucker Prager material models are given in section 205.3 on page 827.

Drucker and Prager (1952) proposed a right circle cone to match with the Mohr-Coulomb irregular hexagonal pyramid, which can be expressed by

$$f = \alpha I_1 + \sqrt{J_2} - \beta = 0 \tag{104.229}$$

or if considering the kinematic hardening,

$$f = \alpha I_1 + [\frac{1}{2}(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})]^{\frac{1}{2}} - \beta = 0 \tag{104.230}$$

where α and β are material constants.

By coinciding Drucker-Prager cone with the outer apexes of the Mohr-Coulomb hexagon locus, we get the compressive cone of Drucker-Prager model, with the constants as

$$\alpha = \frac{2\sin\phi}{\sqrt{3}(3-\sin\phi)}, \quad \beta = \frac{6\cos\phi}{\sqrt{3}(3-\sin\phi)}c \tag{104.231}$$

By coinciding Drucker-Prager cone with the inner apexes of the Mohr-Coulomb hexagon locus, we get the tensile cone of Drucker-Prager model, with the constants as

$$\alpha = \frac{2\sin\phi}{\sqrt{3}(3+\sin\phi)}, \quad \beta = \frac{6\cos\phi}{\sqrt{3}(3+\sin\phi)}c \tag{104.232}$$

We can also get the mean cone of the compressive and tensile cone, with the constants as

$$\alpha = \frac{\sqrt{3}\sin\phi}{9-\sin^2\phi}, \quad \beta = \frac{2\sqrt{3}\cos\phi}{9-\sin^2\phi}c \tag{104.233}$$

Another inner-tangent cone to the the Mohr-Coulomb pyramid, with the constants as

$$\alpha = \frac{\tan\phi}{\sqrt{9+12\tan^2\phi}}, \quad \beta = \frac{3c}{\sqrt{9+12\tan^2\phi}} \tag{104.234}$$

Obviously, in practice α and β are not directly obtained from experiments. They are functions of Mohr-Coulomb parameters, the cohesion c and the friction angle ϕ, which can be determined by experiments. The shape of Drucker-Prager yield surface has different types. They only partially satisfy the above requirements for locus in the π plane: they do not coincide with both compressive and tensile experimental points.

A useful formulation on Equation 104.229 is

$$\frac{\partial f}{\partial \sigma_{ij}} = \alpha\delta_{ij} + \frac{s_{ij}}{2\sqrt{J_2}} \tag{104.235}$$

For cohesionless sands, $k = 0$, Drucker-Prager yield function can thus be simplified as

$$f = \alpha I_1 + \sqrt{J_2} = 0 \tag{104.236}$$

or in terms of p and q,

$$f = q - Mp = 0 \tag{104.237}$$

If Equation 104.231 is adopted, then M can be easily derived as

$$M = \frac{6\sin\phi}{3-\sin\phi} \tag{104.238}$$

If the kinematic hardening is taken account, Equation 104.237 can be extended into

$$f = \frac{3}{2}[(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})] - M^2p^2 = 0 \tag{104.239}$$

Useful formulations for this yield function are

$$\frac{\partial f}{\partial \sigma_{ij}} = 3\bar{s}_{ij} + \left(\bar{s}_{mn}\alpha_{mn} + \frac{2}{3}M^2 p\right)\delta_{ij} \tag{104.240}$$

$$\frac{\partial f}{\partial \alpha_{ij}} = -3p\bar{s}_{ij} \tag{104.241}$$

where $\bar{s}_{ij} = s_{ij} - p\alpha_{ij}$.

If the plastic flow is assumed associated, $g = f$, then

$$m_{ij} = \frac{\partial g}{\partial \sigma_{ij}} = 3\bar{s}_{ij} + \left(\bar{s}_{mn}\alpha_{mn} + \frac{2}{3}M^2 p\right)\delta_{ij} \tag{104.242}$$

the 'deviatoric' plastic flow is therefore

$$m_{eq} = 2Mp \tag{104.243}$$

104.6.7.1 Yield and Plastic Potential Functions: Drucker-Prager Model (form I)

Yield function and related derivatives

$$f = \frac{3}{2}\left[\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right)\right] - k^2p^2 = 0 \tag{104.244}$$

$$\begin{aligned}
\frac{\partial f}{\partial \sigma_{ij}} &= \frac{3}{2}\left[2\frac{\partial s_{mn}}{\partial \sigma_{ij}}\left(s_{mn} - p\alpha_{mn}\right)\right] + \frac{3}{2}\left[-2\alpha_{mn}\frac{\partial p}{\partial \sigma_{ij}}\left(s_{mn} - p\alpha_{mn}\right)\right] - 2k^2p\frac{\partial p}{\partial \sigma_{ij}} \\
&= 3\left(\delta_{mi}\delta_{nj} - \frac{1}{3}\delta_{mn}\delta_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right) + 3\left[\alpha_{mn}\frac{1}{3}\delta_{ij}\left(s_{mn} - p\alpha_{mn}\right)\right] + \frac{2}{3}k^2p\delta_{ij} \\
&= 3\left(s_{ij} - p\alpha_{ij}\right) + \alpha_{mn}\left(s_{mn} - p\alpha_{mn}\right)\delta_{ij} + \frac{2}{3}k^2p\delta_{ij}
\end{aligned} \tag{104.245}$$

$$\frac{\partial f}{\partial \alpha_{ij}} = -3p\left(s_{ij} - p\alpha_{ij}\right) \tag{104.246}$$

$$\frac{\partial f}{\partial k} = -2kp^2 \tag{104.247}$$

Plastic flow (associated plasticity) and related derivatives

$$m_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = 3\left(s_{ij} - p\alpha_{ij}\right) + \alpha_{rs}\left(s_{rs} - p\alpha_{rs}\right)\delta_{ij} + \frac{2}{3}k^2 p\delta_{ij} \tag{104.248}$$

$$\begin{aligned}
\frac{\partial m_{ij}}{\partial \sigma_{mn}} &= 3\left(\left(\delta_{im}\delta_{jn} - \frac{1}{3}\delta_{ij}\delta_{mn}\right) - \frac{1}{3}\delta_{mn}\alpha_{ij}\right) + \alpha_{rs}\frac{\partial\left(s_{rs} - p\alpha_{rs}\right)}{\partial \sigma_{mn}}\delta_{ij} + \frac{2}{3}k^2\frac{\partial p}{\partial \sigma_{mn}}\delta_{ij} \\
&= 3\delta_{im}\delta_{jn} - \delta_{ij}\delta_{mn} - \delta_{mn}\alpha_{ij} + \alpha_{rs}\left(\delta_{rm}\delta_{sn} - \frac{1}{3}\delta_{rs}\delta_{mn} + \frac{1}{3}\delta_{mn}\alpha_{rs}\right)\delta_{ij} + \frac{2}{3}k^2\frac{\partial p}{\partial \sigma_{mn}}\delta_{ij} \\
&= 3\delta_{im}\delta_{jn} - \delta_{ij}\delta_{mn} - \delta_{mn}\alpha_{ij} + \alpha_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{rs}\alpha_{rs}\delta_{ij} - \frac{2}{9}k^2\delta_{mn}\delta_{ij} \\
&= 3\delta_{im}\delta_{jn} + \left(-1 + \frac{1}{3}\alpha_{rs}\alpha_{rs} - \frac{2}{9}k^2\right)\delta_{ij}\delta_{mn} - \delta_{mn}\alpha_{ij} + \alpha_{mn}\delta_{ij}
\end{aligned} \tag{104.249}$$

$$\frac{\partial m_{ij}}{\partial k} = \frac{4}{3}kp\delta_{ij} \tag{104.250}$$

$$\begin{aligned}
\frac{\partial m_{ij}}{\partial \alpha_{mn}} &= -3p\delta_{im}\delta_{jn} + \delta_{rm}\delta_{sn}\left(s_{rs} - p\alpha_{rs}\right)\delta_{ij} - \alpha_{rs}p\delta_{rm}\delta_{sn}\delta_{ij} \\
&= -3p\delta_{im}\delta_{jn} + \left(s_{mn} - p\alpha_{mn}\right)\delta_{ij} - \alpha_{mn}p\delta_{ij} \\
&= -3p\delta_{im}\delta_{jn} + s_{mn}\delta_{ij} - 2p\alpha_{mn}\delta_{ij}
\end{aligned} \tag{104.251}$$

104.6.7.2 Yield and Plastic Potential Functions: Drucker-Prager Model (form II)

Yield function and related derivatives

$$f = \left[\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right)\right]^{0.5} - \sqrt{\frac{2}{3}}kp = 0 \tag{104.252}$$

$$\begin{aligned}
\frac{\partial f}{\partial \sigma_{ij}} &= \left(\frac{\partial s_{mn}}{\partial \sigma_{ij}} - \alpha_{mn}\frac{\partial p}{\partial \sigma_{ij}}\right)\left(s_{mn} - p\alpha_{mn}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} - \sqrt{\frac{2}{3}}k\frac{\partial p}{\partial \sigma_{ij}} \\
&= \left(\delta_{mi}\delta_{nj} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\alpha_{mn}\delta_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} + \sqrt{\frac{2}{27}}k\delta_{ij} \\
&= \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{mn}\delta_{ij}\left(s_{mn} - p\alpha_{mn}\right)\right]\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} + \sqrt{\frac{2}{27}}k\delta_{ij}
\end{aligned} \tag{104.253}$$

$$\begin{aligned}
\frac{\partial f}{\partial \alpha_{ij}} &= -p\delta_{mi}\delta_{nj}\left(s_{mn} - p\alpha_{mn}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\
&= -p\left(s_{ij} - p\alpha_{ij}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5}
\end{aligned} \tag{104.254}$$

$$\frac{\partial f}{\partial k} = -\sqrt{\frac{2}{3}}p \tag{104.255}$$

Plastic flow (associated plasticity) and related derivatives

$$m_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{pq}\delta_{ij}\left(s_{pq} - p\alpha_{pq}\right)\right]\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} + \sqrt{\frac{2}{27}}k\delta_{ij} \tag{104.256}$$

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \sigma_{mn}} = & \left[\left(\delta_{mi}\delta_{nj} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{ij}\right) + \frac{1}{3}\alpha_{pq}\delta_{ij}\left(\delta_{mp}\delta_{nq} - \frac{1}{3}\delta_{mn}\delta_{pq} + \frac{1}{3}\delta_{mn}\alpha_{pq}\right)\right] \\ & \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\ - & \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{pq}\delta_{ij}\left(s_{pq} - p\alpha_{pq}\right)\right]\left(\delta_{mr}\delta_{ns} - \frac{1}{3}\delta_{mn}\delta_{rs} + \frac{1}{3}\delta_{mn}\alpha_{rs}\right) \\ & \left(s_{rs} - p\alpha_{rs}\right)\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right)\right]^{-1.5}\end{aligned} \tag{104.257}$$

$$\frac{\partial m_{ij}}{\partial k} = \sqrt{\frac{2}{27}}\delta_{ij} \tag{104.258}$$

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \alpha_{mn}} = & \left[-p\delta_{mi}\delta_{nj} + \frac{1}{3}\delta_{mp}\delta_{nq}\delta_{ij}\left(s_{pq} - p\alpha_{pq}\right) - \frac{1}{3}p\alpha_{pq}\delta_{ij}\delta_{mp}\delta_{nq}\right]\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\ - & \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{pq}\delta_{ij}\left(s_{pq} - p\alpha_{pq}\right)\right]\left[-p\delta_{rm}\delta_{sn}\left(s_{rs} - p\alpha_{rs}\right)\right]\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right)\right]^{-1.5}\end{aligned} \tag{104.259}$$

Plastic flow (non-associated plasticity) and related derivatives

$$m_{ij} = \left(\frac{\partial f}{\partial \sigma_{ij}}\right)^{dev} - \frac{1}{3}D\delta_{ij} = \left(s_{ij} - p\alpha_{ij}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} - \frac{1}{3}D\delta_{ij} \tag{104.260}$$

where

$$D = \xi\left(\sqrt{\frac{2}{3}}k_d - \frac{\sqrt{s_{mn}s_{mn}}}{p}\right) \tag{104.261}$$

$$\frac{\partial D}{\partial \sigma_{mn}} = -p^{-1}s_{mn}(s_{kl}s_{kl})^{-0.5} - \frac{1}{3}p^{-2}\delta_{mn}(s_{ot}s_{ot})^{0.5} \tag{104.262}$$

Therefore,

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \sigma_{mn}} = & \left(\delta_{mi}\delta_{nj} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{ij}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\ - & \left(s_{ij} - p\alpha_{ij}\right)\left(\delta_{mr}\delta_{ns} - \frac{1}{3}\delta_{mn}\delta_{rs} + \frac{1}{3}\delta_{mn}\alpha_{rs}\right) \\ & \left(s_{rs} - p\alpha_{rs}\right)\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right)\right]^{-1.5} \\ + & \frac{1}{3}\delta_{ij}s_{mn}p^{-1}(s_{kl}s_{kl})^{-0.5} + \frac{1}{9}\delta_{ij}\delta_{mn}p^{-2}(s_{ot}s_{ot})^{0.5}\end{aligned} \tag{104.263}$$

$$\frac{\partial m_{ij}}{\partial k} = 0 \tag{104.264}$$

$$\frac{\partial m_{ij}}{\partial \alpha_{mn}} = -p\delta_{mi}\delta_{nj}\left[(s_{rs} - p\alpha_{rs})(s_{rs} - p\alpha_{rs})\right]^{-0.5} - \left(s_{ij} - p\alpha_{ij}\right)\left[-p\delta_{rm}\delta_{sn}(s_{rs} - p\alpha_{rs})\right]\left[(s_{tu} - p\alpha_{tu})(s_{tu} - p\alpha_{tu})\right]^{-1.5} \tag{104.265}$$

104.6.7.3 Hardening and Softening Functions: Drucker-Prager Model

Note that the linear isotropic and linear kinematic hardening equations for Drucker-Prager model are the same as the ones for von Mises model. Here they are shown again for completeness.

Linear isotropic hardening and related derivatives

$$\bar{k} = Hm^{equivalent} = H\left(\frac{2}{3}m_{ij}m_{ij}\right)^{0.5} \tag{104.266}$$

$$\frac{\partial \bar{k}}{\partial \sigma_{ij}} = \frac{2}{3}Hm_{pq}\frac{\partial m_{pq}}{\partial \sigma_{ij}}\left(\frac{2}{3}m_{mn}m_{mn}\right)^{-0.5} \tag{104.267}$$

$$\frac{\partial \bar{k}}{\partial k} = \frac{2}{3}Hm_{pq}\frac{\partial m_{pq}}{\partial k}\left(\frac{2}{3}m_{mn}m_{mn}\right)^{-0.5} \tag{104.268}$$

$$\frac{\partial \bar{k}}{\partial \alpha_{ij}} = \frac{2}{3}Hm_{pq}\frac{\partial m_{pq}}{\partial \alpha_{ij}}\left(\frac{2}{3}m_{mn}m_{mn}\right)^{-0.5} \tag{104.269}$$

Linear kinematic hardening and related derivatives

$$\bar{\alpha}_{ij} = Hm^{dev}_{ij} = H\left(m_{ij} - \frac{1}{3}m_{kl}\delta_{kl}\delta_{ij}\right) \tag{104.270}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \sigma_{mn}} = H\left(\frac{\partial m_{ij}}{\partial \sigma_{mn}} - \frac{1}{3}\frac{\partial m_{kl}}{\partial \sigma_{mn}}\delta_{kl}\delta_{ij}\right) \tag{104.271}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial k} = H\left(\frac{\partial m_{ij}}{\partial k} - \frac{1}{3}\frac{\partial m_{kl}}{\partial k}\delta_{kl}\delta_{ij}\right) \tag{104.272}$$

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \alpha_{mn}} = H\left(\frac{\partial m_{ij}}{\partial \alpha_{mn}} - \frac{1}{3}\frac{\partial m_{kl}}{\partial \alpha_{mn}}\delta_{kl}\delta_{ij}\right) \tag{104.273}$$

Armstrong-Frederick Kinematic Hardening for Drucker-Prager

$$\bar{\alpha}_{ij} = \frac{2}{3}\frac{h_a}{p} m_{ij}^{dev} - c_r \left(\frac{2}{3} m_{rs}^{dev} m_{rs}^{dev}\right)^{0.5} \alpha_{ij} \tag{104.274}$$

where p is pressure of the current stress state. The unit of parameter h_a is Pascal. The parameter c_r is unitless. The α_{ij} in Drucker-Prager is unitless.

The pressure p is introduced for two reasons.

- The center of the yield surface is $p\alpha_{ij}$, not α_{ij}. The kinematic hardening rule is to control the center of the yield surface.
- The unit in equation (104.303) matches after the pressure p is introduced.

When the derivative of backstress $\bar{\alpha}_{ij} = 0$, the tensor α_{ij} reaches the tensor limit.

$$\alpha_{ij}^{lim} = \sqrt{\frac{2}{3}} \frac{h_a}{p c_r} \frac{m_{ij}^{dev}}{\sqrt{m_{rs}^{dev} m_{rs}^{dev}}} \tag{104.275}$$

Some useful tensor derivatives for Drucker-Prager $\bar{\alpha}$.

$$m_{ij}^{dev} = m_{ij} - \frac{1}{3} m_{kl} \delta_{kl} \delta_{ij} \tag{104.276}$$

- Useful tensor derivatives for Drucker-Prager $\bar{\alpha}$ with respect to σ.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \sigma_{mn}} = \frac{2}{3}\frac{h_a}{p}\frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} + \frac{2}{9p^2} h_a m_{ij}^{dev} \delta_{mn} - \frac{2}{3} c_r m_{rs}^{dev} \frac{\partial m_{rs}^{dev}}{\partial \sigma_{mn}} \left(\frac{2}{3} m_{kl}^{dev} m_{kl}^{dev}\right)^{-0.5} \alpha_{ij} \tag{104.277}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} = \frac{\partial m_{ij}}{\partial \sigma_{mn}} - \frac{1}{3}\frac{\partial m_{ot}}{\partial \sigma_{mn}} \delta_{ot} \delta_{ij} \tag{104.278}$$

- Useful tensor derivatives for Drucker-Prager $\bar{\alpha}$ with respect to α.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \alpha_{mn}} = \frac{2}{3}\frac{h_a}{p}\frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} - \frac{2}{3} c_r m_{rs}^{dev} \frac{\partial m_{rs}^{dev}}{\partial \alpha_{mn}} \left(\frac{2}{3} m_{kl}^{dev} m_{kl}^{dev}\right)^{-0.5} \alpha_{ij} - c_r \left(\frac{2}{3} m_{pq}^{dev} m_{pq}^{dev}\right)^{0.5} \delta_{im} \delta_{jn} \tag{104.279}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} = \frac{\partial m_{ij}}{\partial \alpha_{mn}} - \frac{1}{3}\frac{\partial m_{ot}}{\partial \alpha_{mn}} \delta_{ot} \delta_{ij} \tag{104.280}$$

- Useful tensor derivatives for Drucker-Prager $\bar{\alpha}$ with respect to k.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial k} = \frac{2}{3}\frac{h_a}{p}\frac{\partial m_{ij}^{dev}}{\partial k} - \sqrt{\frac{2}{3}} c_r \alpha_{ij} (m_{rs}^{dev} m_{rs}^{dev})^{-0.5} \frac{\partial m_{pq}^{dev}}{\partial k} m_{pq}^{dev} \tag{104.281}$$

where

$$\frac{\partial m_{ij}^{dev}}{\partial k} = \frac{\partial m_{ij}}{\partial k} - \frac{1}{3}\frac{\partial m_{ot}}{\partial k} \delta_{ot} \delta_{ij} \tag{104.282}$$

104.6.7.4 Federico's Description of a Drucker–Prager Kinematic Hardenig Model

Presented is a concise description of nonlinear rotational kinematic hardening (Armstrong-Frederick) Drucker-Prager model (Lemaitre and Chaboche, 1990).

Elastic behavior The standard Hooke's law has been assumed for the sake of simplicity.

Yield function The yield locus is of the same kind described by Prevost (1985a) and Manzari and Dafalias (1997), i.e. conical and allowed to rotate around its apex (the centre of rotation coincides – for cohesionless materials – with the origin of the principal stress space):

$$f = \sqrt{\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right)} - \sqrt{\frac{2}{3}}kp = 0 \tag{104.283}$$

in which p is the isotropic mean pressure, α_{ij} the back–stress ratio tensor and k a constitutive surface parameter[62]. While this latter governs the opening angle of the cone, α_{ij} is a second–rank deviatoric tensor determining the yield locus rotation.

Plastic flow rule As usual, the incremental plastic strain tensor can be expressed as:

$$\epsilon_{ij}^{p} = \dot{\lambda} m_{ij} \tag{104.284}$$

where $\dot{\lambda}$ is a scalar plastic multiplier and m_{ij} assigning the direction of the plastic flow. While in the associated version of the model m_{ij} would coincide with the stress gradient of the yield function (104.283), here the following non–associated flow rule has been adopted (Prevost, 1985a; Manzari and Dafalias, 1997):

$$m_{ij} = \left(\frac{\partial f}{\partial \sigma_{ij}}\right)^{dev} - \frac{1}{3}D\delta_{ij} \tag{104.285}$$

where the superscript $^{\text{dev}}$ and δ_{ij} denote the "deviatoric" tensor operator and the Kronecker hydrostatic tensor, respectively, and D is a dilatancy coefficient defined as:

$$D = \xi\left(\sqrt{\frac{2}{3}}k_d - \sqrt{r_{mn}r_{mn}}\right) \tag{104.286}$$

Here, we defined normalized deviatoric stress tensor $r_{ij} = s_{ij}/p$.

---

[62] stresses are meant here to be effective

Apparently, the flow rule (104.285) implies the deviatoric plastic strain increment to be associated, while non-associativeness holds for the volumetric component. The definition (104.286) requires two consitutive parameters to be identified, namely k_d and ξ: the former represents the stress obliquity for the transition from contractive to dilative response; the latter quantitatively governs the volumetric plastic strain rate. Specifically, k_d denotes the existence of a "dilatancy surface", the soil response being contractive for inner stress states and dilative otherwise; this surface – characterized by no volumetric plastic strain – is still a Drucker–Prager conical locus, fixed in the principal stress space and with an opening angle given by k_d.

Armstrong–Frederick kinematic hardening rule The last ingredient in the model formulation is represented by the hardening rule for the internal variable α_{ij}. Here, an Armstrong–Frederick hardening (Armstrong and Frederick, 1966; Lemaitre and Chaboche, 1990) has been introduced:

$$\dot{\alpha}_{ij} = \frac{2}{3} h_a \left(\epsilon^p_{ij}\right)^{dev} - c_r \alpha_{ij} \sqrt{\frac{2}{3} \left(\epsilon^p_{rs}\right)^{dev} \left(\epsilon^p_{rs}\right)^{dev}} \tag{104.287}$$

where h_a and c_r are two hardening constitutive parameters. Equation (104.287) yields a saturation–type evolution under deviatoric plastic straining, up to the achievement of a limit back–stress ratio α^{lim}_{ij}. Starting from (104.287), it could be easily proven that:

$$\left\|\alpha^{lim}_{ij}\right\| = \sqrt{\frac{2}{3}} \frac{h_a}{c_r} \tag{104.288}$$

i.e. the norm of the limit tensor α^{lim}_{ij} exclusively depends on the h_a/c_r ratio for any value of the Lode angle. The existence of an outer bound for α_{ij} implies all feasible stress states to lie within a so–called bounding surface, determined both by α^{lim}_{ij} and the opening of the yield locus $f = 0$ (104.283). The bounding surface, governing the shear strength of the material, is in this case a Lode–angle insensitive Drucker–Prager cone: in the simplest case of triaxial loading, the limit stress obliquity M can be shown to equal:

$$M = \left(\frac{q}{p'}\right)_{failure} = k + \frac{h_a}{c_r} \tag{104.289}$$

both in compression and extension. From the above analytical relationships it can be inferred that the material shear strength is ruled by the ratio h_a/c_r, whereas c_r determines the evolution rate of the back–stress tensor α_{ij}.

104.6.7.5 Han's Description of Drucker–Prager Model with Armstrong–Frederick Kinematic Hardening

Presented is a new description of non-associated Drucker-Prager model with nonlinear Armstrong-Frederick kinematic hardening. Compared with the traditional description shown in earlier sections, the main difference in this description is taking into consideration of the symmetry nature of stress and strain tensors. As a result, some of the derivatives of plastic flow and internal variable are different. More importantly, this change leads to a consistent stiffness tensor that has minor symmetry.

Elastic Behavior The elastic behavior is modeled as linear elastic, following classic generalized Hook's law. The elastic stiffness tensor is that for isotropic, linear elastic material (Equation 104.163).

$$E_{ijkl} = \frac{E}{2(1+\nu)} \left(\frac{2\nu}{1-2\nu} \delta_{ij}\delta_{kl} + \delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk} \right) \tag{104.290}$$

Yield Function The yield function and its derivatives remain unchanged.

$$f = \left[\left(s_{ij} - p\alpha_{ij}\right) \left(s_{ij} - p\alpha_{ij}\right) \right]^{0.5} - \sqrt{\frac{2}{3}} kp = 0 \tag{104.291}$$

$$\frac{\partial f}{\partial \sigma_{ij}} = \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{mn}\delta_{ij} \left(s_{mn} - p\alpha_{mn}\right) \right] \left[\left(s_{rs} - p\alpha_{rs}\right) \left(s_{rs} - p\alpha_{rs}\right) \right]^{-0.5} + \sqrt{\frac{2}{27}} k\delta_{ij} \tag{104.292}$$

$$\frac{\partial f}{\partial \alpha_{ij}} = -p \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right) \left(s_{rs} - p\alpha_{rs}\right) \right]^{-0.5} \tag{104.293}$$

$$\frac{\partial f}{\partial k} = -\sqrt{\frac{2}{3}} p \tag{104.294}$$

Plastic Flow The changes in derivatives of plastic flow, and later in hardening, comes from the clarification of derivative of the stress tensor with respect to itself. According to Park (2018), since the stress tensor is intrinsically symmetric, its derivative with respect to itself should be:

$$\frac{\partial \sigma_{ij}}{\partial \sigma_{mn}} = \frac{1}{2} \left(\delta_{im}\delta_{jn} + \delta_{in}\delta_{jm} \right) \tag{104.295}$$

Then, the derivative of deviatoric stress with respect to stress becomes:

$$\frac{\partial s_{ij}}{\partial \sigma_{mn}} = \frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm} - \frac{1}{3}\delta_{mn}\delta_{ij} \tag{104.296}$$

The non-associated plastic flow still has the same form:

$$m_{ij} = \left(\frac{\partial f}{\partial \sigma_{ij}} \right)^{dev} - \frac{1}{3} D\delta_{ij} = \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right) \left(s_{rs} - p\alpha_{rs}\right) \right]^{-0.5} - \frac{1}{3} D\delta_{ij} \tag{104.297}$$

where

$$D = \xi \left(\sqrt{\frac{2}{3}} k_d - \frac{\sqrt{s_{mn} s_{mn}}}{p} \right) \tag{104.298}$$

and

$$\frac{\partial D}{\partial \sigma_{mn}} = -\xi \left[p^{-1} s_{mn} (s_{kl} s_{kl})^{-0.5} + \frac{1}{3} p^{-2} \delta_{mn} (s_{ot} s_{ot})^{0.5} \right] \tag{104.299}$$

Therefore,

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \sigma_{mn}} =& \left(\frac{1}{2} \delta_{im} \delta_{jn} + \frac{1}{2} \delta_{in} \delta_{jm} - \frac{1}{3} \delta_{mn} \delta_{ij} + \frac{1}{3} \delta_{mn} \alpha_{ij} \right) \left[(s_{rs} - p\alpha_{rs}) (s_{rs} - p\alpha_{rs}) \right]^{-0.5} \\ & - \left(s_{ij} - p\alpha_{ij} \right) \left[(s_{mn} - p\alpha_{mn}) + \frac{1}{3} \alpha_{rs} (s_{rs} - p\alpha_{rs}) \delta_{mn} \right] \left[(s_{tu} - p\alpha_{tu}) (s_{tu} - p\alpha_{tu}) \right]^{-1.5} \\ & + \frac{1}{3} \xi \left[s_{mn} p^{-1} (s_{kl} s_{kl})^{-0.5} + \frac{1}{3} \delta_{mn} p^{-2} (s_{ot} s_{ot})^{0.5} \right] \delta_{ij}\end{aligned} \tag{104.300}$$

$$\frac{\partial m_{ij}}{\partial k} = 0 \tag{104.301}$$

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \alpha_{mn}} =& -p \left(\frac{1}{2} \delta_{mi} \delta_{nj} + \frac{1}{2} \delta_{mj} \delta_{ni} \right) \left[(s_{rs} - p\alpha_{rs}) (s_{rs} - p\alpha_{rs}) \right]^{-0.5} \\ & + p \left(s_{ij} - p\alpha_{ij} \right) (s_{mn} - p\alpha_{mn}) \left[(s_{tu} - p\alpha_{tu}) (s_{tu} - p\alpha_{tu}) \right]^{-1.5}\end{aligned} \tag{104.302}$$

Armstrong-Frederick kinematic hardening for Drucker-Prager

$$\bar{\alpha}_{ij} = \frac{2}{3} \frac{h_a}{p_{atm}} m_{ij}^{dev} - c_r \left(\frac{2}{3} m_{rs}^{dev} m_{rs}^{dev} \right)^{0.5} \alpha_{ij} \tag{104.303}$$

where p_{atm} is the atmospheric pressure of 101.325 kPa. The unit of parameter h_a is Pascal. The parameter c_r is unitless. The α_{ij} in Drucker-Prager is unitless. The atmospheric pressure p_{atm} is introduced so that the unit in equation (104.303) matches.

Notice that

$$m_{rs}^{dev} m_{rs}^{dev} = (s_{rs} - p\alpha_{rs}) (s_{rs} - p\alpha_{rs}) \left[(s_{tu} - p\alpha_{tu}) (s_{tu} - p\alpha_{tu}) \right]^{-1} = 1 \tag{104.304}$$

This means the hardening equation and related derivatives can be simplified:

$$\bar{\alpha}_{ij} = \frac{2}{3} \frac{h_a}{p_{atm}} m_{ij}^{dev} - \sqrt{\frac{2}{3}} c_r \alpha_{ij} \tag{104.305}$$

When the derivative of backstress $\bar{\alpha}_{ij} = 0$, the tensor α_{ij} reaches the tensor limit:

$$\alpha_{ij}^{lim} = \sqrt{\frac{2}{3}} \frac{h_a}{p_{atm} c_r} m_{ij}^{dev} \tag{104.306}$$

Some useful tensor derivatives for Drucker-Prager $\bar{\alpha}$.

$$m_{ij}^{dev} = \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \tag{104.307}$$

$$\begin{aligned}\frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} = & \left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\ & - \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{mn} - p\alpha_{mn}\right) + \frac{1}{3}\alpha_{rs}\left(s_{rs} - p\alpha_{rs}\right)\delta_{mn}\right] \left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right)\right]^{-1.5}\end{aligned} \tag{104.308}$$

$$\frac{\partial m_{ij}^{dev}}{\partial k} = 0 \tag{104.309}$$

$$\begin{aligned}\frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} = & -p\left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right)\right]^{-0.5} \\ & - p\left(s_{ij} - p\alpha_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right) \left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right)\right]^{-1.5}\end{aligned} \tag{104.310}$$

- Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to σ_{ij}.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \sigma_{mn}} = \frac{2h_a}{3p_{atm}} \frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} \tag{104.311}$$

- Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to k.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial k} = 0 \tag{104.312}$$

- Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to α_{ij}.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \alpha_{mn}} = \frac{2h_a}{3p_{atm}} \frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} - \sqrt{\frac{2}{3}} c_r \left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm}\right) \tag{104.313}$$

104.6.8 Hyperbolic Drucker Prager Model

104.6.8.1 Original Yield Function and Hyperbolic Function

The original Drucker-Prager yield function is

$$\Phi(\sigma) = \sqrt{J_2} - \eta p - \xi \tag{104.314}$$

where

$$\eta = \frac{3tan\phi}{\sqrt{9 + 12tan^2\phi}} \tag{104.315}$$

$$\xi = \frac{3c}{\sqrt{9 + 12tan^2\phi}} \tag{104.316}$$

where ϕ is the friction ratio, and c is the cohesion. Besides, the constant η is unitless. The unit of constant ξ is $Pascal$. In addition, here we define that p is compression-positive. Namely, $p = -\frac{\sigma_{ii}}{3}$.

Rewrite the yield function (104.314) with p, q such that

$$\Phi(\sigma) = \frac{q}{\sqrt{3}} - \eta p - \xi \tag{104.317}$$

The slope of the yield surface is $\sqrt{3}\eta$, and the hydrostatic cutoff point is at $(-\frac{\xi}{\eta}, 0)$.

104.6.8.2 Hyperbolic Drucker Prager Model

Assume a standard hyperbolic function is

$$\left(\frac{x-d}{a}\right)^2 - \left(\frac{y}{b}\right)^2 = 1 \tag{104.318}$$

In the hyperbolic function, as showed in the Figure 104.9, the distance between the original apex to the rounded hydrostatic cut-off is a, and the corresponding y value is b. The hydrostatic cut off of the asymptotic line is d.

104.6.8.3 Modified Hyperbolic Drucker Prager

Mapping the Hyperbolic Equation. In the modified hyperbolic Drucker Prager yield surface, the asymptotic line is the original yield surface.

The slope of the asymptotic line is

$$\frac{b}{a} = \sqrt{3}\eta \tag{104.319}$$

The hydrostatic cut-off of the asymptotic line is

$$d = \frac{\xi}{\eta} \tag{104.320}$$

The rounded distance a of the hyperbolic line is a new parameter.

The hyperbolic function is

$$\left(\frac{p + \frac{\xi}{\eta}}{a}\right)^2 - \left(\frac{q}{\sqrt{3}\ a\ \eta}\right)^2 = 1 \tag{104.321}$$

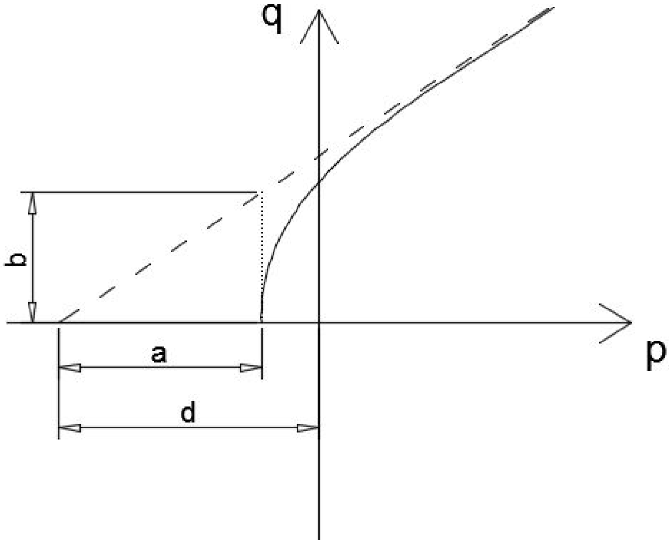

Figure 104.9: The standard hyperbolic function parameters.

Removing the Negative Branch. To remove the negative branch, we need the pressure $(p + \frac{\xi}{\eta})$ always be positive. Therefore,

$$\left(\frac{p + \frac{\xi}{\eta}}{a} \right)^2 = \left(\frac{q}{\sqrt{3}\ a\ \eta} \right)^2 + 1 \tag{104.322}$$

Take the root on both sides,

$$\frac{p + \frac{\xi}{\eta}}{a} = \sqrt{\left(\frac{q}{\sqrt{3}\ a\ \eta} \right)^2 + 1} \tag{104.323}$$

Inside the hyperbolic To make the yield surface value smaller than zero when the stress state is inside the modified cone, the yield surface is

$$0 = \sqrt{\left(\frac{q}{\sqrt{3}\ a\ \eta} \right)^2 + 1} - \frac{p + \frac{\xi}{\eta}}{a} \tag{104.324}$$

Avoiding Zero Denominator. To avoid the zero denominator situation, multiply the equation on both sides by η and a.

$$0 = \sqrt{\left(\frac{q}{\sqrt{3}} \right)^2 + a^2\eta^2} - \eta p - \xi \tag{104.325}$$

The basic yield function The yield function now has one internal variable η for isotropic hardening.

$$\Phi(\sigma,\eta) = \sqrt{\left(\frac{q}{\sqrt{3}}\right)^2 + a^2\eta^2} - \eta p - \xi \tag{104.326}$$

Simplify the yield function and substitute $q = \sqrt{\frac{3}{2}s_{ij}s_{ij}}$, we have

$$\Phi(\sigma,\eta) = \sqrt{\frac{1}{2}s_{ij}s_{ij} + a^2\eta^2} - \eta p - \xi \tag{104.327}$$

Introduce the capability of rotational kinematic hardening by α.

$$\Phi(\sigma,\eta,\alpha) = \sqrt{\frac{1}{2}(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij}) + a^2\eta^2} - \eta p - \xi \tag{104.328}$$

104.6.8.4 The Non-Associative Plastic Potential Function.

The non-associative plastic flow direction is

$$m_{ij} = \left(\frac{\partial f}{\partial \sigma_{ij}}\right)^{dev} + \frac{1}{3}\bar{\eta}\delta_{ij} \tag{104.329}$$

where $\bar{\eta}$ controls the plastic flow direction. When $\bar{\eta} = 0$, the material has the deviatoric plastic flow only.

The relation between the dilatancy angle and $\bar{\eta}$ is similar to the relation between the friction angle and η.

$$\bar{\eta} = \frac{3tan\psi}{\sqrt{9 + 12tan^2\psi}} \tag{104.330}$$

where ψ is the dilatancy angle.

Numerical Issues in the Non-Associative Plastic Potential Function. The non-associative plastic flow rule will have asymmetric stiffness matrix, which requires a asymmetric solver. The non-associative requires smaller subincrements for convergence. One important non-associative plastic potential is the purely deviatoric plastic flow.

The purely deviatoric plastic flow may have the numerical issues for the convergence. For example, in Fig 104.10, the purely deviatoric plastic flow direction can never return back to the yield surface. Subincrements can solve this problem.

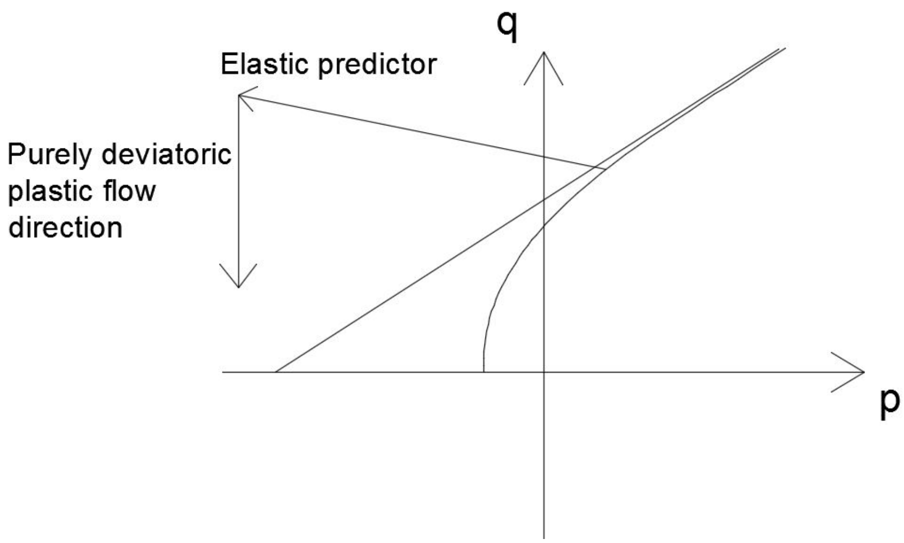

Figure 104.10: The inconvergence situation for purely deviatoric plastic flow.

104.6.8.5 Han's Description of Hyperbolic Drucker–Prager Model with Armstrong–Frederick Kinematic Hardening

Presented is a new description of non-associated hyperbolic Drucker-Prager model with nonlinear Armstrong-Frederick kinematic hardening. It's intended to keep the same theoretical framework and the same set of material parameters as the Drucker-Prager material model shown in section 104.6.7.5.

Classic Drucker–Prager Yield Function with Cohesion This is the yield function shown in Equation 104.237, extended to considering cohesion

$$f = q - Mp - \sqrt{3}\beta \tag{104.331}$$

where

$$M = \frac{6\sin\phi}{3-\sin\phi} \quad \text{and} \quad \beta = \frac{6\cos\phi_0}{\sqrt{3}\,(3-\sin\phi_0)}c \tag{104.332}$$

Note that ϕ is the friction angle, which can evolve if hardening is present in the model, and ϕ_0 is the initial friction angle.

Rewrite Equation 104.333 using the parameters in Real-ESSI implementation

$$f = \sqrt{\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right)} - \sqrt{\frac{2}{3}}kp - \sqrt{2}\beta \tag{104.333}$$

Hyperbolic Drucker–Prager Yield Function Assume the same generic hyperbolic function shown in Equation 104.318, the hyperbolic Drucker-Prager yield function considering isotropic and kinematic hardening is given as

$$f = \sqrt{\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right) + \frac{2}{3}k^2a^2} - \sqrt{\frac{2}{3}}kp - \sqrt{2}\beta \tag{104.334}$$

where a is the rounded distance shown in Figure 104.9.

Derivatives of the yield function Equation 104.334 are shown below.

$$\frac{\partial f}{\partial \sigma_{ij}} = \left[\left(s_{ij} - p\alpha_{ij}\right) + \frac{1}{3}\alpha_{kl}\left(s_{kl} - p\alpha_{kl}\right)\delta_{ij}\right]\left[\left(s_{mn} - p\alpha_{mn}\right)\left(s_{mn} - p\alpha_{mn}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} + \sqrt{\frac{2}{27}}k\delta_{ij} \tag{104.335}$$

$$\frac{\partial f}{\partial \alpha_{ij}} = -p\left(s_{ij} - p\alpha_{ij}\right)\left[\left(s_{mn} - p\alpha_{mn}\right)\left(s_{mn} - p\alpha_{mn}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} \tag{104.336}$$

$$\frac{\partial f}{\partial k} = \frac{2}{3}ka^2\left[\left(s_{mn} - p\alpha_{mn}\right)\left(s_{mn} - p\alpha_{mn}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} - \sqrt{\frac{2}{3}}p \tag{104.337}$$

Plastic Flow The non-associated plastic flow is defined as

$$m_{ij} = \left(\frac{\partial f}{\partial \sigma_{ij}}\right)^{dev} - \frac{1}{3}D\delta_{ij} = \left(s_{ij} - p\alpha_{ij}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} - \frac{1}{3}D\delta_{ij} \tag{104.338}$$

where

$$D = \xi\left(\sqrt{\frac{2}{3}}k_d - \frac{\sqrt{s_{mn}s_{mn}}}{p}\right) \tag{104.339}$$

The derivatives of the plastic flow are shown below.

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \sigma_{mn}} = &\left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{ij}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} \\ &- \left(s_{ij} - p\alpha_{ij}\right)\left[\left(s_{mn} - p\alpha_{mn}\right) + \frac{1}{3}\alpha_{rs}\left(s_{rs} - p\alpha_{rs}\right)\delta_{mn}\right]\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right) + \frac{2}{3}k^2a^2\right]^{-1.5} \\ &+ \frac{1}{3}\xi\left[s_{mn}p^{-1}(s_{kl}s_{kl})^{-0.5} + \frac{1}{3}\delta_{mn}p^{-2}(s_{ot}s_{ot})^{0.5}\right]\delta_{ij}\end{aligned} \tag{104.340}$$

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \alpha_{mn}} = &-p\left(\frac{1}{2}\delta_{mi}\delta_{nj} + \frac{1}{2}\delta_{mj}\delta_{ni}\right)\left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3}k^2a^2\right]^{-0.5} \\ &+ p\left(s_{ij} - p\alpha_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right)\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right) + \frac{2}{3}k^2a^2\right]^{-1.5}\end{aligned} \tag{104.341}$$

$$\frac{\partial m_{ij}}{\partial k} = -\frac{2}{3}ka^2\left(s_{ij} - p\alpha_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right)\left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right) + \frac{2}{3}k^2a^2\right]^{-1.5} \tag{104.342}$$

Linear Isotropic Hardening Linear isotropic hardening is used for this material model. The evolution of the internal variable k is defined as

$$\bar{k} = H m^{equi} \quad , \quad m^{equi} = \left(\frac{2}{3} m_{ij} m_{ij}\right)^{0.5} \tag{104.343}$$

where H is a material constant.

The derivatives of the internal variable k are shown below.

$$\frac{\partial \bar{k}}{\partial \sigma_{ij}} = \frac{2H}{3} m_{kl} \frac{\partial m_{kl}}{\partial \sigma_{ij}} \left(m^{equi}\right)^{-1} \tag{104.344}$$

$$\frac{\partial \bar{k}}{\partial \alpha_{ij}} = \frac{2H}{3} m_{kl} \frac{\partial m_{kl}}{\partial \alpha_{ij}} \left(m^{equi}\right)^{-1} \tag{104.345}$$

$$\frac{\partial \bar{k}}{\partial k} = \frac{2H}{3} m_{kl} \frac{\partial m_{kl}}{\partial k} \left(m^{equi}\right)^{-1} \tag{104.346}$$

Armstrong-Frederick kinematic hardening for Hyperbolic Drucker-Prager

$$\bar{\alpha}_{ij} = \frac{2}{3} \frac{h_a}{p_{atm}} m_{ij}^{dev} - c_r \left(\frac{2}{3} m_{rs}^{dev} m_{rs}^{dev}\right)^{0.5} \alpha_{ij} \tag{104.347}$$

where p_{atm} is the atmospheric pressure of 101.325 kPa. The unit of parameter h_a is Pascal. The parameter c_r is unitless. The α_{ij} in Drucker-Prager is unitless.

Some useful tensor derivatives for Drucker-Prager $\bar{\alpha}$.

$$m_{ij}^{dev} = \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3} k^2 a^2\right]^{-0.5} \tag{104.348}$$

$$\begin{aligned}\frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} = & \left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm} - \frac{1}{3}\delta_{mn}\delta_{ij} + \frac{1}{3}\delta_{mn}\alpha_{ij}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3} k^2 a^2\right]^{-0.5} \\ & - \left(s_{ij} - p\alpha_{ij}\right) \left[\left(s_{mn} - p\alpha_{mn}\right) + \frac{1}{3}\alpha_{rs}\left(s_{rs} - p\alpha_{rs}\right)\delta_{mn}\right] \left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right) + \frac{2}{3} k^2 a^2\right]^{-1.5}\end{aligned} \tag{104.349}$$

$$\begin{aligned}\frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} = & -p\left(\frac{1}{2}\delta_{im}\delta_{jn} + \frac{1}{2}\delta_{in}\delta_{jm}\right) \left[\left(s_{rs} - p\alpha_{rs}\right)\left(s_{rs} - p\alpha_{rs}\right) + \frac{2}{3} k^2 a^2\right]^{-0.5} \\ & - p\left(s_{ij} - p\alpha_{ij}\right)\left(s_{mn} - p\alpha_{mn}\right) \left[\left(s_{tu} - p\alpha_{tu}\right)\left(s_{tu} - p\alpha_{tu}\right) + \frac{2}{3} k^2 a^2\right]^{-1.5}\end{aligned} \tag{104.350}$$

$$\frac{\partial m_{ij}^{dev}}{\partial k} = -\frac{2}{3}ka^2\left(s_{ij}-p\alpha_{ij}\right)\left(s_{mn}-p\alpha_{mn}\right)\left[\left(s_{tu}-p\alpha_{tu}\right)\left(s_{tu}-p\alpha_{tu}\right)+\frac{2}{3}k^2a^2\right]^{-1.5} \tag{104.351}$$

Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to σ_{ij}.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial \sigma_{mn}} = \frac{2h_a}{3p_{atm}}\frac{\partial m_{ij}^{dev}}{\partial \sigma_{mn}} - \frac{2}{3}c_r m_{kl}^{dev}\frac{\partial m_{kl}^{dev}}{\partial \sigma_{mn}}\left(\frac{2}{3}m_{rs}^{dev}m_{rs}^{dev}\right)^{-0.5}\alpha_{ij} \tag{104.352}$$

Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to α_{ij}.

$$\begin{aligned}\frac{\partial \bar{\alpha}_{ij}}{\partial \alpha_{mn}} &= \frac{2h_a}{3p_{atm}}\frac{\partial m_{ij}^{dev}}{\partial \alpha_{mn}} - \frac{2}{3}c_r m_{kl}^{dev}\frac{\partial m_{kl}^{dev}}{\partial \alpha_{mn}}\left(\frac{2}{3}m_{rs}^{dev}m_{rs}^{dev}\right)^{-0.5}\alpha_{ij} \\ &\quad - c_r\left(\frac{2}{3}m_{rs}^{dev}m_{rs}^{dev}\right)^{0.5}\left(\frac{1}{2}\delta_{mi}\delta_{nj}+\frac{1}{2}\delta_{mj}\delta_{ni}\right)\end{aligned} \tag{104.353}$$

Tensor derivative of Drucker-Prager $\bar{\alpha}_{ij}$ with respect to k.

$$\frac{\partial \bar{\alpha}_{ij}}{\partial k} = \frac{2h_a}{3p_{atm}}\frac{\partial m_{ij}^{dev}}{\partial k} - \frac{2}{3}c_r m_{kl}^{dev}\frac{\partial m_{kl}^{dev}}{\partial k}\left(\frac{2}{3}m_{rs}^{dev}m_{rs}^{dev}\right)^{-0.5}\alpha_{ij} \tag{104.354}$$

104.6.9 Rounded Mohr-Coulomb Model

DSL COMMANDS for the rounded Mohr-Coulomb material models are given in section 205.3 on page 827.

The model consists of a smooth conical yield surface. This conical yield surface has an apex that is located at the zero of stress coordinate system or to the extension side, depending on the cohesion characteristic of material in question. The yield surface is defined by:

$$F\left(p,q,\theta,\kappa_{cone}\right) = q\left(1+\frac{q}{q_a}\right)^m g\left(\theta\right) - \eta_{cone}\left(\kappa_{cone}\right)\ \left(p-p_c\right) \tag{104.355}$$

where q_a is a (positive) reference deviator stress, m is a material constant such that $0 \le m \le 1$, controlling the curvature of the cone in the meridian $(p,\ q)$ planes, η_{cone} represents the angle of internal friction, and p_c represents the cohesion. η_{cone} is a function of the hardening variable κ_{cone} which, in turn, is a function of the plastic work. Moreover, an asymmetric trace of the yield surface in the deviatoric plane is generated through the introduction of $g(\theta)$ according to the expression by Willam and Warnke (1974):

$$g\left(\theta\right) = \frac{4\left(1-e^2\right)\cos^2\theta + (2e-1)^2}{2\left(1-e^2\right)\cos\theta + (2e-1)\sqrt{4\left(1-e^2\right)\cos^2\theta + 5e^2 - 4e}} \tag{104.356}$$

and e is an eccentricity parameter that satisfies the condition $1/2 < e \le 1$. From eqn. (104.356) we conclude that $g\left(0\right) = 1/e$ and $g\left(\pi/3\right) = 1$. For $e = 1 \quad \Rightarrow \quad g\left(\theta\right) = 1$, so the influence of the third stress invariant via θ is dropped and the conical surface represents a curved cone[63]. For $e \to 1/2$ the triangular cone[64] is obtained. A nice pictorial representation of function $1/g\,(\theta)$ is presented in the Figure (104.6.9), showing material model traces in the deviatoric plane.

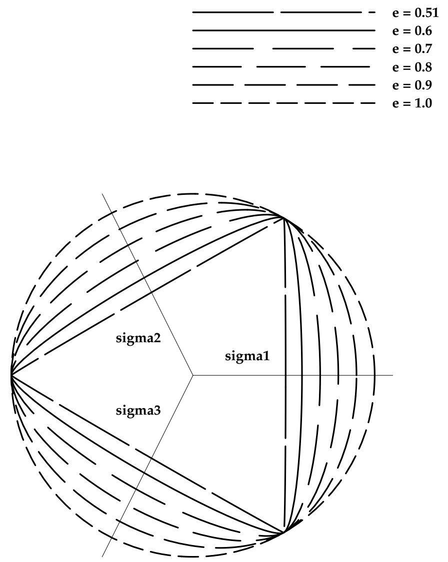

Figure 104.11: Willam Warnke function 1/g for different values of e (e = 0.51, 0.6, 0.7, 0.8, 0.9, 1.0) representing traces of rounded Mohr-Coulomb model in deviatoric space.

104.6.10 Modified Cam-Clay Model

DSL COMMANDS for the Modified Cam Clay material models are given in section 205.3 on page 827.

The pioneering research work on the critical state soil mechanics by the researchers at Cambridge University (Roscoe et al., 1958), (Roscoe and Burland, 1968), (Muir Wood, 1990)) has made great contribution on the modern soil elastoplastic models. The original Cam Clay model (Roscoe et al., 1963), and later the modified Cam Clay model (Schofield and Wroth, 1968) were within the critical state soil mechanics framework. We focus on only the modified Cam Clay model and herein the word 'modified' is omitted to shorten writing.

---

[63] extended Drucker Prager cone.

[64] extended Rankine yield criteria.

104.6.10.1 Critical State

The critical state line (CSL) takes the form

$$e_c = e_{c,r} - \lambda_c \ln p_c \tag{104.357}$$

where e_c is the critical void ratio at the critical mean effective stress p_c [65], $e_{c,r}$ is the reference critical void ratio, λ_c is the normal consolidation slope.

The critical state soil mechanics assumes that the normal consolidation line (NRL) is parallel to the CSL, which is expressed by

$$e = e_\lambda - \lambda \ln p \tag{104.358}$$

where e_λ is the intercept on the NRL at $p = 1$. λ is the normal consolidation slope or the elastoplastic slope of $e - \ln p$ relation, and $\lambda_c = \lambda$.

The unloading-reloading line (URL) take the similar form but with different slope by

$$e = e_\kappa - \kappa \ln p \tag{104.359}$$

where e_κ is the intercept on the URL at $p = 1$. λ_c is the normal consolidation slope or the elastoplastic slope of $e - \ln p$ relation.

104.6.10.2 Elasticity

The elastic bulk modulus K can be directly derived from the Equation 104.359 and takes the form

$$K = \frac{(1+e)\,p}{\kappa} \tag{104.360}$$

If a constant Poisson's ratio ν is assumed, since the isotropic elasticity needs only two material constants, the shear elastic modulus can be obtained in terms of K and ν by

$$G = \frac{3\,(1-2\nu)}{2\,(1+\nu)}K = \frac{3\,(1-2\nu)\,(1+e)}{2\,(1+\nu)\,\kappa}p \tag{104.361}$$

Alternatively, a constant shear elastic modulus G can be assumed and then the Poisson's ratio ν is expressed in terms of K and G as

$$\nu = \frac{3K - 2G}{2\,(G+3K)} \tag{104.362}$$

---

[65] In this chapter, only single-phase (dry phase) is studied, the total and effective stresses are thus identical, e.g. $p_c' = p_c$.

104.6.10.3 Yield Function

The yield function of the Cam Clay model is defined by

$$f = q^2 - M_c^2[p\,(p_0 - p)] = 0 \tag{104.363}$$

where M_c is the critical state stress ration in the $q-p$ plane, and the p_0 is the initial internal scalar variable, which is controlled by the change of the plastic volumetric strain.

The gradient of the yield surface to the stress can be obtained as

$$\frac{\partial f}{\partial \sigma_{ij}} = 2q\frac{\partial q}{\partial \sigma_{ij}} - M_c^2\,(2p - p_0)\,\frac{\partial p}{\partial \sigma_{ij}} = 3s_{ij} + \frac{1}{3}M_c^2\,(p_0 - 2p)\,\delta_{ij} \tag{104.364}$$

where $\partial q/\partial \sigma_{ij}$ and $\partial p/\partial \sigma_{ij}$ are independent of the yield function.

The gradient of the yield surface to p_0 will be used in the integration algorithm, and can be expressed by

$$\frac{\partial f}{\partial p_0} = M_c^2 p \tag{104.365}$$

104.6.10.4 Plastic Flow

The plastic flow of the Cam Clay model is associated with its yield function, in other words, the plastic flow is defined by the potential function, g, which is assumed the same as the yield function, f.

$$g = f = q^2 - M_c^2[p\,(p_0 - p)] = 0 \tag{104.366}$$

The stress gradient to the yield surface can be obtained as

$$m_{ij} = \frac{\partial g}{\partial \sigma_{ij}} = 2q\frac{\partial q}{\partial \sigma_{ij}} + M_c^2\,(2p - p_0)\,\frac{\partial p}{\partial \sigma_{ij}} = 3s_{ij} + \frac{1}{3}M_c^2\,(p_0 - 2p)\,\delta_{ij} \tag{104.367}$$

It can define the plastic dilation angle β, which is related to the ratio of plastic volumetric and deviatoric strain (Muir Wood, 1990), by

$$\tan\beta = -\frac{\Delta\epsilon_v^p}{\Delta\epsilon_q^p} = \frac{M_c^2\,(p_0 - 2p)}{2q} \tag{104.368}$$

It is interesting to find that from Equation 104.368, when $p < p_0/2$, the plastic dilation angle is positive; when $p > p_0/2$, the plastic dilation angle is negative. If $p = p_0/2$, the plastic dilation angle is zero, which is corresponding to the critical state. This is evidently more realistic than Drucker-Prager model, whose associated plastic flow always gives positive plastic dilation angle.

104.6.10.5 Evolution Law

The evolution law of the Cam Clay model is a scalar one, which can be expressed by

$$\dot{p}_0 = \frac{(1+e)\, p_0}{\lambda - \kappa} \dot{\epsilon}_v^p \tag{104.369}$$

With this scalar evolution law, the change of p_0 is decided by the change of plastic volumetric strain. When it reaches the critical state, or when there is no plastic volumetric strain, the evolution of p_0 will cease. From Equation 104.369, one gets

$$\dot{p}_0 = \dot{\lambda} \frac{(1+e)\, p_0}{\lambda - \kappa} m_{ii} \tag{104.370}$$

so if using Equation 104.367 further, one obtains

$$h = \frac{(1+e)\, p_0}{\lambda - \kappa} M_c^2 \,(2p - p_0) \tag{104.371}$$

or using dilation angle,

$$h = \frac{2\,(1+e)\, p_0 q}{\lambda - \kappa} \tan\beta \tag{104.372}$$

104.6.10.6 Yield and Plastic Potential Functions: Cam-Clay Model

Yield function and related derivatives

$$f = q^2 - M_c^2 [p\,(p_0 - p)] = 0 \tag{104.373}$$

$$\begin{aligned} \frac{\partial f}{\partial \sigma_{ij}} &= 2q \frac{\partial q}{\partial \sigma_{ij}} - M_c^2 \,(2p - p_0)\, \frac{\partial p}{\partial \sigma_{ij}} \\ &= 3 s_{ij} + \frac{1}{3} M_c^2 \,(p_0 - 2p)\, \delta_{ij} \end{aligned} \tag{104.374}$$

$$\frac{\partial f}{\partial p_0} = -M_c^2 p \tag{104.375}$$

Plastic flow (associated plasticity) and related derivatives

$$m_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = 3 s_{ij} + \frac{1}{3} M_c^2 \,(p_0 - 2p)\, \delta_{ij} \tag{104.376}$$

$$\begin{aligned} \frac{\partial m_{ij}}{\partial \sigma_{mn}} &= 3 \frac{\partial s_{ij}}{\partial \sigma_{mn}} - \frac{2}{3} M_c^2 \delta_{ij} \frac{\partial p}{\partial \sigma_{mn}} \\ &= 3 \delta_{im} \delta_{jn} - \delta_{ij} \delta_{mn} + \frac{2}{9} M_c^2 \delta_{ij} \delta_{mn} \\ &= 3 \delta_{im} \delta_{jn} + \left(\frac{2}{9} M_c^2 - 1 \right) \delta_{ij} \delta_{mn} \end{aligned} \tag{104.377}$$

$$\frac{\partial m_{ij}}{\partial p_0} = \frac{1}{3} M_c^2 \delta_{ij} \tag{104.378}$$

Isotropic Hardening and related derivatives (CC_Ev) Note the due to the current definition of p (i.e. $p = -\frac{1}{3}\sigma_{ii}$), a minus sign appears in from of the evolution of p_0 as follows:

$$\bar{p}_0 = -\frac{(1+e)\, p_0}{\lambda - \kappa} m_{ii} \tag{104.379}$$

$$= \frac{(1+e)\, p_0}{\lambda - \kappa} M_c^2 \left(2p - p_0\right) \tag{104.380}$$

$$\frac{\partial \bar{p}_0}{\partial \sigma_{ij}} = \frac{(1+e)\, p_0}{\lambda - \kappa} M_c^2 \left(-\frac{2}{3}\delta_{ij}\right) \tag{104.381}$$

$$\frac{\partial \bar{p}_0}{\partial p_0} = \frac{2\,(1+e)}{\lambda - \kappa} M_c^2 \left(p - p_0\right) \tag{104.382}$$

104.6.11 SaniSand2004 (aka Dafalias-Manzari) Model

DSL COMMANDS for the Dafalias-Manzari material models are given in section 205.3 on page 827.

Within the critical state soil mechanics framework, Manzari and Dafalias (1997) proposed a two-surface sand model. This model considered the effects of the state parameter on the behaviors of the dense or loose sands. The features of this model include successfully predicting the softening at the dense state in drained loading, and also softening at the loose state but in the undrained loading. Dafalias and Manzari (2004a) later presented an improved version. This version introduced the fabric dilatancy tensor which has a significant effect on the contraction unloading response. It is also considered the Lode's angle effect on the bounding surface, which produces more realistic responses in non-triaxial conditions. Here only the new version is summarized. The compression stress is assumed negative here, which is different from the original reference by Dafalias and Manzari (2004a).

104.6.11.1 Critical State

Instead of using the most common linear line of critical void ration vs. logarithmic critical mean effective stress, the power relation recently suggested by Li and Wang (1998) was used:

$$e_c = e_{c,r} - \lambda_c \left(\frac{p_c}{P_{at}}\right)^{\xi} \tag{104.383}$$

where e_c is the critical void ratio at the critical man effective stress p'_c, $e_{c,r}$ is the reference critical void ratio, λ_c and ξ (for most sands, $\xi = 0.7$) are material constants, and P_{at} is the atmospheric pressure for normalization.

104.6.11.2 Elasticity

The elastic incremental moduli of shear and bulk, are following Richart et al. (1970):

$$G = G_0 \frac{(2.97 - e)^2}{(1+e)} \left(\frac{p}{P_{at}} \right)^{0.5} P_{at} \;\; ; \;\; K = \frac{2\,(1+\nu)}{3\,(1 - 2\nu)} G \tag{104.384}$$

where G_0 is a material constant, e is the void ratio, and ν is the Poisson's ratio.

The isotropic hypoelasticity is then defined by

$$\dot{e}^e_{ij} = \frac{\dot{s}_{ij}}{2G}, \;\; \dot{\epsilon}^e_v = \frac{\dot{p}}{K} \tag{104.385}$$

104.6.11.3 Yield Function

The yield function is defined by

$$f = |\Lambda| - \sqrt{\frac{2}{3}} mp = 0 \tag{104.386}$$

where s_{ij} is the deviatoric stress tensor, α_{ij} is the deviatoric back stress-ratio tensor, m is a material constant, and

$$|\Lambda| = \left\| s_{ij} - p\alpha_{ij} \right\| = [(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})]^{0.5} \tag{104.387}$$

The gradient of the yield surface to the stress can be obtained as

$$\frac{\partial f}{\partial \sigma_{ij}} = n_{ij} + \frac{1}{3}(\alpha_{pq} n_{pq} + \sqrt{\frac{2}{3}} m)\delta_{ij} \tag{104.388}$$

where $r_{ij} = s_{ij}/p$ is the normalized deviatoric stress tensor, and n_{ij} is the unit gradient tensor to the yield surface defined by

$$n_{ij} = \frac{s_{ij} - p\alpha_{ij}}{|\Lambda|} \tag{104.389}$$

It is evident that $n_{ii} \equiv 0$ and $n_{ij} n_{ij} \equiv 1$.

The gradient of the yield surface to α_{ij} can be easily obtained as

$$\frac{\partial f}{\partial \alpha_{ij}} = -p n_{ij} \tag{104.390}$$

The tensor of n_{ij} is to defined θ_n, the Lode's angle of the yield gradient, by the equation

$$\cos 3\theta_n = -\sqrt{6} n_{ij} n_{jk} n_{ki} \tag{104.391}$$

where $0 \leq \theta_n \leq \pi/6$ and $\theta_n = 0$ at triaxial compression and $\theta_n = \pi/6$ at triaxial extension.

The critical stress ratio M at any stress state can be interpolated between M_c, the triaxial compression critical stress ratio, and M_e, the triaxial extension critical stress ratio.

$$M = M_c g(\theta_n, c), \quad g(\theta_n, c) = \frac{2c}{(1+c) - (1-c)\cos 3\theta_n}, \quad c = \frac{M_e}{M_c} \tag{104.392}$$

The line from the origin of the π plane parallel to n_{ij} will intersect the bounding, critical and dilation surfaces at three 'image' back-stress ratio tensor α^b_{ij}, α^c_{ij}, and α^d_{ij} respectively (Figure 104.12), which are expressed as

$$\alpha^b_{ij} = \sqrt{\frac{2}{3}}[M \exp(-n^b \psi) - m] n_{ij} = \left(\sqrt{\frac{2}{3}} \alpha^b_\theta\right) n_{ij} \tag{104.393}$$

$$\alpha^c_{ij} = \sqrt{\frac{2}{3}}[M - m] n_{ij} = \left(\sqrt{\frac{2}{3}} \alpha^c_\theta\right) n_{ij} \tag{104.394}$$

$$\alpha^d_{ij} = \sqrt{\frac{2}{3}}[M \exp(n^d \psi) - m] n_{ij} = \left(\sqrt{\frac{2}{3}} \alpha^d_\theta\right) n_{ij} \tag{104.395}$$

where $\psi = e - e_c$ is the state parameter; n^b and n^d are material constants.

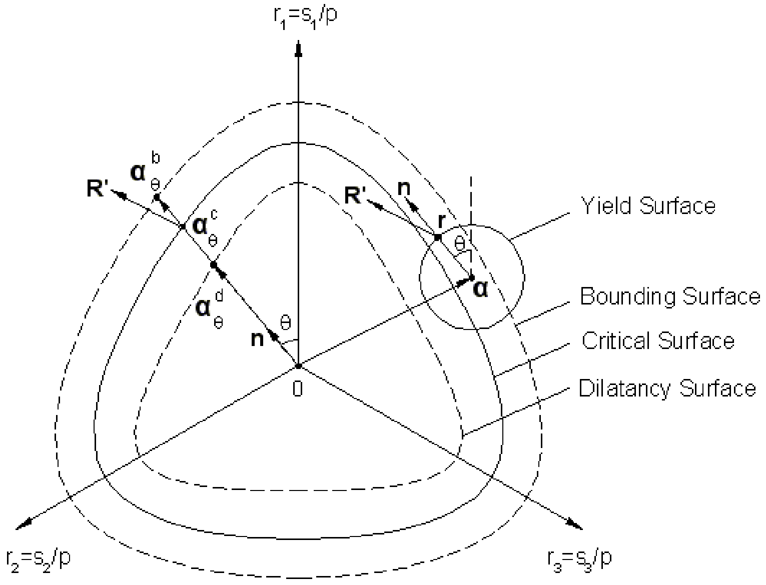

Figure 104.12: Schematic illustration of the yield, critical, dilatancy, and bounding surfaces in the π-plane of deviatoric stress ratio space (after Dafalias and Manzari 2004).

104.6.11.4 Plastic Flow

The plastic strain is given by

$$\dot{\epsilon}^p_{ij} = \dot{\lambda} R_{ij} = \dot{\lambda}(R'_{ij} + \frac{1}{3}D\delta_{ij}) \tag{104.396}$$

The deviatoric plastic flow tensor is

$$R'_{ij} = Bn_{ij} + C(n_{ik}n_{kj} - \frac{1}{3}\delta_{ij}) \tag{104.397}$$

where

$$B = 1 + \frac{3}{2}\frac{1-c}{c}g\cos 3\theta_n, \quad C = 3\sqrt{\frac{3}{2}}\frac{1-c}{c}g \tag{104.398}$$

The volumetric plastic flow part is

$$D = -A_d(\alpha^d_{ij} - \alpha_{ij})n_{ij} = -A_d\left(\sqrt{\frac{2}{3}}\alpha^d_\theta - \alpha_{ij}n_{ij}\right) \tag{104.399}$$

where

$$A_d = A_0(1 + \langle z_{ij}n_{ij}\rangle) \tag{104.400}$$

A_0 is a material constant, and z_{ij} is the fabric dilation tensor. The Macauley brackets $\langle\rangle$ is defined that $\langle x\rangle = x$, if $x > 0$ and $\langle x\rangle = 0$, if $x \leq 0$.

104.6.11.5 Evolution Laws

This model has two tensorial evolution internal variable, namely, the back stress-ratio tensor α_{ij} and the fabric dilation tensor z_{ij}.

The evolution law for the back stress-ratio tensor α_{ij} is

$$\dot{\alpha}_{ij} = \dot{\lambda}[\frac{2}{3}h(\alpha^b_{ij} - \alpha_{ij})] \tag{104.401}$$

with

$$h = \frac{b_0}{(\alpha_{ij} - \tilde{\alpha}_{ij})n_{ij}} \tag{104.402}$$

where $\tilde{\alpha}_{ij}$ is the initial value of α_{ij} at initiation of a new loading process and is updated to the new value when the denominator of Equation 104.402 becomes negative. b_0 is expressed by

$$b_0 = G_0h_0(1 - c_he)\left(\frac{p}{P_{at}}\right)^{-0.5} \tag{104.403}$$

where h_0 and c_h are material constants.

The evolution law for the fabric dilation tensor z_{ij} is

$$\dot{z}_{ij} = -c_z\left\langle\dot{D}\right\rangle(z_{max}n_{ij} + z_{ij}) \tag{104.404}$$

where c_z and z_{max} are material constants.

104.6.11.6 Analytical Derivatives for the Implicit Algorithm

When implemented into an implicit algorithm for the Dafalias-Manzari model, some complicated additional analytical derivatives are needed. This section gives the analytical derivatives expressions based on the tensor calculus.

Analytical expression of $\dfrac{\partial m_{ij}}{\partial \sigma_{kl}}$:

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \sigma_{mn}} &= B\frac{\partial n_{ij}}{\partial \sigma_{mn}} + n_{ij}\frac{\partial B}{\partial \sigma_{mn}} + C\frac{\partial n_{ik}}{\partial \sigma_{mn}} n_{kj} + (n_{ik}n_{kj} - \frac{1}{3}\delta_{ij})\frac{\partial C}{\partial \sigma_{mn}} \\ &\quad + \frac{1}{3}\delta_{ij}\frac{\partial D}{\partial \sigma_{mn}}\end{aligned} \tag{104.405}$$

where

$$\frac{\partial n_{ij}}{\partial \sigma_{mn}} = \frac{1}{|\Lambda|}\left[I^{s}_{ijmn} - \frac{1}{3}\delta_{ij}\delta_{mn} + \frac{1}{3}\alpha_{ij}\delta_{mn} - n_{ij}n_{mn} - \frac{1}{3}(\alpha_{ab}n_{ab})n_{ij}\delta_{mn}\right] \tag{104.406}$$

$$\frac{\partial D}{\partial \sigma_{mn}} = -\frac{\partial A_d}{\partial \sigma_{mn}}\left(\sqrt{\frac{2}{3}}\alpha^{d}_{\theta} - \alpha_{ab}n_{ab}\right) - A_d\left(\sqrt{\frac{2}{3}}\frac{\partial \alpha^{d}_{\theta}}{\partial \sigma_{mn}} - \alpha_{ab}\frac{\partial n_{ab}}{\partial \sigma_{mn}}\right) \tag{104.407}$$

and

$$\frac{\partial B}{\partial \sigma_{mn}} = \frac{3}{2}\left(\frac{1-c}{c}\right)\left(\frac{\partial g}{\partial \sigma_{mn}}\cos 3\theta + g\frac{\partial \cos 3\theta}{\partial \sigma_{mn}}\right) \tag{104.408}$$

$$\frac{\partial C}{\partial \sigma_{mn}} = 3\sqrt{\frac{3}{2}}\left(\frac{1-c}{c}\right)\frac{\partial \alpha^{d}_{\theta}}{\partial \sigma_{mn}} \tag{104.409}$$

$$\frac{\partial \alpha^{d}_{\theta}}{\partial \sigma_{mn}} = M_c \exp\left(n^{d}\psi\right)\left(g n^{d}\frac{\partial \psi}{\partial \sigma_{mn}} + \frac{\partial g}{\partial \sigma_{mn}}\right) \tag{104.410}$$

$$\frac{\partial \psi}{\partial \sigma_{mn}} = -\frac{\xi\lambda_c}{3P_{at}}\left(\frac{p}{P_{at}}\right)^{(\xi-1)}\delta_{mn} \tag{104.411}$$

$$\frac{\partial g}{\partial \sigma_{mn}} = g^{2}\left(\frac{1-c}{2c}\right)\frac{\partial \cos 3\theta}{\partial \sigma_{mn}} \tag{104.412}$$

$$\frac{\partial \cos 3\theta}{\partial \sigma_{mn}} = -3\sqrt{6}\frac{\partial n_{ij}}{\partial \sigma_{mn}}(n_{jk}n_{ki}) \tag{104.413}$$

$$\frac{\partial A_d}{\partial \sigma_{mn}} = A_0 z_{ab}\frac{\partial n_{ab}}{\partial \sigma_{mn}}\left\{\overline{z_{ab}n_{ab}}\right\} \tag{104.414}$$

and define $\left\{\overline{X}\right\} = 1$ if $X > 0$, and $\left\{\overline{X}\right\} = 0$ if $X \leq 0$.

Analytical expression of $\dfrac{\partial m_{ij}}{\partial \alpha_{kl}}$:

$$\begin{aligned}\frac{\partial m_{ij}}{\partial \alpha_{mn}} &= B\frac{\partial n_{ij}}{\partial \alpha_{mn}} + n_{ij}\frac{\partial B}{\partial \alpha_{mn}} + C\frac{\partial n_{ik}}{\partial \alpha_{mn}}n_{kj} + (n_{ik}n_{kj} - \frac{1}{3}\delta_{ij})\frac{\partial C}{\partial \alpha_{mn}} \\ &+\frac{1}{3}\delta_{ij}\frac{\partial D}{\partial \alpha_{mn}}\end{aligned} \tag{104.415}$$

where

$$\frac{\partial n_{ij}}{\partial \alpha_{mn}} = \frac{p}{|\Lambda|}\left(n_{ij}n_{mn} - I^{s}_{ijmn}\right) \tag{104.416}$$

$$\frac{\partial D}{\partial \alpha_{mn}} = -\frac{\partial A_d}{\partial \alpha_{mn}}\left(\sqrt{\frac{2}{3}}\alpha^{d}_{\theta} - \alpha_{ab}n_{ab}\right) - A_d\left(\sqrt{\frac{2}{3}}\frac{\partial \alpha^{d}_{\theta}}{\partial \alpha_{mn}} - n_{mn} - \alpha_{ab}\frac{\partial n_{ab}}{\partial \alpha_{mn}}\right) \tag{104.417}$$

and

$$\frac{\partial B}{\partial \alpha_{mn}} = \frac{3}{2}\left(\frac{1-c}{c}\right)\left(\frac{\partial g}{\partial \alpha_{mn}}\cos 3\theta + g\frac{\partial \cos 3\theta}{\partial \alpha_{mn}}\right) \tag{104.418}$$

$$\frac{\partial C}{\partial \alpha_{mn}} = 3\sqrt{\frac{3}{2}}\left(\frac{1-c}{c}\right)\frac{\partial \alpha^{d}_{\theta}}{\partial \alpha_{mn}} \tag{104.419}$$

$$\frac{\partial \alpha^{d}_{\theta}}{\partial \alpha_{mn}} = M_c \exp\left(n^{d}\psi\right)\frac{\partial g}{\partial \alpha_{mn}} \tag{104.420}$$

$$\frac{\partial g}{\partial \alpha_{mn}} = g^{2}\left(\frac{1-c}{2c}\right)\frac{\partial \cos 3\theta}{\partial \alpha_{mn}} \tag{104.421}$$

$$\frac{\partial \cos 3\theta}{\partial \alpha_{mn}} = -3\sqrt{6}\frac{\partial n_{ij}}{\partial \alpha_{mn}}(n_{jk}n_{ki}) \tag{104.422}$$

$$\frac{\partial A_d}{\partial \alpha_{mn}} = A_0 z_{ab}\frac{\partial n_{ab}}{\partial \alpha_{mn}}\{\overline{z_{ab}n_{ab}}\} \tag{104.423}$$

Analytical expression of $\dfrac{\partial m_{ij}}{\partial z_{mn}}$:

$$\frac{\partial m_{ij}}{\partial z_{mn}} = \frac{1}{3}\delta_{ij}\frac{\partial D}{\partial z_{mn}} \tag{104.424}$$

where

$$\frac{\partial D}{\partial z_{mn}} = -\frac{\partial A_d}{\partial z_{mn}}\left(\sqrt{\frac{2}{3}}\alpha^{d}_{\theta} - \alpha_{ab}n_{ab}\right) \tag{104.425}$$

and

$$\frac{\partial A_d}{\partial z_{mn}} = A_0 n_{mn} \{\overline{z_{ab} n_{ab}}\} \tag{104.426}$$

Analytical expression of $\frac{\partial A_{ij}}{\partial \sigma_{mn}}$:

$$\frac{\partial A_{ij}}{\partial \sigma_{mn}} = \frac{2}{3}\left[\frac{\partial h}{\partial \sigma_{mn}}\left(\sqrt{\frac{2}{3}}\alpha^b_\theta n_{ij} - \alpha_{ij}\right) + \sqrt{\frac{2}{3}}h\left(n_{ij}\frac{\partial \alpha^b_\theta}{\partial \sigma_{mn}} + \alpha^b_\theta \frac{\partial n_{ij}}{\partial \sigma_{mn}}\right)\right] \tag{104.427}$$

where

$$\frac{\partial \alpha^b_\theta}{\partial \sigma_{mn}} = M_c \exp\left(-n^b \psi\right)\left(\frac{\partial g}{\partial \sigma_{mn}} - n^b g \frac{\partial \psi}{\partial \sigma_{mn}}\right) \tag{104.428}$$

$$\frac{\partial h}{\partial \sigma_{mn}} = \frac{1}{(\alpha_{ab} - \alpha^{in}_{ab})n_{ab}}\left[\frac{\partial b_0}{\partial \sigma_{mn}} - h(\alpha_{pq} - \alpha^{in}_{pq})\frac{\partial n_{pq}}{\partial \sigma_{mn}}\right] \tag{104.429}$$

and

$$\frac{\partial b_0}{\partial \sigma_{mn}} = \frac{b_0}{6p}\delta_{mn} \tag{104.430}$$

Analytical expression of $\frac{\partial A_{ij}}{\partial \alpha_{mn}}$:

$$\begin{aligned}\frac{\partial A_{ij}}{\partial \alpha_{mn}} = \frac{2}{3}\Bigg[&\left(\sqrt{\frac{2}{3}}\alpha^b_\theta n_{ij} - \alpha_{ij}\right)\frac{\partial h}{\partial \alpha_{mn}} \\ &+ \sqrt{\frac{2}{3}}h\left(n_{ij}\frac{\partial \alpha^b_\theta}{\partial \alpha_{mn}} + \alpha^b_\theta\frac{\partial n_{ij}}{\partial \alpha_{mn}} - I^s_{ijmn}\right)\Bigg]\end{aligned} \tag{104.431}$$

where

$$\frac{\partial \alpha^b_\theta}{\partial \alpha_{mn}} = M_c \exp\left(-n^b \psi\right)\frac{\partial g}{\partial \alpha_{mn}} \tag{104.432}$$

$$\frac{\partial h}{\partial \alpha_{mn}} = -\frac{h}{(\alpha_{ab} - \alpha^{in}_{ab})n_{ab}}\left[n_{mn} + (\alpha_{pq} - \alpha^{in}_{pq})\frac{\partial n_{pq}}{\partial \alpha_{mn}}\right] \tag{104.433}$$

Analytical expression of $\frac{\partial A_{ij}}{\partial z_{mn}}$:

$$\frac{\partial A_{ij}}{\partial z_{mn}} = \emptyset \tag{104.434}$$

Analytical expression of $\frac{\partial Z_{ij}}{\partial \sigma_{mn}}$:

$$\frac{\partial Z_{ij}}{\partial \sigma_{mn}} = -c_z \left[(z_{max} n_{ij} + z_{ij}) \frac{\partial D}{\partial \sigma_{mn}} + z_{max} D \frac{\partial n_{ij}}{\partial \sigma_{mn}} \right] \{\overline{D}\} \tag{104.435}$$

Analytical expression of $\frac{\partial Z_{ij}}{\partial \alpha_{mn}}$:

$$\frac{\partial Z_{ij}}{\partial \alpha_{mn}} = -c_z \left[(z_{max} n_{ij} + z_{ij}) \frac{\partial D}{\partial \alpha_{mn}} + z_{max} D \frac{\partial n_{ij}}{\partial \alpha_{mn}} \right] \{\overline{D}\} \tag{104.436}$$

Analytical expression of $\frac{\partial Z_{ij}}{\partial z_{mn}}$:

$$\frac{\partial Z_{ij}}{\partial z_{mn}} = -c_z \left(D I^s_{ijmn} + z_{max} n_{ij} \frac{\partial D}{\partial z_{mn}} \right) \{\overline{D}\} \tag{104.437}$$

104.6.12 SaniSand2008 (aka SANISAND) Model

Taiebat and Dafalias (2008)

104.6.13 SANICLAY Model

Dafalias et al. (2006)

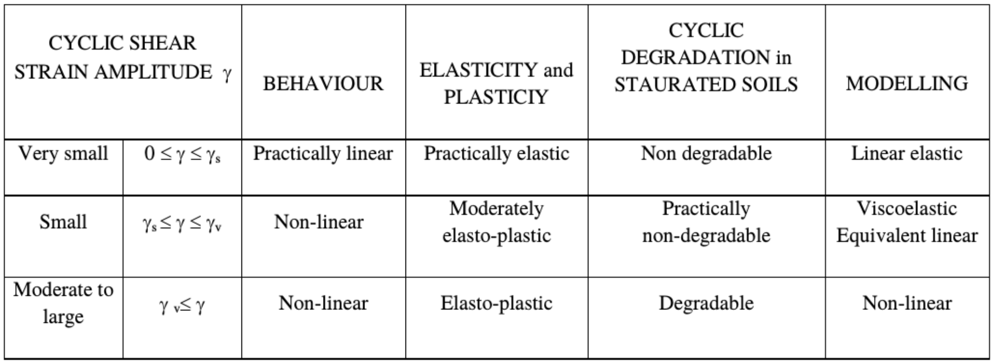
104.6.14 G/G_{max} Modeling

Modeling of stiffness reduction using G/G_{max} curves is frequently used. It is important to note that such modeling is essentially using linear elastic stiffness, reduced stiffness, secant stiffness to model an inelastic, nonlinear process. As such, some important simplifying assumptions are made. As noted by Pecker et al. (2022), using G/G_{max} models is appropriate if certain conditions are met, as shown in Figure 104.13.

104.6.15 Pisanò Elastic-Plastic Model with Vanishing Elastic Region (for G/G_{max} Modeling)

A more recent description of this model is available by Pisanò and Jeremić (2014).

Modeling the mechanical behavior of soils under cyclic/dynamic loading is crucial in most Geotechnical Earthquake Engineering (GEE) applications, including site response analysis and soil structure interaction (SSI) problems. In the last decades, a number of experimental studies (Ishihara, 1996; di Prisco and Wood, 2012) pointed out the complexity of such behavior – especially in the presence of pore



CYCLIC SHEAR STRAIN AMPLITUDE γ		BEHAVIOUR	ELASTICITY and PLASTICIY	CYCLIC DEGRADATION in STAURATED SOILS	MODELLING
Very small	$0 \leq \gamma \leq \gamma_s$	Practically linear	Practically elastic	Non degradable	Linear elastic
Small	$\gamma_s \leq \gamma \leq \gamma_v$	Non-linear	Moderately elasto-plastic	Practically non-degradable	Viscoelastic Equivalent linear
Moderate to large	$\gamma_v \leq \gamma$	Non-linear	Elasto-plastic	Degradable	Non-linear

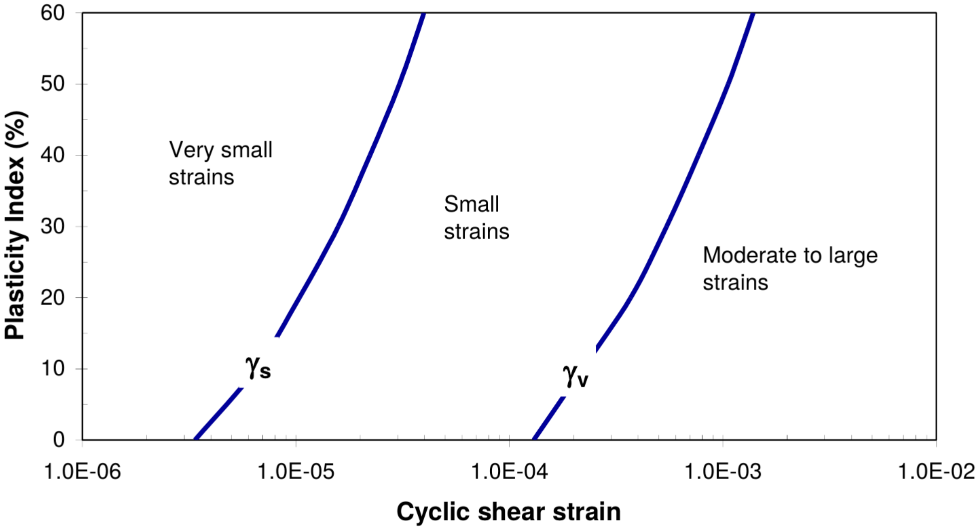


Figure 104.13: Pecker thresholds for G/G_{max} modeling.

fluid(s) – characterized by non-linearity, irreversibility, anisotropy, barotropy, picnotropy, rate-sensitivity, etc. In principle, a comprehensive soil model should be capable of reproducing all the aspects of the mechanical response for any loading condition, as well as predicting the occurrence of liquefaction and cyclic mobility, distinguishing the conditions for shakedown or ratcheting under repeated loads and so forth. However, such an ideal model would probably require too many data for calibration, along with a cumbersome numerical treatment.

Traditionally, many GEE problems are still tackled in the frequency domain through 1D (equivalent) linear models, mainly because of their computational convenience and straightforward calibration. In the light of a Kelvin-Voigt visco-elastic idealization, the dynamic soil behavior is fully described in terms of strain-dependent stiffness degradation (G/G_{max}) and damping (ζ) ratios (Kramer, 1996a). As it holds in the linear regime, the shear and the volumetric responses are assumed to be decoupled, so that G/G_{max} and ζ curves are derived from the experimental cyclic shear tests (triaxial, simple shear or torsional) as a function of the cyclic shear strain amplitude.

Owing to the availability of computer programs for 1D site response analysis (SHAKE (Schnabel et al., 1972), EERA (Bardet et al., 2000), DEEPSOIL (Hashash and Park, 2001)) and SSI problems (SASSI (Lysmer, 1988)), the visco-elastic approach has become more and more popular among practitioners, regardless of drawbacks:

- despite a non-negligible rate-sensitiveness, most energy dissipation in soils derives from frictional inter-granular mechanisms rather than viscous flow (as it is implicitly assumed by using $\mathrm{G/G^{max}}$ and damping approaches);
- G/G_{max} and ζ curves do not allow to evaluate irreversible deformations, nor the influence of pore fluid(s);
- adopting 1D shear constitutive relationships has poor mechanical soundness, since soil behavior exhibits a pronounced deviatoric-volumetric multiaxial coupling;
- the meaning of cyclic shear strain amplitude for the choice of G/G_{max} and ζ values is not evident in the presence of irregular seismic loads.

The above observations justify the need for alternative approaches and more physically consistent soil models. From this standpoint, the incremental elastic-plastic theory represents the main modeling framework, within which significant efforts have been spent in the last decades to simulate the response of cyclically loaded soils. Several approaches have been explored and gradually refined, including e.g. "multi-surface plasticity", "bounding surface plasticity", "generalized plasticity" and "hypoplasticity". Comprehensive overviews on cyclic elasto-plasticity modeling can be found in Lemaitre and Chaboche (1990) and, with specific reference to soils, Prevost and Popescu (1996), Zienkiewicz et al. (1999b) and di Prisco and Wood (2012). In most cases, rotational kinematic hardening formulations have been adopted in conjunction with increasingly accurate flow rules and hardening laws; a number of valuable contributions are worth citing, such as – to mention only a few – Mróz et al. (1978); Prevost (1985a); Borja and Amies (1994); Manzari and Dafalias (1997); Papadimitriou and Bouckovalas (2002); Elgamal et al. (2002); Taiebat and Dafalias (2008); recently, it has been also shown how a good simulation of dynamic properties can be achieved by means of even elastic-perfectly plastic models, as long as formulated in a probabilistic elastic-plastic framework (Sett et al., 2011b). The major issues about the practical use of elastic-plastic models concern the complexity of the mathematical formulations, the computer implementation and the possible high number of material parameters. For a model to appeal to practicing engineers, a tradeoff is needed between the overall accuracy and the number of parameters to be calibrated, particularly provided the frequent lack of detailed *in situ* or laboratory data.

Among the aforementioned models, the one by Borja and Amies (1994) is here taken into special consideration. These authors proposed a total-stress von Mises-type model in the framework of kinematic-hardening bounding surface plasticity, then successfully applied to the seismic simulation of fine-grained deposits at Lotung site in Taiwan (Borja et al., 1999, 2000). Based on work by Dafalias and Popov (1977) and Dafalias (1979), the multiaxial model is characterized by the assumption of vanishing elastic domain, thus implying soil plastification under any load level and a redefinition of the standard loading/unloading criterion. Apart from the mathematical aspects, the model possesses sufficient flexibility to reproduce the undrained dynamic properties of clayey/silty soils, while keeping a minimum number of physically-based parameters.

In this paper similar bounding surface approach with vanishing elastic region is adopted to derive a Drucker-Prager effective-stress model, incorporating pressure sensitivity and non-associativeness, essential ingredients for material modeling of granular materials. As a result, the following constitutive relationship is suitable for the effective-stress time-domain analysis of even liquefiable soils. In addition, the dissipative model performance is here explored in combination with a further viscous mechanism, which can be wisely exploited to improve the simulation of the experimental damping. Although numerical convenience often motivates the embedment of viscous dissipation into elastic-plastic computations, it has a *de facto* physical origin, coming from rate-dependent processes occurring at both inter-granular contacts and grain/pore fluid interfaces.

104.6.15.1 Frictional and viscous dissipative mechanisms

The time-domain finite element (FE) solution of dynamic problems is usually carried out by solving an incremental discrete system of the following form (Bathe, 1982; Zienkiewicz and Taylor, 1991a):

$$\mathbf{M}\Delta\ddot{\mathbf{U}} + \mathbf{C}\Delta\dot{\mathbf{U}} + \mathbf{K}^t\Delta\mathbf{U} = \Delta\mathbf{F}^{ext} \tag{104.438}$$

where Δ and dots stand respectively for step increment and time derivative, $\mathbf{U}$ is the generalized DOF vector (nodal displacement for example), $\mathbf{F}^{ext}$ the nodal external force vector and $\mathbf{M}$, $\mathbf{C}$, $\mathbf{K}^t$ are the mass, damping and (tangent) stiffness matrices, respectively.

In system (104.438) two dissipative sources are readily recognizable, namely the viscous (velocity-proportional) and the frictional (displacement-proportional) terms (Argyris and Mlejnek, 1991). While the latter is given by the variation of the elastic-plastic tangent stiffness $\mathbf{K}^t$, the viscous term related to the damping matrix $\mathbf{C}$ can represent interaction of solid skeleton and pore fluid, and constitutive time-sensitiveness of the soil skeleton. The above combination of frictional and viscous dissipation can be interpreted in terms of two distinct effective stress components acting on the soil skeleton:

$$\sigma_{ij} = \sigma^f_{ij} + \sigma^v_{ij} \tag{104.439}$$

where the effective stress tensor σ_{ij} has been split into frictional (elastic-plastic) and viscous stresses[66]. From a rheological point of view, the resulting scheme can be defined as visco-elastic-plastic – not elastic-viscoplastic – as the elastic-plastic response is rate-independent and accompanied by a parallel viscous resisting mechanism. In what follows, the frictional component is first specified via the formulation of the bounding surface model with vanishing elastic domain; then, the role and the calibration of the linear viscous term is discussed.

Index tensor notation is used, along with the standard Einstein convention for repeated indices; the norm of any second-order tensor x_{ij} is defined as $\|x_{ij}\| = \sqrt{x_{ij}x_{ij}}$, whereas the deviatoric component can be extracted as $x^{dev}_{ij} = x_{ij} - x_{kk}\delta_{ij}/3$ (δ_{ij} is the Kronecker delta). In accordance with usual Solid Mechanics conventions, positive tensile stresses/strains are considered, whereas – as is done in Fluid Mechanics – only the isotropic mean pressure is positive if compressive.

104.6.15.2 Bounding surface frictional model with vanishing elastic domain

The formulated constitutive model represents the frictional effective-stress version of the previous work by Borja and Amies (1994); for the sake of clarity, the presentation sequence of the former publication is here maintained, highlighting both differences and similarities. As was expected, the introduction of pressure-dependence into the constitutive equations implies somewhat more involved derivations, so that the analytical details skipped in this section are reported toward the end in section 104.6.15.7; the superscript f referring to the frictional component of the global effective stress (Equation (104.439)) is avoided for the sake of brevity.

Elastic relationship Provided the usual additive (incremental) strain split into elastic and plastic components $d\epsilon_{ij} = d\epsilon^e_{ij} + d\epsilon^p_{ij}$, the incremental linear elastic Hooke's law is expressed as follows:

$$d\sigma_{ij} = D^e_{ijhk}\left(d\epsilon_{hk} - d\epsilon^p_{hk}\right) \tag{104.440}$$

where d stands for a differentially small increment of strain and D^e_{ijhk} is the fourth-order elastic stiffness tensor. Under the elastic deviatoric/volumetric decoupling, the deviatoric and volumetric counterparts of Equation (104.440) can be also given:

$$ds_{ij} = 2G_{max}\left(de_{hk} - de^p_{hk}\right) \tag{104.441}$$

---

[66] Henceforth, effective stresses are exclusively accounted for

$$dp = -K \left(d\epsilon_{vol} - d\epsilon^{p}_{vol}\right) \tag{104.442}$$

in which $p = -\sigma_{kk}/3$ is the mean stress, $\epsilon_{vol} = \epsilon_{kk}$ is the volumetric strain, $s_{ij} = \sigma^{dev}_{ij}$ is the stress deviator, and $e_{ij} = \epsilon^{dev}_{ij}$ is the strain deviator. The shear modulus $G_{max} = E/2\left(1+\nu\right)$ and the bulk modulus $K = E/3\left(1-2\nu\right)$ are derived from the Young modulus E and the Poisson's ratio ν. Henceforth, G_{max} will be always used for the elastic small-strain shear modulus, whereas the secant cyclic shear stiffness will be referred to as G.

Drucker-Prager yield and bounding loci A conical Drucker-Prager type yield locus is first introduced, similar to what is used by Prevost (1985a) and Manzari and Dafalias (1997):

$$f_y = \frac{3}{2}\left(s_{ij} - p\alpha_{ij}\right)\left(s_{ij} - p\alpha_{ij}\right) - k^2p^2 = 0 \tag{104.443}$$

where α_{ij} is the so called deviatoric back-stress ratio ($\alpha_{kk} = 0$) governing the kinematic hardening of the yield surface; k is a parameter determining the opening angle of the cone. It is also important to note that the variation of the back-stress ratio α_{ij} in (104.443) determines a rigid rotation of the yield locus and, therefore, a rotational kinematic hardening.

The stress derivative of the yield function is also reported for the following developments:

$$\frac{\partial f_y}{\partial \sigma_{ij}} = \left(\frac{\partial f_y}{\partial \sigma_{ij}}\right)^{dev} + \left(\frac{\partial f_y}{\partial \sigma_{ij}}\right)^{vol} = 3\left(s_{ij} - p\alpha_{ij}\right) + \left[\alpha_{hk}\left(s_{hk} - p\alpha_{hk}\right) + \frac{2}{3}k^2p\right]\delta_{ij} \tag{104.444}$$

The yield locus must always reside within the so called bounding surface, here assumed to be a further Drucker-Prager cone (non kinematically hardening, fixed in size):

$$f_B = \frac{3}{2}s_{ij}s_{ij} - M^2p^2 = 0 \tag{104.445}$$

where M provides the bounding cone opening and, as a consequence, the material shear strength (as a function of the mean effective pressure p).

Plastic flow and translation rule When dealing with granular materials, a non-associated plastic flow rule is needed (Nova and Wood, 1979), allowing for plastic contractancy or dilatancy depending on whether loose or dense materials are analyzed. Here, the plastic flow rule is borrowed from Manzari and Dafalias (1997):

$$d\epsilon^p_{hk} = d\lambda \left(n^{dev}_{ij} - \frac{1}{3} D\delta_{ij} \right) \tag{104.446}$$

where $d\lambda$ is the plastic multiplier, n^{dev}_{ij} is a deviatoric unit tensor ($\|n^{dev}_{ij}\| = 1$) and D is a dilatancy coefficient defined as (Manzari and Dafalias, 1997):

$$D = \xi \left(\alpha^d_{ij} - \alpha_{ij} \right) n^{dev}_{ij} = \xi \left(\sqrt{\frac{2}{3}} k_d n^{dev}_{ij} - \alpha_{ij} \right) n^{dev}_{ij} \tag{104.447}$$

in which ξ and k_d are two positive constitutive parameters. While the former controls the amount of volumetric plastic strain, the latter determines the position of the so called "dilatancy surface" and rules the transition from contractive ($D > 0$) to dilative ($D < 0$) behavior.

The kinematic hardening evolution of the yield locus is imposed via the standard Prager translation rule for the (deviatoric) back-stress ratio (Borja and Amies, 1994):

$$d\alpha_{ij} = \|d\alpha_{ij}\| n^{dev}_{ij} \tag{104.448}$$

with both n^{dev}_{ij} and the norm $\|d\alpha_{ij}\|$ to be determined.

Vanishing elastic region and consistency condition As previously mentioned, the most notable feature of the present model concerns the vanishing elastic domain, corresponding with the limit $k \to 0$ in Equation (104.443). Accordingly, the Drucker-Prager cone reduces to its symmetry axis, so that:

$$\lim_{k\to 0} f_y = 0 \Rightarrow \lim_{k\to 0} s_{ij} = p\alpha_{ij} \Rightarrow ds_{ij} = d\alpha_{ij} p + \alpha_{ij} dp \tag{104.449}$$

and, after substituting the Prager rule (104.448) (for more detailed derivation, see section 104.6.15.7):

$$n^{dev}_{ij} = \frac{ds_{ij} - \alpha_{ij} dp}{\|ds_{ij} - \alpha_{ij} dp\|} \tag{104.450}$$

The direction of the deviatoric plastic strain increment n^{dev}_{ij} depends on the variation of both the stress deviator and the mean pressure, which differs from the cohesive version by Borja and Amies (1994). It is also worth noting that purely hydrostatic stress increments ($ds_{ij} = 0$) from initial hydrostatic states ($\alpha_{ij} = 0$) yield $n^{dev}_{ij} = 0$ and thus generates no deviatoric plastic strains.

From a theoretical standpoint, since the direction of the deviatoric plastic strain increment n^{dev}_{ij} depends on $d\sigma_{ij}$, the resulting constitutive formulation can be properly defined as "hypoplastic", this being a spontaneous outcome of the limit operation applied on the elastic region (Dafalias, 1986).

The norm of the back-stress increment in Equation (104.448) is obtained by imposing the standard consistency condition, that is the fulfillment of $df_y = 0$ during plastic loading (section 104.6.15.7):

$$df_y = 0 \Leftrightarrow \frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} + \frac{\partial f}{\partial \alpha_{ij}} d\alpha_{ij} = 0 \tag{104.451}$$

whence:

$$\|d\alpha_{ij}\| = \frac{1}{pN^{dev}} \frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} \tag{104.452}$$

and $N^{dev} = \| \left(\partial f_y / \partial \sigma_{ij}\right)^{dev} \| = 3\|s_{ij} - p\alpha_{ij}\|$. From Equation (104.452), the norm of $d\alpha_{ij}$ can be further specified for the case of radial loading paths in the deviatoric plane, characterized by the nullity of dp and the coaxiality of s_{ij}, α_{ij} and their increments. After simple manipulations (see section 104.6.15.7) this results in:

$$\|d\alpha_{ij}\| = \sqrt{\frac{2}{3}} \frac{dq}{p} \tag{104.453}$$

where $q = \sqrt{3/2}\|s_{ij}\|$ stands for the usual deviatoric stress invariant.

Hardening relationship and plastic multiplier An incremental hardening relationship is directly established (Borja and Amies, 1994):

$$dq = \sqrt{\frac{2}{3}} H \|de^p_{ij}\| \tag{104.454}$$

where H is the hardening modulus. Then, the substitution of both the flow rule (104.446) and the hardening relationship (104.454) into (104.453) leads to:

$$\|d\alpha_{ij}\| = \frac{2}{3} \frac{H d\lambda}{p} \tag{104.455}$$

By equaling the right–hand sides of Equations (104.441) and (104.449) the following relationship is obtained:

$$2G_{max} \left(de_{ij} - d\lambda n^{dev}_{ij}\right) = \|d\alpha_{ij}\| n^{dev}_{ij} p + \alpha_{ij} dp = \frac{2}{3} \frac{H d\lambda}{p} n^{dev}_{ij} p - \alpha_{ij} K \left(d\epsilon_{vol} + d\lambda D\right) \tag{104.456}$$

whence:

$$d\lambda = \frac{2G_{max}\|de_{ij}\| + Kd\epsilon_{vol}\alpha_{ij}n_{ij}^{dev}}{2G + \frac{2}{3}H - KD\alpha_{ij}n_{ij}^{dev}} \tag{104.457}$$

Equation (104.457) represents the consistent "frictional" generalization of Equation (18) in Borja and Amies (1994), as well as the limit of Equation (12) in Manzari and Dafalias (1997)[67] for a vanishing yield locus size.

Stress projection, hardening modulus and unloading criterion The bounding surface plasticity theory relies on the basic concept that the plastic modulus explicitly depends on the distance between the current stress state and an *ad hoc* stress projection onto the bounding surface. While Borja and Amies (1994) defined a purely deviatoric projection operator, here the whole stress state is involved:

$$\bar{\sigma}_{ij} = \sigma_{ij} + \beta\left(\sigma_{ij} - \sigma_{ij}^{0}\right) \tag{104.458}$$

where β is a scalar distance coefficient and σ_{ij}^{0} embodies the stress state at the last stress reversal (Figure 104.14). The coefficient β must be such that the projected stress $\bar{\sigma}_{ij}$ lies on the bounding surface (Equation (104.445)):

$$\frac{3}{2}\bar{s}_{ij}\bar{s}_{ij} = M^2\bar{p}^2 \tag{104.459}$$

whence, after substituting (104.458) into (104.459), β can be obtained as the positive root of the following second-order algebraic equation:

$$\begin{aligned} &\left[\left\|s_{ij} - s_{ij}^{0}\right\|^2 - \frac{2}{3}M^2\left(p - p_0\right)^2\right]\beta^2 + \\ 2&\left[\left(s_{ij} - s_{ij}^{0}\right)s_{ij} - \frac{2}{3}M^2 p\left(p - p_0\right)\right]\beta + \\ &\left[\|s_{ij}\|^2 - \frac{2}{3}M^2p^2\right] = 0 \end{aligned} \tag{104.460}$$

Apparently, the limit situations $\beta = 0$ and $\beta \to \infty$ correspond with the current stress state being right on the bounding locus or at instantaneous unloading (stress reversal).

In principle, any analytical relationship can be adopted to relate H and β, as long as two fundamental requirements are satisfied, i.e. $H(\beta = 0) = 0$ and $H(\beta \to \infty) \to \infty$: the former ensures the material shear strength to be fully mobilized when the bounding surface is attained; the latter guarantees an

---

[67] Different signs result because of the opposite sign conventions adopted by these authors

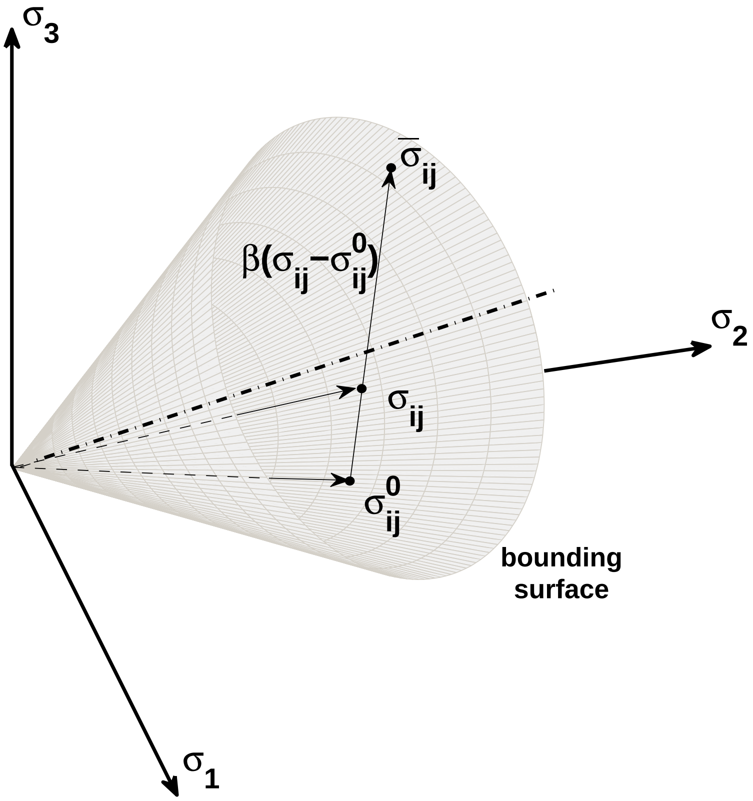

Figure 104.14: Representation of the stress projection onto the bounding surface.

instantaneous elastic stiffness upon any stress reversal, as is explained next. In this case, the expression by Borja and Amies (1994) has been extended to frictional media by accounting for the influence of the mean pressure:

$$H = ph\beta^m \tag{104.461}$$

in which h and m are two additional constitutive parameters.

The last element of the model formulation is the unloading criterion, which in this case is ill-defined due to the lack of the elastic region and the yield surface. The same multiaxial unloading criterion suggested by Borja and Amies (1994) is employed, based on the observation that the hardening modulus H increases at the onset of unloading. Accordingly, as long as $H(\beta)$ is a monotonically increasing function, instantaneous unloading is assumed to occur whenever $dH > 0$, i.e. $d\beta > 0$. The variation of β (and thus its sign) can be readily derived by substituting (104.458) into (104.459), and then differentiating the latter with respect to β:

$$d\beta = -(1+\beta)\,\frac{\bar{s}_{ij} ds_{ij} - \dfrac{2}{3} M^2 \bar{p} dp}{\bar{s}_{ij}\left(s_{ij} - s^0_{ij}\right) - \dfrac{2}{3} M^2 \bar{p}\left(p - p^0\right)} > 0 \tag{104.462}$$

It is worth noting that the variation of β, $d\beta$, plays here the same role of the scalar product $\left(\partial f/\sigma_{ij}\right) d\sigma_{ij}$ in standard elastic-plastic models, i.e. it defines the alternatives of elastic-plastic loading ($d\beta < 0$), neutral loading ($d\beta = 0$) or elastic unloading ($d\beta > 0$). The last key point concerns the update of the stress σ^0_{ij} in Equation (104.458), which must be set equal to the current stress state when $d\beta > 0$ is instantaneously found.

Possible refinements The frictional model has been developed trying to keep the number of material parameters as low as possible, even with a non-associated flow rule. However, it is worth mentioning which kind of improvements might be introduced if required by the problem under examination.

It should be first noted that, as a Drucker-Prager type bounding surface has been adopted, the material shear strength is unaffected by the Lode angle, so that for instance the same failure obliquity is predicted for triaxial compression and extension. This drawback could be easily remedied by modifying the deviatoric cross-section of the bounding surface itself, e.g. by adopting the well known Mohr-Coulomb deviatoric locus or other smooth loci (Matsuoka and Nakai, 1974; Willam and Warnke, 1974; Lade, 1977). A change in the deviatoric cross-section would negligibly influence the overall formulation, as just the evaluation of the projection distance β and of its increment should be modified (Equations (104.459)-(104.460) and (104.462)).

Secondly, the present version of the model cannot predict a possible brittle behavior of the soil, usually taking place in the case of dense materials. Constitutive brittleness could be accounted for by incorporating a further isotropic hardening mechanism at the bounding surface level, allowing for a gradual shrinkage of the outer surface during plastifications.

Another relevant point is about the fact that different parameters must be calibrated for different relative densities of the same granular material, as if distinct materials were indeed considered. As a matter of fact, continuous transitions from loose to dense states (and vice versa) spontaneously take place during straining: this aspect has been successfully addressed and reproduced via the concept of “state parameter” (Been and Jefferies, 1985; Wood et al., 1994; Manzari and Dafalias, 1997), which could be also introduced into a critical-state version of the proposed model.

The above and further refinements – related for instance to non-linear elastic behavior, anisotropy, fabric effects, delayed plastic response, etc. – might result in a more accurate soil model, implying though higher difficulties in terms of calibration, implementation and, as a consequence, practical employment.

104.6.15.3 The role of linear viscous damping

An additional viscous mechanism (Equation (104.439)) can be usually exploited in finite element (FE) analysis, even though it is not directly included in the constitutive model. Indeed, many numerical codes solve discrete systems with a viscous damping term (Equation (104.438)), usually assembled as a linear combination of the mass and the (elastic) stiffness matrices (Rayleigh formulation (Argyris and Mlejnek, 1991; Chopra, 2000)):

$$\mathbf{C} = a_0\mathbf{M} + a_1\mathbf{K}^e \tag{104.463}$$

where a_0 and a_1 are two constant parameters, related to the n^{th} modal damping ratio ζ_n of the discrete structural system.

It could be easily shown that a constitutive viscosity of the form:

$$\sigma^v_{ij} = D^v_{ijhk}\dot{\epsilon}_{hk} \tag{104.464}$$

gives rise to a stiffness-proportional damping matrix, which can be equivalently reproduced through the following calibration of the Rayleigh damping parameters (Borja et al., 2000; Hashash and Park, 2002):

$$a_0 = 0 \qquad a_1 = \frac{2\zeta_0}{\omega} \tag{104.465}$$

The calibration (104.465) establishes the same ratio between tangential/bulk elastic and the viscous moduli, that is $G^e_{max}/G^v_{max} = K^e/K^v$. More importantly, a damping ratio ζ_0 is ensured for a given circular frequency ω, as long as the parallel resisting mechanism (σ^f_{ij}) is purely elastic; as a consequence, provided the a_1 value at the beginning of the analysis, modal frequencies and the corresponding damping ratios are linearly related.

It is also worth remarking some further points about the implications of linear viscous damping in conjunction with non-linear soil models. If a soil element undergoes an imposed shear strain history, the overall shear stress/strain cycles $\tau - \gamma$ differ from the purely frictional component $\tau^f - \gamma$, this difference being due to the viscous shear stress τ^v. As will be shown in next section, the viscous component implies smoother cycles and avoid the sharp transitions at stress reversal usually exhibited by purely elastic-plastic responses (Borja et al., 2000). However, the overall G/G_{max} ratio between the average cyclic stiffness and the elastic shear modulus is unaffected by viscosity.

As far as the damping ratio is concerned, its standard definition (Kramer, 1996a) can be easily adapted to point out the frictional/viscous splitting of the energy ΔW dissipated in a loading cycle:

$$\zeta = \frac{\Delta W}{2\pi G \gamma_{max}^2} = \frac{\Delta W^f + \Delta W^v}{2\pi G \gamma_{max}^2} = \zeta^f + \zeta^v \tag{104.466}$$

where γ_{max} is the imposed cyclic shear strain amplitude and G the corresponding (secant) cyclic shear stiffness. As γ_{max} approaches zero, the plastic dissipation tends to zero as well, so that $\zeta = \zeta^v$; therefore, the Rayleigh parameter a_1 can be calibrated to obtain $\zeta(\gamma_{max} \to 0) = \zeta_0$ for a given circular frequency ω (see Equation (104.465)). This is a desirable feature of the model, as natural soils are well known to dissipate energy at even very small strain amplitudes.

At progressively larger strains, both the frictional and viscous components contribute to the global damping, although the relative quantitative significance is hard to assess *a priori*. In addition, the viscous component of the ζ–γ_{max} curve is not constant, since ζ^v depends on the strain-dependent secant modulus $G(\gamma_{max})$ and, implicitly, on the strain rate. This is different to what has been argued by Borja et al. (2000).

As an example, consider the response of an elastic-perfectly plastic model with additional viscosity under a sinusoidal shear excitation $\gamma(t) = \gamma_{max} \sin(\omega t)$. The simplicity of the elastic-perfectly plastic response allows derivation of instructive analytical formulas for the G/G_{max} and the damping ratios, even in the presence of viscous dissipation. While $\gamma_{max} < \gamma_y$ (yielding shear strain), the material behavior is linear elastic, so that $G/G_{max} = 1$ and ζ equals the purely viscous contribution at $\gamma_{max} = 0$, i.e. $\zeta = \zeta_0$; γ_y depends on the elastic stiffness and the shear strength of the material, $\gamma_y = \tau_{lim}/G_{max}$, where τ_{lim} is the limit (frictional) shear stress for a given confining pressure. For $\gamma_{max} > \gamma_y$ plastifications take place with a flat elastic-perfectly plastic $\tau^f - \gamma$ branch, and the following expressions can be easily derived:

$$\frac{G}{G_{max}} = \frac{\tau_{lim}}{G_{max}\gamma_{max}} \tag{104.467}$$

$$\zeta = \frac{\Delta W^f + \Delta W^v}{2\pi G \gamma_{max}^2} = \underbrace{\frac{2}{\pi}\left(1 - \frac{\tau_{lim}}{G_{max}\gamma_{max}}\right)}_{\zeta^f} + \underbrace{\zeta_0 \frac{G_{max}\gamma_{max}}{\tau_{lim}}}_{\zeta^v} \tag{104.468}$$

In Figure 104.15 the G/G_{max} and ζ ratios are plotted for increasing ζ_0 values. As γ_{max} increases, the frictional damping tends to $2/\pi \approx 0.63$, while the viscous one keeps increasing because of the reduction in the secant stiffness and the increase in the shear strain rate (depending on the strain amplitude). Hence, the value of ζ_0 is to be carefully chosen, in order to avoid excessive dissipation when medium/large strains are induced by the loading process.

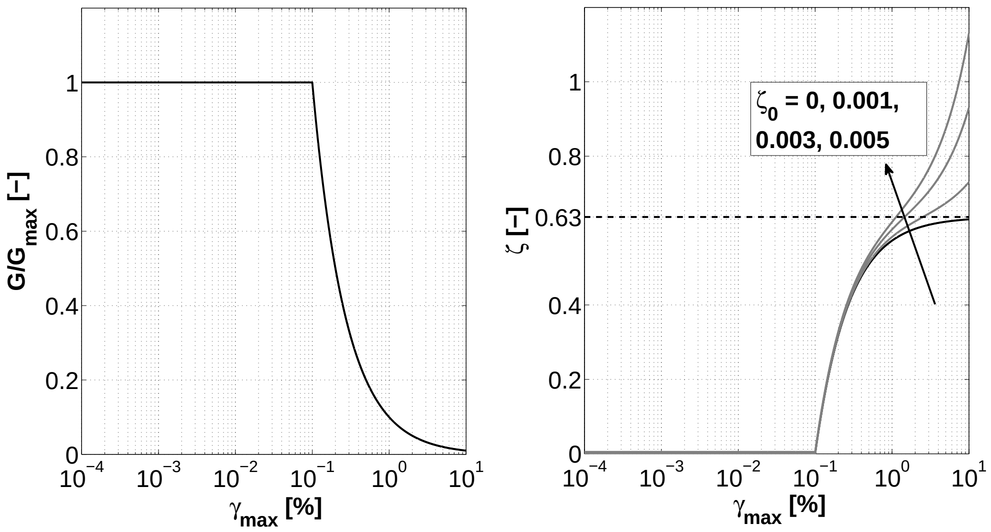

Figure 104.15: G/G_{max} and damping curves for a elastic-perfectly plastic model with linear viscous damping at varying ζ_0 (τ_{lim}=100 kPa, G_{max}=100 MPa)

The fact that the viscous mechanism can modify the purely frictional $\zeta-\gamma_{max}$ curve without altering the cyclic stiffness degradation can be fruitfully exploited to remedy the (frequent) cases in which the experimental-numerical agreement is not satisfactory in terms of energy dissipation properties.

104.6.15.4 Model performance and calibration

The frictional mechanism of the above model is characterized by a rather low number of material parameters, namely the following seven:

- two elastic parameters, the Young modulus E (or the shear modulus G_{max}) and the Poisson's ratio ν;
- the shear strength parameter M for the definition of the bounding surface (Equation (104.445));
- the flow rule parameters, ξ and k_d, governing the increment of the volumetric plastic strain under shearing and the size of the dilatancy surface, respectively (Equation (104.446));
- the hardening parameters h and m for the dependence of the hardening modulus on the distance coefficient β (Equation (104.461)), affecting the pre-failure deformational behavior and, in overall, the resulting dynamic properties (G/G_{max} and damping curves).

Provided a reasonable value for the Poisson's ratio (usually in the range $0.25-0.3$), the small-strain elastic stiffness can be evaluated from dynamic laboratory (RC tests) or *in situ* (seismic geophysical surveys) tests. As far as the shear strength is concerned, the parameter M can be related to the friction angle ϕ as follows:

$$M = \frac{6 \sin \phi}{3 \pm \sin \phi} \tag{104.469}$$

depending on whether triaxial compression (sign – in (104.469)) or extension (sign + in (104.469)) failure conditions are to be reproduced (a change in the deviatoric section of the bounding surface would allow to capture both compressive and extensive limits).

The calibration of the flow rule parameters, ξ and k_d, requires at least a triaxial test to be performed, in order to obtain some information about the volumetric behavior. Figure 104.16 shows the predicted triaxial response for three different values of k_d (and fixed ξ), that is by varying the opening angle of the dilatancy surface (the employed parameters are reported in the figure caption, where p_0 stands for the initial mean pressure).

While the limit stress deviator q is exclusively given by M, the pre-failure behavior is influenced by the plastic deformability and therefore by k_d. The model possesses sufficient flexibility to reproduce contractive, dilative or contractive/dilative behavior; also, such a feature is necessary to reproduce undrained conditions (liquefying and non-liquefying responses), this being a further motivation for non-associativeness when dealing with sandy materials.

Figure 104.17 exemplifies the response predicted under pure shear (PS) cyclic loading, applied as a sinusoidal shear strain history (γ_{max} = $0.2\%, 20\%$, period T=2π s) at constant normal stresses (and thus constant mean pressure p_0 as well. This corresponds with a radial loading path on the deviatoric plane); for the sake of clarity, the volumetric plastic response has been inhibited (ξ=0), in order to evaluate the deviatoric mechanism exclusively. Both purely frictional (solid line) and frictional/viscous (dashed line) responses are plotted.

Owing to the kinematic hardening of the vanished yield locus, the model is capable of reproducing both the Bauschinger and the Masing effects, the latter implying the stabilization of the cyclic response to take place after more than one loading cycle. As expected, the additional viscous damping increases the area of the cyclic loop and therefore the overall dissipated energy; however, the effect of the viscous dissipation becomes significant only at medium-high shear strains, corresponding – for a given loading frequency – with higher strain rates. Further, viscosity causes the aforementioned "smoothing" of stress reversals, as it can be readily noticed in Figure 104.18 by comparing the purely frictional and the frictional/viscous responses.

Given the elastic stiffness and the strength of the soil, the shape of the resulting loading cycles is totally governed by the hardening properties, by h and m in Equation (104.461): this directly affects the simulation of experimental G/G_{max} and damping curves, which can be therefore exploited for the

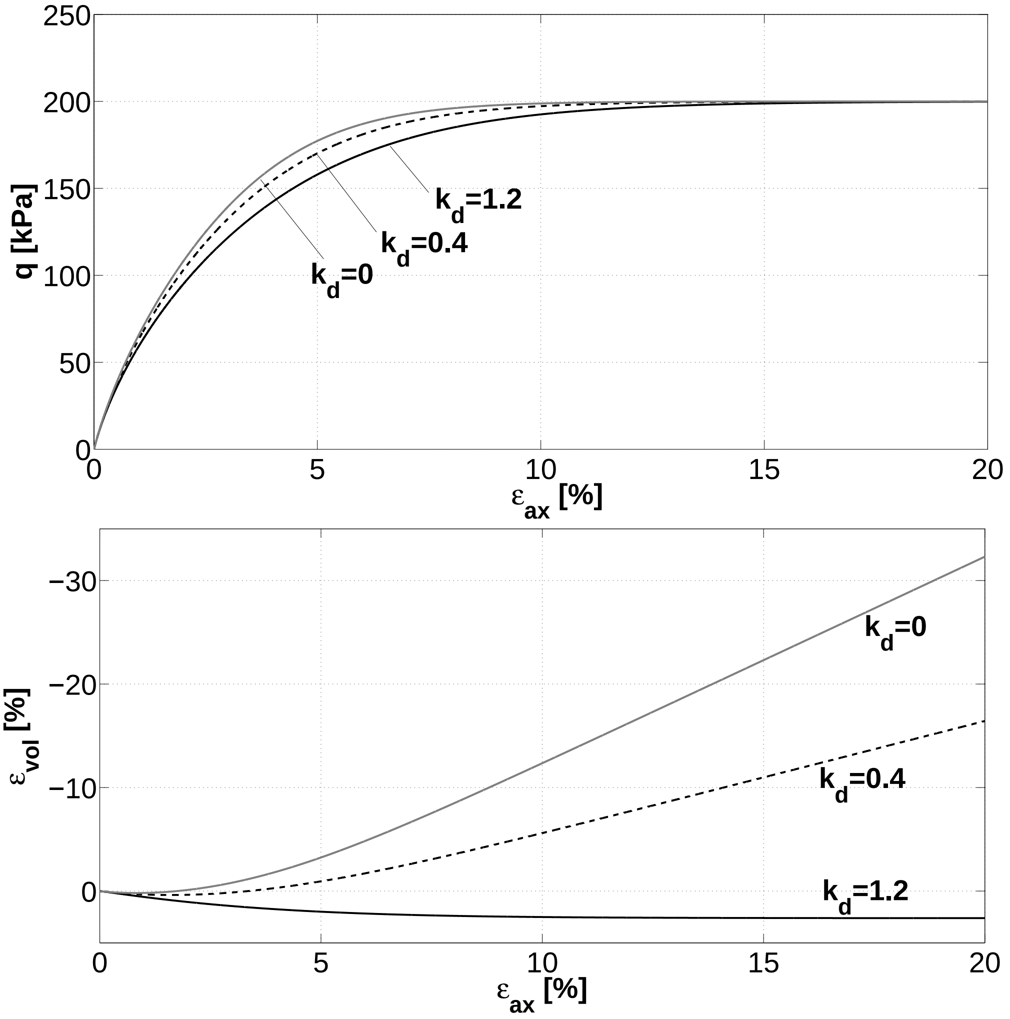

Figure 104.16: Predicted triaxial responses for different dilatancy surfaces (p_0=100 kPa, G_{max} = 4 MPa, ν=0.25, M=1.2, ξ=1, h=$G/(1.5p_0)$, m=1)

calibration of both h and m. As can be easily demonstrated (the proof is given in section 104.6.15.7), the following equality holds under PS loading conditions, i.e. under constant pressure shearing:

$$1 = \frac{G}{G_{max}} \left[1 + \frac{6G_{max}}{hp_0\gamma_{max}} \int_0^{\gamma_{max}} \left(\frac{\gamma}{\tau_{lim}/G - 2\gamma + \gamma_{max}} \right)^m d\gamma \right] \tag{104.470}$$

where $\tau_{lim} = Mp_0/\sqrt{3}$. Relationship (104.470) has been obtained by integrating the constitutive equations over the first loading cycle, and represents the frictional counterpart of Equation (6) in Borja et al. (2000) – as is testified by the explicit influence of the confining pressure p_0. The proper use of Equation (104.470) requires first the choice of two meaningful points on the G/G_{max} experimental curve, i.e. two $(\gamma_{max}, G/G_{max})$ couples; then, the unknowns h and m are obtained by solving the integral system arising

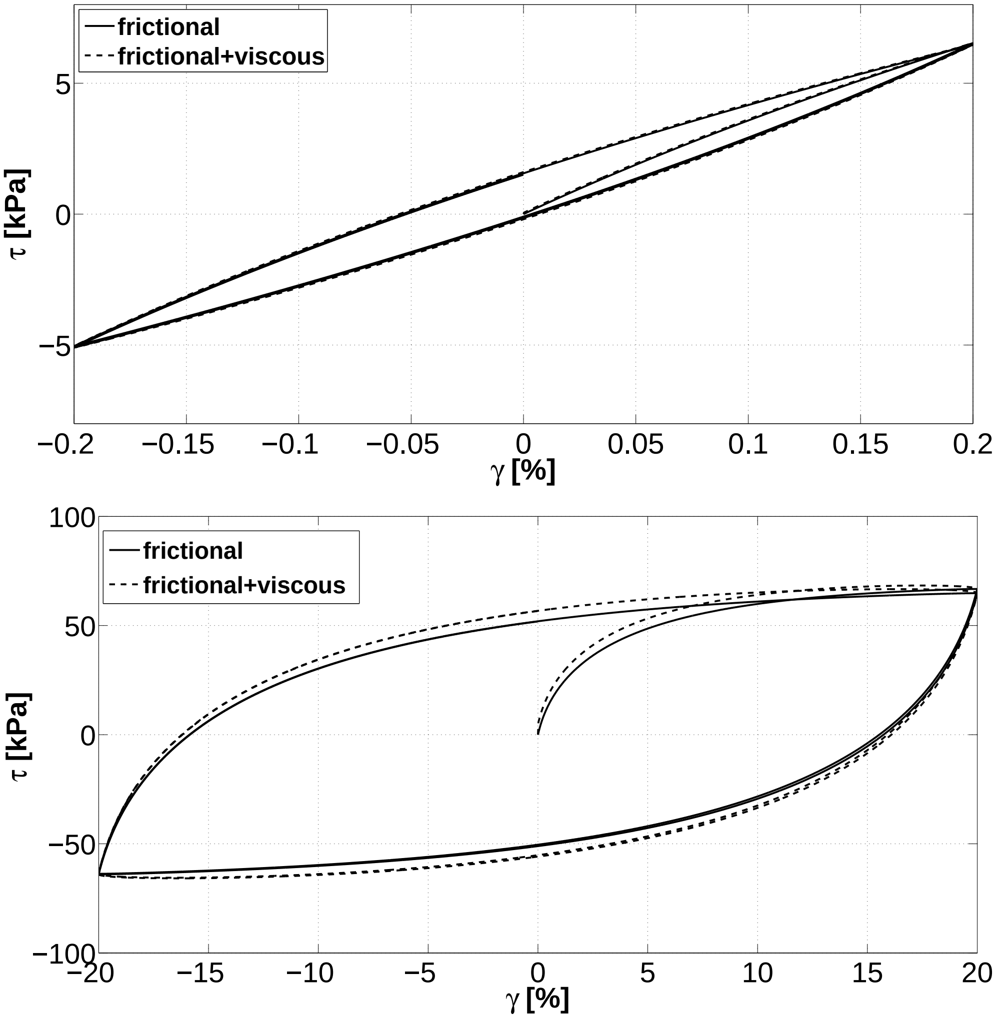

Figure 104.17: Predicted pure shear response at two different shear strain amplitudes (p_0=100 kPa, T=2π s, ζ_0 = 0.003, G_{max}= 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G/(1.5p_0)$, m=1)

from the specification of Equation (104.470) for both selected $(\gamma_{max}, G/G_{max})$ couples.

Figure 104.19 illustrates the result of the above calibration procedure, applied on the G/G_{max} and ζ curves for sands implemented into the code EERA (Bardet et al., 2000) and formerly obtained by Seed and Idriss (1970b).

Since Equation (104.470) exclusively accounts for the G/G_{max} curve, the very satisfactory agreement in terms of stiffness degradation (viscosity has no effect on it) should not surprise. On the other hand, once h and m are set, the predicted damping curve may or may not match the experimental outcome irrespective of the calibration procedure. In this respect, Figure 104.19 also presents the comparison between the damping curve by Seed and Idriss and the model prediction. The frictional ζ curve lies in the same experimental range, even though the accuracy at γ_{max} = $0.03-1\%$ is not as good as for the

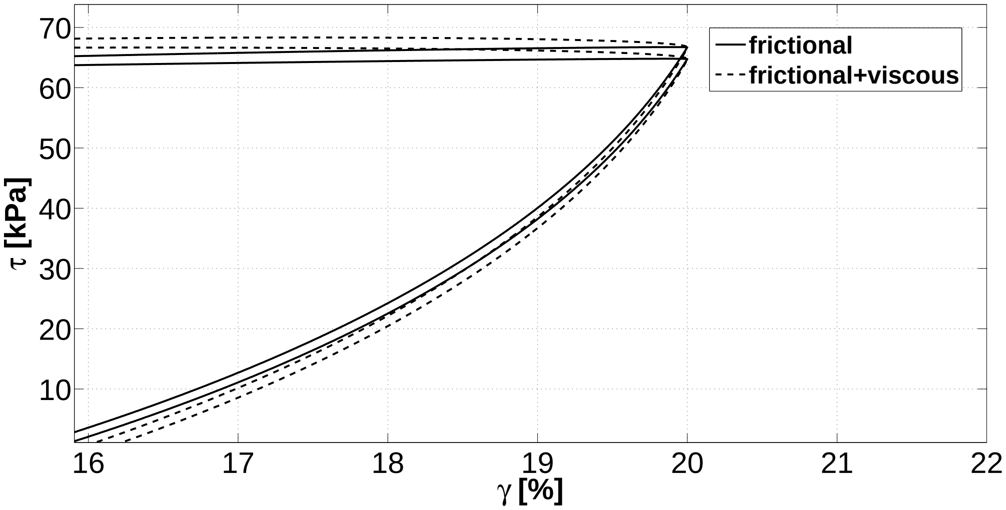

Figure 104.18: Detail of stress reversals for the pure shear response in Figure 104.17 (γ_{max} = 20%)

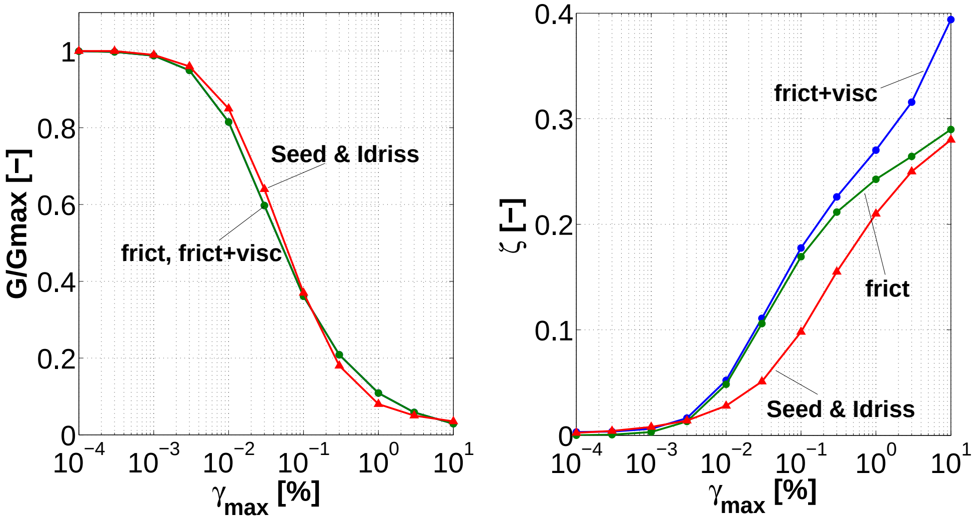

Figure 104.19: Comparison between experimental and simulated G/G_{max} and damping curves (p_0=100 kPa, T=2π s, ζ = 0.003, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G/(112p_0)$, m=1.38)

G/G_{max} ratio. In this case, the contribution of the viscous mechanism is practically non-existent, as it only increases the total ζ ratio for $\gamma_{max} > 0.1\%$.

Depending on the specific application, a "trial and error" calibration might be preferable, sacrificing some of the accuracy in terms of G/G_{max} ratio to improve the damping performance. A possible outcome of a manual calibration is plotted in Figure 104.20: apparently, while the simulation of the stiffness curve is still acceptable, the damping curve appears to be much better than the previous one. The use of the viscous mechanism seems to be highly beneficial, since it remedies the lack of accuracy in the frictional curve at medium/large cyclic strains.

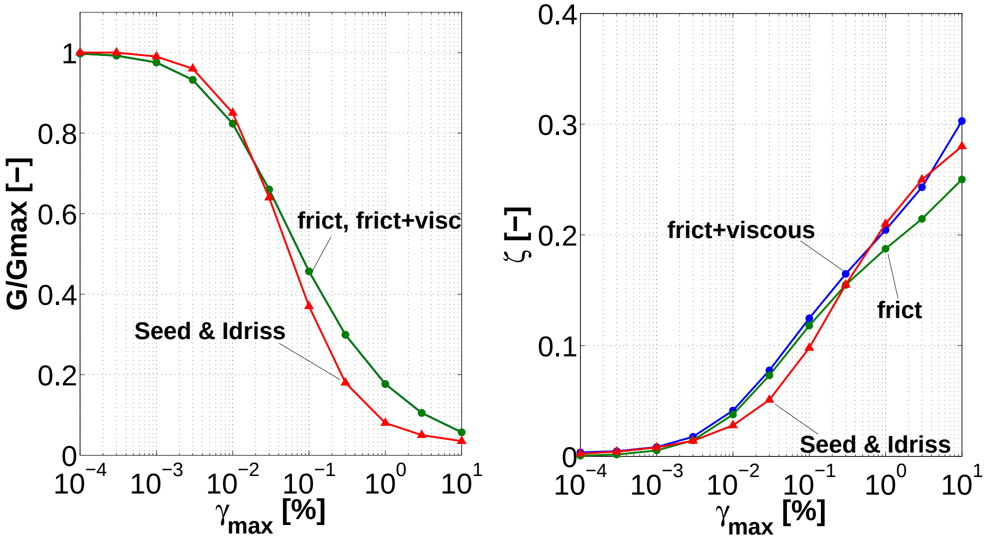

Figure 104.20: Comparison between experimental and simulated G/G_{max} and damping curves (p_0=100 kPa, T=2π s, $\zeta = 0.003$, $G_{max} = 4$ MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G_{max}/(15 p_0)$, m=1)

It is also worth noting that the experimental/numerical agreement is good up to γ_{max} = 10%, this being a rather high cyclic strain level, for equivalent elastic modeling of soil. In fact, even though the interpretation of experimental cyclic tests is questionable when substantial plasticity occurs, the proposed model produces, within a different framework, the same mechanical response incorporated into traditional equivalent-linear approaches. Besides, if the experimental data under examination are unsatisfactorily reproduced for any h and m combination, the user still has the chance of substituting the interpolation function (104.461) with no further changes in the model formulation.

104.6.15.5 Parametric analysis

In this section the sensitivity of the model predictions to some relevant input parameters is parametrically investigated.

Influence of the confining pressure Figure 104.21 illustrates the sensitivity, under PS loading, of both G/G_{max} and damping frictional curves to the initial confining pressure. As can be noticed, increasing p_0 does enlarge the "pseudo-elastic" range, that is the strain interval within which the deviation by the elastic behavior is negligible even with a vanishing yield locus. It is also noted that the variations in the confining pressure do not imply appreciable changes in the shape of the curves.

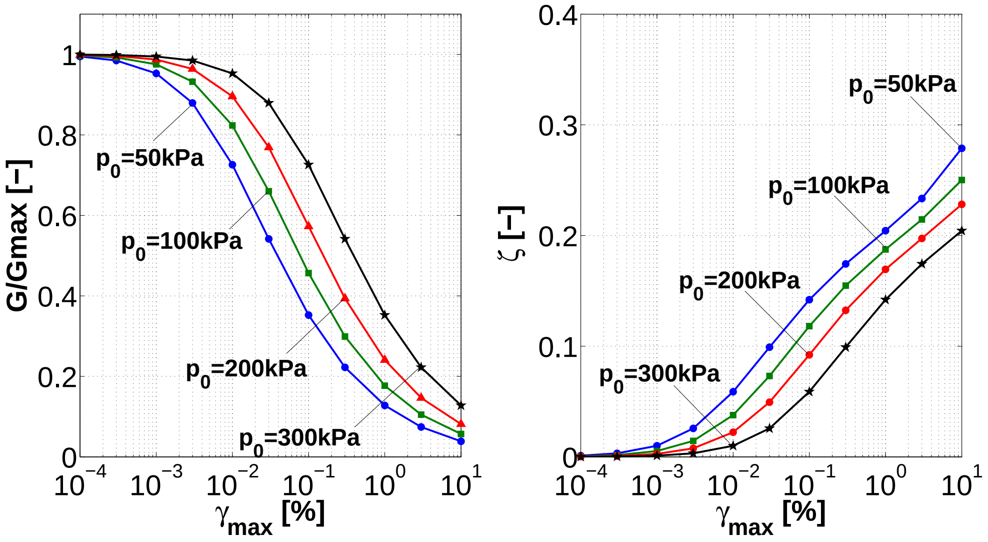

Figure 104.21: Simulated G/G_{max} and damping curves at varying confining pressure (T=2π s, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G/(15p_0)$, m=1)

Influence of the hardening parameters Figures 104.22 and 104.23 show the influence of the hardening parameters h and m on the predicted cyclic properties. As the material strain-hardening is accelerated by decreasing either h or m, the pseudo-elastic range tends to disappear, so that $G/G_{max} < 1$ and $\zeta > 0$ at even $\gamma_{max} = 10^{-4}\%$; conversely, an extended pseudo-elastic behavior can be obtained over a large strain range by increasing the hardening parameters. Apparently, the model ensures high flexibility in terms of cyclic curve shapes, so that the response of standard elastic-plastic models (i.e. with non-vanishing elastic region) can be smoothly approximated (compare for instance the $m = 3$ curves in Figure 104.23 and the analytical elastic-perfectly plastic frictional curves in Figure 104.15).

Influence of the viscous mechanism The influence of the viscous parameter ζ_0 on the resulting frictional/viscous damping curve is illustrated in Figure 104.24 (the G/G_{max} is not affected by the parallel viscous mechanism). As was expected, an increase in ζ_0 induce larger values of $\zeta\,(\gamma_{max} \rightarrow 0)$, as well as a faster increase of the ζ curve at medium/high cyclic strains. Figure 104.24 confirms the suitability of the viscous mechanism, as an additional degree of freedom for reproducing the cyclic dissipative soil behavior.

Influence of the volumetric behavior in constrained problems So far, all the simulations have been performed by inhibiting the elastic-plastic soil dilatancy ($\xi = 0$), which in most cases cannot be done to represent real soil behavior. As previously shown for triaxial loading conditions (Figure 104.16), in the absence of kinematic boundary constraints, a variation in the volumetric behavior slightly affects only the

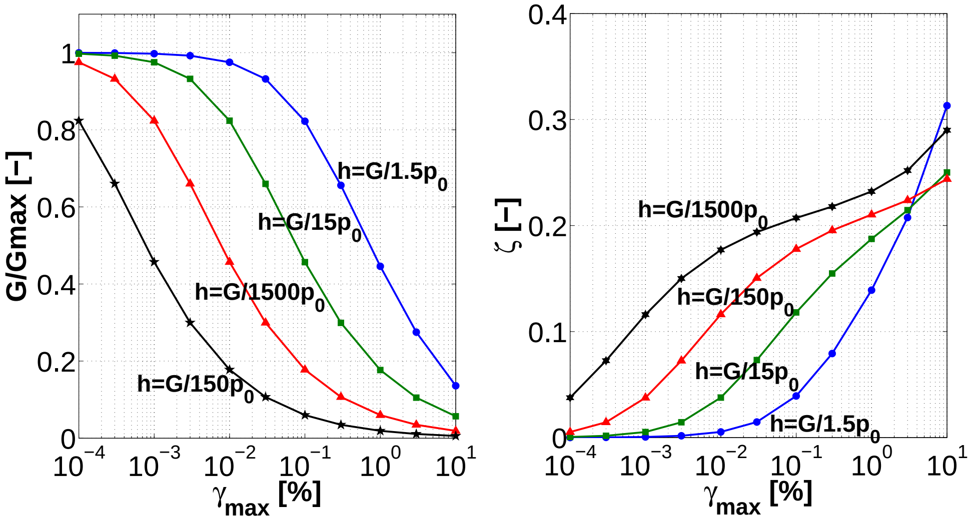

Figure 104.22: Simulated G/G_{max} and damping curves at varying h (p_0=100 kPa, T=2π s, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, m=1)

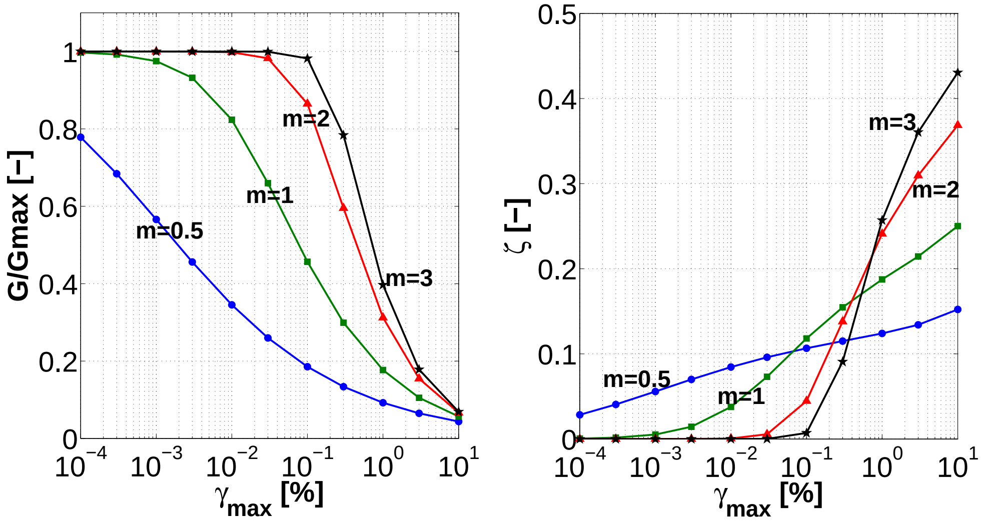

Figure 104.23: Simulated G/G_{max} and damping curves at varying m (p_0=100 kPa, T=2π s, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G_{max}/(15p_0)$)

hardening evolution of the stress-strain response toward the limit shear strength; a similar consideration applies to PS loading conditions, since even in this case the normal confinement is statically determined.

However, computational (FE) models contain kinematic constraints arising from certain symmetries (consider plane strain or one-dimensional schemes) (Prevost, 1989; Borja et al., 1999; di Prisco et al., 2012). In addition, for SSI problems, where soil interacts with a (stiff) structural foundations and wall, the soil volume change plays an important role. The presence of kinematic constraints implies that some

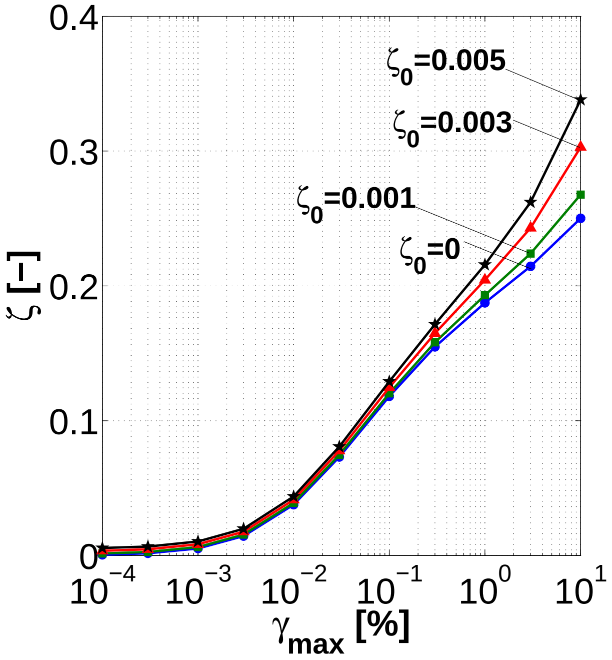

Figure 104.24: Damping curves simulated at varying ζ_0 (p_0=100 kPa, T=2π s, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=ξ=0, h=$G_{max}/(15p_0)$, m=1)

stress components are to be derived through compatibility conditions (e.g. prevented lateral expansion). That means that the local mean confinement is directly affected by the tendency of the material to dilate or contract. In particular, dilative frictional materials will increase the limit shear stress (with respect to unconfined conditions), while compactive frictional materials will decrease the limit shear stress. Further, not only the limit shear stress, but also the whole pre-failure response depends on the plastic flow rule whenever kinematic constraints are imposed (di Prisco and Pisanò, 2011; di Prisco et al., 2012).

The above considerations suggest that both experimental and numerical results are certainly affected by the kinematics of the system, even though this effect is not easy to be *a priori* quantified in terms of, for instance, G/G_{max} and damping curves. The kinematic conditions of an infinite soil layer during 1D shear wave propagation are experimentally approximated through the well known "simple shear (SS) apparatus" (Wood, 2004), in which the soil specimen is cyclically sheared with no lateral expansion allowed. In order to assess how the kinematic confinement influences the cyclic response, stiffness degradation and damping curves are hereafter simulated under SS conditions by varying the volumetric response of the soil; in particular, three different calibrations of the plastic flow rule (104.446) are considered, namely (i) isochoric ($k_d = \xi = 0$), (ii) compactive ($k_d = M$, $\xi = 1$) and (iii) dilative ($k_d = 0.4$, $\xi = 1$)

The results reported in Figure 104.25 provide an insight into the possible effect of the volumetric response in combination with constrained loading conditions. In the isochoric case, the PS and the SS curves perfectly match (compare e.g. with the p_0 =100 kPa curves in Figure 104.21), as, with no plastic expansion (or contraction), the lateral constraints do not affect the mean pressure during the shear loading; conversely, non-negligible SS-PS differences arise when dilative or contractive materials are considered. As is evident in Figure 104.25, the discrepancy between isochoric and non-isochoric curves becomes evident at medium/high cyclic strains, i.e. at the onset of significant plastifications. Indeed, while the mechanical response is barely inelastic, the deviatoric and the volumetric responses are practically decoupled, so that no variation of the normal confinement takes place.

Apparently, the quantitative significance of the above effects is strictly related to the actual dilational properties and confinement conditions. It can be in general concluded that the cyclic properties are expected to vary depending on specific loading conditions (triaxial, biaxial, simple shear, torsional shear, etc), so that, when numerical models are calibrated, this aspect should be always explicitly considered.

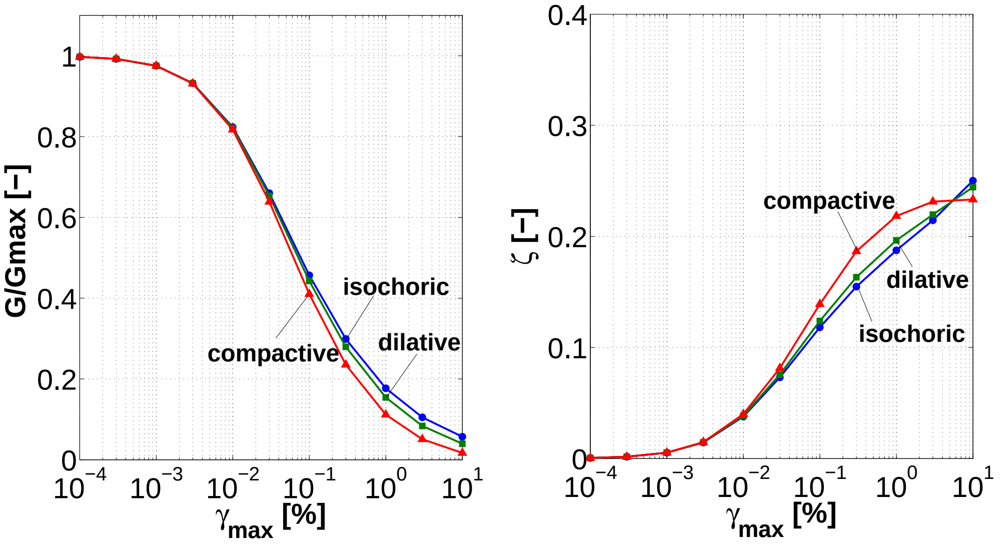

Figure 104.25: G/G_{max} and damping curves simulated under SS conditions and different volumetric responses (p_0=100 kPa, T=2π s, G_{max} = 4 MPa, ν=0.25, M=1.2, k_d=[1.2, 0.4], ξ=[0,1], h=$G_{max}/(15p_0)$, m=1)

104.6.15.6 Concluding remarks

An incremental 3D elastic-plastic constitutive model was developed to reproduce the mechanical response of soils under cyclic/dynamic loading. The model is based on an effective-stress formulation with two parallel dissipative mechanisms, purely frictional (elastic-plastic) and viscous.

As far as the frictional mechanism is concerned, a bounding surface formulation with vanishing elastic region was adopted, extending to the case of pressure-sensitive non-associative soils the previous cohesive model by Borja and Amies (1994) for total-stress analysis. Notable features of the frictional model are: (i) the vanishing yield locus implies an elastic-plastic response at any load levels, as is observed in real experiments; (ii) a minimum number of physically meaningful parameters, which can be easily calibrated on the basis of a few experimental data; (iii) excellent performance and flexibility in reproducing in the elasto-plastic framework the standard stiffness degradation and damping curves. With reference to these latter, the parallel viscous mechanism – easy to be introduced in FE computations – was shown to provide an additional degree of freedom to improve the simulation of the cyclic energy dissipation, as long as the viscous parameter is properly calibrated. As a matter of fact, the viscous mechanism, used here, does physically exist in the form of viscous interaction between the soil solid skeleton and the pore fluid(s), and needs to be taken into account (as for example done here).

Future work will concern the investigation of the model performance in dynamic problems with pronounced hydro-mechanical coupling (cyclic mobility and liquefaction), as well as the comparison of the present model and traditional equivalent-linear approaches in seismic site response and SSI analysis. Further research is also needed to evaluate the accuracy of the model under non-symmetric loading conditions, these being particularly important in seismic slope stability applications.

104.6.15.7 Derivations of Various Equations

Derivation for Equation (104.449) The vanishing size of the yield locus implies:

$$\lim_{k\to 0} s_{ij} = p\alpha_{ij} \Rightarrow ds_{ij} = d\alpha_{ij} p + \alpha_{ij} dp = \|d\alpha_{ij}\| n_{ij}^{dev} p + \alpha_{ij} dp \tag{104.471}$$

and, after substituting the Prager translation rule (104.448):

$$n_{ij}^{dev} = \frac{ds_{ij} - \alpha_{ij} dp}{\|d\alpha_{ij}\| p} = \frac{ds_{ij} - \alpha_{ij} dp}{\|ds_{ij} - \alpha_{ij} dp\|} \tag{104.472}$$

In this last equality the property $\|n_{ij}^{dev}\| = 1$ has been exploited.

Derivations for Equations (104.452) – (104.453) The consistency condition:

$$df_y = 0 \Leftrightarrow \frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} + \frac{\partial f}{\partial \alpha_{ij}} d\alpha_{ij} = 0 \tag{104.473}$$

results in the following equality chain

$$\frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} = 3p\left(s_{ij} - p\alpha_{ij}\right) \|d\alpha_{ij}\| n_{ij}^{dev} = 3p\left(s_{ij} - p\alpha_{ij}\right) \|d\alpha_{ij}\| \frac{3\left(s_{ij} - p\alpha_{ij}\right)}{N^{dev}} = 0 \tag{104.474}$$

leading to:

$$\|d\alpha_{ij}\| = \frac{\frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij}}{pN^{dev}} \tag{104.475}$$

where $N^{dev} = \| \left(\partial f_y / \partial \sigma_{ij}\right)^{dev} \| = 3\|s_{ij} - p\alpha_{ij}\|$. The above equation can be further simplified for the case of radial loading paths in the deviatoric plane, characterized by $d\sigma_{ij} = ds_{ij}$ and coaxiality between the current stress state and its increment:

$$\|d\alpha_{ij}\| = \frac{\frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij}}{pN^{dev}} = \frac{\frac{\partial f}{\partial \sigma_{ij}} ds_{ij}}{pN^{dev}} = \frac{\frac{\partial f}{\partial \sigma_{ij}}^{dev} ds_{ij}}{pN^{dev}} = \frac{n_{ij}^{dev} ds_{ij}}{p} = \frac{s_{ij} ds_{ij}}{p\|s_{ij}\|} \tag{104.476}$$

The final relationship can be re-expressed in terms of standards invariants $q = \sqrt{3/2}\|s_{ij}\|$ and p:

$$\|d\alpha_{ij}\| = \sqrt{\frac{2}{3}} \frac{dq}{p} \tag{104.477}$$

Derivation for Equation (104.470) Under PS loading conditions (constant mean pressure), Equation (104.458) can be reduced to a simpler scalar form:

$$\beta = \frac{\tau_{lim} - \tau}{\tau - \tau_0} \tag{104.478}$$

where $\tau_{lim} = Mp_0/\sqrt{3}$. By exploiting the previous definitions of deviatoric stress and strain invariants, the elastic-plastic response can be expressed as:

$$d\epsilon_d = \frac{dq}{3G_{max}} + \left(\frac{\tau - \tau_0}{\tau_{lim} - \tau}\right)^m \frac{dq}{hp_0} \tag{104.479}$$

and specialized to the case of PS loading:

$$\frac{d\gamma}{\sqrt{3}} = \frac{\sqrt{3} d\tau}{3G_{max}} + \left(\frac{\tau - \tau_0}{\tau_{lim} - \tau}\right)^m \frac{\sqrt{3} d\tau}{hp_0} \tag{104.480}$$

Integration over a strain interval between two stress reversals ($\gamma \in [-\gamma_{max}; \gamma_{max}]$) yields:

$$2\gamma_{max} = \frac{2\tau}{G_{max}} + \frac{3}{hp_0} \int_{-\tau}^{\tau} \left(\frac{\tau' + \tau}{\tau_{lim} - \tau'}\right)^m d\tau' \tag{104.481}$$

where $\tau_0 = -\tau$ has been set. Straightforward variable changes lead to:

$$1 = \frac{G}{G_{max}} + \frac{3}{2hp_0\gamma_{max}} \int_0^{2G\gamma_{max}} \left(\frac{\tau''}{\tau_{lim} - \tau'' + G\gamma_{max}}\right)^m d\tau'' \tag{104.482}$$

$$1 = \frac{G}{G_{max}} \left[1 + \frac{6G_{max}}{hp_0\gamma_{max}} \int_0^{\gamma_{max}} \left(\frac{\gamma}{\tau_{lim}/G - 2\gamma + \gamma_{max}} \right)^m d\gamma \right] \tag{104.483}$$

It is worth highlighting that two approximations are implicitly contained in Equation (104.483): (i) the integration over the first loading cycle does not exactly reproduce the stabilized cyclic response (because of the aforementioned Masing effect); (ii) a symmetric loading cycle in terms of shear strain does not in general ensure the symmetry of the corresponding shear stress range (as it is assumed in Equation (104.481)). However, such approximations do not prevent reasonable values for the hardening parameters h and m to be obtained.

104.6.16 Cosserat Elastoplasticity

Four components of the classical elastoplasticity.

- Elasticity law, E_{ijkl} and C_{ijkl}.
- Yield surface, $f(\sigma, t, \kappa)$
- Plastic flow direction, $m_{ij}^{force} = \frac{\partial Q(\sigma,t,\kappa)}{\partial \sigma_{ij}}$ and $m_{ij}^{curvature} = \frac{\partial Q(\sigma,t,\kappa)}{\partial t}$.
- Hardening law for internal variables, $\kappa = d\lambda h(\sigma, t)$.

where σ is the stress, and t is the couple-stress.

104.6.16.1 Elasticity Law

$$\begin{aligned} E_{ijkl} &= \lambda\delta_{ij}\delta_{kl} + \mu\delta_{ik}\delta_{jl} + (\mu + \chi)\delta_{jk}\delta_{il} \\ C_{ijkl} &= \pi_1\delta_{ij}\delta_{kl} + \pi_2\delta_{ik}\delta_{jl} + \pi_3\delta_{jk}\delta_{il} \end{aligned} \tag{104.484}$$

104.6.16.2 Yield Criterion

Hencky (1924) provided a physical interpretation of von Mises criterion suggesting that yielding begins when the elastic energy of distortion reaches a critical value.[4] So von Mises is called maximum distortion strain energy yield criterion.

In the von-Mises plasticity for the classical elasticity, the distortion extent is measured by

$$J_2 = \frac{1}{2} s_{ij} s_{ij} \tag{104.485}$$

where,

$$s_{ij} = \sigma_{ij} + p\delta_{ij} \tag{104.486}$$

In the von-Mises plasticity for the Cosserat elasticity, the distortion extent de Borst (1993) can be measured by

$$J_2 = \frac{1}{2}(h_1 s_{ij} s_{ij} + h_2 s_{ij} s_{ji} + h_3 t_{kl} t_{kl}/l^2) \tag{104.487}$$

where, $h_1 = 3/4$, $h_2 = -1/4$, and $h_3 = 1/8$. The length l is the characteristic length. The yield strength is

$$\sigma_y = \sqrt{3J_2} \tag{104.488}$$

such that the yield criterion is

$$f(\sigma, t) = \sqrt{3J_2} - k = \sqrt{\frac{3}{2}(h_1 s_{ij} s_{ij} + h_2 s_{ij} s_{ji} + h_3 t_{kl} t_{kl}/l^2)} - k \tag{104.489}$$

where k is a constant for perfectly plasticity, and k is a function of stress and couple-stress for hardening materials.

104.6.16.3 Plastic Flow

The plastic flow direction is

$$\begin{aligned} m_{ij}^{force} &= \frac{\partial Q(\sigma, t, \kappa)}{\partial \sigma_{ij}} \quad , \quad d\sigma_{ij} = d\lambda m_{ij}^{force} \\ m_{ij}^{curvature} &= \frac{\partial Q(\sigma, t, \kappa)}{\partial t} \quad , \quad dt_{ij} = d\lambda m_{ij}^{curvature} \end{aligned} \tag{104.490}$$

In the conventional elastoplasticity, the plastic potential function Q is a function of stress σ and the internal variables κ.

In the Cosserat elastoplasticity, the plastic potential function Q is a function of stress σ, couple-stress t, and the internal variables κ.

104.6.16.4 Hardening Rule

The hardening rule describes how to update the internal variables with the plastic multiplier.

$$dq = d\lambda h(\sigma, t, \kappa) \tag{104.491}$$

In the conventional elastoplasticity, the hardening rule is a function of stress σ and the internal variables κ.

In the Cosserat elastoplasticity, the hardening rule is a function for stress σ, couple-stress t, and the internal variables κ.

104.6.16.5 Forward Euler Algorithm

Forward Euler Algorithm uses the cross point on the yield surface as the starting point to calculate the plastic flow direction and the normal to the yield surface.

104.6.16.6 Explicit Formulation

The governing equation of the forward Euler, explicit algorithm is

$$\begin{aligned}
{}^{n+1}\boldsymbol{\sigma} + \lambda \boldsymbol{C}^{force} \boldsymbol{m}({}^{cross}\boldsymbol{\sigma}, {}^{cross}\boldsymbol{t}, {}^{cross}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{\sigma} + \boldsymbol{C}^{force} \triangle\boldsymbol{\epsilon} \\
{}^{n+1}\boldsymbol{t} + \lambda \boldsymbol{C}^{curvature} \boldsymbol{m}({}^{cross}\boldsymbol{\sigma}, {}^{cross}\boldsymbol{t}, {}^{cross}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{t} + \boldsymbol{C}^{curvature} \triangle\boldsymbol{\omega} \\
{}^{n+1}\boldsymbol{\kappa} - \lambda \boldsymbol{h}({}^{cross}\boldsymbol{\sigma}, {}^{cross}\boldsymbol{t}, {}^{cross}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{\kappa} \\
F({}^{cross}\boldsymbol{\sigma}, {}^{cross}\boldsymbol{t}, {}^{cross}\boldsymbol{\kappa}) &= 0
\end{aligned} \tag{104.492}$$

where ${}^{n}\boldsymbol{\sigma}$, ${}^{n}\boldsymbol{t}$, $\triangle\boldsymbol{\epsilon}$, $\triangle\boldsymbol{\omega}$, and ${}^{n}\boldsymbol{\kappa}$ are known, which represents the stress state, couple-stress state, total strain increment, and internal variables state in the previous step. The four unknowns are ${}^{n+1}\boldsymbol{\sigma}$, ${}^{n+1}\boldsymbol{t}$, ${}^{n+1}\boldsymbol{\kappa}$ and λ, which represents the stress state, internal variables state, and plastic multiplier in the current step.

Continuum Stiffness Tensor The explicit algorithm is derived by starting from the first order Taylor expansion about the starting point (σ_{ij}, t, κ).

$$f^{new} = f^{old} + \frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} + \frac{\partial f}{\partial t_{kl}} dt_{kl} + \frac{\partial f}{\partial \kappa} d\kappa \tag{104.493}$$

Since both yield surface values should be zeroes, the Taylor expansion is simplified to

$$\begin{aligned}
&\frac{\partial f}{\partial \sigma_{ij}} d\sigma_{ij} + \frac{\partial f}{\partial t_{kl}} dt_{kl} + \frac{\partial f}{\partial \kappa} d\kappa = 0 \\
&\frac{\partial f}{\partial \sigma_{ij}} (E_{ijkl} d\epsilon - E_{ijkl} d\lambda m^{s}_{kl}) + \frac{\partial f}{\partial t_{kl}} (C_{ijkl} d\omega - C_{ijkl} d\lambda m^{c}_{kl}) + \xi_{*} h_{*} d\lambda = 0 \\
&d\lambda = \frac{\frac{\partial f}{\partial \sigma_{ij}} E_{ijkl} d\epsilon + \frac{\partial f}{\partial t_{kl}} C_{ijkl} d\omega}{\frac{\partial f}{\partial \sigma_{ij}} E_{ijkl} m^{s}_{kl} + \frac{\partial f}{\partial t_{kl}} C_{ijkl} m^{c}_{kl} - \xi_{*} h_{*}}
\end{aligned} \tag{104.494}$$

Simplify the $d\lambda$ expression by $n^{s}_{ij} = \frac{\partial f}{\partial \sigma_{ij}}$ and $n^{c}_{ij} = \frac{\partial f}{\partial t_{ij}}$. So we have

$$d\lambda = \frac{n^{s}_{ij} E_{ijkl} d\epsilon + n^{c}_{ij} C_{ijkl} d\omega}{n^{s}_{ij} E_{ijkl} m^{s}_{kl} + n^{c}_{ij} C_{ijkl} m^{c}_{kl} - \xi_{*} h_{*}} \tag{104.495}$$

104.6.16.7 Backward Euler, Implicit Algorithm

Forward Euler Algorithm uses the final stress state to calculate the plastic flow direction and the normal to the yield surface.

Iterations are required to find the final stress state.

Implicit Formulation The governing equations of the backward Euler, implicit algorithm

$$\begin{aligned} {}^{n+1}\boldsymbol{\sigma} + \lambda \boldsymbol{E}\boldsymbol{m}^s({}^{n+1}\boldsymbol{\sigma}, {}^{n+1}\boldsymbol{t}, {}^{n+1}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{\sigma} + \boldsymbol{E}\triangle\boldsymbol{\epsilon} \\ {}^{n+1}\boldsymbol{t} + \lambda \boldsymbol{C}\boldsymbol{m}^c({}^{n+1}\boldsymbol{\sigma}, {}^{n+1}\boldsymbol{t}, {}^{n+1}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{t} + \boldsymbol{C}\triangle\boldsymbol{\omega} \\ {}^{n+1}\boldsymbol{\kappa} - \lambda \boldsymbol{h}({}^{n+1}\boldsymbol{\sigma}, {}^{n+1}\boldsymbol{t}, {}^{n+1}\boldsymbol{\kappa}) &= {}^{n}\boldsymbol{\kappa} \\ F({}^{n+1}\boldsymbol{\sigma}, {}^{n+1}\boldsymbol{t}, {}^{n+1}\boldsymbol{\kappa}) &= 0 \end{aligned} \tag{104.496}$$

where ${}^{n}\boldsymbol{\sigma}$, ${}^{n}\boldsymbol{t}$, $\triangle\boldsymbol{\epsilon}$, $\triangle\boldsymbol{\omega}$, and ${}^{n}\boldsymbol{\kappa}$ are known, which represents the stress state, couple-stress state, total strain increment, and internal variables state in the previous step. The four unknowns are ${}^{n+1}\boldsymbol{\sigma}$, ${}^{n+1}\boldsymbol{t}$, ${}^{n+1}\boldsymbol{\kappa}$ and λ, which represents the stress state, internal variables state, and plastic multiplier in the current step.

Consistent Stiffness Tensor The consistent stiffness tensor for a Cosserat elastoplastic algorithm is extended from the classic elastoplastic algorithmPérez-Foguet et al. (2001). The Jacobian of the backward algorithm can be written as

$$ {}^{n+1}\boldsymbol{J} = \begin{pmatrix} (\boldsymbol{I} + \lambda \boldsymbol{E}\frac{\partial \boldsymbol{m}^s}{\partial \boldsymbol{\sigma}}) & (\frac{\partial \boldsymbol{\sigma}}{\partial \boldsymbol{t}} + \lambda \boldsymbol{E}\frac{\partial \boldsymbol{m}^s}{\partial \boldsymbol{t}}) & \lambda \boldsymbol{E}\frac{\partial \boldsymbol{m}^s}{\partial \boldsymbol{\kappa}} & \boldsymbol{E}\boldsymbol{m}^s \\ (\frac{\partial \boldsymbol{t}}{\partial \boldsymbol{\sigma}} + \lambda \boldsymbol{C}\frac{\partial \boldsymbol{m}^c}{\partial \boldsymbol{\sigma}}) & (\boldsymbol{I} + \lambda \boldsymbol{C}\frac{\partial \boldsymbol{m}^c}{\partial \boldsymbol{t}}) & \lambda \boldsymbol{C}\frac{\partial \boldsymbol{m}^c}{\partial \boldsymbol{\kappa}} & \boldsymbol{C}\boldsymbol{m}^c \\ -\lambda\frac{\partial \boldsymbol{h}}{\partial \boldsymbol{\sigma}} & -\lambda\frac{\partial \boldsymbol{h}}{\partial \boldsymbol{t}} & (\boldsymbol{I} - \lambda\frac{\partial \boldsymbol{h}}{\partial \boldsymbol{\kappa}}) & -\boldsymbol{h} \\ \boldsymbol{n}_s^T & \boldsymbol{n}_c^T & \boldsymbol{\xi}^T & 0 \end{pmatrix} \tag{104.497}$$

104.6.17 Cosserat von-Mises Elastoplastic Model

Following the fundamental Cosserat elastoplastic material model defined above, an full Cosserat von-Mises plastic model is defined below.

104.6.17.1 Cosserat Plastic Model

Cosserat von-Mises Yield Surface :

$$f(\sigma, t) = \left(\frac{1}{2}s_{ij}s_{ij} + \frac{1}{2}s_{ij}s_{ji} + \frac{1}{2l_p^2}(t_{ij}t_{ij} + t_{ij}t_{ji})\right)^{1/2} - \sqrt{\frac{2}{3}}k \tag{104.498}$$

The normal to the yield surface with respect to the force

$$\begin{aligned} n^f &= \frac{\partial f}{\partial \sigma} \\ &= \frac{1}{2}(s_{ij} + s_{ji})\left(\frac{1}{2}s_{ij}s_{ij} + \frac{1}{2}s_{ij}s_{ji} + \frac{1}{2l_p^2}(t_{ij}t_{ij} + t_{ij}t_{ji})\right)^{-1/2} \end{aligned} \tag{104.499}$$

The normal to the yield surface with respect to the curvature

$$\begin{aligned} n^c =& \frac{\partial f}{\partial t} \\ =& \frac{1}{2l_p^2}(t_{ij} + t_{ji})\left(\frac{1}{2}s_{ij}s_{ij} + \frac{1}{2}s_{ij}s_{ji} + \frac{1}{2l_p^2}(t_{ij}t_{ij} + t_{ij}t_{ji})\right)^{-1/2} \end{aligned} \tag{104.500}$$

Plastic Flow :

$$\begin{aligned} m^f &= n^f \\ m^c &= n^c \end{aligned} \tag{104.501}$$

Hardening Law:

$$\bar{k} = Hm_{equiv} = H\left(\frac{1}{3}m_{ij}^f m_{ij}^f + \frac{1}{3}m_{ij}^f m_{ji}^f + \frac{1}{3}l_p^2(m_{ij}^c m_{ij}^c + m_{ij}^c m_{ji}^c)\right)^{0.5} \tag{104.502}$$

Calculation of dλ : The algorithm is derived by starting from the first order Taylor expansion about the starting point (σ_{ij}, t, κ).

$$f^{new} = f^{old} + \frac{\partial f}{\partial \sigma_{ij}}d\sigma_{ij} + \frac{\partial f}{\partial t_{kl}}dt_{kl} + \frac{\partial f}{\partial \kappa}d\kappa \tag{104.503}$$

Since both yield surface values should be zeros, the Taylor expansion is simplified to

$$\begin{aligned} &\frac{\partial f}{\partial \sigma_{ij}}d\sigma_{ij} + \frac{\partial f}{\partial t_{kl}}dt_{kl} + \frac{\partial f}{\partial \kappa}d\kappa = 0 \\ &\frac{\partial f}{\partial \sigma_{ij}}(E_{ijkl}d\epsilon - E_{ijkl}d\lambda m_{kl}^s) + \frac{\partial f}{\partial t_{kl}}(C_{ijkl}d\omega - C_{ijkl}d\lambda m_{kl}^c) + \xi_* h_* d\lambda = 0 \\ &d\lambda = \frac{\frac{\partial f}{\partial \sigma_{ij}}E_{ijkl}d\epsilon + \frac{\partial f}{\partial t_{kl}}C_{ijkl}d\omega}{\frac{\partial f}{\partial \sigma_{ij}}E_{ijkl}m_{kl}^s + \frac{\partial f}{\partial t_{kl}}C_{ijkl}m_{kl}^c - \xi_* h_*} \end{aligned} \tag{104.504}$$

Simplify the $d\lambda$ expression by $n^s_{ij} = \frac{\partial f}{\partial \sigma_{ij}}$ and $n^c_{ij} = \frac{\partial f}{\partial t_{ij}}$. So we have

$$d\lambda = \frac{n^s_{ij} E_{ijkl} d\epsilon + n^c_{ij} C_{ijkl} d\omega}{n^s_{ij} E_{ijkl} m^s_{kl} + n^c_{ij} C_{ijkl} m^c_{kl} - \xi_* h_*} \tag{104.505}$$

For this Cosserat von-Mises isotropic hardening case,

$$\xi_* = \frac{\partial f}{\partial k} = -\sqrt{\frac{2}{3}} \tag{104.506}$$

$$h_* = \bar{k} = H m_{equiv} \tag{104.507}$$

104.6.17.2 Analysis of Cosserat Elastoplastic Solids

For the elastoplastic analysis, a rectangular plate of 10 m width and 20 m height is horizontally fixed at one end while the other end is subjected to a given horizontal displacement. The geometry and boundary conditions used for the plate are shown in Fig.104.26. In addition, the upper left corner of the plate is vertically fixed. The elastic material constants are $\lambda = 20MPa$, $\mu = 10MPa$, $\chi = 0$, $\pi_1 = 10MN$, $\pi_2 = 0$, $\pi_3 = 1kN$, and the plastic constants are internal length $l_p = 1E-6m$, von-Mises radius $k = 50kPa$, and hardening (softening) rate $H = -500kPa$. For the sake of comparison, the geometry, material properties and loadings used in this problem are the same as the ones used where classical elasticity is employed.

Fig.104.27 illustrates the plastic zone obtained for the problem when the classical and Cosserat theories with different discretization are used. As it is expected, the plastic zone obtained for the classical theory becomes narrowed as the discretization refines. In fact, the plastic zone is two elements wide for all discretization which shows the mesh-dependency of the results based on the classical theory. One the other hand, the plastic zone obtained for the Cosserat theory approximately remains the unchanged when discretization refines.

104.6.18 Accelerated Constitutive Models

One of the concerns of elastic-plastic analysis is the computational effort. In this section developed are closed form elastic-plastic stress increments and elastic-plastic tangent stiffness matrices for commonly used elastic-plastic models. This is achieved by multiplying, in closed form, explicit, forward Euler elastic-plastic stress incremental solution and explicit, tangent elastic-plastic stiffness tensor, as developed in section 104.3 on page 206.

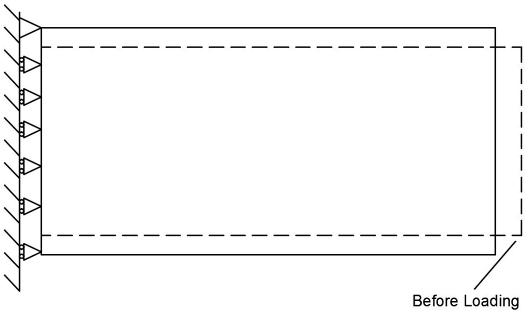

Figure 104.26: Loading Condition and Boundary Conditions of the Cosserat Elastoplastic Model.

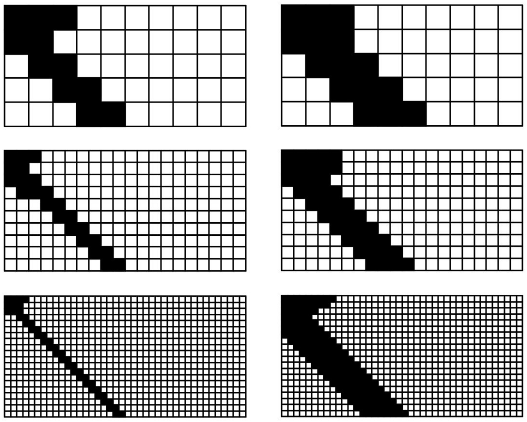

Figure 104.27: Comparison of the Plastic Zone of the Cosserat Elastoplastic Model. Left side is the classical elastoplastic material model, where the mesh refinement leads to localization of the plastic zone. Right side is the Cosserat elastoplastic material model, where the plastic zone is independent of the mesh sizes.

Relation between stress increment $d\sigma_{ij}$ and strain increments $d\epsilon_{kl}$ can be written for linear isotropic elasticity as:

$$d\sigma_{ij} = E_{ijkl} d\epsilon_{kl} \tag{104.508}$$

where E_{ijkl} is the fourth order elastic stiffness tensor. The elastic stiffness tensor features both minor symmetry $E_{ijkl} = E_{jikl} = E_{ijlk}$ and major symmetry $E_{ijkl} = E_{klij}$ (Jeremić and Sture (1997)). The elastic stiffness tensor for isotropic material can be written as:

$$E_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mu \left(\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk} \right) \tag{104.509}$$

where λ and μ are the Lamé constants and E and ν are Young's Modulus and Poisson's ratio, respectively:

$$\lambda = \frac{\nu E}{(1+\nu)(1-2\nu)} \quad ; \quad \mu = \frac{E}{2(1+\nu)} \tag{104.510}$$

The relation between the stress tensor increment $d\sigma_{ij}$ and strain tensor increment $d\epsilon_{kl}$ is:

$$d\epsilon_{kl} = D_{klpq} d\sigma_{pq} \tag{104.511}$$

where D_{klpq} is the elastic compliance fourth order tensor, defined as:

$$D_{klpq} = \frac{-\lambda}{2\mu\,(3\lambda + 2\mu)}\,\delta_{kl}\delta_{pq} + \frac{1}{4\mu}\left(\delta_{kp}\delta_{lq} + \delta_{kq}\delta_{lp}\right) \tag{104.512}$$

104.6.18.1 Elasto-plasticity

Using developments from section 104.3 on page 206, one can write

$$d\sigma_{ij} = E_{ijkl} d\epsilon^{e}_{kl} \tag{104.513}$$

$$d\epsilon^{p}_{ij} = d\lambda\,\frac{\partial Q}{\partial \sigma_{ij}} = d\lambda\; m_{ij}(\sigma_{ij}, q) \tag{104.514}$$

$$d\epsilon_{ij} = d\epsilon^{e}_{ij} + d\epsilon^{p}_{ij} \tag{104.515}$$

$$dq_{*} = d\lambda\; h(\tau_{ij}, q) \tag{104.516}$$

where, ϵ_{ij}, ϵ^{e}_{ij}, and ϵ^{p}_{ij} are total, elastic, and plastic strain tensors respectively, σ_{ij} is stress tensor, and q_{*} represents internal variables. Moreover, m_{ij} is the plastic flow direction, h is the plastic moduli, and $d\lambda$ is a plastic constistency parameter that is to be determined. Equation (104.513) is the Hooke's law that relates stress to elastic strain using the stiffness tensor E_{ijkl}. Equation(104.514) shows relations of plastic strains to the associated or non-associated plastic flow rule. Equation (104.515) represents the additive decomposition of strain increment into elastic strain increment and plastic strain increments, that is applicable for small deformation analysis. Equation (104.516) represents evolution law for internal variables.

104.6.18.2 Elastic-Plastic Constitutive Models

For each elastic-plastic constitutive model, there are four components to be specified. Those components are (a) elasticity relation, (b) yield function, (c) plastic flow function, and (d) hardening and/or softening laws.

Once those four components are chosen, specified, elastic-plastic stiffness tensor, developed earlier in section 104.3 on page 206, can be developed for each model, by analytically multiplying functions and tensor equations for each component. In following sections this is done for von Mises, Drucker-Prager, and Cam-Clay material models.

The tanget elastic-plastic tensor is written as

$$E^{el-pl}_{pqmn} = E_{pqmn} - \frac{E_{pqkl} \, {}^{n}m_{kl} \, {}^{n}n_{ij} E_{ijmn}}{{}^{n}n_{ot} E_{otrs} \, {}^{n}m_{rs} - \xi_* \; h_*} \tag{104.517}$$

For perfectly plastic materials ξ_* and h_* would be zero while for the cases with evolution laws, the appropriate evolution laws should be used in derivation of tangent stiffness E^{el-pl}_{pqmn}. Elastic modulus tensor is written as:

$$E_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mu(\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk}) \tag{104.518}$$

where $\lambda = \nu E/(1 + \nu)(1 - 2\nu)$, $\mu = E/2(1 + \nu)$.

104.6.18.3 von Mises Model

von Mises yield criteria can be written as

$$f = \left[\left(s_{ij} - \alpha_{ij} \right) \left(s_{ij} - \alpha_{ij} \right) \right]^{0.5} - \sqrt{\frac{3}{2}} k = 0 \tag{104.519}$$

where k is the scalar internal variable where initial value is related to the uniaxial tension strength, α_{ij} is the tensorial internal variable, the so called back stress that controls translational kinematic hardening.

The stress derivative of the yield function is

$$n_{ij} = \frac{\partial f}{\partial \sigma_{ij}} = \frac{1}{\sqrt{(s_{ij} - \alpha_{ij})(s_{ij} - \alpha_{ij})}} (s_{ij} - \alpha_{ij}) \tag{104.520}$$

In case of associated plastic flow rule where the plastic potential function is considered to be the same of yield function, stress derivative of plastic flow function is:

$$m_{ij} = \frac{\partial g}{\partial \sigma_{ij}} = \frac{1}{\sqrt{(s_{ij} - \alpha_{ij})(s_{ij} - \alpha_{ij})}} (s_{ij} - \alpha_{ij}) \tag{104.521}$$

In order to find the closed form equation for elastic-plastic modulus for case of perfectly-plastic, Equation (104.519) is used for both yield surface and plastic potential and no evolution law is considered. Relevant stress derivatives are:

$$n_{ij} = \frac{1}{\sqrt{s_{ij}s_{ij}}} s_{ij} \quad ; \quad m_{ij} = \frac{1}{\sqrt{s_{ij}s_{ij}}} s_{ij} \tag{104.522}$$

Base on obtained stress derivatives, plastic consistency parameter is derived as

$$d\lambda = \frac{n_{ij} E_{ijpq} d\epsilon_{pq}}{n_{ij} E_{ijkl} m_{kl}} = \frac{n_{ij} d\sigma_{ij}}{2\mu} \tag{104.523}$$

The elastic-plastic tangent tensor is then

$$\begin{aligned} E^{pl}_{pqmn} &= \frac{E_{pqkl} n_{kl} m_{ij} E_{ijmn}}{n_{ab} E_{abcd} m_{cd}} = 2\mu n_{pq} n_{mn} \\ &= 2\mu \frac{1}{\sqrt{s_{kl}s_{kl}}} s_{pq} \frac{1}{\sqrt{s_{ij}s_{ij}}} s_{mn} = 2\mu \frac{1}{s_{kl}s_{kl}} s_{pq} s_{mn} \end{aligned} \tag{104.524}$$

In case isotropic hardening, ξ and h are not zero anymore, since k is scalar internal variable that is updated in each increment. Harderning/softenig functions, scalar functions in this case. ξ and h can be calculated as

$$\xi = -\sqrt{\frac{2}{3}} \tag{104.525}$$

$$h = \sqrt{\frac{2}{3} m_{ij} m_{ij}} k = \sqrt{\frac{2}{3}} k \tag{104.526}$$

Therefore, plastic parameter $(d\lambda)$ and tangnet elastic-plastic tensor (E^{pl}_{pqmn}) can be written as:

$$d\lambda = \frac{n_{ij} E_{ijpq} d\epsilon_{pq}}{n_{ij} E_{ijkl} m_{kl} - \xi\ h} = \frac{n_{ij} d\sigma_{ij}}{2\mu + \frac{2}{3}k} \tag{104.527}$$

$$\begin{aligned} E^{pl}_{pqmn} &= \frac{E_{pqkl} n_{kl} m_{ij} E_{ijmn}}{n_{ab} E_{abcd} m_{cd} - \xi\ h} = \frac{4\mu^2 n_{pq} n_{mn}}{2\mu + \frac{2}{3}k} \\ &= \frac{4\mu^2 \frac{1}{\sqrt{s_{kl}s_{kl}}} s_{pq} \frac{1}{\sqrt{s_{ij}s_{ij}}} s_{mn}}{2\mu - \frac{2}{3}k} = \frac{4\mu^2 \frac{1}{s_{kl}s_{kl}} s_{pq} s_{mn}}{2\mu + \frac{2}{3}k} \end{aligned} \tag{104.528}$$

The value of k should be updated at each step using the following equation:

$$k^{updated} = k + dk = k + hd\lambda = k + \sqrt{\frac{2}{3}}kd\lambda = k(1 + \sqrt{\frac{2}{3}}d\lambda) \tag{104.529}$$

For case the of von Mises with kinematic hardening, α_{ij} is the tensorial internal variable to be updated at each step of analysis, while tensor functions ξ_{ab} and h_{ab} can be calculated from the following equations using Armstrong-Frederick saturation-type kinematic hardening rule (Armstrong and Frederick (1966); Lemaitre and Chaboche (1990)) :

$$\xi_{ab} = \frac{\partial F}{\partial \alpha_{ab}} = -\frac{1}{\sqrt{(s_{ab} - \alpha_{ab})(s_{ab} - \alpha_{ab})}}(s_{ab} - \alpha_{ab}) \tag{104.530}$$

Recall that $dq_{ij} = d\alpha_{ij} = d\lambda h_{ij}$, and $d\epsilon^{pl}_{ij} = d\lambda m_{ij}$ and that the Armstrong-Frederic kinematic hardening rule for the internal variable α_{ij} is given as:

$$d\alpha_{ij} = \frac{2}{3}h_a \left(d\epsilon^p_{ij}\right)^{dev} - c_r\alpha_{ij}\sqrt{\frac{2}{3}\left(d\epsilon^p_{st}\right)^{dev}\left(d\epsilon^p_{st}\right)^{dev}} \tag{104.531}$$

so that

$$h_{st} = \frac{2}{3}h_a m_{st} - \alpha_{st}c_r\sqrt{\frac{2}{3}} \tag{104.532}$$

since $\sqrt{m_{ij}m_{ij}} = 1$.

Plastic consistency parameter $(d\lambda)$ and tanget elastic-plastic tensor (E^{pl}_{pqmn}) can be expressed as:

$$d\lambda = \frac{n_{ij}E_{ijpq}d\epsilon_{pq}}{n_{ij}E_{ijkl}m_{kl} - \xi\ h} = \frac{n_{ij}d\sigma_{ij}}{2\mu - \xi_{ab}\ h_{ab}} \tag{104.533}$$

$$E^{pl}_{pqmn} = \frac{E_{pqkl}n_{kl}m_{ij}E_{ijmn}}{n_{ab}E_{abcd}m_{cd} - \xi\ h} = \frac{4\mu^2 n_{pq}n_{mn}}{2\mu - \xi_{ij}\ h_{ij}} \tag{104.534}$$

Full, developed form of tangent elastic-plastic stiffness can be written as

$$
E^{pl}_{pqmn} = \frac{E_{pqkl}\left(\frac{1}{\sqrt{(s_{ab}-\alpha_{ab})(s_{ab}-\alpha_{ab})}}\left(s_{kl}-\alpha_{kl}\right)\right)\left(\frac{1}{\sqrt{(s_{ab}-\alpha_{ab})(s_{ab}-\alpha_{ab})}}\left(s_{ij}-\alpha_{ij}\right)\right)E_{ijmn}}{\left(\frac{1}{\sqrt{(s_{mn}-\alpha_{mn})(s_{mn}-\alpha_{mn})}}\left(s_{ab}-\alpha_{ab}\right)\right)E_{abcd}\left(\frac{1}{\sqrt{(s_{mn}-\alpha_{mn})(s_{mn}-\alpha_{mn})}}\left(s_{cd}-\alpha_{cd}\right)\right)-\left(-\frac{1}{\sqrt{(s_{ab}-\alpha_{ab})(s_{ab}-\alpha_{ab})}}(s_{rs}-\alpha_{rs})\right)\left(\frac{2}{3}h_a m_{ab}-\frac{2}{3}\alpha_{rs}c_r\right)} \tag{104.535}
$$

Above equation can be simplified, written in a shorter form by using a substitution

$$\mathbb{A} = \frac{1}{\sqrt{(s_{ab} - \alpha_{ab})(s_{ab} - \alpha_{ab})}} \tag{104.536}$$

it can be written as:

$$E^{pl}_{pqmn} = \frac{E_{pqkl}\left(\mathbb{A}\left(s_{kl} - \alpha_{kl}\right)\right)\left(\mathbb{A}\left(s_{ij} - \alpha_{ij}\right)\right)E_{ijmn}}{\left(\mathbb{A}\left(s_{ab} - \alpha_{ab}\right)\right)E_{abcd}\left(\mathbb{A}\left(s_{ab} - \alpha_{ab}\right)\right) - (-\mathbb{A})\left(\frac{2}{3}h_a\left(\mathbb{A}\left(s_{cd} - \alpha_{cd}\right)\right) - \sqrt{\frac{2}{3}}\alpha_{cd}c_r\right)\left(s_{cd} - \alpha_{cd}\right)} \tag{104.537}$$

Finally the full elastic-plastic tangent stiffness tensor can be written as:

$$\begin{aligned}
&E^{el\text{–}pl}_{pqmn} = \\
&E^{el}_{pqmn} - E^{pl}_{pqmn} = \\
&E^{el}_{pqmn} - \frac{E_{pqkl}\left(\mathbb{A}\left(s_{kl} - \alpha_{kl}\right)\right)\left(\mathbb{A}\left(s_{ij} - \alpha_{ij}\right)\right)E_{ijmn}}{\left(\mathbb{A}\left(s_{ab} - \alpha_{ab}\right)\right)E_{abcd}\left(\mathbb{A}\left(s_{cd} - \alpha_{cd}\right)\right) - (-\mathbb{A})\left(\frac{2}{3}h_a\ \left(\mathbb{A}\left(s_{cd} - \alpha_{cd}\right)\right) - \sqrt{\frac{2}{3}}\alpha_{cd}c_r\right)\left(s_{cd} - \alpha_{cd}\right)}
\end{aligned} \tag{104.538}$$

104.6.18.4 Nonlinear Elastic Model in 1D based on Armstrong Frederick Equation

$$d\sigma_{ij} = d\alpha_{ij} = \frac{2}{3}h_a\left(d\epsilon^{p}_{ij}\right)^{dev} - c_r\sigma_{ij}\sqrt{\frac{2}{3}\left(d\epsilon^{p}_{st}\right)^{dev}\left(d\epsilon^{p}_{st}\right)^{dev}} \tag{104.539}$$

104.6.18.5 Drucker-Prager Model

Drucker-Prager model yield surface, including rotational kinematic hardening can be written as

$$f = \alpha I_1 + [\frac{1}{2}(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})]^{\frac{1}{2}} - \beta = 0 \tag{104.540}$$

where α and β are material constants.

By coinciding Drucker-Prager cone with the outer apexes of the Mohr-Coulomb hexagon locus, the constants for compressive cone of Drucker-Prager can be evaluated as shown in Equation (104.541) by knowing the soil strength parameters of cohesion (c) and friction angle (ϕ):

$$\alpha = \frac{2\sin\phi}{\sqrt{3}(3 - \sin\phi)}, \quad \beta = \frac{6\cos\phi}{\sqrt{3}(3 - \sin\phi)}c \tag{104.541}$$

Drucker-Prager yield function for cohesionless sands ($k = 0$) can be obtained as:

$$f = \alpha I_1 + \sqrt{J_2} = 0 \tag{104.542}$$

or in $p-q$ space:

$$f = q - Mp = 0 \tag{104.543}$$

which then M can be obtained as:

$$M = \frac{6\sin\phi}{3-\sin\phi} \tag{104.544}$$

By considering kinematic hardening, Equation (104.543) can be expressed as:

$$f = \left[\left(s_{ij}-p\alpha_{ij}\right)\left(s_{ij}-p\alpha_{ij}\right)\right]^{0.5} - \sqrt{\frac{2}{3}}kp = 0 \tag{104.545}$$

which then stress derivative of yield function and plastic potential function in case of associated plasticity can be defined as:

$$\begin{aligned} n_{ij} &= m_{ij} = \frac{\partial f}{\partial\sigma_{ij}} = \frac{\partial g}{\partial\sigma_{ij}} \\ &= \left[\left(s_{ij}-p\alpha_{ij}\right) + \frac{1}{3}\alpha_{pq}\delta_{ij}\left(s_{pq}-p\alpha_{pq}\right)\right]\left[\left(s_{rs}-p\alpha_{rs}\right)\left(s_{rs}-p\alpha_{rs}\right)\right]^{-0.5} \\ &+ \sqrt{\frac{2}{27}}k\delta_{ij} \end{aligned} \tag{104.546}$$

To find the closed form equation of elastic-plastic modulus for case of perfectly-plastic, Equation (104.545) is used for associated plasticity rule with no hardening. By these assumptions stress derivative is calculated as:

$$n_{ij} = m_{ij} = \frac{1}{\sqrt{s_{ij}s_{ij}}}s_{ij} + \sqrt{\frac{2}{27}}k\delta_{ij} \tag{104.547}$$

Splitting plastic modulus to different parts:

$$\begin{aligned} Hq_{ij} &= E_{ijkl}m_{kl} = \{\lambda\delta_{ij}\delta_{kkl} + \mu(\delta_{ik}\delta_{jl}+\delta_{il}\delta_{jk})\}\{\frac{1}{\sqrt{s_{mn}s_{mn}}}s_{kl} + \sqrt{\frac{2}{27}}k\delta_{kl}\} \\ &= 2\mu\frac{1}{\sqrt{s_{mn}s_{mn}}}s_{ij} + \delta_{ij}\{\frac{1}{\sqrt{s_{mn}s_{mn}}}\lambda(s_{pq}\delta_{pq}) + \sqrt{\frac{2}{27}}k(3\lambda+2\mu)\} \\ &= 2\mu\frac{1}{\sqrt{s_{mn}s_{mn}}}s_{ij} + B\delta_{ij} \end{aligned} \tag{104.548}$$

Assuming:

$$B = \frac{1}{\sqrt{s_{mn}s_{mn}}}\lambda(s_{pq}\delta_{pq}) + \sqrt{\frac{2}{27}}k(3\lambda + 2\mu) \tag{104.549}$$

Plastic parameter can be written as:

$$d\lambda = \frac{n_{ij}E_{ijpq}d\epsilon_{pq}}{n_{ij}E_{ijpq}m_{kl}} = \frac{\lambda_{nominator}}{\lambda_{denominator}} \tag{104.550}$$

$$\lambda_{nominator} = n_{ij}E_{ijpq}d\epsilon_{pq} = n_{ij}d\sigma_{ij} \tag{104.551}$$

$$\begin{aligned}\lambda_{denominator} &= n_{ij}E_{ijpq}m_{kl} = n_{ij}Hq_{ij}\\ &= \{\frac{1}{\sqrt{s_{ij}s_{ij}}}s_{ij} + \sqrt{\frac{2}{27}}k\delta_{ij}\}\{2\mu\frac{1}{\sqrt{s_{mn}s_{mn}}}s_{ij} + B\delta_{ij}\}\\ &= 2\mu + \frac{1}{\sqrt{s_{mn}s_{mn}}}(B + 2\mu\sqrt{\frac{2}{27}}k)(s_{ij}\delta_{ij}) + 3B\sqrt{\frac{2}{27}}k\end{aligned} \tag{104.552}$$

Finally plastic tensor can be expressed as:

$$E^{pl}_{pqmn} = \frac{E_{pqkl}n_{kl}m_{ij}E_{ijmn}}{n_{ab}E_{abcd}m_{cd}} = \frac{Hq_{pq}Hq_{mn}}{\lambda_{denominator}} \tag{104.553}$$

where:

$$\begin{aligned}Hq_{pq}Hq_{mn} &= \{\frac{2\mu}{\sqrt{s_{ij}s_{ij}}}s_{pq} + B\delta_{pq}\}\{\frac{2\mu}{\sqrt{s_{ij}s_{ij}}}s_{mn} + B\delta_{mn}\}\\ &= 4\mu^2\frac{1}{s_{ij}s_{ij}}s_{pq}s_{mn} + 4\mu\frac{1}{\sqrt{s_{ij}s_{ij}}}Bs_{pq}\delta_{mn} + B^2\delta_{pq}\delta_{mn}\end{aligned} \tag{104.554}$$

When isotropic hardening is considered for Drucker-Prager model, ξ and h are not zero. These parameters can be obtained using following equations:

$$\xi = -p\sqrt{\frac{2}{3}} \tag{104.555}$$

$$h = \sqrt{\frac{2}{3} m_{ij} m_{ij}} k = \sqrt{\frac{2}{3}(1 + \frac{2}{9}k^2)} k \tag{104.556}$$

Plastic parameter ($d\lambda$) and plastic modulus (E^{pl}_{pqmn}) can be written as:

$$\lambda_{denominator} \;\; = \;\; n_{ij} E_{ijpq} m_{kl} - \xi\ h = n_{ij} H q_{ij} - \xi\ h \tag{104.557}$$

$$E^{pl}_{pqmn} = \frac{E_{pqkl} n_{kl} m_{ij} E_{ijmn}}{n_{ab} E_{abcd} m_{cd}} = \frac{H q_{pq} H q_{mn}}{\lambda_{denominator}} \tag{104.558}$$

k is the scalar internal variable to be updated at each step of analysis using following equation:

$$\begin{aligned} k^{updated} &= k + dk = k + h d\lambda \\ &= k + \sqrt{\frac{2}{3}(1 + \frac{2}{9}k^2)} k d\lambda = k(1\sqrt{\frac{2}{3}(1 + \frac{2}{9}k^2)} d\lambda) \end{aligned} \tag{104.559}$$

By considering kinematic hardening for Drucker-Prager material model, tensorial internal variable (α_{ij}) is introduced and has to be updated at each step of analysis. The stress derivatives of yield function and plastic potential function can be written as:

$$n_{ij} = m_{ij} = \frac{1}{\sqrt{(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})}} (s_{ij} - p\alpha_{ij}) + \sqrt{\frac{2}{27}} k \delta_{ij} \tag{104.560}$$

Tensorial parameters of $\xi)ij$ and h_{ij} can be calculated using Armstrong-Frederick saturation-type kinematic hardening rule (Armstrong and Frederick (1966)):

$$\xi_{ij} = -\frac{p}{\sqrt{(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})}} (s_{ij} - p\alpha_{ij}) \tag{104.561}$$

$$h_{ij} = \frac{2}{3} h_a m_{ij} - \alpha_{ij} c_r \sqrt{\frac{2}{3} m_{ij} m_{ij}} \tag{104.562}$$

Plastic parameter ($d\lambda$) and plastic modulus (E^{pl}_{pqmn}) are obtained from following equations:

$$d\lambda = \frac{n_{ij} E_{ijpq} d\epsilon_{pq}}{n_{ij} E_{ijkl} m_{kl} - \xi_{ij}\ h_{ij}} = \frac{n_{ij} d\sigma_{ij}}{2\mu - \xi_{ij}\ h_{ij}} \tag{104.563}$$

$$E^{pl}_{pqmn} = \frac{E_{pqkl} n_{kl} m_{ij} E_{ijmn}}{n_{ab} E_{abcd} m_{cd} - \xi_{ij}\ h_{ij}} \tag{104.564}$$

Tensorial internal variable (α_{ij}) can be updated using following equation:

$$\begin{aligned} {\alpha_{ij}}^{updated} &= \alpha_{ij} + d\alpha_{ij} = \alpha_{ij} + h_{ij} d\lambda \\ &= \alpha_{ij} + (\frac{2}{3} h_a m_{ij} - \alpha_{ij} c_r \sqrt{\frac{2}{3} m_{ij} m_{ij}}) d\lambda \end{aligned} \tag{104.565}$$

104.6.18.6 Modified Cam-Clay Model

The critical state line for Cam-Clay can be written as

$$e_c = e_{c,r} - \lambda_c \ln p_c \tag{104.566}$$

where e_c is the critical void ratio at critical mean stress (p_c), $e_{c,r}$ is the reference critical void ratio, and λ_c is the normal consolidation slope. In general it is assumed that the normal consolidation line (NCL) is parallel to CSL, which is defined as:

$$e = e_\lambda - \lambda \ln p \tag{104.567}$$

where e_λ is the intercept on the NRL at $p = 1$. λ is the normal consolidation slope or the elasto-plastic slope of $e - \ln p$ relation. The same relation is used for unloading-reloading line (URL) with different slope as:

$$e = e_\kappa - \kappa \ln p \tag{104.568}$$

where e_κ is the intercept on the URL at $p = 1$. The yield function for Cam-Clay model can be defined as

$$f = q^2 - M^2[p(p_0 - p)] = 0 \tag{104.569}$$

where M is the critical state stress ration in $q - p$ space and p_0 is the initial internal scalar variable which will be changed by change in plastic volumetric strain.

Cam-Clay model is one of the associated flow rule models which means the same function is used for both yield and plastic potential surfaces ($f = g$). The plastic flow of the Cam-Clay model is associated with its yield function, in other words, the plastic flow is defined by the potential function (g), which is assumed the same as the yield function (f).

The evolution law of for Cam-Clay model is a scalar one which can be expressed by:

$$\dot{p}_0 = \frac{(1+e)p_0}{\lambda - \kappa}\dot{\epsilon}_v^p \tag{104.570}$$

where e is the void ratio, λ is the normal consolidation slope or the elasto-plastic slope of $e-\ln p$ relation, and κ is the slope of unloading-reloading line. This equation proves that the change of p_0 is controlled by change of plastic volumetric strain. By considering the yield function expressed in Equation (104.569) and considering the associated flow rule, stress derivatives can be evaluated as:

$$n_{ij} = m_{ij} = 3s_{ij} + \frac{1}{3}M^2(p_0 - 2p)\delta_{ij} \tag{104.571}$$

Elastic modulus in terms of shear modulus (G) and bulk modulus (K) can be expressed as:

$$E_{ijkl} = (K - \frac{2}{3}G)\delta_{ij}\delta_{kl} + G(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}) \tag{104.572}$$

$$\begin{aligned}
Hq_{ij} &= E_{ijkl}m_{kl} \\
&= \{(K - \frac{2}{3}G)\delta_{ij}\delta_{kl} + G(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk})\}\{3s_{ij} + \frac{1}{3}M^2(p_0 - 2p)\delta_{ij}\} \\
&= 6Gs_{ij} + \{(K - \frac{2}{3}G)M^2(p_0 - 2p) + \frac{2}{3}M^2(p_0 - 2p)G\}\delta_{ij}
\end{aligned} \tag{104.573}$$

Defining D as:

$$D = (K - \frac{2}{3}G)M^2(p_0 - 2p) + \frac{2}{3}M^2(p_0 - 2p)G \tag{104.574}$$

ξ and h in case of using Cam-Clay constitutive model can be expressed as following equations:

$$\xi = M^2 p \tag{104.575}$$

$$h = (1 + e_0)p_0\frac{d\epsilon_v}{\lambda - \kappa} \tag{104.576}$$

where $d\epsilon_v = M^2(2p - p_0)$. Plastic parameter can be written as:

$$d\lambda = \frac{n_{ij} E_{ijpq} d\epsilon_{pq}}{n_{ij} E_{ijpq} m_{kl} - \xi\, h} = \frac{\lambda_{nominator}}{\lambda_{denominator}} \tag{104.577}$$

$$\lambda_{nominator} = n_{ij} E_{ijpq} d\epsilon_{pq} = n_{ij} d\sigma_{ij} \tag{104.578}$$

$$\begin{aligned} \lambda_{denominator} &= n_{ij} E_{ijpq} m_{kl} - \xi\, h = n_{ij} H q_{ij} - \xi\, h \\ &= \{3 s_{ij} + \frac{1}{3} M^2 (p_0 - 2p) \delta_{ij}\}\{6 G s_{ij} + D \delta_{ij}\} - \xi\, h \\ &= 18 G s_{ij} s_{ij} + D M^2 (p_0 - 2p) - \xi\, h \end{aligned} \tag{104.579}$$

Then the plastic tensor can be expressed as:

$$\begin{aligned} E^{pl}_{pqmn} &= \frac{E_{pqkl} n_{kl} m_{ij} E_{ijmn}}{n_{ab} E_{abcd} m_{cd} - \xi\, h} \\ &= \frac{H q_{pq} H q_{mn}}{\lambda_{denominator}} \end{aligned} \tag{104.580}$$

where:

$$\begin{aligned} H q_{pq} H q_{mn} &= \{6 G s_{ij} + D \delta_{ij}\}\{6 G s_{ij} + D \delta_{ij}\} \\ &= D^2 \delta_{pq} \delta_{mn} + 6 G D \delta_{pq} s_{mn} + 6 G D s_{pq} \delta_{mn} + 36 G^2 s_{pq} s_{mn} \end{aligned} \tag{104.581}$$

p_0 is the scalar internal variable to be updated at each step of analysis using the following equation:

$$p_0{}^{updated} = p_0 + dp_0 = p_0 + h d\lambda \tag{104.582}$$

104.6.18.7 Comparison of Computational Time of Accelerated Constitutive Models with NewTemplate3Dep

In order to compare the computational time of accelerated constitutive models with the ones available in NewTemplate3Dep, cyclic simulations are done in constitutive level using explicit integration method. Simulations are done for all the mentioned cases of von Mises, Drucker-Prager, and Cam-Clay constitutive models. The ratios of computational time of NewTemplate3Dep (t_N) to accelerated constitutive models (t_{Acc}) are summarized in Table (104.1). As it is observed, there are improvements in range of 2 to 3 times in computational time which can lead to reducing the computational time of soil-structure systems.

Table 104.1: Comparison of computational time of accelerated constitutive models with NewTemplate3Dep

Constitutive Model	t_N/t_{Acc}	Constitutive Model	t_N/t_{Acc}
von Mises Perfectly Plastic	3.1	Drucker-Prager Perfectly Plastic	2.9
von Mises Isotropic Hardening	2.6	Drucker-Prager Isotropic Hardening	2.5
von Mises Kinematic Hardening	2.3	Drucker-Prager Kinematic Hardening	1.9
Cam-Clay	2.2	————	

104.7 Elastic-Plastic Models for Contacts, Joints and Interfaces

This section is based on Sinha and Jeremić (2017).

104.7.1 Experimental Data

The response of the interface plays a very important role on the behavior of deep and shallow foundations, retaining walls, geo-membranes, submerged structures and soil-structure interaction. The load transfer mechanism from structure to the soil acts at the interface. The soil-structure interface comprise of a very thin small shearing band. The initial investigation by Yoshimi and Kishida (1981) indicated the thickness of the shear band as nine times the mean grain size diameter D_{50}. Tejchman and Wu (1995) conducted several tests on sand-steel interface and concluded that the thickness of the interface for rough interface is 30-40 D_{50} and for smooth interface is 6-10 D_{50}. Dejong et al. (2006); DeJong and Westgate (2009) investigated the shear-zone thickness to be 5-10 times the mean particle diameter D_{50}. Martinez et al. (2015) conducted several axial and torsional shear experiments on sand-steel interface to understand the micro mechanics involved at interface. The micro-mechanical hypothesis proposed by Martinez et al. (2015) is shown in Figure 104.28. The thickness of the interface zone formed by the particle in axial shearing migrates along the interface whereas for torsional shearing it migrates away from the interface.Similar mechanical hypothesis was observed by Dejong et al. (2006) It was also observed that for torsional shear the shear band zone was 2-3 times larger than the purely axial shearing. It also depends upon the characteristics of the soil beneath and the surface structural material and its roughness.

Since 1960's, researchers have been carrying out experiments to understand the interface behavior. The initial works have been contributed by Potyondy (1961); Brumund and Leonards (1973); Littleton

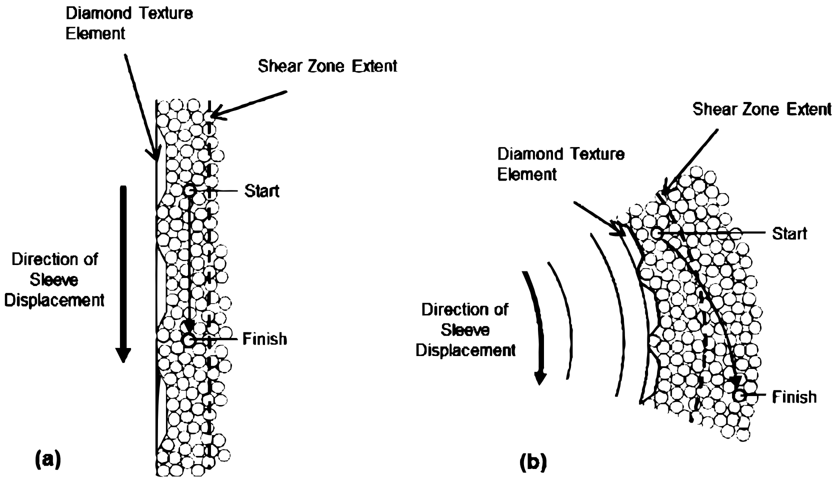

Figure 104.28: Hypothesis for a particle movement under (a) axial and (b) torsional loading (Martinez et al. (2015))

(1976). Potyondy (1961) studied the effect of soil-moisture content, structural surface roughness, soil-composition and normal load intensity on the skin-friction of the soil-structure interface. Brumund and Leonards (1973) investigated the static and dynamic friction angle between sand steel interface. Littleton (1976) performed drained and undrained tests on clay-steel interface and found that the shear stress response was steeper than the usual clay-clay interface. Based on the normal confinement σ_n, an initial hardening was observed until the peak shear strength τ_p is reached. After that softening to residual τ_r was observed. Later Desai (1981) emphasized on the importance of modeling of interface behavior for real soil-structure interactions. He also pointed out the lack of existing experimental data which could be used to develop constitutive models defining the interface behavior. Yoshimi and Kishida (1981) used a ring torsion apparatus to find the friction angle between dry sand and steel surface over a wide variation of surface roughness and sand density. Uesugi and Kishida (1986a,b); Kishida and Uesugi (1987) carried a series of laboratory experiments between steel and air-dried sands using simple shear apparatus shown in Figure 104.29 and Figure 104.30. It was found that the interface behavior is highly influenced by the sand type and surface roughness R_{max} while the effect of normal stress σ_n and mean grain size D_{50} are of poor significance. Thus, Kishida and Uesugi (1987) proposed a normalized roughness R_n to evaluate the relative coefficient of friction μ_y of sand-steel interface as shown in Figure ??.

$$R_{max}(L = D_{50})/D_{50} \tag{104.583}$$

where, $R_{max}(L = D_{50})$ is the R_{max} value of the steel surface with gauge length $L = D_{50}$.

Desai and Nagaraj (1988) performed a cyclic normal and shear tests on dry sand and concrete interface in translational shear box. Monotonic and cyclic normal loads along with cyclic shear loads

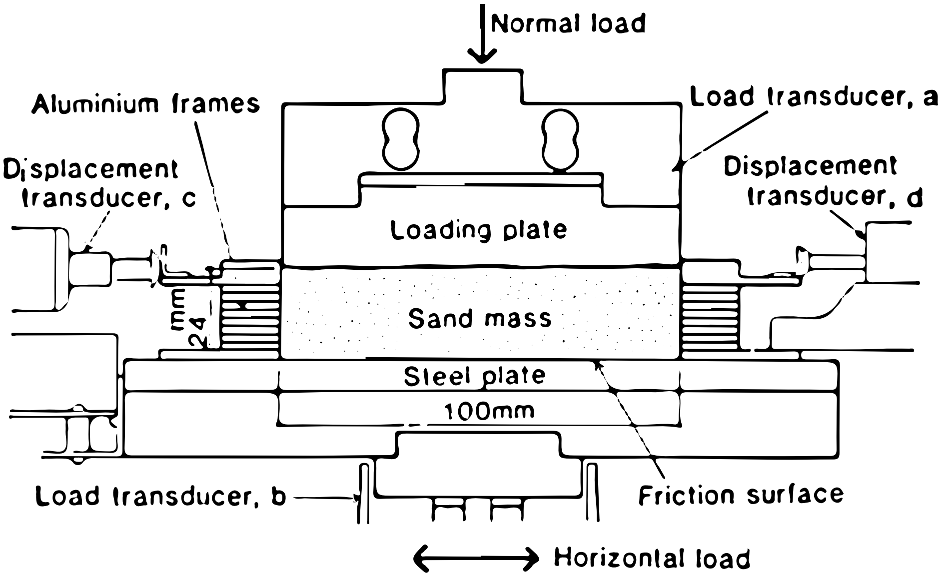

Figure 104.29: Section of friction test apparatus (Uesugi and Kishida (1986b)).

were applied. The shear behavior was modeled with a modified form of Ramberg-Osgood (R-O) model. Although Desai and Nagaraj (1988) did not show any experimental results, he idealized the normal interface behavior to be composed of (1) Virgin loading; (2) unloading; (3) reloading; 4 tensile condition; (5) partial debonding; and 6 rebonding as shown in Figure 104.32. Uesugi et al. (1989, 1990) studied the frictional behavior of sand-steel interface subject to repeated shearing under one-way or two-way loadings. It was found that under repeated loading conditions the coefficient of friction μ converged close to the residual coefficient of friction μ_r as could be observed in Figure ?? Boulon (1989) performed a lot of experiments on piles in sand. Direct simple shear tests were carried out to investigate the shear behavior between the granular soil and rough construction material. Based on the experimental results obtained later Boulon and Nova (1990) proposed a mathematical model and constitutive integration to model the interface behavior in finite element method (FEM). Aubry et al. (1990) proposed a dilatancy based cyclic elastic-plastic constitutive model for the interface. Cyclic loading functions with memory of last loading reversal was used to model subsequent loadings and unloading. The yield function was defined using simple Mohr Coulomb with additional parameter F as a function of normal stress σ_n and plastic compressibility β to account for curvature and dilation of the yield surface.

Fakharian and Evgin (1995) developed a 3-D apparatus capable of performing direct and simple shear type testing of interfaces between soil and structure. The developed apparatus was subsequently used to perform numerous experiments Fakharian and Evgin (1996); Evgin and Fakharian (1997); Fakharian and Evgin (1997); Fakharian (1996); Fakharian et al. (2002) over sand-steel interface for different stress paths for different relative densities D_r of sand. The 3-D apparatus made it possible to conduct 2-D

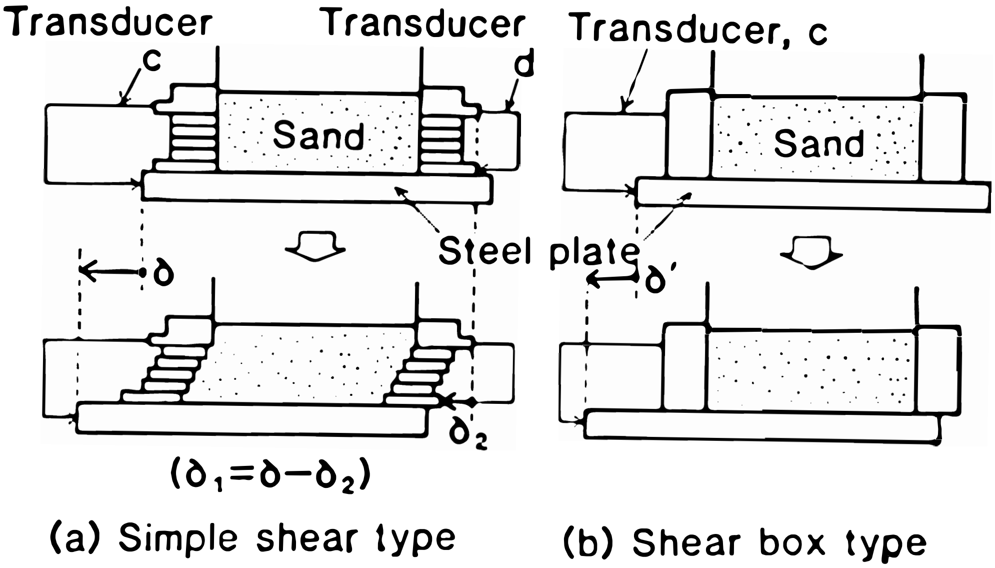

Figure 104.30: Measurement of tangential displacement (Uesugi and Kishida (1986b)).

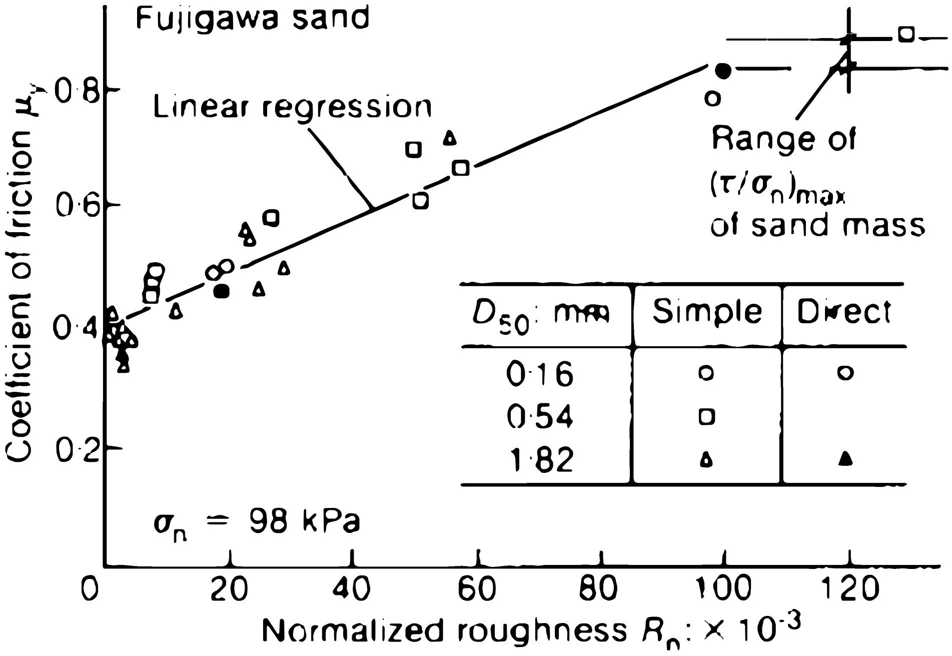

Figure 104.31: Coefficient of friction at yield μ_y and normalized roughness (after Kishida and Uesugi (1987)).

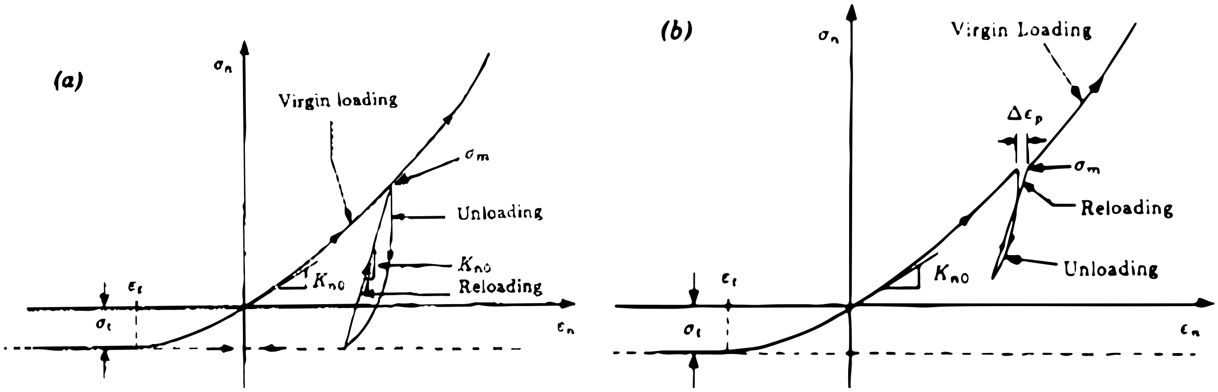

Figure 104.32: Schematic of Stress-Strain Response for Normal Behavior (Desai and Nagaraj (1988)) : (a) Virgin Loading and unloading with Tensile stress Condition; (b) Partial Loading.

shear test with constant normal stress σ_n. Monotonic and cyclic test results are shown in Figure 104.34 and Figure 104.34. The experiment results in Figure 104.34 clearly shows a peak shear stress ratio $(\tau/\sigma_n)_p$ and a residual stress ratio $(\tau/\sigma_n)_r$. Initial hardening and then softening depends upon the relative density D_r of the sand was observed. A higher relative density $D_r = 80\%$ sand shows dilation for lower confinement and thus a peak behavior whereas a low relative density $D_r = 25\%$ sand shows no dilation. For cyclic shear tests, the loose soil $D_r = 25\%$ shown in Figure 104.35(b) showed gain in strength due to densification resulting from particle breakage. While for soil with high relative density $D_r = 80\%$ almost no gain in shear strength was observed during cyclic shearing. The 3-D tests performed showed that the shear stress τ is almost isotropic for different shear stress paths.

Shahrour and Rezaie (1997) performed a series of monotonic and cyclic tests on Hostun Sand with rough and smooth surface with constant normal load condition. The results obtained were used to propose an elasto-plastic bounding surface based constitutive model for the interface behavior. The monotonic and cyclic test are shown in Figure 104.36 for rough and smooth interface surface. From Figure 104.36, it could be observed that for smooth interface, the shear stress τ increases only upto the critical shear stress τ_c. Whereas for rough soil, the shear stress τ hardens to a peak strength τ_p and then softens to the critical shear strength τ_c. The behavior observed for rough and smooth interface is similar to dense and loose soil as observed in tests by Fakharian and Evgin (1996). The cyclic test shown in Figure 104.36(c) showed similar response as was observed by Fakharian and Evgin (1996).

Dejong et al. (2006) performed laboratory soil-structure investigation under constant normal stiffness using particle image velocimetry (PIV)method. Cyclic shearing was carried out to simulate and understand the the shear behavior at pile interface. Cyclic degradation exponential model was proposed of model the change in void ratio. Later Mortara et al. (2007) also performed cyclic shear tests on sand

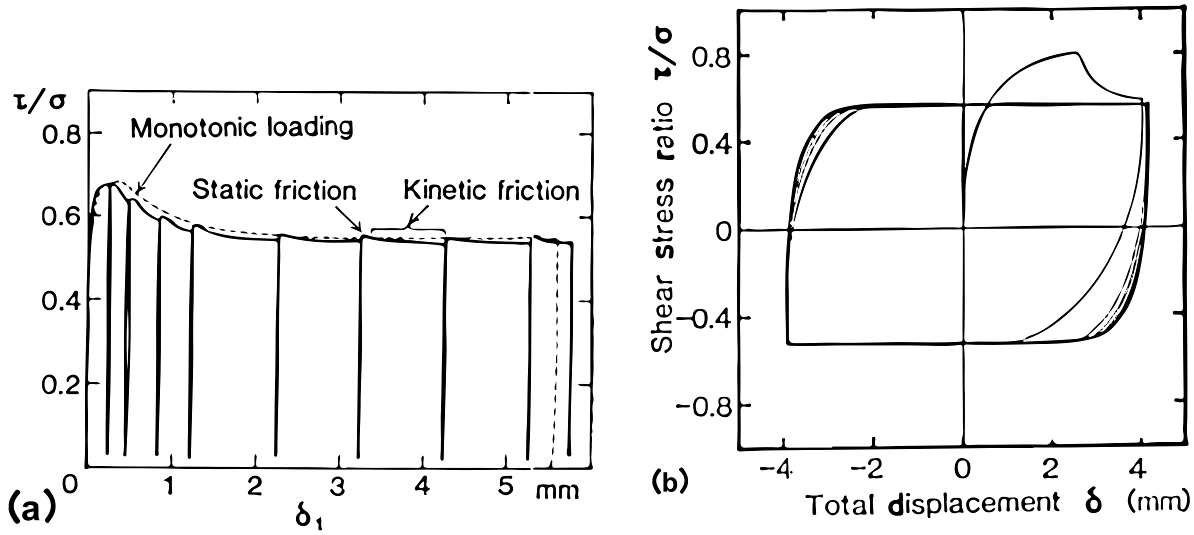

Figure 104.33: (a) Monotonic and (b) cyclic response of Toyora sand with steel interface (Uesugi et al. (1989)) ($D_r = 90\%, \sigma_n = 98kPa, R_n = 150e^{-3}$).

steel interfaces. DeJong and Westgate (2009) quantified the soil-structure interface behavior to the shearing on the factor like relative density D_r, particle angularity, particle hardness, surface roughness, normal stress and normal stiffness. Local as well as global load displacement response was recorded to understand the load-transfer mechanism.

104.7.2 Axial Contact, Joint, Interface

The contact/joint/interface behavior in the normal direction is modeled as penalty stiffness function as described in the Section 104.7.2.1. The penalty function can be chosen as linear with fixed stiffness also known as Hard Contact/Joint/Interface (Section 104.7.2.2), or it can be assumed to be a non-linear function with stiffness increasing exponentially with penetration. This type of normal behavior is called as Soft Contact/Joint/Interface (Section 104.7.2.3). Soft Contact/Joint/Interface represents more realistic soil-structure interface behavior. The soil becomes stiff as the penetration increases and gets relaxed upon unloading.

104.7.2.1 Penalty Method

At the interface of the soil-foundation system, an impenetrability constraint exists as shown in Equation ?? to ??. The contacting/interfacing bodies cannot penetrate into each other. The impenetrability leads to an inequality constraint, which requires special methods such as penalty method, Lagrange, barrier,

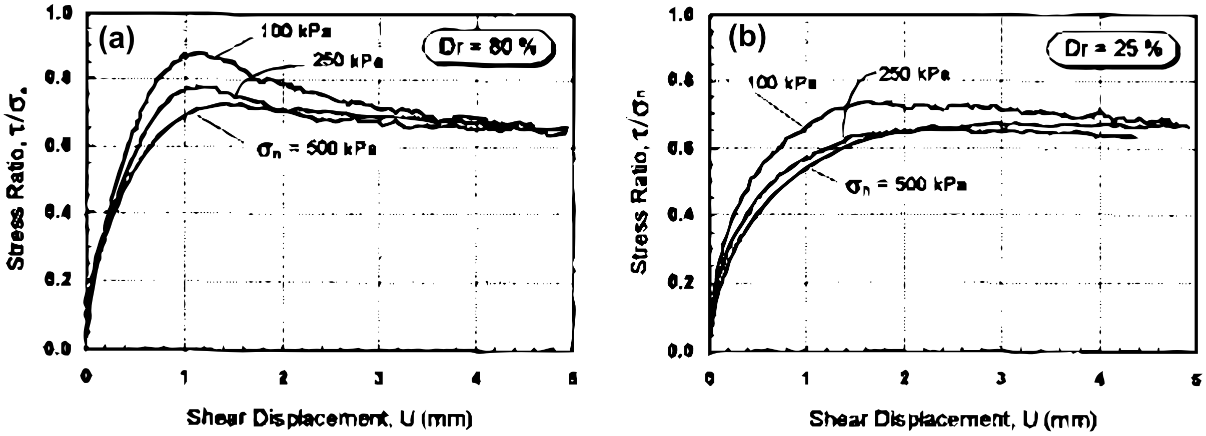

Figure 104.34: Stress ratio versus shear displacement for $\sigma_n = 100, 200, 500 kPa$: (a) rough surface-dense sand ($D_r = 80\%$); (b) rough surface loose sand ($D_r = 25\%$) (Fakharian and Evgin (1996)).

augmented Lagrangian, etc. as described in (Wriggers, 2002). Penalty method is a common approach used for solving constrained minimization (or maximization) problems involving inequalities as described in section ?? and Section ??. In this approach, a large penalty term is added to the minimizing functional to prevent the solution from escaping the constrained space.

Figure 104.37 shows a two contact/interface node pairs initially separated by a small distance of g in the contact/interface normal direction. During pure contact/interface/joint, the two node penetrates against each other by Δ_n. The instantaneous relative distance between the two contact/interface surfaces is u. Thus, if $u < g$ there is no contact/interface and normal force $N = 0$ otherwise there is contact/interface and a normal force N will act.

In the penalty stiffness formulation, a small penetration Δ_n is allowed between the mass and the floor having stiffness k_n such that during contact the normal force N is defined as

$$N = k_n \Delta_n \;\; if \;\; \Delta_n \geq 0 \tag{104.584}$$

where k_n can be thought of the normal contact/interface stiffness and Δ_n is the relative displacement between the two contact/interface surfaces with respect to the initial gap g in contact/interface normal direction. It is defined as the following

$$\Delta_n = u_n^r - g_n = u - g \tag{104.585}$$

where u_n^r is the relative displacement in the contact/interface normal direction and g_n is the initial gap in contact/interface normal direction. Theoretically, for rigid contact/interface case, the penalty stiffness k_n is assumed to infinite resulting in $\Delta_n = 0$. However, for numerical reasons, infinity is not possible, and

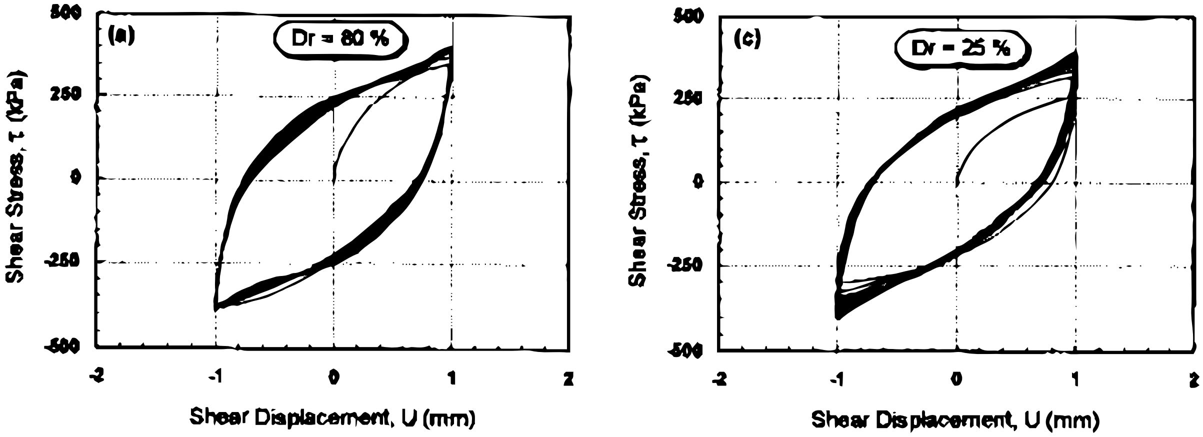

Figure 104.35: Cyclic test results, shear stress versus shear displacement for $\sigma_n = 500kPa$: (a) rough surface, dense sand ($D_r = 80\%$); (b) rough surface, loose sand ($D_r = 25\%$) (Fakharian and Evgin (1996)).

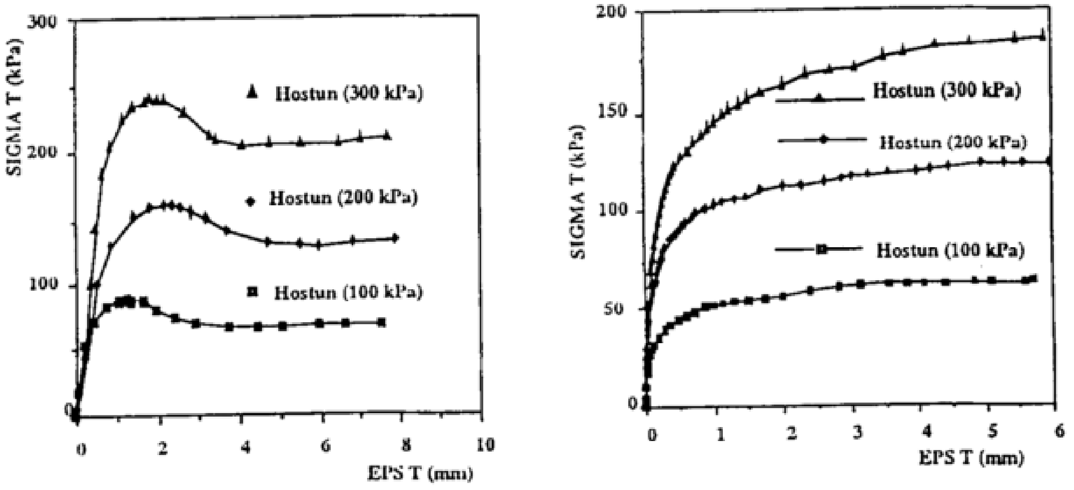
thus $\Delta_n = 0$ is never enforced. This results in small penetration at contact/interface surfaces resulting in $\Delta_n < 0$ during contact. For penalty method, the term penetration is thus normally referred to Δ_n defining the two possible states as:

- *No Contact/Joint/Interface* (Penetration $\Delta_n > 0$)
- *Contact/Joint/Interface State* (Penetration $\Delta_n \leq 0$)

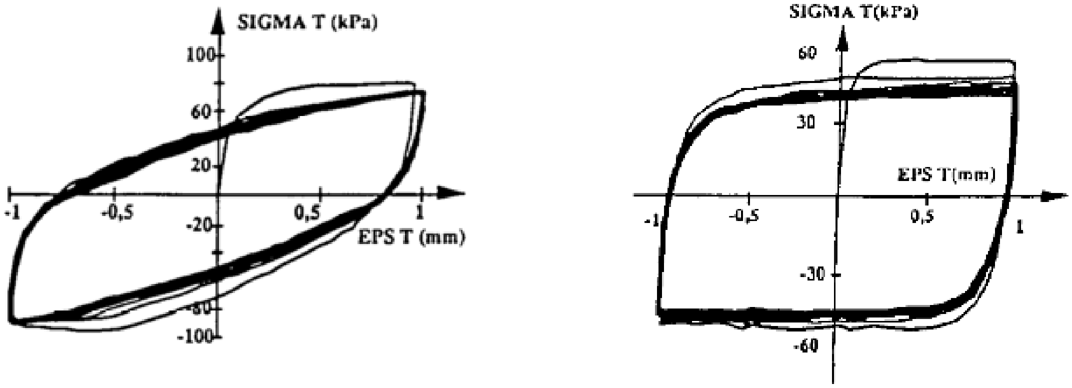
In equation 104.584, if the penalty stiffness parameter k_n is assumed to be constant and independent of penetration (Δ_n), it is referred as a hard contact. This type of contact/interface is more physical for interactions between two rigid surfaces or bodies. However, to model interaction between soft-soil and rigid foundation, a soft contact/interface with penalty stiffness increasing with penetration is preferred. The following Section 104.7.2.2 and 104.7.2.3 describes hard and soft contact/interface respectively.

For coupled contact/interface problems described in Section ??, in order to enforce the no-drainage condition in contact/interface normal direction between U (soil) and u (foundation) degrees of freedom, an additional penalty stiffness parameter k_p is required. Section ?? describes how penalty stiffness k_p is used to enforce the undrained condition.

It must be noted that in the penalty or any other method (Lagrange, barrier .. etc.) as described in (Wriggers, 2002), to get to the solution it has to take into account of whether the contact/interface is active or not. Thus, the inequality constraint has to be changed to the active (closed gap) or inactive (open gap) based on the state of contact. As a result, the topology of the structure changes due to



(a) Rough Interface (b) Smooth Interface



(c) Cyclic test on rough Interface (d) Cyclic test on smooth interface

Figure 104.36: (a) and (b) Monotonic and (c) and (d) cyclic test on dense Hostun sand and steel interface(Shahrour and Rezaie (1997)).

contact. This points out one of the difficulties while solving the contact/interface problem i.e. the stiffness matrix changes with active or inactive constraint equations.

As compared to one of the popular Lagrange method, the penalty method leads to non-physical penetration but does not create any additional variables. However, the non-physical penetration could be utilized to model more complicated normal contact/interface force function as such for soft contact/interface shown in Figure ?? and non-linear shear interface models as described in section ??.

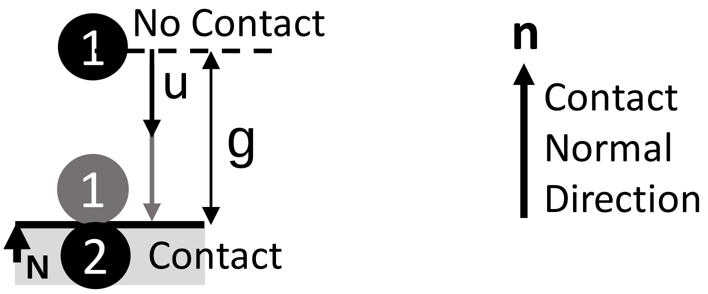


Figure 104.37: Contact/Interface/Joint Node Pairs.

104.7.2.2 Hard Contact/Joint/Interface

In hard contact, the normal penalty stiffness k_n is assumed to be constant with penetration Δ_n. As a result, the normal contact/interface force F_n or stress σ_n varies linearly with penetration.

$$\begin{aligned} F_n &= k_n \Delta_n \\ \sigma_n &= k_n \epsilon \end{aligned} \tag{104.586}$$

where k_n represents the normal stiffness between soil-structure interface and Δ_n is the penetration in contact/interface normal direction.

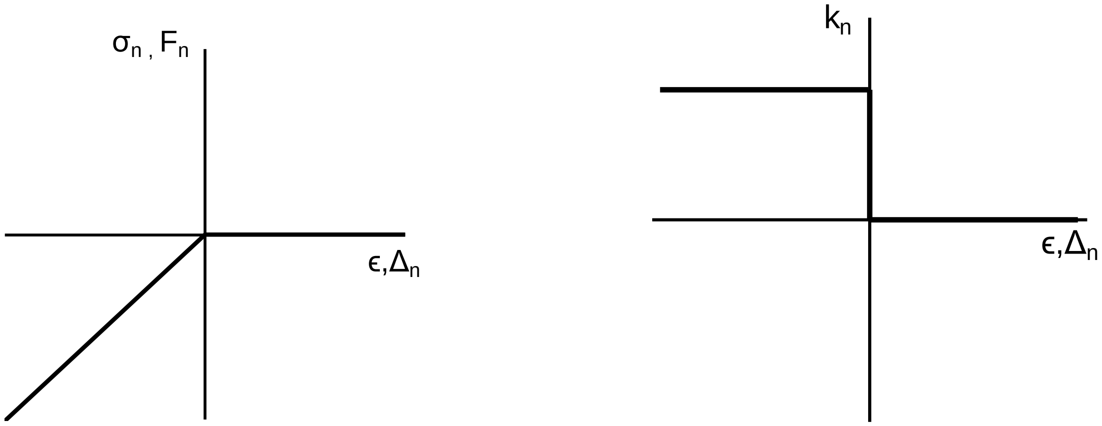

Figure 104.38: Hard contact/interface normal (a) force and (b) stiffness function with penetration Δ_n

Figure 104.38 shows the normal force F_n or stress σ_n and stiffness k_n as a function of penetration Δ_n or normal strain ϵ respectively. The normal stiffness k_n is assumed to be constant and thus has an abrupt jump or discontinuity at $\Delta_n = 0$ leading to C^0 continuity. The abrupt change of stiffness could often lead to numerical convergence problems.

104.7.2.3 Soft Contact/Joint/Interface

For rocks, (Gens et al., 1990) presented a nonlinear (hyperbolic) function of elastic normal stress with penetration. The function had different stiffness for loading and unloading up-to a permanent deformation u_{mc}. The hyperbolic function $u/(u - u_{mc})$ has a singularity at $u = u_{mc}$. It does not increase monotonically and does not poses continuous derivatives for $u \geq 0$. In FEM since, the stiffness cannot be infinite at $u = u_{mc}$ and the displacement u can be greater than $u \geq u_{mc}$, which can lead to numerical instability and convergence problems. As per authors knowledge, there has not been enough experimental investigation to understand the normal contact/interface behavior of the soil-structure interface. Desai and Nagaraj (1988) claim to have performed cyclic normal tests on a concrete-soil interface on a shear box but did not show any experimental results. Desai and Nagaraj (1988) idealized the normal behavior based on the critical state soil mechanics as shown in Figure 104.32. (Bandis et al., 1983) investigated the response of fresh and weathered rock. It could be observed that after some $(2-4)$ cycles, the loading and unloading curve fairly overlaps and could be approximated by the same function. More recently, Lei and Barton (2022) presented a very nice set of experiments with data for proper choice of interface parameters.

The normal behavior at the interface being modeled here using penalty stiffness approach, a non-linear exponential elastic function is assumed for the soft contact. The parameters include an initial stiffness k_i and a stiffening rate S_r to control the normal stress σ_n function with penetration Δ_n. In comparison to hard contact, soft contact/interface thus has a smooth exponential, normal contact/interface force function with penetration as shown in Figure ??. The exponential variation is expected to match the realistic increasing contact force with penetration as shown in Figure 104.32. As stated earlier, it must

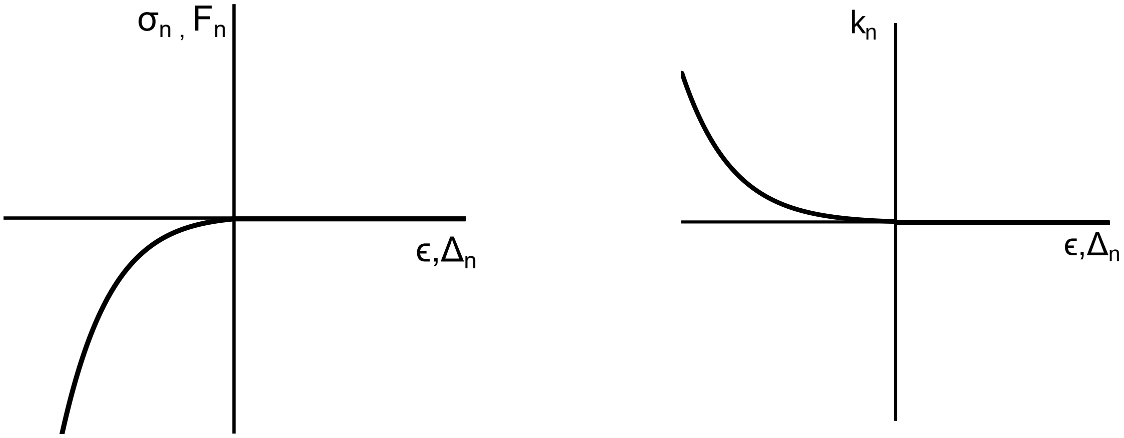

Figure 104.39: Soft contact/interface normal (a) force and (b) stiffness function with penetration Δ_n

be noted that in this model the response is assumed to be fully non-linear elastic with no tensile region. As a result, the loading and unloading stiffness and response is the same.

The non-linear normal force F_n or stress σ_n is defined as:

$$\begin{aligned} F_n &= k_i exp(-S_r \Delta_n) \Delta_n \\ \sigma_n &= k_i exp(-S_r \epsilon) \epsilon \end{aligned} \tag{104.587}$$

where k_i represents the initial normal stiffness between soil-structure interface and S_r represents the stiffening (or hardening) rate with penetration Δ_n or normal strain ϵ. Equation 104.587 represents the normal force F_n and stress σ_n for force based and stress based contact respectively. At soil-foundation interface, as the foundation penetrates more, the soil becomes harder resulting in an increase of interface normal stiffness k_n and normal stress σ_n. The stiffening rate leads to an exponential increment of contact/interface stress per unit of penetration Δ_n. From the above formulation it must be noted that for the stress based contact, the penetration Δ_n is replaced with normal strain ϵ. Subsequently, the parameters initial normal stiffness k_i and stiffening rate S_r should also be calibrated accordingly. Similarly, the stiffness and other derivatives could be obtained by replacing penetration Δ_n with normal strain ϵ. The normal stiffness k_n has unit of n/m for the force based contact/interface and Pa for the stress based contact.

Equation 104.587 could be differentiated to get the stiffness k_n as:

$$\begin{aligned} k_n &= k_i exp(-S_r \Delta_n)(1 - S_r \Delta_n) \\ k_n &= k_i exp(-S_r \epsilon)(1 - S_r \epsilon) \end{aligned} \tag{104.588}$$

It can be observed from equation 104.588 that putting $\Delta_n = 0$, the normal stiffness k_n becomes equal to initial normal stiffness k_i i.e. $k_n = k_i$. When $\Delta_n \geq 0$, the stiffness grows exponentially. Extending Equation 104.587 and 104.588 to uplift (no-contact) ($\Delta_n \geq 0$), with the assumption of small initial stiffness k_i, the force and stiffness function would lead to C^1 continuity. The C^1 continuity thus would lead to a smooth stiffness function even at the border of contact/interface and non-contact region resulting in quadratic convergence at global FEM level for the Newton-Raphson method. However the non-linear behavior would lead to comparatively larger number f iteration than hard contact,

It is also interesting to note that by setting the stiffening rate $S_r = 0$, hard contact/interface can be recovered i.e. $k_n = k_i$ and $\sigma_n = k_n \epsilon$. This demonstrates the generality of soft contact/interface formulation.

The exponential growth of stiffness in finite element method (FEM) can lead to numerical instability for large values. To avoid this, a maximum normal stiffness k_n^{max} is applied to restrict its further growth. Figure 104.40 shows the stiffness k_n function with and without a cap. The stiffness function thus can

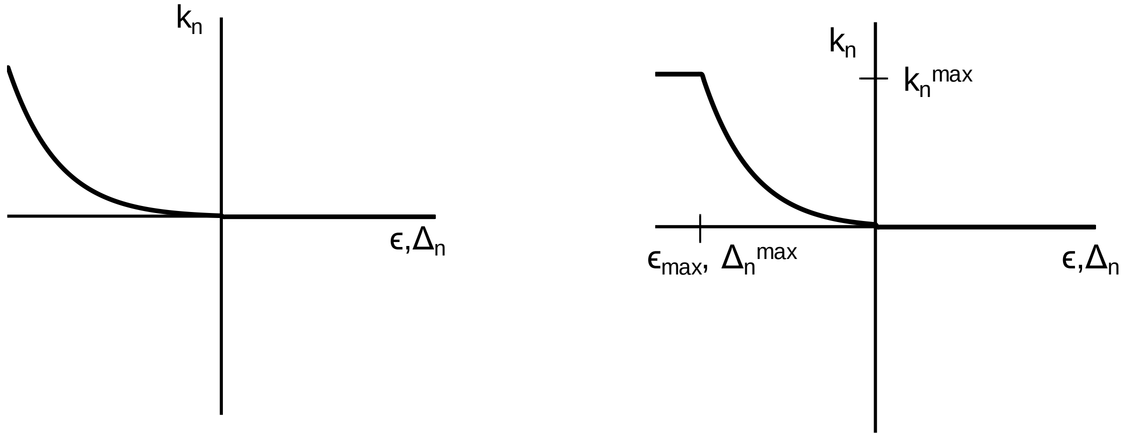

Figure 104.40: Soft Contact Stiffness function (a) without any limit and (b) with limit

be written as:

$$\begin{aligned} k_n &= max(k_i exp(-S_r \Delta_n)(1 - S_r \Delta_n), k_n^{max}) \\ k_n^{max} &= k_i exp(-S_r \Delta_n^{max})(1 - S_r \Delta_n^{max}) \end{aligned} \tag{104.589}$$

For implementing the above Equation 104.589 in FEM, there would be a need to find Δ_n^{max} corresponding to maximum allowable normal stiffness k_n^{max} in order to integrate the stiffness function k_n. An efficient method to get Δ_n^{max} is described in Section 104.7.2.3 below.

Iterative Method To Find Δ_n^{max} . For soft contact/interface implementation in FEM, it would be required to find out Δ_n^{max} for a given initial normal stiffness k_i, stiffening rate S_r and maximum normal stiffness k_n^{max}. Since Equation 104.589 is a nonlinear function, an iterative method is needed to get to the solution. One of the best solution search methods is the bisection method, which repeatedly bisects an assumed solution interval, choosing only one of the branches where the solution might exist. In this method, an initial guess of solution space is required.

Theoretically, a large solution space could be given but would not be computationally feasible and optimal. For the given problem, it is often desired to predict solution space to get in as fewer iterations as possible. To reach the solution optimally and efficiently, an initial guess of solution range for penetration Δ_n was found to be $[k_n^{max}/k_i, 0.5 k_n^{max}/k_i]$.

104.7.3 Shear Contact/Joint/Interface

104.7.3.1 Interface Shear Zone

At the soil-structure interface, there exists a thin shearing zone of 5-20 times the D_{50} Yoshimi and Kishida (1981); Martinez et al. (2015); Dejong et al. (2006); DeJong and Westgate (2009) as shown in Figure 104.41. Since the interface constitutive models are defined in stress-strain space, the applied displacements must be converted to strains. Based on the shear zone thickness SZ_h, the total shear strain γ and incremental shear strain $\Delta\gamma$ can be calculated as

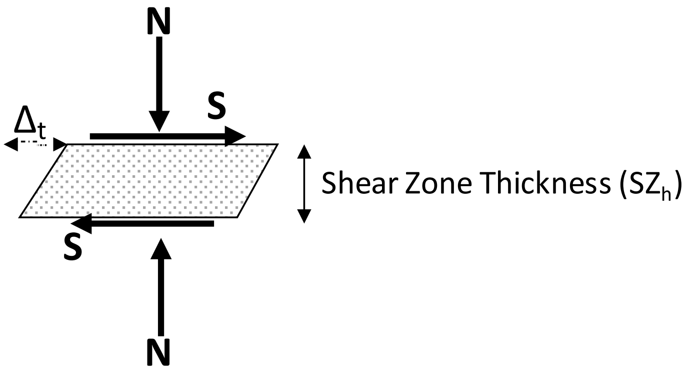

Figure 104.41: Thin shear zone at soil-structure interface

$$\begin{aligned} \gamma &= \Delta_t / SZ_h \\ \Delta\gamma &= \delta\Delta_t / SZ_h \end{aligned} \tag{104.590}$$

where Δ_t and $\delta\Delta_t$ are the total and incremental shear displacement at the interface between the two soil-structure contact/interface surface.

Similarly, the normal strain ϵ and incremental normal strain $\Delta\epsilon$ can be calculated as

$$\begin{aligned} \epsilon &= \Delta_n / SZ_h \\ \Delta\epsilon &= \delta\Delta_n / SZ_h \end{aligned} \tag{104.591}$$

where Δ_n and $\delta\Delta_n$ are the total and incremental penetration in contact/interface normal direction. In the interface constitutive models, the normal strain ϵ is generally also referred as volumetric strain ϵ_v Stutz (2016). The normal stress is assumed to offer confinement to the interface shear band. It must be noted that although a shear band of thickness SZ_h is assumed, the interface element itself has zero thickness. The shear zone thickness SZ_h is a material parameter for the interface models. The shear zone thickness can vary based on the roughness of the soil-structure interface but could be generally assumed to be around 5-20 mean particle size diameter D_{50}.

Shear Contact/Joint/Interface Models. This section describes three models to describe the non-linear shear interface behavior which is intended to capture some of the actual soil-structure interface response.

Apart from the traditional Mohr-Coulomb i.e. Elastic-Perfectly Plastic Shear (EPPS) model, two additional non-linear models have been proposed. The Non-Linear Hardening Shear (NLHS) is a non-linear Armstrong-Frederick type hardening model where the normalized shear stress parameter $\mu = \tau/\sigma_n$ increases non-linearly from 0 to residual normalized shear stress $\mu_r = \tau_r/\sigma_n$. Non-Linear Hardening Softening Shear (NLHSS) adds one more level of sophistication. It can model the softening of normalized shear stress parameter μ. Once the peak normalized shear stress $\mu_p = \tau_p/\sigma_n$ is attained, it starts to decrease to the residual normalized shear stress μ_r. Figure 104.42 shows a typical monotonic response of the three models for a constant normal stress σ_n;

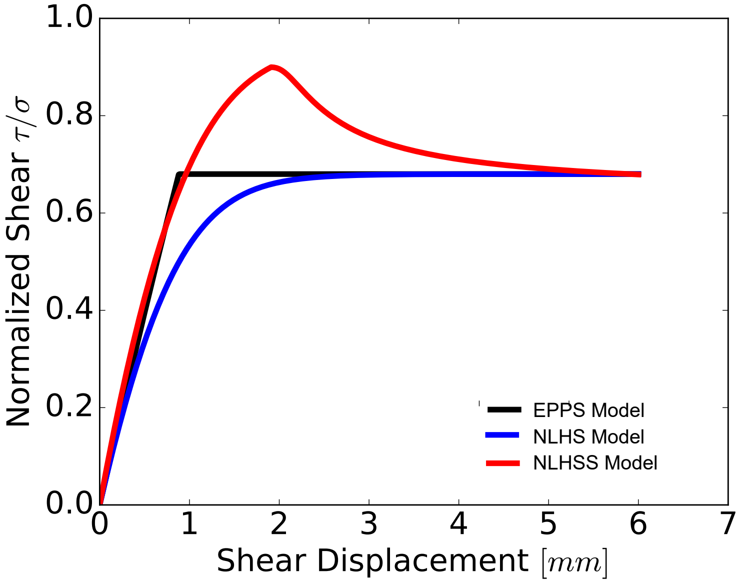

Figure 104.42: Comparison of the interface models with monotonic response

From the Figure 104.42, it can be observed that the models behave quite differently. The EPPS model reaches the residual state at very small shear strain $\gamma = \Delta_u/SZ_h$ level where as because of non-linear hardening both NLHS and NLHSS reach at larger shear strains γ. EPPS and NLHS do not show any peak behavior whereas NLHSS shows a peak followed by softening to residual strength. The models are explained in detail in the next section. NLHS and NLHSS model assume to have negligible to no elastic region and follow the elasto-plasticity theory. And since, the linear Armstrong-Frederick hardening parameter H_a is assumed to be equal to the elastic stiffness k_t resulting in the overall elasto-plastic stiffness equal to $0.5k_t$. The thin shear zone at the soil-structure interface starts to develop plastic deformation as soon as a small shear stress τ is applied. It must also be noted in Figure 104.42 that the elastic shear stiffness k_t depends upon the normal stress σ_n. Thus, for a given normal stress σ_n, the shear stiffness k_t is defined as

$$k_t = k_t^{\sigma_n} = (k_t)^{\sigma_{p0}} \frac{\sigma_n}{\sigma_{p0}} \tag{104.592}$$

where σ_{p0} is the constant stress of $101.3kPa$ and $(k_t)^{\sigma_{p0}}$ is the shear stiffness for a normal stress of $\sigma_n = \sigma_{p0} = 100kPa$. The models are thus developed using kinematic hardening plasticity with initial kinematic hardening stiffness H_a equal to the elastic stiffness k_t. As stated above, this leads to initial elastic-plastic stiffness equal to $0.5k_t$ and also results in incremental elastic strain energy equal to the incremental plastic free energy as described in Section ??.

104.7.3.2 Elastic Perfectly Plastic Shear (EPPS) Model

The simplest shear interface model is the Mohr Coulomb interface model with an elastic stiffness under no slippage and zero stiffness when it slips. The material behavior is of type elastic-perfectly plastic type. The yield function (f) is thus given as

$$f := \tau - \mu\sigma_n \leq 0 \tag{104.593}$$

where μ is a constant coefficient of friction, τ is the shear stress and σ_n is the normal stress.

Figure 104.43 shows the performance of EPPS model for different loading conditions. Since it is a elastic perfectly-plastic model, the shear stiffness k_t is constant with shear strain γ or displacement Δ_t and becomes zero (perfectly-plastic state) when it reaches its residual friction coefficient μ_r. Figure 104.43(a) and 104.43(c) shows the monotonic and full cyclic response with elastic perfectly-plastic behavior respectively. Figure 104.43(b) and 104.43(d) shows the monotonic cyclic behavior before and after reaching the residual friction coefficient μ_r. This kind of interface behavior is mostly observed between rigid surfaces in contact. For more realistic soil-structure interface non-linear yield function should be used as described in the coming sections.

104.7.3.3 Nonlinear Hardening Shear (NLHS) Model

In this model, the normalized shear stress hardening variable μ increases from 0 to critical or residual normalized shear stress μ_r using the non-linear Armstrong Frederick type hardening law. The evolution rule for frictional hardening variable μ is given as

$$\Delta\mu = k_t \Delta\gamma^p - \frac{k_t}{\mu_r} |\Delta\gamma^p| \mu \tag{104.594}$$

where k_t is the non-linear elastic hardening variable and $\Delta\gamma^p$ is the plastic part of the shear strain $\Delta\gamma$. The material behavior is thus of type non-linear hardening type.

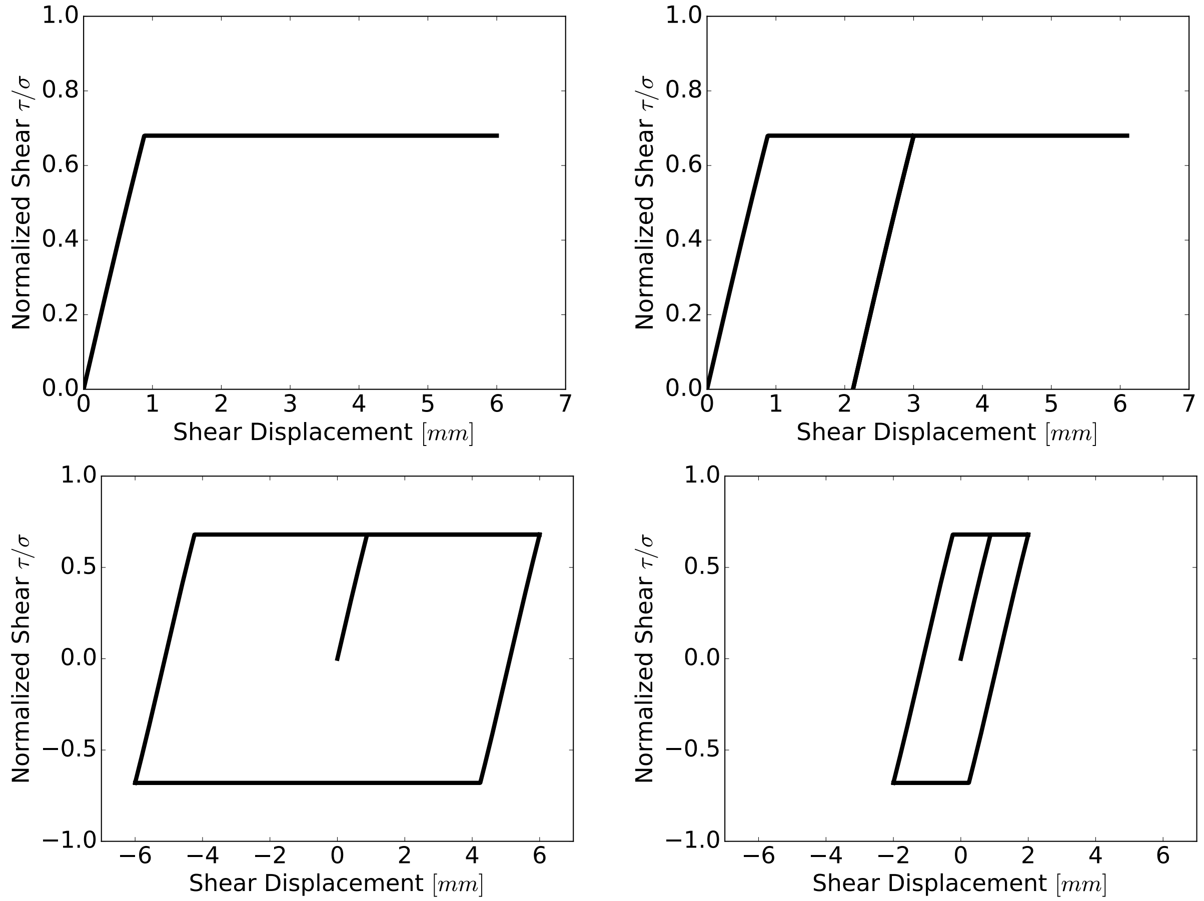

Figure 104.43: Response of Linear Elastic Perfectly Plastic Shear (EPPS) Model with normal stress of $100kPa$, residual coefficient of friction $\mu_r = 0.68$, shear stiffness $k_t = 200kPa$ and shear zone length $SZ_h = 5mm$.

The yield function (f) is still given as

$$f := \tau - \mu\sigma_n \leq 0 \tag{104.595}$$

where the normalized shear stress hardening variable μ evolves by Equation 104.594, τ is the shear stress and σ_n is the normal stress.

Figure 104.44 shows the performance of NLHS model for different loading conditions. It can be observed that the hardening variable μ increases non-linearly from 0 to residual normalized shear stress ratio μ_r at large shear displacements. As compared to the EPPS models, it is more realistic as the soil-structure interface develops the shear strength gradually with increments of shear strain $\Delta\gamma$ or shear displacements Δ_t.

For loose or low relative density D_r soil at soil-structure interface Fakharian and Evgin (1996);

Shahrour and Rezaie (1997) as shown in Figure 104.34(b) and 104.36(b), this model could be calibrated to model the non-linear hardening response. The monotonic and full cyclic response of this model shown in Figure 104.44(b) can be seen to match the interface behavior investigated by Uesugi et al. (1989) and is shown in Figure ??. Figure 104.44(d) shows the response of the model subject to cyclic shearing before reaching the residual strength. It could be observed that it is able to model the non-linear interface behavior as investigated by Fakharian and Evgin (1996); Shahrour and Rezaie (1997) which is shown in Figure 104.35 and Figure 104.36(c) respectively.

For dense soil with higher relative density D_r, it is important to model the peak normalized shear stress μ_p, followed by the softening behavior until the residual shear stress μ_r is reached. The NLHSS model proposed in next section can be used to model both hardening and softening.

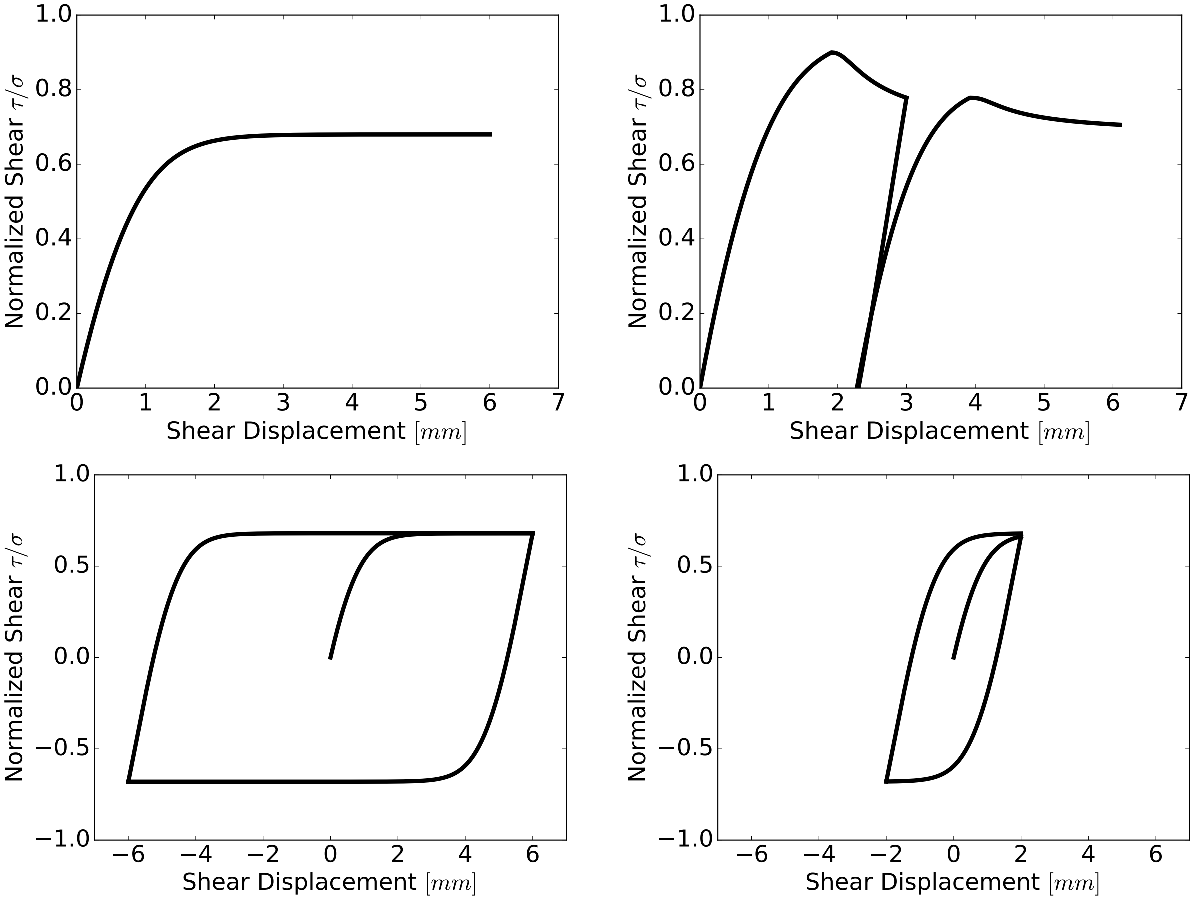

Figure 104.44: Response of Non-Linear Hardening Plastic Contact/Joint/Interface (NLHS) model with normal stress of $100kPa$, residual normalized shear stress of $\mu_r = 0.68$, shear stiffness $k_t = 400kPa$ and shear zone length $SZ_h = 5mm$.

104.7.3.4 Nonlinear Hardening Softening Shear (NLHSS) Model

In this model, the normalized shear stress hardening/softening variable μ increases from 0 to its peak limit μ_p and then with more shear displacement reaches to the residual normalized shear stress of μ_r using a non-linear Armstrong Frederick type hardening/softening law. The evolution of the hardening/softening variable μ during hardening phase is given as

$$\Delta\mu = k_t \Delta\gamma^p - \frac{k_t}{\mu_p}|\Delta\gamma^p|\mu \tag{104.596}$$

where k_t is the non-linear hardening variable and $\Delta\gamma^p$ is the the plastic part of incremental shear strain $\Delta\gamma$. Once the peak normalized shear stress is attained, the material starts to soften. The softening behavior is modeled as reduction of normalized shear stress ratio μ as

$$\Delta\mu = -\frac{n * b(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta\Delta\gamma^p \tag{104.597}$$

$$\theta = \frac{\mu_p - \mu}{\mu_p - \mu_r}(\pi/2)^n \tag{104.598}$$

where b is the softening rate, $\Delta\gamma^p$ is the incremental plastic shear strain and n represents the size of the peak plateau as shown in Figure 104.45. This incremental form of softening phase is derived from the inverse tangent function raised to power n as

$$f = a * (arctan(b * \gamma^P))^n \tag{104.599}$$

where a is a constant parameter of the function and in Equation 104.598 is equal to $(\mu_p - \mu)/(\mu_p - \mu_r)$. The softening rate parameter b represents the rate at which the normalized shear stress μ_p decreases with further application of shear displacement Δ_t as shown in Figure 104.45. A larger value of b would result in faster decay. The size of peak plateau parameter n determines the size of the plateau formed at the peak as shown in Figure 104.45. A larger value of n would result in a larger plateau. It must be noted that the peak plateau size parameter n also influences the overall rate of softening as could be seen from the derived incremental Equation 104.598. The parameters n and b can be calibrated from monotonic shearing tests. Figure 104.46 shows the response of the model with the peak plateau size parameter $n = 4$ and softening rate parameter $b = 40$.

The yield function (f) is again given as

$$f := \tau - \mu\sigma_n \leq 0 \tag{104.600}$$

where μ is a normalized shear stress hardening/softening variable evolved by Equation 205.17 and 104.598, τ is the shear stress and σ_n is the normal stress.

Since in the model, the hardening law is defined as Armstrong-Frederick type, the peak shear stress ratio μ_p is defined as only 95% of the asymptotic limit of the Equation 205.17. Thus, the asymptotic

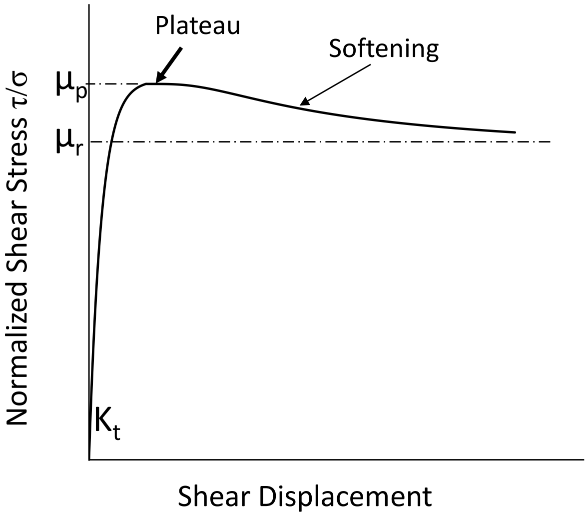

Figure 104.45: Non-Linear Hardening Softening Shear model parameters

limit of Armstrong-Frederick type hardening is raised by a factor of $1/0.95$ times the peak shear stress ratio μ_p.

In this model during cyclic shearing, it is assumed that once the peak strength is passed, the material would not be able to again attain the peak strength during cyclic loading. It is based on the assumption that as the material passes the peak strength, particle breakage and smoothening of the surface takes place which cannot be recovered back by any process. Thus as the material softens, the peak coefficient of friction μ_p is iteratively redefined to the coefficient of friction μ in the softening phase. This effect can also be observed from the tests performed by Uesugi et al. (1989) as shown in Figure ??(b). As soon as the peak shear stress ratio μ_p degrades to residual strength in the first cycle, other cycles follow the residual shear stress ratio μ_r.

Figure 104.44 shows the performance of NLHSS model for different loading conditions. The response of the model is very close to the realistic interface behavior observed by Uesugi et al. (1989) as shown in Figure ??(b) . During cyclic shearing shown in Figure 104.44(c), the model predicts the peak behavior only in the first cycle. After that, the response is governed by the residual normalized shear stress μ_r. Figure 104.44(c) shows the cyclic shearing behavior when the residual normalized shear stress μ_r is not attained in the first cycle. As a result of unloading and reloading, it again attains the last peak normalized shear stress μ_p that it had attained during the softening phase.

NLHSM can be extended further to model the variation of peak normalized shear stress μ_p for different normal stress σ_n conditions as observed in tests by Fakharian and Evgin (1996); Shahrour and Rezaie (1997); Evgin and Fakharian (1997); Fakharian and Evgin (1997); Fakharian (1996); Fakharian

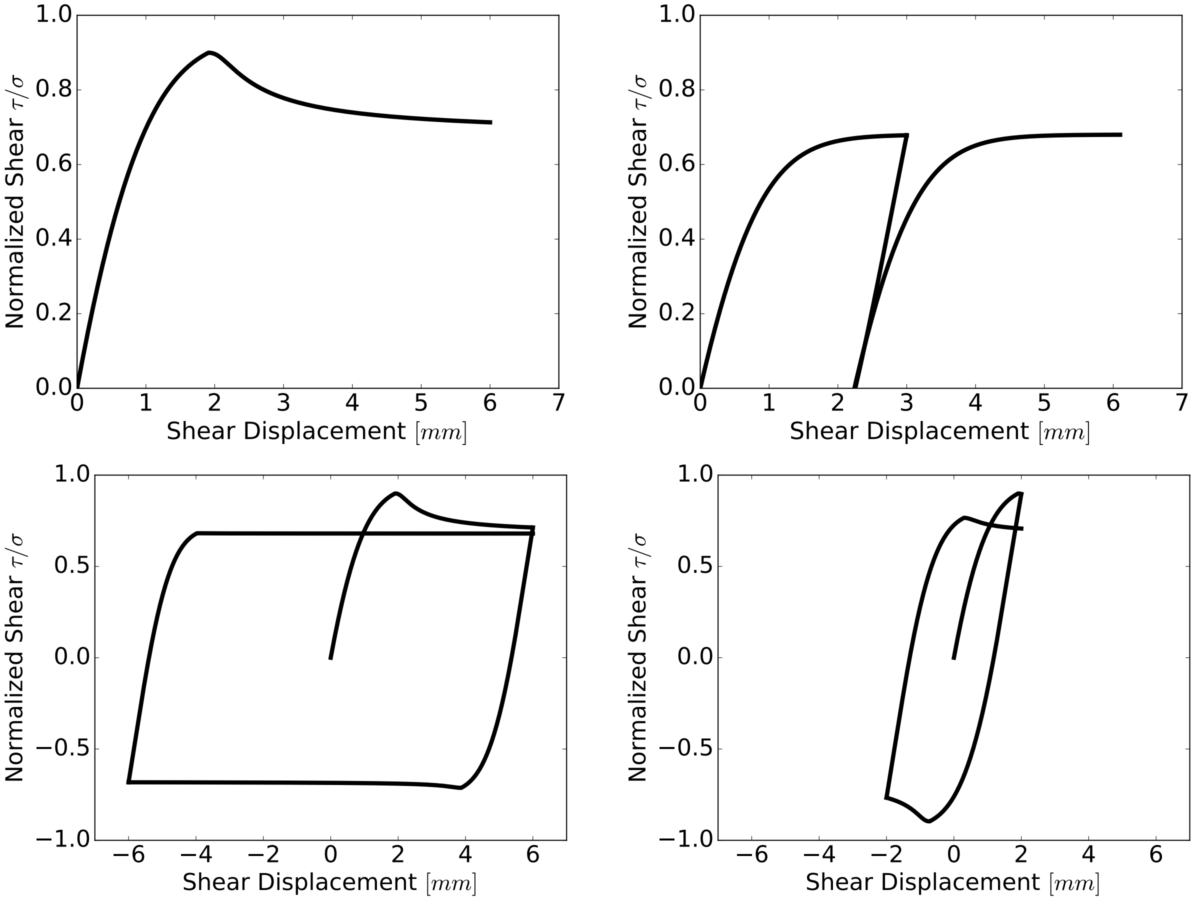

Figure 104.46: Response of Non-Linear Hardening Softening Shear (NLHSS) model with normal stress of $100kPa$, residual normalized shear stress $\mu_r = 0.68$, peak normalized shear stress $\mu_p = 0.9$, shear stiffness $k_t = 800kPa$, peak-plateau parameter $n = 4$, softening rate parameter $b = 40$ and shear zone length $SZ_h = 5mm$.

et al. (2002). For a given relative density D_r of soil in the sheared zone, the peak normalized shear stress μ_p can be generalized to be a logarithmic function of normal stress σ_n as

$$\mu_p = \mu_{p_0} - k * log(\sigma_n/P_0) \tag{104.601}$$

where μ_{p_0} is the peak normalized shear stress at normal stress of $\sigma_n = P_0$, k is the peak normalized shear stress rate of decrease and P_0 is the reference stress of $P_0 = 100kPa$. This is similar to the Bolton (1986) stress-dilatancy relationship observed in sands. In the above Equation 104.601, for the normal stress of $\sigma_n \leq P_0$, the peak normalized shear stress μ_p would become greater than μ_{p_0} as the term $log(\sigma_n/P_0)$ becomes negative. This would result in high peak normalized shear stress μ_p for low confining stress σ_n. As a result, the peak normalized shear stress μ_p needs to be restricted to a value. In this model, it is assumed that μ_{p_0} would also act as the maximum possible peak normalized shear stress μ_p for low normal stresses or confinement. Thus the above Equation 104.601 can be re-written with the limit on peak normalized shear stress μ_p as

$$\mu_p = max(\mu_{p_0}, \mu_{p_0} - k * log(\sigma_n/P_0)) \tag{104.602}$$

where μ_{p_0} also represents the maximum peak normalized shear stress μ_p^{max}, that the sheared zone soil could attain. Thus, with experiments conduction for different normal stress σ_n, the peak normalized shear stress μ_p can be calibrated as the function of normal stress σ_n with peak normalized shear stress limit μ_{p0} and peak normalized shear stress rate of decrease k. Figure ?? shows the response of the model for different normal loads of $100kPa$, $250kPa$ and $500kPa$ and also validates the model with the experimental results from Fakharian and Evgin (1996) as shown in Figure 104.34.

Extending The Models to 3D . Section ?? described the model in 2-D in $\tau - \sigma_n$ space, to make the reader understand the basics of the model. The model can be easily extended to 3-D using the back stress variable α instead of the normalized shear stress μ for NLHS and NLHSS models. In 3-D, there would be normal stress component σ_n in contact/interface normal direction n and two tangential stress components τ_1 and τ_2 in tangential contact/interface plane in directions 1 and 2 respectively. Similarly, the shear strain γ has two components as γ_1 and γ_2 in the two tangential directions 1 and 2 respectively. As stated earlier, since normal interface behavior is assumed to be non-linear elastic, the plastic strains are only developed in shear. Thus the incremental plastic strain $\Delta\gamma^p$ and its magnitude $|\Delta\gamma^p|$ in these models is defined as

$$|\Delta\gamma^p| = \sqrt{\Delta\gamma_1^p \Delta\gamma_2^p} \tag{104.603}$$

$$\Delta\gamma^p = [\Delta\gamma_1^p, \Delta\gamma_2^p] \tag{104.604}$$

where $\Delta\gamma_1^p$ and $\Delta\gamma_2^p$ represents the incremental plastic shear strain components in contact/interface tangential (shear) direction 1 and 2 respectively. The plastic flow direction m is defined as the direction of incremental plastic shear strain $\delta\gamma^p$ and thus is defined as $m = \delta\gamma^p/|\Delta\gamma^p|$

104.7.3.5 EPPS Model

EPPS Model described in Section 104.7.3.2, is the simplest Mohr Coulomb type elastic perfectly-plastic model. The yield function (f) is defined as

$$f := (\tau_1/\sigma_n - \mu_r)^2 + (\tau_2/\sigma_n - \mu_r)^2 = 0 \tag{104.605}$$

where σ_n is the normal stress, τ_1, τ_2 are the shear stress and μ_r is the residual friction coefficient. Being an elastic-perfectly plastic model with no internal variables, there is no hardening/softening evolution rule.

104.7.3.6 NLHS Model

The non-linear hardening shear model described in Section 104.7.3.3 is modeled in 3-D using the back stress internal variable α. The yield function (f), is defined as

$$f := (\tau_1/\sigma_n - \alpha_1)^2 + (\tau_2/\sigma_n - \alpha_2)^2 = 0 \tag{104.606}$$

where σ_n is the normal stress, τ_1, τ_2 are the shear stress and α_1, α_2 are the back stress components in contact/interface tangential direction 1 and 2 respectively on the contact-interface plane. The hardening law would be then defined as

$$\Delta\alpha = k_t \Delta\gamma^p - \frac{k_t}{\mu_p}|\Delta\gamma^p|\alpha \tag{104.607}$$

$$\Delta\alpha = H_m|\Delta\gamma^p| \tag{104.608}$$

$$H_m = k_t m - \frac{k_t}{\mu_p}\alpha \tag{104.609}$$

where μ_p is the peak normalized shear stress, which depends upon the normal stress σ_n as stated in Equation 104.601 and k_t represents the initial elastic shear stiffness of soil-structure interface. H_m represents the non-linear Armstrong-Frederick type hardening modulus and m represents the plastic flow direction.

104.7.3.7 NLHSS Model

The non-linear hardening softening shear model described in Section 104.7.3.4 is also modeled in 3D using the back stress internal variable α. The yield function (f) is defined as Equation 104.606. The hardening evolution law for the back stress α is defined by Equation 104.609. The softening law is defined as Von-Mises type as

$$\Delta\alpha = -\frac{n * b(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta \Delta\gamma^p \tag{104.610}$$

$$\theta = \frac{\mu_p - |\alpha|}{\mu_p - \mu_r}(\pi/2)^n \tag{104.611}$$

$$\Delta\alpha = S_m \Delta\gamma^p \tag{104.612}$$

$$S_m = -\frac{n * b(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta \tag{104.613}$$

where μ_r is the residual normalized shear stress that is constant and depends upon the soil and structure material, μ_p is the peak normalized shear stress at the start of softening phase and S_m represents the softening modulus.

As stated in Section 104.7.3.4, for NLHSS model, the peak normalized shear stress μ_p of the material is iteratively defined to the back stress $\mu_p = |\alpha|$ in softening phase. This means that the dilatancy surface squeezes towards the critical surface as the sheared zone soil at interface continues to shear.

Using the incremental Equation 104.609 Equation 104.613 presented for both hardening and softening phase respectively, the 3-D model can be integrated. using the elastic-plastic theory Hill (1950); Temam (1985); Wu Tai (1966); Lubliner (1990); de Borst and Feenstra (1990); de Borst (1987). The elastic-plastic stiffness or consistent tangent stiffness Jeremić (1994); Crisfield (1987) can then be computed easily at each loading increment or iteration. Section ?? presents the elastic-plastic integration for the interface models.

104.8 Inelastic Behavior and Models for Rock

104.8.1 Overview of Intact Rock Behavior

(Stavrogin et al., 2001), (Fairhurst, 2003), (Mogi, 2006)

Rock, and other geomaterials, feature a distinct set of material behavior that separates them from other natural and/or man made materials. Rock material subjected to shock waves in particular shows a variety of response regimes and behavior that warrant further discussion. Of particular interest are the following specifics of rock behavior: pressure sensitivity, dilative and compactive response, inherent and induced anisotropy, full coupling of porous rock solid with pore fluid and temperature fields and bifurcation response, resulting in shear and compaction bands. Each of these aspects of rock behavior will be described in sections below.

It is also very important to note that this study will focus on behavior of intact rock material, while main focus of research in rock mechanics is on behavior of jointed rock masses. While behavior of discontinuous, jointed rock mass is very important for construction in rock (tunnels, dams, foundations...), behavior of intact rock mass becomes very important for any modeling and simulation of deeper rock structures, particularly where strong shock waves are involved. This is emphasized by the fact that rock blocks do behave like solid for high pressures. For example, during shock loading blocks might fuse at contact/interface and behave like a solid, in which case the inelastic (elastic-plastic) behavior of intact rock mass has major impact on overall rock mass response.

This section uses selection of published results to emphasize distinct features of mechanical response of rock that are considered important for proper modeling of shock wave propagation. While there exist a significant body of published work on behavior of intact rock (which is still much smaller than body of published work on behavior of rock as discrete media), chosen here are publications and results that provide important results used to emphasize distinct features of mechanical behavior of rock. Emphasizing these distinct feature of rock behavior is important for a number of reasons. Two main reasons are that while the shock wave theory was developed over last two centuries (see brief overview in section 104.8.3) main focus was on ideal domains (linear elastic solids or fluids), rock features many distinct modes of mechanical response that demand use of high fidelity numerical modeling. In addition to that, even when shock wave theories were developed for inelastic (elastic-plastic) solids, this was done for metals, elastic-plastic response of which lacks many features found in rock (geomaterial) response (pressure sensitivity, anisotropy, dilative and compactive response...)

104.8.1.1 Pressure Sensitivity

Rock material response shows strong pressure sensitivity. Both initial yielding response, inelastic response and ultimate strength strongly depend on confinement pressure experienced by rock material. Confinement pressure acting on rock can be inherent, coming from location of rock mass (depth) and from geologic factors (tectonics). Fairhurst (2003) details initial stress determination procedures. Initial stress determination (stress level from previous, historical loading stages, tectonics, erosion) is very important in view of pressure sensitivity and elastic-plastic response of rock. Depending on the type of rock material, the effects of confinement pressure on response vary. Figures 104.47 – 104.55) show rest data for a full elastic-plastic response of various rock specimens for varying confinement pressures. Both axial (ϵ_1) and radial (ϵ_2) strains are shown versus axial stress ($\Delta\sigma_1$). It is very important to recognize a number of distinct features of rock behavior that these test show:

- Varying confinement pressure influences yield stress, that is an increase of yield stress is observed with the increase in confinement pressure,
- Elastic stiffness increases with increase in confinement pressure,
- Ductility increases with increase in confinement pressure,
- Increase in confinement pressure significantly influences final strain level achieved
- Volume change (dilation, as observed from radial strain results (ϵ_2) is significant, however, in some cases it increases and in some decreases with confinement pressure increase (as observed in Figures 104.47 – 104.52)
- Elastic degradation/damage is increasing with cycles of loading (Fig. 104.54 for example, reduction of loading-unloading-reloading slope signifies elastic damage)
- Presence of energy dissipation in rock for various confinement pressures (area of hysteresis loops, see for example Fig. 104.53 – 104.55)

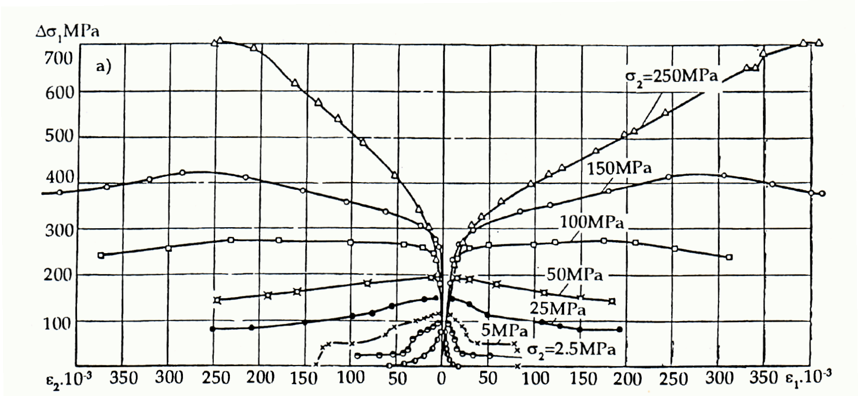

Figure 104.47: Full elastic-plastic response of marble specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

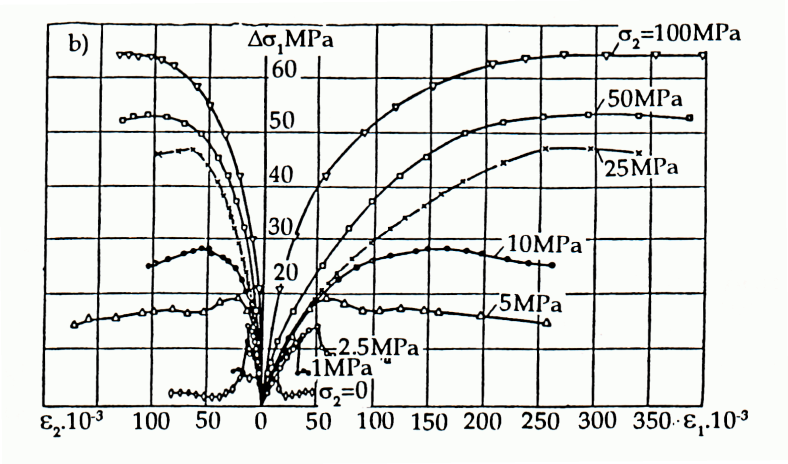

Figure 104.48: Full elastic-plastic response of lignite specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

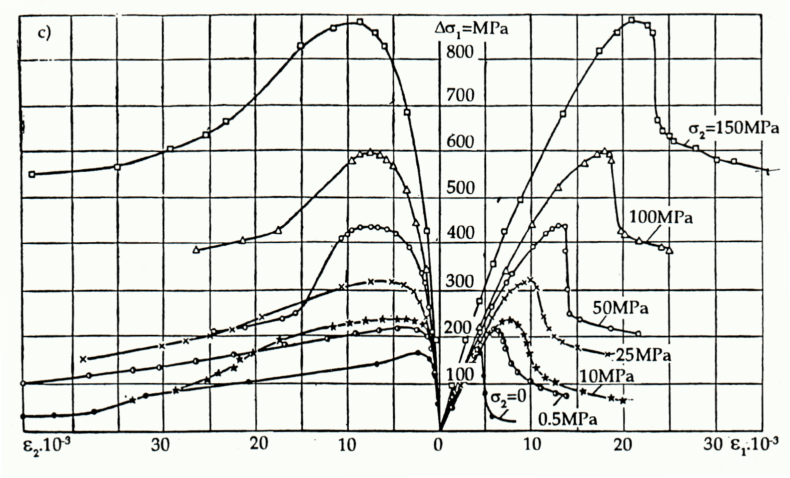

Figure 104.49: Full elastic-plastic response of granite specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

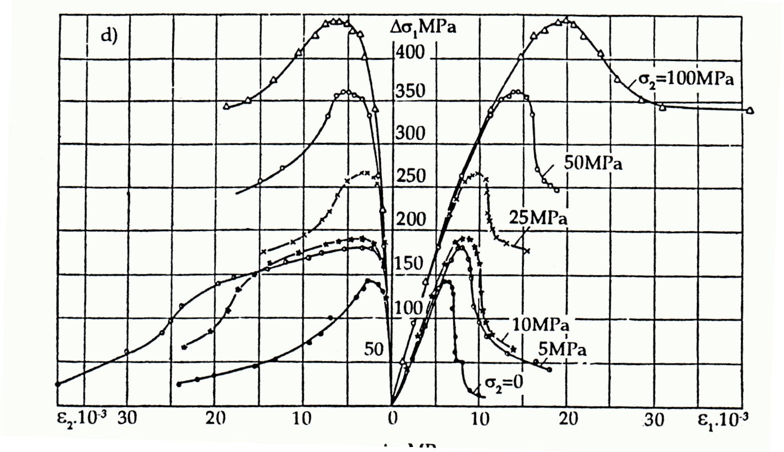

Figure 104.50: Full elastic-plastic response of sandstone (non-burst prone) specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

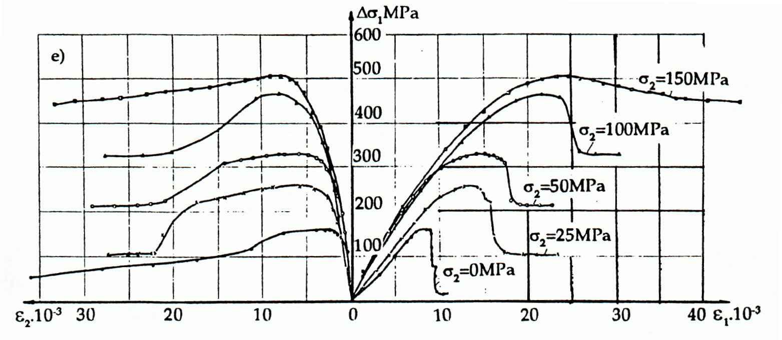

Figure 104.51: Full elastic-plastic response of sandstone (burst prone) specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

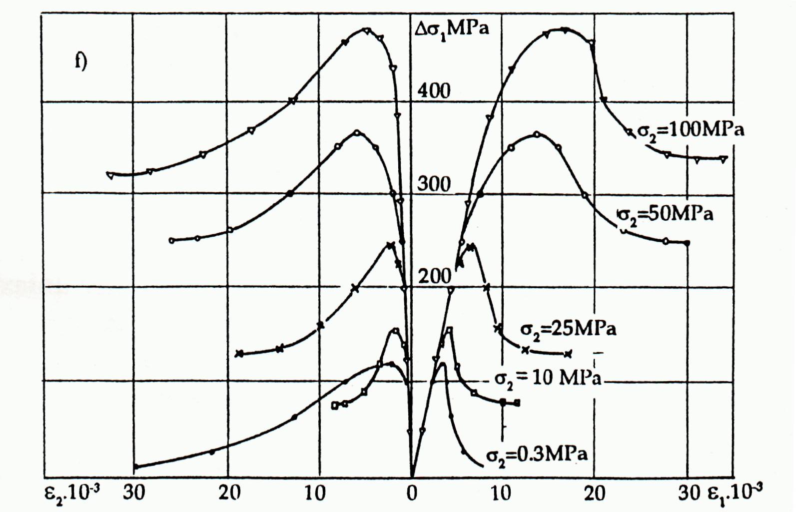

Figure 104.52: Full elastic-plastic response of sulphidic ore specimens for varying confinement pressures. Shown are axial (ϵ_1) and radial (ϵ_2) strains versus axial stress ($\Delta\sigma_1$) for triaxial loading of 3D samples (Stavrogin et al., 2001).

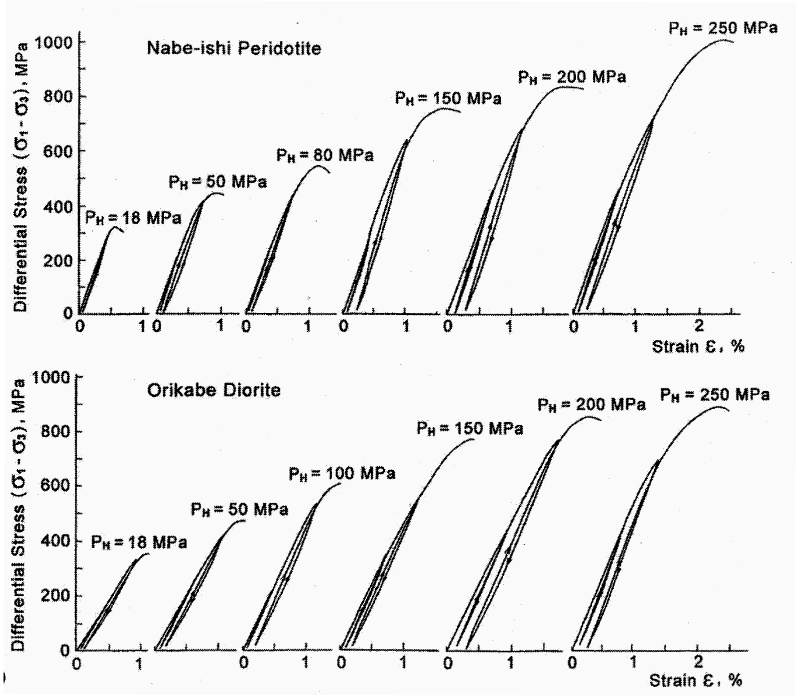

Figure 104.53: Full elastic-plastic response, with loading-reloading cycles of Periodite (upper) and Diorite (lower) specimens for varying confinement pressures. Shown are axial (ϵ_1) strains versus differential stresses ($\sigma_1 - \sigma_2$) for triaxial loading of 3D samples (Mogi, 2006).

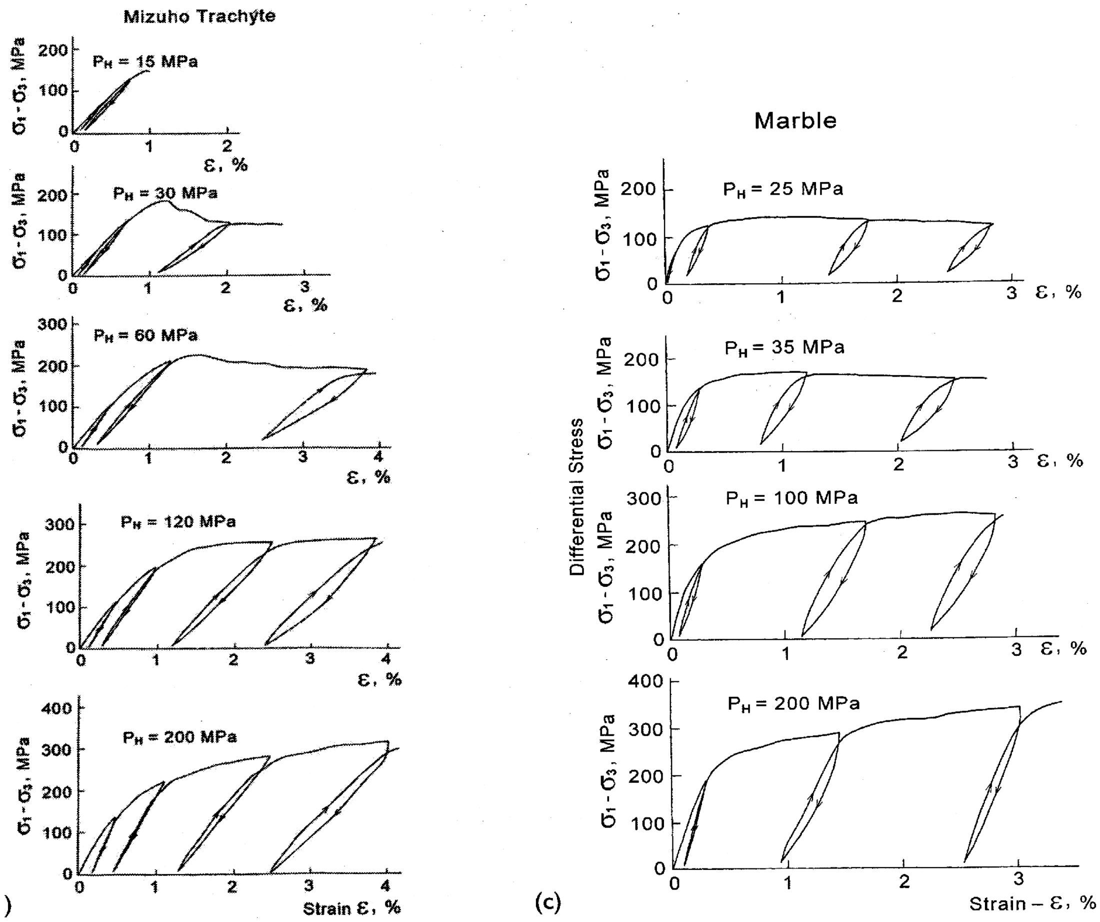

Figure 104.54: Full elastic-plastic response, with loading-reloading cycles of Trachite (left) and Marble (right) specimens for varying confinement pressures. Shown are axial (ϵ_1) strains versus differential stresses ($\sigma_1 - \sigma_2$) for triaxial loading of 3D samples (Mogi, 2006).

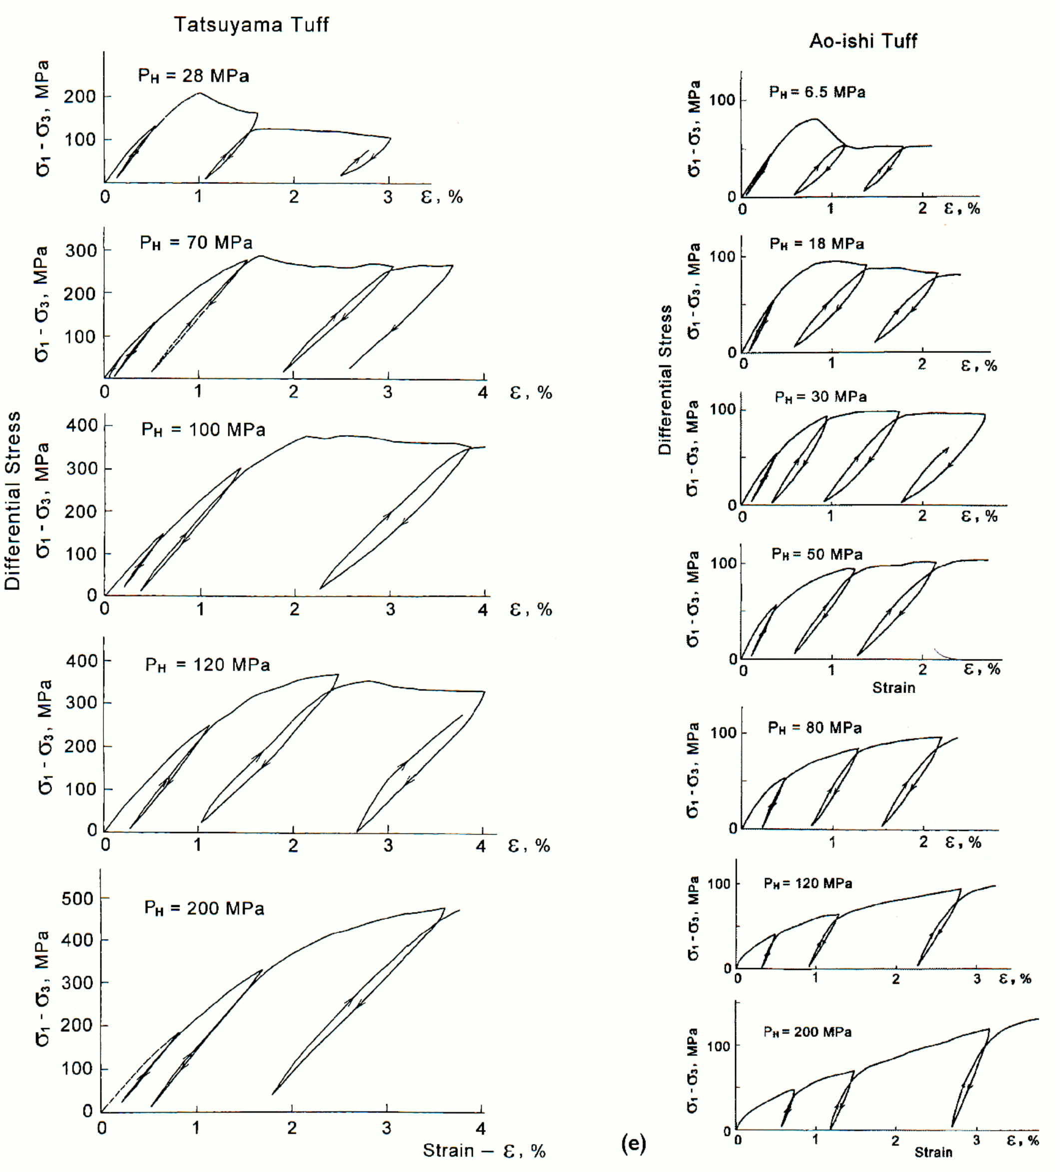

Figure 104.55: Full elastic-plastic response, with loading-reloading cycles of Tuff specimens (two different rock sources) for varying confinement pressures. Shown are axial (ϵ_1) strains versus differential stresses ($\sigma_1 - \sigma_2$) for triaxial loading of 3D samples (Mogi, 2006).

104.8.1.2 Dilative and Compactive Response

Rock (similar to other geomaterials) feature dilative (increase in volume) and compactive (decrease in volume) response for both hydrostatic confinement as well as for deviatoric loading (shear stresses). Lockner and Stanchits (2002) performed a number of tests on (initially isotropic) sandstone and measured the undrained poroelastic response for changes in mean (hydrostatic, normal) and deviatoric (shear) stress. While change in pore pressure was found to result from changes in mean (hydrostatic) stress, it was also resulting from changes in deviatoric stress. This dependence of pore pressure, and consequentially pore volume, on deviatoric stress is called dilatancy and is a feature found in most geomaterials. Figure 104.56 shows measured dependence of a coefficient η, defined as a ratio of change in pore pressure due to change in deviatoric stress ($\Delta p = -\eta \Delta \sigma_{deviatoric}$).

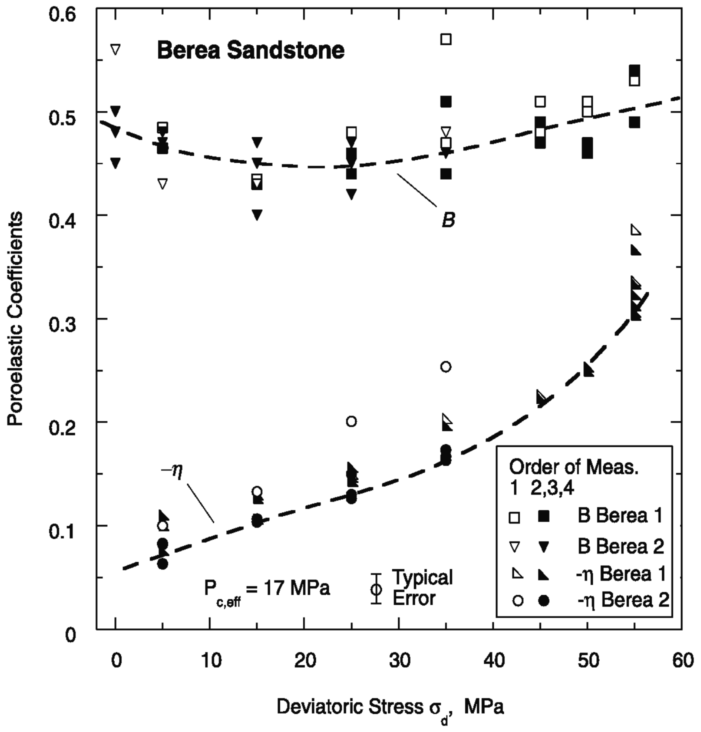

Figure 104.56: Measured poroelastic (Skempton's) coefficient B and η for Berea Sandstone. (Lockner and Stanchits, 2002).

Figure 104.56 also shows measured values for coefficient B, which defines a ratio of change in pore pressures due to change in mean stress ($\Delta p = -\eta \Delta \sigma_{mean}$). Coefficient B and η are also known as Skempton's coefficients (Skempton, 1954). Hamiel et al. (2005) developed a model based on data provided by Lockner and Stanchits (2002) that captures dilatancy in poroelastic regime. In addition to that, one of their models allows for variability in Skempton's coefficients and seems to capture test data quite well. While presented development focuses on seismic pore fluid pressure development (positive and negative) it has modeling and simulation implications for other dynamic, rock events where pores are filled with fluid and dilatancy is involved (which is always the case).

Dilatant response in elastic-plastic regime can be observed in Figures 104.47 – 104.52. In particular, volumetric strain calculations ($\epsilon_{volumetric} = \epsilon_{ii} = \epsilon_1 + 2\epsilon_2$) reveal that dilatant response is present during elastic phase of loading (before yielding), significant dilation occurs after plastic limit. Thus we can conclude that while dilatancy is present in elastic phase of loading (as concluded by Lockner and Stanchits (2002)) dilatancy is even more pronounced in elastic-plastic loading regime.

In the limit of compactive and dilative response is the localized compactive/explosive deformation. Olsson (1999, 2001) details recent findings of compaction bands. They are thin zones of pure compressional deformation with very low permeability and porosity. porosity drop for such zones is on the order of ten times $(10\times)$ when compared to porosity of surrounding rock (Olsson, 1999). In addition to that, compaction zones (bands) growth is described in terms of shock wave analysis. Issen and Rudnicki (2001) developed a more general theory of compaction band formation, particularly in view of plasticity models with cap. Plasticity models with cap are necessary if realistic behavior of rock is to be modeled, covering a wide range of stress states, from tension, shear to compression. Borja (2006) reviews analytical conditions for appearance of volume implosion/explosion (diffuse process) and compaction bands (localized process). He shows that general conditions for localization of deformation can be used for both shear as well as for compaction and dilative localization of deformation.

104.8.1.3 Anisotropy

Various rock types feature directional features (bedding, foliation, flow structures) which are reflected in anisotropic elastic and plastic properties. Anisotropy of rock behavior can be inherent and/or induced. Inherent anisotropy is present before the current loading is applied and is most likely resulting from past geological processes in rock (past loading). Induced anisotropy results from current loading processes and can significantly change orientation and value of elastic constants from inherent values (Amadei and Goodman, 1982; Amadei, 1983). Anisotropy can also be apparent, when bedding planes obvious and hidden when bedding planes not directly observable. Measurements of anisotropy are not readily available in literature as such tests are quite involved and complex. For example Pariseau (2006) reports that measurements indicate that Young's modulus is parallel to bedding plane is often about twice as large as Young's modulus perpendicular to bedding plane. Figure 104.57 shows usual test setup when rock cores are extracted with different orientations to the test loading. For such anisotropic test setups, variations of axial Young's modulus are shown in Figure 104.58.

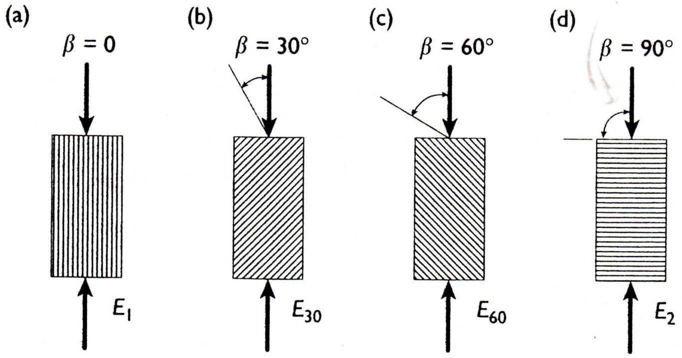

Figure 104.57: Test setup for measuring elastic anisotropy for rock cores extracted at different orientations (Pariseau, 2006).

In addition to influence of anisotropy on elastic constants, permeability is significant influenced by anisotropy of rock. A.Angabini (2003) shows significant influence of rock anisotropy on both elastic properties and on anisotropic permeability. He used 438 samples with distinct orientations to measure isotropic and anisotropic material properties out of research wells in The Netherlands along of 2.6 km test section and going to depths of up to 1.6 km. His measurements indicate that in addition elastic anisotropy, permeability anisotropy is significant. Figure 104.59 shows differences (variation) in measured specific permeabilities at different depths for wells in The Netherlands.

In addition to significant anisotropy in permeability (for example at depth 345m permeability in

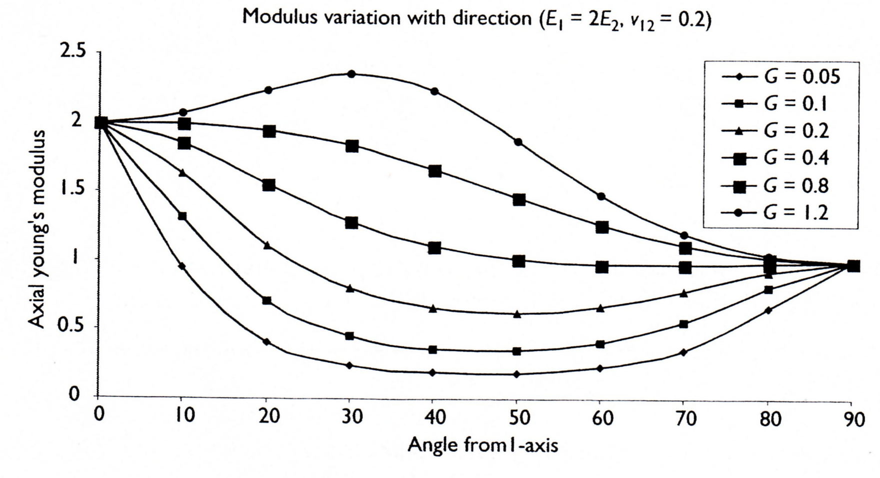

Figure 104.58: Anisotropic variations of axial Young's moduli for different orientation of core samples (Pariseau, 2006).

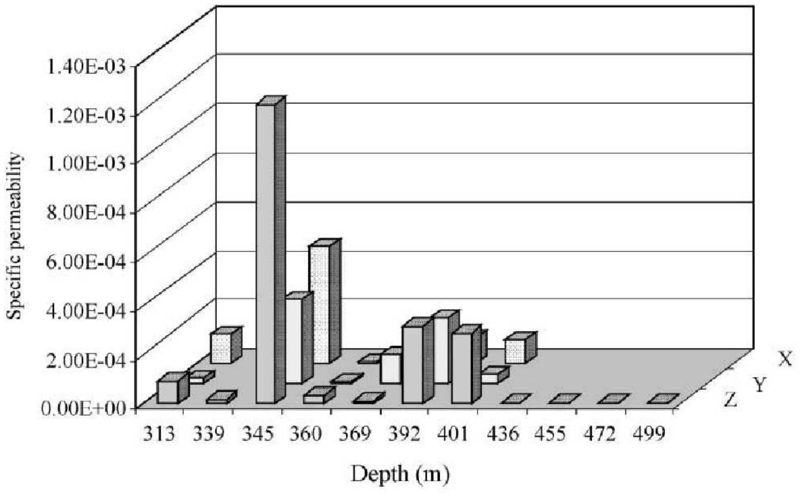

Figure 104.59: Measured specific permeabilities at different depths for wells in The Netherlands, parallel to bedding (x, y) and perpendicular to bedding (z) (A.Angabini, 2003).

vertical direction (Z) is three times higher than the one in X and 5 times higher than permeability in Y direction), significant spatial variation of permeability is present. For example, within 6 meters (between depth of 339m and 345m difference is two orders of magnitude!

Measured anisotropy of elastic and elastic-plastic properties is also significant. For example, Figure 104.60 shows directional elastic moduli (obtained using either static or dynamic tests, for dry and saturated conditions) for mudstone and sandstone.

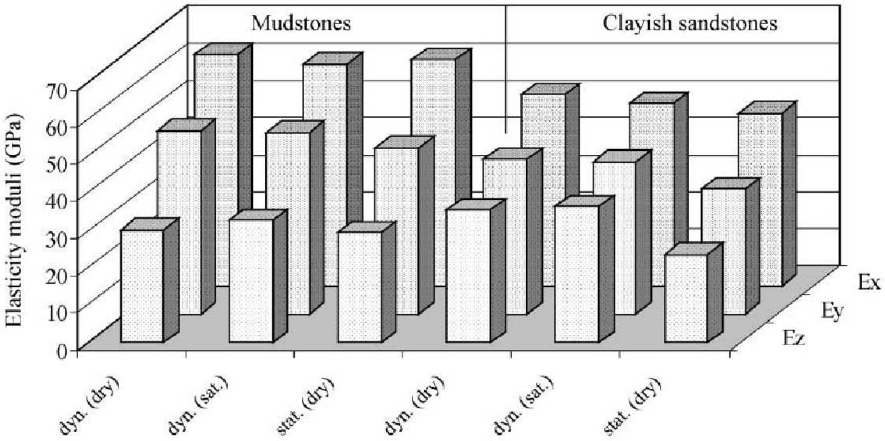

Figure 104.60: Measured anisotropic elastic moduli for different rock samples (Mudstone and Clayish sandstone) for wells in The Netherlands. Young's modulus parallel to bedding (x, y) and perpendicular to bedding (z) (A.Angabini, 2003).

Differences between elastic moduli in different directions of two or more are obvious. In addition to that, since elastic moduli in all three directions are different, rock exhibits general anisotropy (as opposed to cross anisotropy, where two elastic moduli would be the same).

Similar to elastic moduli (Young's moduli), Poisson's ratios do show significant anisotropy as shown in Figure 104.61.

In addition to elastic anisotropy (as shown in Figures 104.60 and 104.61) uniaxial strength also shows very strong directional dependence as shown in Figure 104.62.

Anisotropy of rock is not localized to one region of the domain, rather it is present in every level. Figure 104.63 shows elastic anisotropic moduli for wells in the Netherlands test area for a full depth of 1.7km. It is important to note that in addition to anisotropy that extends throughout depth. inherent uncertainty on measured moduli is present as well. This uncertainty (spread of data points for same depth) will be discussed in some more details in section 104.8.2.

In view of importance of anisotropy on rock response, determination of anisotropy is very important if simulations are to be used in predicting rock behavior. This is particularly true for modeling and simulation of shock wave propagation as anisotropy (both in elasticity and permeability) can significantly influence results.

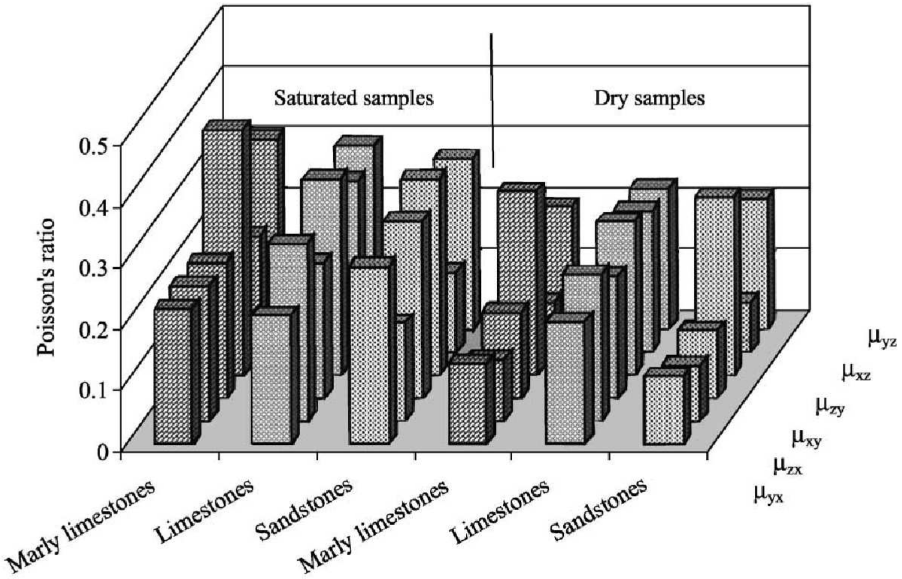

Figure 104.61: Dynamic Poisson's ratios for different rock samples (limestone and sandstone) in dry and saturated conditions, for wells in The Netherlands, (A.Angabini, 2003).

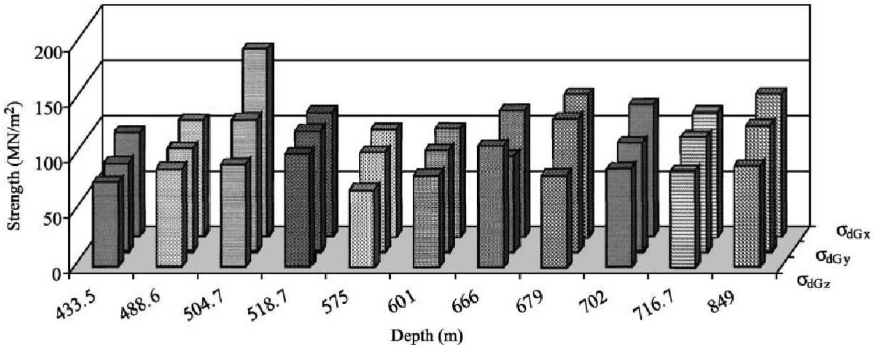

Figure 104.62: Uniaxial strength of mudstone for three different orientations of core sample, for various sampling depths, for wells in The Netherlands, (A.Angabini, 2003).

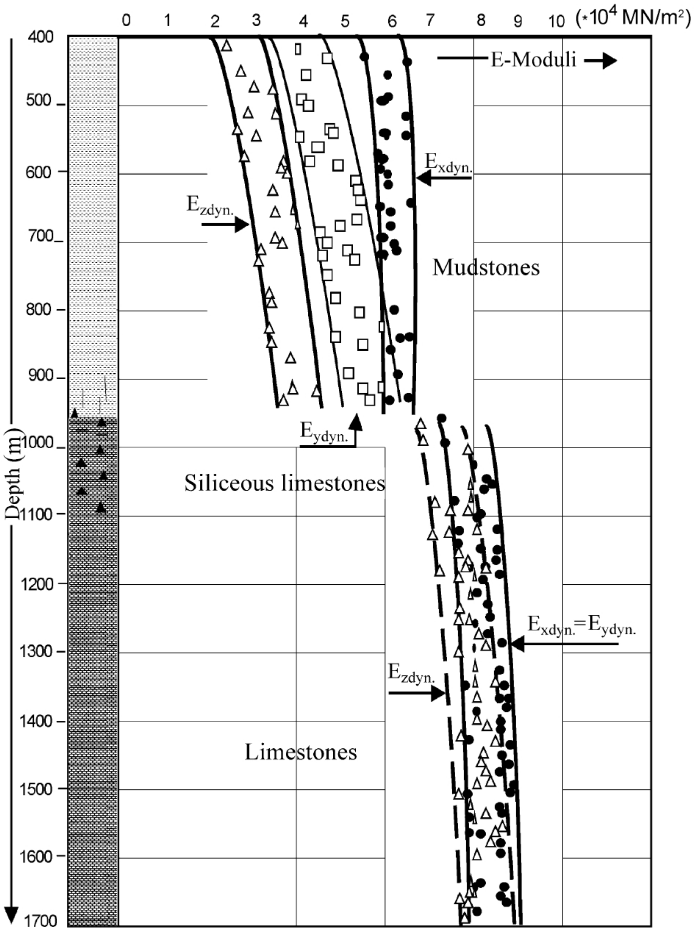

Figure 104.63: Anisotropic properties of mudstone and limestone an three directions at different depths (full depth profile), for wells in The Netherlands, (A.Angabini, 2003).

104.8.1.4 High Rate Elastic-Plastic Loading

Experimental data presenting (controlled) high rate elastic-plastic loading is fairly limited compared to the abundance of low rate data. It is very important to note that high rate controlled tests are of much value as they allow separation of high rate constitutive response from shock loading tests that are accomplished using high energy shock application to rock samples, which then initiate many other facets of multi-physics of rock behavior (described in more detail in section 104.8.3 on page 354). One of the best controlled high loading rate data sets were published by Stavrogin and Protosenya (1983); Stavrogin and Pevzner (1983); Stavrogin et al. (2001). A wide range of loading rates (strain rates, ranging over 12 orders of magnitude), presented (Stavrogin and Protosenya, 1983; Stavrogin and Pevzner, 1983; Stavrogin et al., 2001), allows development of qualitative understanding and development of quantitative model parameters for rock material. Figures 104.64, 104.65 and 104.66 show the influence of rate of loading on peak strength and elastic limit (yield stress) for rock samples (marble, diabase and sandstone respectively) confined to different pressures,

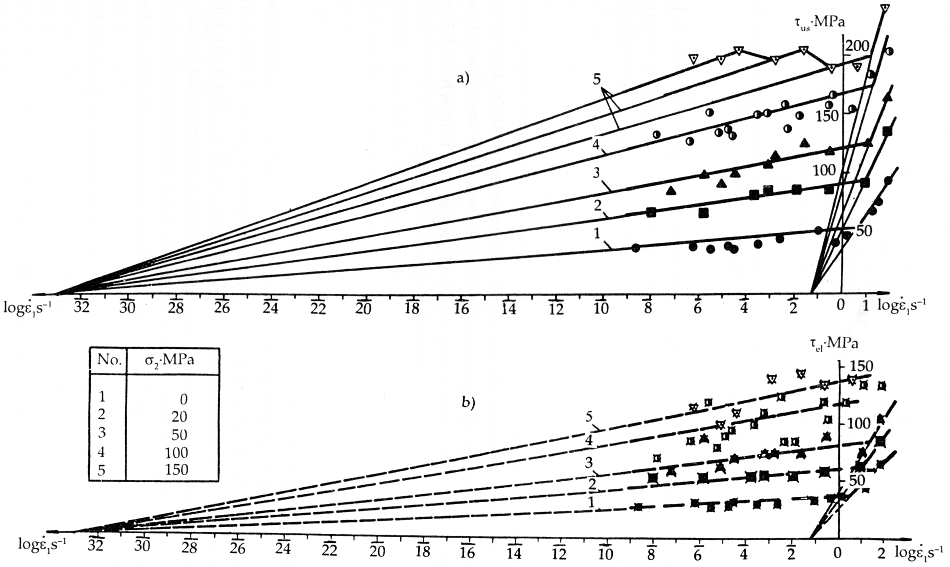

Figure 104.64: Marble: dependence of peak strength (a) upper) and elastic limit (yield stress) (b) lower) on loading rate ($\dot{\epsilon}$) for different confining stresses ($1 - \sigma_2 = 0$ Mpa; $2 - \sigma_2 = 20$ Mpa; $3 - \sigma_2 = 50$ Mpa; $4 - \sigma_2 = 100$ Mpa; $5 - \sigma_2 = 150$ Mpa) (Stavrogin and Protosenya, 1983).

While highest loading (strain) rates are on the order of $\dot{\epsilon} = 10^2$ 1/s which is lower than shock loading rates (estimated to be over $\dot{\epsilon} = 10^5$ 1/s) this data is still very useful as it can be used to calibrated models where strength and elastic limits are dependent or loading rate, and then use those models

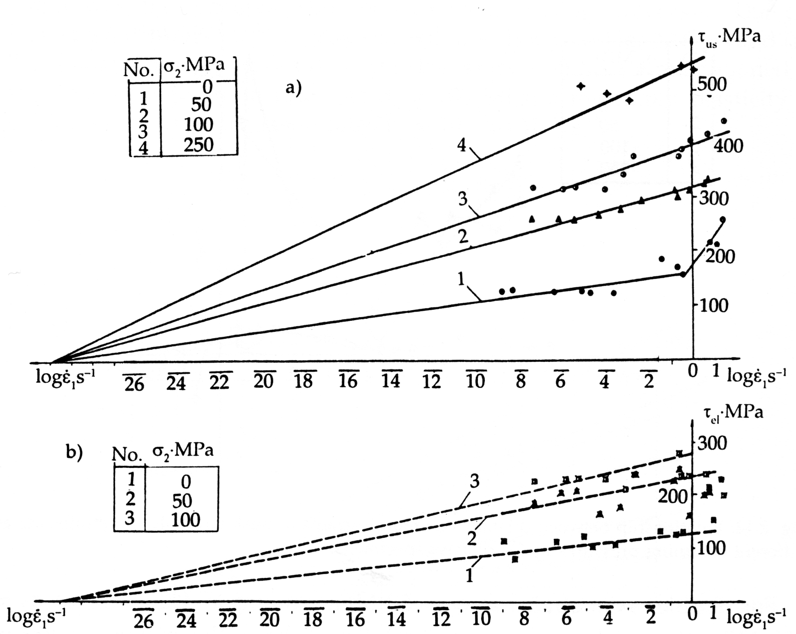

Figure 104.65: Diabase: dependence of peak strength (a) upper) and elastic limit (yield stress) (b) lower) on loading rate ($\dot{\epsilon}$) for different confining stresses ($1 - \sigma_2 = 0$ Mpa; $2 - \sigma_2 = 50$ Mpa; $3 - \sigma_2 = 100$ Mpa; $4 - \sigma_2 = 150$ Mpa) (Stavrogin et al., 2001).

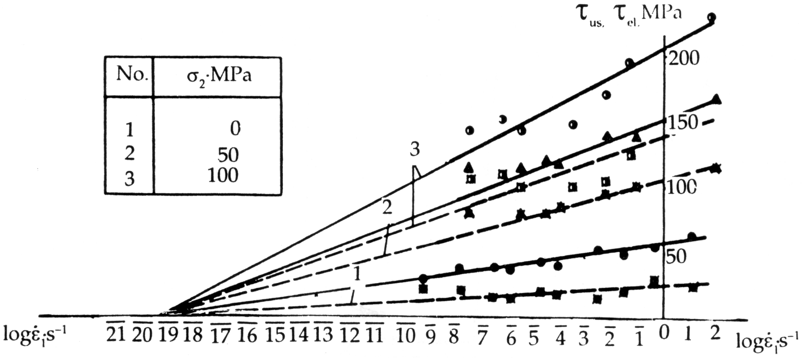

Figure 104.66: Sandstone: dependence of peak strength (full lines) and elastic limit (dashed lines) on loading rate ($\dot{\epsilon}$) for different confining stresses ($1 - \sigma_2 = 0$ Mpa; $2 - \sigma_2 = 50$ Mpa; $3 - \sigma_2 = 100$ Mpa) (Stavrogin et al., 2001).

to predict (in the sense of true prediction (Oberkampf et al., 2002)) shock wave propagation. Data presented in above Figures suggests that both peak strength and elastic limit increase with confinement pressures (pressure sensitive material, as discussed in section 104.8.1.1 on page 331). Presented data also suggest that both peak strength and elastic limit increase (linearly!) with the increase of rate of loading. Dependence of peak strength and elastic limits is proportional to loading rate increase, although such factor of proportionality is not very high. This is move evident from Figures 104.67 and 104.68 where full stress strain curves are shown for marble and granite respectively.

While data shown in Figures 104.67 and 104.68 does not cover such wide range of loading strain rates, it still leads to similar conclusion, that is increase in strain rate will lead to proportional increase in elastic limit and peak strength. Similar conclusion was drawn by Zhao et al. (1999), however, their results show much larger variation and weaker factor of proportionality.

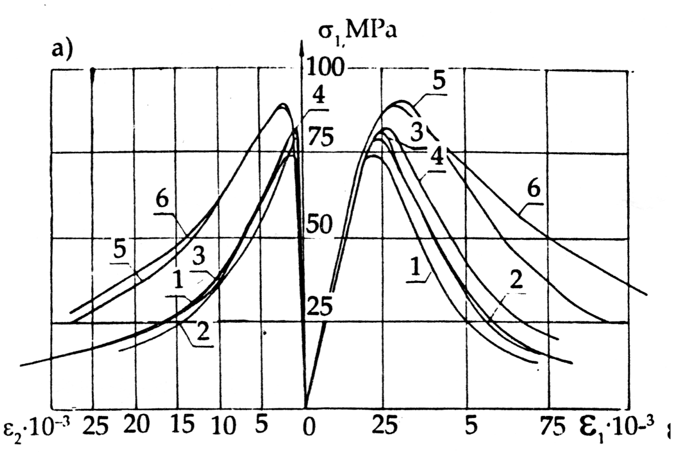

Figure 104.67: Marble: stress-strain response for different strain rates ($\dot{\epsilon}_1$) 1 – $\dot{\epsilon}_1 = 2 \times 10^{-6} 1/s$; 2 – $\dot{\epsilon}_1 = 2 \times 10^{-5} 1/s$; 3 – $\dot{\epsilon}_1 = 2 \times 10^{-4} 1/s$; 4 – $\dot{\epsilon}_1 = 2 \times 10^{-3} 1/s$; 5 – $\dot{\epsilon}_1 = 2 \times 10^{-2} 1/s$; 6 – $\dot{\epsilon}_1 = 2 \times 10^{-1} 1/s$; (Stavrogin et al., 2001).

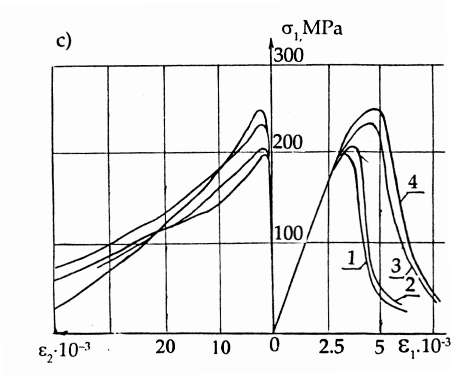

Figure 104.68: Granite: stress-strain response for different strain rates ($\dot{\epsilon}_1$) 1 – $\dot{\epsilon}_1 = 10^{-5} 1/s$; 2 – $\dot{\epsilon}_1 = 2 \times 10^{-4} 1/s$; 3 – $\dot{\epsilon}_1 = 5 \times 10^{-2} 1/s$; 4 – $\dot{\epsilon}_1 = 2 \times 10^{-1} 1/s$; (Stavrogin et al., 2001).

104.8.1.5 Coupling with Pore Fluid Pressure and Temperature

In addition to constitutive response of elastic, plastic and damaged matrix (solid porous skeleton) pore fluid and temperature fields have large influence on behavior of rock. Pore pressure directly influences mechanical response of solid skeleton through effective stress principle (see section 104.8.6). In addition to that, changes in temperature field will affect both pore fluid and elastic-plastic-damage characteristics of the porous solid (rock skeleton).

For example, Figure 104.69 shows dependence of stress at failure for sandstone. In particular, Figure 104.69(a) (left) shows clear dependence of failure stress on pore pressure, where increase in pore fluid pressure reduces the failure limit (stress). This is the case for different confining stresses, and the dependence is linear, which nicely follows equations that will be given in section 104.8.6. If the dependence is plotted in somewhat different form, as a function of effective stress, as shown in Figure 104.69(b) (right) all the points fall into (almost) same line. Present variation is inherent to all geomaterials and is discussed in some detail in section 104.8.2.

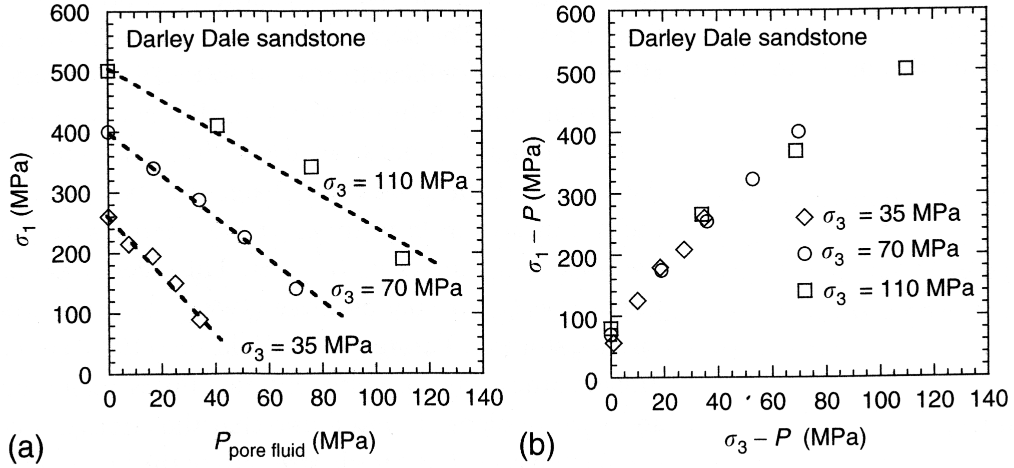

Figure 104.69: Sandstone: ultimate stresses (full capacity mobilized) as a function of (a) left) pore fluid pressure; (b) right) effective principal stress (Jaeger et al., 2007).

In addition to a full saturation, where effective stress principle is fully valid, partial saturation plays a very important role in behavior of porous rock. Partial saturation will affect response of porous rock matrix through increase in pore fluid (mix or water and air) pressures as loading is applied and rock undergoes compactive or dilatant response. Such interaction of pore fluid (mix or air and water) will also be affected by the rate of load application as the fluid viscosity starts having effects on pore pressure advection and diffusion. For example, Figures 104.70 and 104.71 shows effects of moisture content[68] on peak strength. elastic limit and coefficient of cohesion for sandstone and limestone (cohesion only). Full saturation of sandstone samples was achieved at moisture content of 3 % while for limestone it

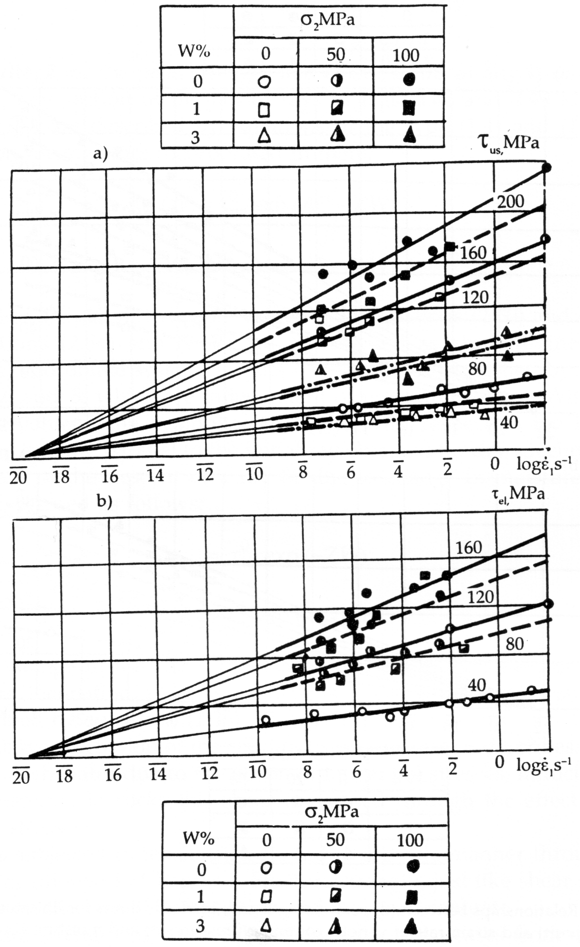

Figure 104.70: Sandstone: dependence of peak strength (a) upper) and elastic limit (yield stress) (b) lower) on loading rate ($\dot{\epsilon}$) for different confining stresses ($1 - \sigma_2 = 0$ Mpa; $2 - \sigma_2 = 50$ Mpa; $3 - \sigma_2 = 100$ Mpa; $4 - \sigma_2 = 150$ Mpa) and moisture content (W) (Stavrogin et al., 2001).

was 8 %. Results show that steady decrease of peak strength, elastic limit and coefficient of cohesion with increase in moisture content. It is very interesting to note that an increase in loading rate still increases the peak strength, elastic limit and coefficient of cohesion (as concluded in section 104.8.1.4 for dry samples), even with increase in influence of pore fluid (water and air) pressures, that now has to advect and diffuse. This type of interaction of pore fluid with loading rate and response of rock skeleton is somewhat counter-intuitive as it was expected that increase in saturation with increase in loading rate

---

[68] Moisture content is here defined as weight percentage of the water content compared to the weight of the sample.

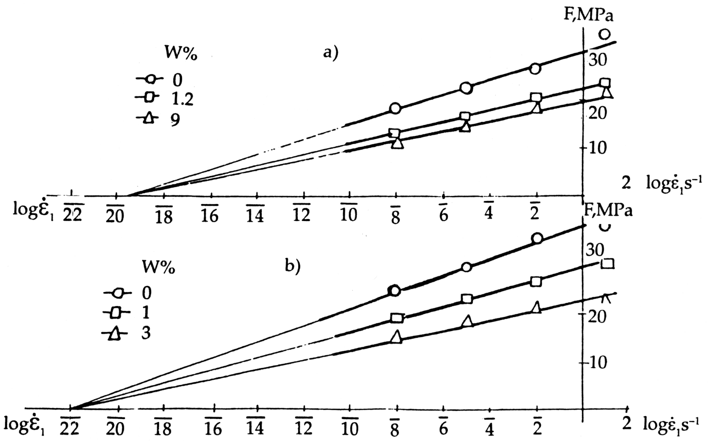

Figure 104.71: Dependence of the coefficient of cohesion for sandstone (a, upper) and limestone (b, lower) on strain rate ($\dot{\epsilon}$) for different levels of moisture content (W) (Stavrogin et al., 2001).

will lead to an increase in pore fluid pressures during high loading rate events, and thus reduce peak strength, elastic limit and coefficient of cohesion.

The influence of pore fluid on response can also be followed on full stress strain curves, as shown in Figure 104.72 for limestone. While increase in water (moisture) content leads to a decrease in stiffness and elastic-plastic strength, increase in strain (loading) rate leads to an increase in stiffness and elastic-plastic strength (stress-strain curves are "higher" for faster loading). This seemingly counter-intuitive response might need to be explored in more depth.

While previously shown results assume that pore space within rock is mostly connected, Curran (1994) uses simple micromechanical models to predict that at high confinement, the behavior of fully water-saturated rock changes from a classical effective stress response (see more about effective stresses in section 104.8.6) to a much stronger and stiffer material. This transition happens at different confining pressures, depending primarily on solids bulk modulus and the pore morphology/fabric. For example, Curran (1994) note that hard rock with small ratio of crack volume to pore volume, the transition begins at 0.2 GPa, while for soft rock (or rock with high ratios of crack volume to pore volume), the transition happens at much higher confinements, of $1-2$ GPa. This change in rock skeleton needs to be taken into account for any modeling and simulations where such threshold compressive values are reached or exceeded. In addition to that, a very important observation was made by (Larson and Anderson, 1979), in that under high confining pressures, liquid water will turn into ice VI [69] thus significantly changing the nature of coupling of pore fluid with porous solid.

Changes in temperature will affect both the pore fluid (by changing the volume and reactivity with

---

[69] Ice VI is a tetragonal crystalline form of ice formed by cooling water to 270 K at 1.1 GPa.

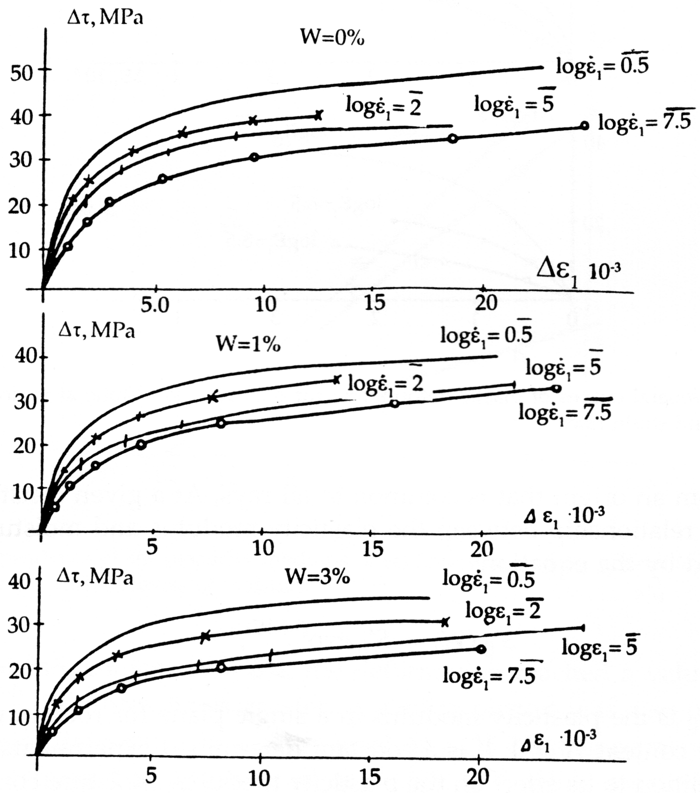

Figure 104.72: Limestone: stress-strain ($\tau - \epsilon_1$) curves for different strain rates ($\dot{\epsilon}$) and different levels of moisture content (W) (Stavrogin et al., 2001).

rock minerals), as well as the behavior of the solid (porous) matrix. With an increase in temperature, rock becomes softer but much more ductile. Inada et al. (1992) performed a number of tests on granite, andesite and sandstone, with changes of temperature from –160^{o} C (–256^{o} F) to +100.00^{o} C (212^{o} F) for both dry and wet (saturated) rock samples. Figure 104.73 shows stress-strain curves resulting from those tests. While the influence of saturation and temperature varies for different types of rock, general trend is that with increased temperature response becomes softer (lower stiffness, lower peak strength) with higher ductility. Temperature range presented does not cover completely application area for shock loading (where temperatures might reach and exceed melting point for rock), however softening and increase in ductility trend will continue as the temperatures increase until close to melting point. At such high temperatures, rock behavior will gradually change from solid to heavy fluid with significant changes in viscosity. Holyoke and Rushmer (2002) did a number of tests on muscovite-biotite metapelite and a biotite gneiss with very high temperatures (from 650^{o} C (1202^{o} F) to 950^{o} C (1742^{o} F)) and reported dilatancy effects and highly ductile response, with strains extending over 15 % and reaching peak strength at 5 – essentially represents a new material that has to be properly modeled.

104.8.2 Uncertainty and Variability of Rock Behavior

Rock material behavior is characterized by point wise uncertainty and spatial variability. While this topic is covered in much more detail in section 506.6, given here is a brief account of experimental data that supports above statement. Test data shown in previous sections exhibits variation. This variation is present in any set of test data were more than one sample was used to determine material properties. For example, Figure 104.74 from Pariseau (2006), shows values for shear modulus for a variety of rock types. It is noted that the variability is quite large, yet this is nothing unusual and is rather characteristic of rock material. In addition to that, variability of rock material parameters is apparent in any other set of test data. For example larger and/or smaller variability is present in data presented in Figures 104.56, 104.59–104.63, 104.64–104.66, 104.69–104.71. This variability is always present (see discussion in section 506.6) and need to be taken into account in order to have higher confidence in modeling and simulation of rock behavior. One possible approach to fully incorporating uncertainty into modeling and simulation is given in section 506.6 on page 2649.

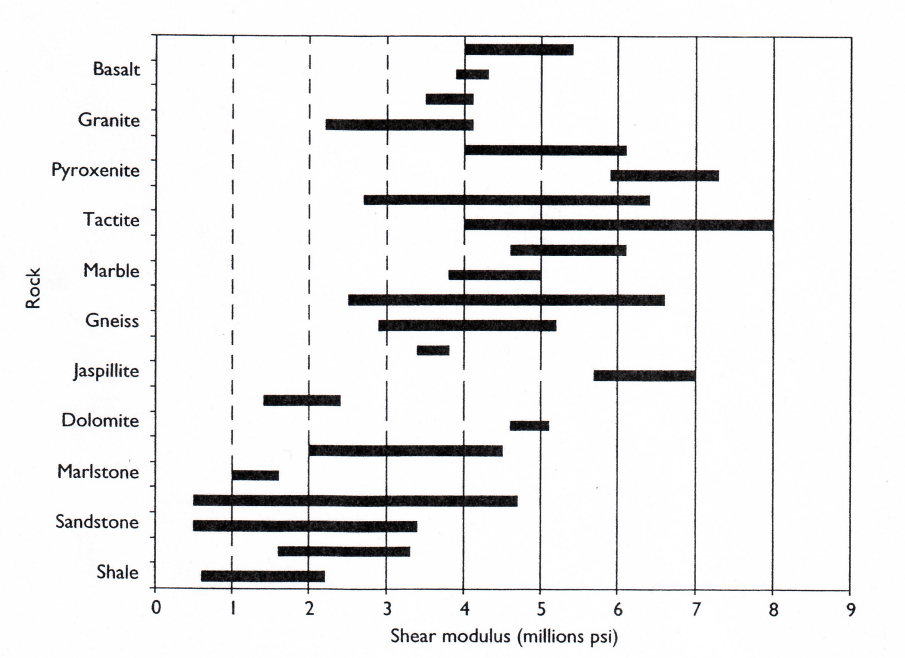

Figure 104.74: Variation of shear modulus for different rock types (Pariseau, 2006).

104.8.3 Effects of Shock Loading on Intact Rock Behavior

In previous sections I have attempted to present main features of intact rock behavior for a variety of loading conditions, loading rates, temperatures... Select set of publications were used to describe specifics of rock behavior, including pressure sensitivity, dilative and compactive response, anisotropy, effects of high rate of loading and effects of pore fluid pressures and temperatures and finally the uncertainty of such data. In this section, select publications on shock loading in rock are reviewed with the main aim of synthesizing previous findings and showing that all of the previous specifics of intact rock behavior influence response to shock loading.

It is very important to note that the history of development of modern theory of shock waves is long and quite interesting. Salas (2006) describes many (unsuccessful) attempts by the greatest mechanics minds of last two centuries to develop a consistent theory of shock waves. Such historic are invaluable in having the right prospective in developing consistent approaches for multi-physics modeling of shock waves in intact rock.

A very interesting set of experimental results and findings for rocks of both high porosity (tuff and limestone) (Larson and Anderson, 1979) and low porosity (granite and sandstone) (Larson and Anderson, 1980) are available in literature. For low porosity tests a number of important observation are made. Relationship of shock wave velocity versus particle velocity shows a discontinuity. It is suggested that this is due to the shear initiated pore collapse, which relates to dilatancy and compactive/shear localized deformation bands. This is indeed more appropriate, in Authors opinion, and in view of recent research on compressive localization (Olsson, 1999, 2001; Issen and Rudnicki, 2001; Borja, 2006) that such pore collapse is due to the initiation of diffusive, implosive and localized, compaction bands. In addition to that Larson and Anderson (1980) show that uniaxial strain data for low strain rates can be used to model high strain rate events, for dry rocks. This is a very important findings as it allows calibration of material models using low rate experiments for prediction of shock wave events. In addition to that, it was found that for very low porosity rock where pore are not in contact, the effective stress principle does indeed need to be used in its original form (Biot and not Terzaghi form) as given in equation 104.616 in section 104.8.6 on page 363, with α having a very low value. This is consistent with findings from micromodels mentioned in section 104.8.1.5 (Curran, 1994). Test result date for highly porous rock (tuff and limestone) (Larson and Anderson, 1979) show that porosity plays a major role in behavior of rock. For example, the irreversible process of compaction and elastic unloading leads to a large hysteresis, dissipating significant amounts of wave energy, effectively damping the wave out. In addition to that, an increase of strength with strain rate is observed, reinforcing experimental observations be Stavrogin and Protosenya (1983); Stavrogin and Pevzner (1983); Stavrogin et al. (2001), described in section 104.8.1.4

on page 344.

Dynamic compaction behavior of intact rock material was and still is of considerable interest. Lysne (1970) did a number of experiments on dry and water saturated tuff. The main conclusion he was able to draw was that the compaction of porous rock material is a process that is slower than the shock wave propagation and that it takes longer time (than for the compressive wave to pass) to complete such compaction process. In addition to that, Lysne (1970) was able to show, that at least for stresses in water below 2.5 GPa, the influence of heating on volume change can be neglected in porous rock saturated with water. D. Erskine and Weir (1994) presents data on dry and wet tuff, which exhibits quite complex behavior. Both pore crushing and phase change (liquefaction) are observed and are responsible for complex compression behavior. Heterogeneity of rock also plays a major role in the observed response. Another very important conclusion is that Gruneisen model (aka Debye-Grüneisen model) does not perform well, indicating that there a likely phase transition is happening and needs to be accounted for.

Hiltl et al. (1999) present interesting set of shock-recovery tests results on dry and fully saturated sandstone. Principle of effective stress is again playing important role as it is observed that water saturated samples had much smaller compaction due to distribution of confining pressures between pore water and porous solid. In addition to that, reduction of porosity due to high pressure of shock waves was much smaller for saturated samples, again proving that pore fluid caries quite a bit of load due to slow drainage, as present during shock wave loading. It is also observed that as the shock pulse duration increases, so does the damage, implying that as the pore fluid gains time to drain, effective stresses in porous solid increase and causes the damage and compaction.

104.8.3.1 Shock Waves of First and Second Kind

The dynamic behavior of saturated porous media was studied at length by M.A.Biot (1956); Biot (1962, 1972). In one of his studies (M.A.Biot, 1956) he concluded that there exist three kinds of coupling between pore fluid and porous solid (inertial, viscous and mechanical). He also concluded that the viscous coupling plays a key role and determines response of a coupled system to dynamic excitation, while making wave propagation dispersive. He demonstrated (analytically) the existence of two kinds of compressional waves corresponding to the mechanical and inertial coupling, while the viscous coupling is responsible for a pure wave. For high viscous coupling, the relative movements between the two phases are prevented, so there is only one compressional wave and the total mass behaves as a single-phase medium.

Recent paper by Lomov et al. (2001), actually shows an experimental proof of such coupling. Figure 104.8.3.1 shows two test results for dry and wet samples. It is important to recognize that these test results can also be used to validate shock wave propagation modeling and simulation as described in section 104.8.6 on page ??.

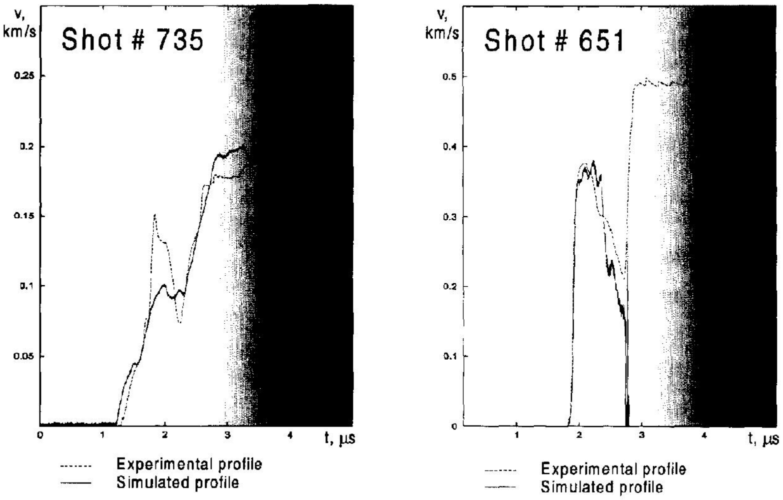

Figure 104.75: Test results for a 1D wave propagation in dry (high coupling) and wet (low coupling) sandstone (Lomov et al., 2001).

For example, for high coupling case (dry sandstone, pore fluid is air), the velocity profile shown in Figure 104.8.3.1 is increasing and when integrated (to get displacements), profile corresponds (at least qualitatively) to high coupling case ($K = 10^{-6}$ cm/s) presented in Figure 310.14. Similarly, low coupling case (wet sandstone, pore fluid is water) the velocity profile increases, then drops to almost zero and then increases again. Upon integration to get displacement, this will correspond (qualitatively) to low coupling case ($K = 10^{-2}$ cm/s) presented in Figure 310.14. Permeabilities are here used qualitatively for both water and air and signify ease with which fluid (water or air) moves past porous solid. While, results presented in Figure 310.14 correspond to a linear elastic case, at least qualitatively, they follow test results, which of course correspond to elastic–plastic behavior of rock material. Such elastic-plastic behavior will affect results in many ways (slow the wave propagation speed for one), but at least it is reassuring that an elastic solution can be used to help gain understanding of the basic mechanics.

Analytical solutions for shock wave propagation, even with many simplifying assumptions, are valuable as candidates for verification and validation. Two such solutions are mentioned below. Vasilev et al. (1980) discusses interaction of gas, liquid and porous medium during and after an underground explosion. A complex interaction is described which eventually leads to the implosion of explosion cavity. Although the analysis presented is based on elastic behavior of the porous medium, it provides excellent basis for understanding phenomena involved as well as for verification. Nikolaevskiy et al. (2006) presents more sophisticated analysis of similar phenomena, using finite difference method (Wilkins, 1999), and an elastic-plastic material model. However, Authors neglect the dilatancy of the material in order to simplify their solutions. Neglecting dilatancy certainly affects results Compaction related to coupling of pore fluid and porous solid. Moreover, influence of temperature fields is also neglected (isothermal process) which might hinder fidelity of modeling where large temperature changes are present and where temperature change influences behavior of pore fluid and porous solid.

104.8.3.2 Hugoniots

The Hugoniot curves (also known as Rankine-Hugoniot) for material present important data about material state. Material compression state defined by initial pressure, density and energy, can be used, to determine new state upon applying shock loads. Such curves prove important in material modeling for rock subjected to shock loading. Early on Afanasenkov et al. (1969) showed that a it is possible to predict shock Hugoniots of any substance up to compression ratio of two with the knowledge of initial density and initial compressibility. Shipman et al. (1971) used a number of experiments to determine Hugoniots for Sandstone. In addition to that they used measured data and developed curves to show that phase boundaries do shift significantly compared to those determined using static means. This important conclusion affects development of elastic-plastic modeling for intact rock where high temperature effects cannot be neglected.

104.8.4 Material Modeling of Rock

104.8.4.1 Lawrence Livermore National Laboratory Models

A number of models originating from researchers from Lawrence Livermore National Laboratory have been developed over the years. While they do not represent a single line of development (and might have been produced by different research groups from different departments) they are summarized in this LLNL section.

Glenn (1995) presents a simple, yet effective total stress model that depends on mean confinement (pressure), temperature and on a damage parameter that serves as an internal variable and depends on degradation due to tensile and shear failure.

$$\sqrt{3 s_{ij} s_{ij}} \leq Y = (1-D)\bar{Y} + \beta D \bar{Y} \tag{104.614}$$

where s_{ij} is the deviatoric stress, β is a constant, and D is a scalar function of the volumetric components of void and equivalent plastic strain tensors. The generalized compressive strength $\bar{Y}$ is a function of unconfined compressive strength, the ultimate compressive strength, the melting temperature, the mean pressure, the cohesion and an material additional constant.

More recently Lomov et al. (2001); Antoun et al. (2003), presented an elastic viscoplastic material model that takes into the account various influences on rock yielding behavior. For example, taken into the account are the effects of scaling, hardening, damage and melting. In addition to that, compaction is modeled using analytic porous compaction model, while also included are the effects of dilatancy. Model is set in a proper thermodynamic framework. However, it should be noted that strictly following thermodynamics for geomaterial behavior, can have negative effects on modeling proper volumetric response (dilatancy and compaction), with alternative material model formulation spaces being suggested by Collins and Houlsby (1997). This is an area which certainly deserves much attention, namely the apparent small disconnect between sound thermodynamic framework for modeling (which nicely applies to metal plasticity) and observed behavior of geomaterials (rock included).

104.8.4.2 Hoek and Brown Model

One of the most often used material models for rock is Hoek and Brown. It is important to note that this model is actually a failure criterion, delineating elastic and failure states of stress, lacking usual plasticity features, such as hardening and/or softening. The most recent edition of the model (Hoek et al., 2002) fixes some earlier observed problems with friction angle determination. This is a valuable model for practical work for rock with low confinement stresses, where behavior is brittle and failure indeed occurs as soon as the failure state of stress is reached. However, in view of shock loading modeling, this model does not hold much promise, as it lacks, as mentioned above, basic elastic-plastic features.

104.8.4.3 Other Models

A number of other material models have been developed for modeling of elastic-plastic-damage behavior of rock. Small selection is presented below. It should be noted that most of those developed models inherit most of their features from models described in previous sections.

Benz and Schwabb (2008) provide comparison for six most commonly used failure criteria for rock. While failure is emphasized, as opposed to full elastic-plastic behavior, the data presented is very telling in view of uncertainty of rock behavior. For example, six deterministic models are calibrated using statistical fitting techniques, and deterministic parameters are developed for a deterministic elastic-plastic (failure) models. The information about the uncertainty of response is thus completely lost.

Das and Basudhar (2009) perform similar exercise with four deterministic models. Moreover, they label some of the test data as outliers thus negatively influencing date regression (removal of statistical moments).

G. W. Ma and Zhou (1998) present an isotropic elastic-plastic model that includes rate dependence, damage development and plasticity of rock. Isotropic damage was used where the elastic constitutive tensor was related to scalar damage parameter D

$$E_{ijkl} = E_{ijkl}(1 - D) \tag{104.615}$$

This is a standard way of incorporating scalar damage (Carol et al., 1995). Of course, anisotropic damage (Rizzi, 1993; Carol et al., 2001a,b; Loret and Rizzi, 1997) is more accurate in modeling realistic materials and should be used whenever possible, however in this case, scalar damage was identified as sufficiently accurate for modeling. In this model, yield strength is controlled by accumulated damage, through a simple linear, isotropic relationship. In addition to that, a non-associated plastic flow is employed. However, plastic flow is limited to deviatoric plane (there is no volumetric component) which reduces accuracy of modeling, since rock material does undergo plastic volumetric change upon plastification (Borja, 2006). Comparison of simulation and experimental data shows somewhat satisfactory similarity, however, bias is present in attenuation plots (similar to results obtained by Wei et al. (2009)).

Bart et al. (2000) presents an interesting approach where an anisotropic poroelastic damage model is used to model slow behavior of rock samples (sandstone). Model is able to predict effects of damage induced by micro-cracking, such as deterioration of elastic and poroelastic properties, induced anisotropy and dilatancy. Model does not feature any plastic deformation, rather inelasticity is completely managed through damage.

Chen et al. (2010) develop an elastic-plastic-damage model which can handle inherent and induced anisotropy. Calibration and application to shale is presented, with main focus on behavior of strongly anisotropic samples. Fabric tensor (not unlike fabric tensor developed for SANISAND family of models described in section 104.6.12) presents an effective modeling tool for modeling anisotropy. However, in their model, Chen and Phoon (2009) simplified modeling of induced anisotropy to isotropic damage (citing complexity of doing it otherwise). This might be unfortunate as induced anisotropy (resulting from anisotropic damage) might be more important than inherent anisotropic, particularly for cases where reversal of loading plays an important role, for example in modeling of shock wave propagation.

104.8.5 Model Calibration / Testing Devices

While a number of material models have been developed over years to model rock behavior, calibration of such models has to be done with great care. Rock is fairly stiff material and as such, stiffness of testing equipment can have significant effects on test results. For example, Labuz and Biolzi (2007) discusses such influence in great detail. Figure 104.8.5 shows how inappropriate stiffness of testing equipment can affect (mask) the real rock response.

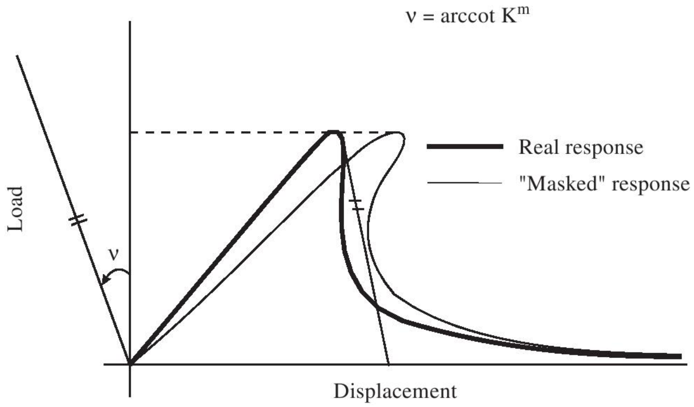

Figure 104.76: Influence of testing machine stiffness on observed and real test specimen behavior (Labuz and Biolzi, 2007).

In addition to that, elastic-plastic models assume intact rock, so that any influence of discontinuities is removed from test results. This is where scaling of samples plays a very important role. For example Lo et al. (1987) show how variation in test specimen volume (see Figure 104.8.5) can affects (bias) measurements of dynamic elastic modulus, by simply including, within the tested volume, discontinuities and not accounting for them.

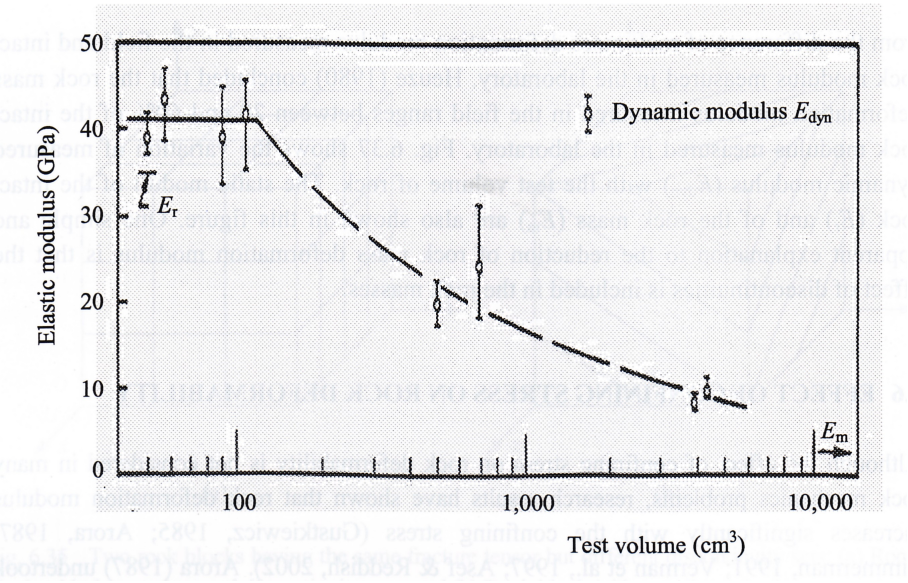

Figure 104.77: Influence of volume of test specimen elastic modulus of rock ((Lo et al., 1987)).

104.8.6 Influence of Pore Fluid Pressure and Temperature on Rock Response

One of the main features of geomaterials is the coupling of pore fluid with the porous solid. Such coupling is taken into account through the effective stress principle. The relationship between effective stress, total stress and pore pressure is (assuming tensile components of stress as positive and compressive pressure, p is positive) (Zienkiewicz et al., 1999a)

$$\sigma_{ij}^{''} = \sigma_{ij} + \alpha \delta_{ij} p \tag{104.616}$$

where $\sigma_{ij}^{''}$ is effective stress tensor, σ_{ij} is total stress tensor, δ_{ij} is Kronecker delta. $\delta_{ij} = 1$, when i=j, and $\delta_{ij} = 0$, when $i \neq j$. For isotropic materials,$\alpha = 1 - K_T/K_S$ (Bouteca and Gueguen, 1999), and K_T is the total bulk modulus of the solid matrix, K_S is the bulk modulus of the solid particle/grains. For most of the geomechanics problems, as the bulk modulus K_S of the solid particles is much larger that that of the whole material, $\alpha \approx 1$ can be assumed. However, in case of rock (as well as for concrete, bone material...), such assumption does not hold all the time so α needs to be kept throughout derivations (Bouteca and Gueguen, 1999).

104.9 Inelastic Behavior and Models for Concrete Beams, Walls and Shells

104.9.1 Uniaxial Material Model for Steel

The uniaxial steel material model used in this study was developed by Menegotto and Pinto (1973) and extended by Filippou et al. (1983). Model is capable of capturing the nonlinear hysteretic behavior and isotropic strain-hardening effect of steel for uniaxial state of stress and strain (1D). The stress–strain response of rebar steel material is shown in Figure 104.93. The model, as presented in Menegotto and Pinto (1973), takes on the form:

$$\sigma^* = b\epsilon^* + \frac{(1-b)\epsilon^*}{(1+\epsilon^{*R})^{1/R}} \tag{104.617}$$

with

$$\epsilon^* = \frac{\epsilon - \epsilon_r}{\epsilon_0 - \epsilon_r}; \quad \sigma^* = \frac{\sigma - \sigma_r}{\sigma_0 - \sigma_r} \tag{104.618}$$

where b is the strain-hardening ratio, ϵ_r and σ_r are the strain and stress at the point of strain reversal, ϵ_0 and σ_0 are the strain and stress at the point of intersection of the two asymptotes, R is the curvature parameter that governs the shape of the transition curve between the two asymptotes. It is noted that this model is for uniaxial material behavior, in which the stresses and strains are scalars instead of tensors.

The expression for the curvature parameter R is suggested by Menegotto and Pinto (1973) as:

$$R = R_0 - \frac{c_{R_1}\xi}{c_{R_2} + \xi} \tag{104.619}$$

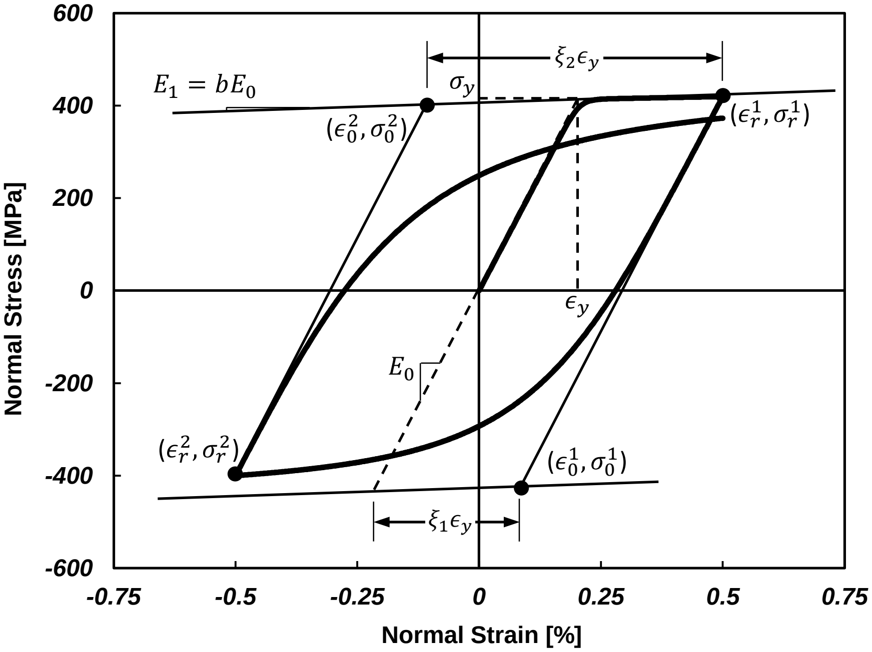

Figure 104.78: Constitutive model for uniaxial steel fiber (Menegotto and Pinto (1973)).

where R_0 is the value of the curvature parameter R during initial loading, c_{R_1} and c_{R_2} are degradation parameters that need to be experimentally determined. The parameter ξ, which is updated after strain reversal, is defined as:

$$\xi = \left| \frac{(\epsilon_m - \epsilon_0)}{\epsilon_y} \right| \tag{104.620}$$

where ϵ_m is the maximum (or minimum) strain at the previous strain reversal point, depending on the loading direction of the material. If the current incremental strain is positive, the parameter ϵ_m takes the value of the maximum reversal strain. Parameter ϵ_y is the monotonic yield strain.

In order to capture isotropic hardening behavior, Filippou et al. (1983) introduced stress shift mechanism into the original model by Menegotto and Pinto (1973). Note that the hardening rate in compression and tension can be different by choosing different hardening parameters for compression and tension. The proposed relation takes the form:

$$\frac{\sigma_{st}}{\sigma_y} = a_1 \left(\frac{\epsilon_{max}}{\epsilon_y} - a_2 \right) \tag{104.621}$$

where σ_{st} is the shift stress that determines the shift of yield asymptote, ϵ_{max} is the absolute maximum strain at strain reversal, and a_1 and a_2 are hardening parameters in compression which are experimentally determined. In the case of tension, the hardening parameters a_1 and a_2 in Equation 104.621 are changed to a_3 and a_4, that are also determined experimentally or from previous studies for given steel.

104.9.2 3D Plastic Damage Concrete Material Model, Faria-Oliver-Cervera

The concrete material model used in this study was developed by Faria et al. (1998). Model features:

- distinct stress-strain envelopes obtained under compression or under tension
- stiffness recovery after loading reversal
- higher concrete strength under 2D or 3D compression test, compared to 1D loading
- plastic deformations discernible after some compressive stress limit is reached

The material model, as presented in Faria et al. (1998), takes on the form:

$$\sigma_{ij} = (1-d^+)\bar{\sigma}^+_{ij} + (1-d^-)\bar{\sigma}^-_{ij} \tag{104.622}$$

where, d^+ and d^- are scalar damage variables corresponding to tensile and compressive degradation. Cauchy stress tensor σ_{ij} involves effective stress components $\bar{\sigma}^+_{ij}$ and $\bar{\sigma}^-_{ij}$, that are related to the total effective stress ($\bar{\sigma}_{ij} = \bar{\sigma}^+_{ij} + \bar{\sigma}^-_{ij}$), defined as follows:

$$\bar{\sigma}_{ij} = D_{ijkl}(\varepsilon_{kl} - \varepsilon^p_{kl}) \tag{104.623}$$

In the previous equation, D_{ijkl} is the fourth order isotropic linear elastic constitutive tensor, ε_{kl} the small strain tensor and ε^p_{kl} is the plastic strain tensor. Damage variables together with the plastic strain constitute the internal variable set. Tensile part of the effective stress tensor can be written using principal stresses ($\bar{\sigma}_i$) and principal directions (p_i):

$$\bar{\boldsymbol{\sigma}}^+ = \sum_i \langle \bar{\sigma}_i \rangle p_i \otimes p_i \tag{104.624}$$

Compressive components of the effective stress can be written as:

$$\bar{\sigma}^-_{ij} = \bar{\sigma}_{ij} - \bar{\sigma}^+_{ij} \tag{104.625}$$

Following adopted stress split, a tensile equivalent stress $\bar{\tau}^+$ and a compressive equivalent stress $\bar{\tau}^-$ are considered. According to Simo and Ju (1987):

$$\bar{\tau}^+ = (\bar{\sigma}^+_{ij} D_{ijkl} \bar{\sigma}^+_{kl})^{1/2} \tag{104.626}$$

$$\bar{\tau}^- = (\sqrt{3}(K\bar{\sigma}^-_{oct} + \bar{\tau}^-_{oct}))^{1/2} \tag{104.627}$$

In the last equation, $\bar{\sigma}^-_{oct}$ and $\bar{\tau}^-_{oct}$ are the octahedral normal and shear stress, respectively, obtained from $\bar{\sigma}^-$. K is a material characteristic, adjusted so that 2D and 1D compressive strength ratio can match ratio of 1.16-1.2 (Kupfer et al., 1969). Two separate damage criteria, functions, g^+ for tension and g^- for compression, are introduced:

$$g^+(\bar{\tau}^+, r^+) = \tau^+ - r^+ \leq 0 \tag{104.628}$$

$$g^-(\bar{\tau}^-, r^-) = \tau^- - r^- \leq 0 \tag{104.629}$$

Variables r^+ and r^- represent current damage thresholds. Their role is to control the size of expanding damage surfaces. Quadrant ($\bar{\sigma}_2 = 0, \bar{\sigma}_1, \bar{\sigma}_3 \geq 0$) shows 2D representation for this surface, when $\bar{\tau}^+ = r^+$, Fig 104.79. The bounding surface associated to the principal effective compressive stresses resembles Drucker-Prager cone. It is obvious that the elastic domain under 2D compression is bounded by stresses greater than the 1D elastic compressive stress, denoted by f_0^-.

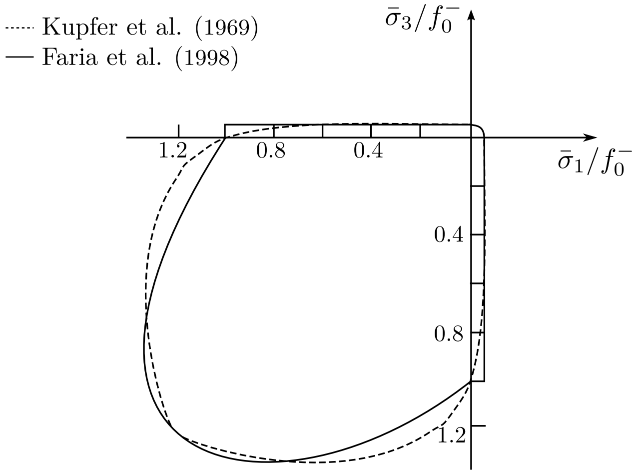

Figure 104.79: Initial 2D elastic domain

For the plastic flow of the tensor ε^p_{ij} the following is proposed in Faria et al. (1998):

$$\dot{\varepsilon}^p_{ij} = \beta\, E\, H(\dot{d}^-) \frac{\langle \bar{\sigma}_{ij} \dot{\varepsilon}_{ij} \rangle}{\bar{\sigma}_{ij} \bar{\sigma}_{ij}}\, D^{-1}_{ijkl}\, \bar{\sigma}_{kl} \tag{104.630}$$

where β is the coefficient which controls the rate of intensity of plastic deformation, E is Young's modulus, $H(\dot{d}^-)$ denotes the Heaviside step function for the compressive damage rate. Proposed model assumes that plastic strain has the direction of the elastic strain tensor $D^{-1}_{ijkl} \bar{\sigma}_{kl}$. It should be noted that the model cannot account for plastic strains for a pure tension test.

Kinematics of damage, internal variables is defined based on the following rate equations:

$$\dot{d}^+ = \dot{\theta}^+ \frac{\partial G^+(r^+)}{\partial r^+} \tag{104.631}$$

$$\dot{r}^+ = \dot{\theta}^+ (\geq 0) \tag{104.632}$$

where G^+ and G^- are monotonically increasing functions for tension and compression, that are experimentally determined, and $\dot{\theta}^+$ and $\dot{\theta}^-$ are damage consistency parameters. Karush-Kuhn-Tucker conditions implies the following (Jeremić et al., 1989-2025):

$$g^+ \leq 0 \quad \text{damage/plastic function} \tag{104.633}$$

$$\dot{\theta}^+ \geq 0 \quad \text{consistency parameter} \tag{104.634}$$

$$g^+ \, \dot{\theta}^+ = 0 \tag{104.635}$$

which leads to the following conclusions:

- when damage/plasticity function is smaller then zero, $g^+ < 0$, consistency parameter must be zero, $\dot{\theta}^+ = 0$, implying that no damage occurs,
- when consistency parameter is greater than zero, $\dot{\theta}^+ > 0$, damage/plastic function is zero, $g^+ = 0$ implying the presence of damage.

It is now possible to define consistency parameter $\dot{\theta}^+$ from the damage consistency condition:

$$\dot{g}^+(\bar{\tau}^+, r^+) = 0 \implies \dot{r}^+ = \dot{\tau}^+ = \dot{\theta}^+, \qquad \dot{\theta}^+ \geq 0 \tag{104.636}$$

Introducing equation (104.636) into (104.631) the flow rule for the tensile damage variable can be expressed as:

$$\dot{d}^+ = \frac{\partial G^+(r^+)}{\partial r^+} \dot{r}^+ = \dot{G}^+(r^+) \geq 0 \tag{104.637}$$

The compression damage variable is then:

$$\dot{d}^- = \frac{\partial G^-(r^-)}{\partial r^-} \dot{r}^- = \dot{G}^-(r^-) \geq 0 \tag{104.638}$$

104.11 Energy Dissipation Calculations for Solids

This section is based on Yang et al. (2018)

104.11.1 Introduction

Energy dissipation in elastic plastic solids and structures is the result of an irreversible dissipative process in which energy is transformed from one form to another and entropy is produced. The transformation and dissipation of energy is related to permanent deformation and damage within an elastic-plastic material. Of particular interest here is the dissipation of mechanical energy that is input into elastic-plastic solids by static or dynamic excitations.

Early work on plastic dissipation was done by Farren and Taylor (1925) and Taylor and Quinney (1934). They performed experiments on metals and proved that a large part, but not all, of the input mechanical energy is converted into heat. The remaining part of the non-recoverable plastic work is known as the stored energy of cold work. The ratio of plastic work converted into heating (Quinney–Taylor coefficient), usually denoted as β, has been used in most later work on this topic. Based on large amount of experimental data, this ratio was determined to be a constant between 0.6 to 1.0 (Clifton et al., 1984; Belytschko et al., 1991; Zhou et al., 1996; Dolinski et al., 2010; Ren and Li, 2010; Osovski et al., 2013).

More recently Rittel (Rittel, 2000; Rittel and Rabin, 2000; Rittel et al., 2003) published several insightful papers on the energy dissipation (heat generation) of polymers during cyclic loading, presenting both experimental and theoretical works. Rosakis et al. Rosakis et al. (2000) presented a constitutive model for metals based on thermoplasticity that is able to calculate the evolution of energy dissipation. Follow up papers (Hodowany et al., 2000; Ravichandran et al., 2002) present assumptions to simplify the problem. One direct application of plastic dissipation to geotechnical engineering is presented by Veveakis et al. (Veveakis et al., 2007, 2012), using thermoporomechanics to model the heating and pore pressure increase in large landslides, like the 1963 Vajont slide in Italy.

In the past few decades, extensive studies have been conducted on energy dissipation in structures and foundations. Work by Uang and Bertero (1990) has been considered a source and a reference for many recent publications dealing with energy as a measure of structural demand. Uang and Bertero (1990) developed an energy analysis methodology based on absolute input energy (or energy demand). Numerical analysis results were compared with experiments on a multi-story building. In work by Uang and Bertero (1990) , hysteretic energy is calculated indirectly by taking the difference of absorbed energy and elastic strain energy. The term absorbed energy of each time step is simply defined as restoring force times incremental displacement. It is also stated that hysteretic energy is irrecoverable, which indicates that this parameter was considered the same as hysteretic dissipation or plastic dissipation. An equation for energy balance, is given by (Uang and Bertero (1990)) as:

$$E_i = E_k + E_\xi + E_a = E_k + E_\xi + E_s + E_h \tag{104.639}$$

where E_i is the (absolute) input energy, E_k is the (absolute) kinetic energy, E_ξ is the viscous damping energy, E_a is the absorbed energy, which is composed of elastic strain energy E_s and hysteretic energy E_h.

The problem with this approach is the absence of plastic free energy, which is necessary to correctly evaluate energy dissipation of elastic-plastic materials and to uphold the second law of thermodynamics. While there is no direct plot of plastic dissipation (hysteretic energy) in Uang and Bertero (1990), since it was not defined directly, there are plots of other energy components. Plastic dissipation can be easily calculated from these plots. After doing this, indications of negative incremental energy dissipation, which violates the basic principles of thermodynamics, were found in various sections of the paper.

This misconception could be clarified by renaming hysteretic energy as plastic work, a sum of plastic dissipation and plastic free energy. Both plastic work and plastic free energy can be incrementally negative, but plastic dissipation (defined as the difference of plastic work and plastic free energy) must be incrementally non-negative during any time period. Unfortunately, this misconception has been inherited (if not magnified) by many following studies on energy analysis of earthquake soils and structures (hundreds of papers).

Even Chopra (2000) used similar set of equations in section 7.9, and equation 7.9.6 is clearly wrong!

The basic principles of thermodynamics are frequently used to derive new constitutive models, for example by Dafalias and Popov (1975), Ziegler and Wehrli (1987), Collins and Houlsby (1997), Houlsby and Puzrin (2000), Collins (2002), Collins and Kelly (2002), Collins (2003) and Feigenbaum and Dafalias (2007). The concept of plastic free energy is introduced to enforce the second law of thermodynamics for developed constitutive models. It is important to distinguish between energy dissipation due to plasticity and plastic work, which is often a source of a confusion. Plastic work is the combination of plastic free energy and plastic energy dissipation, which is defined as the amount of heat (and other forms of energy) transformed from mechanical energy during an irreversible dissipative process. The physical nature of plastic free energy is illustrated later in this section through a conceptual example that is analyzed on particle scale. Essentially, development of plastic free energy is caused by particle rearrangement in granular assembly under external loading.

Specific formulation of free energy depends on whether the elastic and plastic behavior of the material is coupled. According to Collins et al. Collins and Houlsby (1997), Collins (2002), Collins (2003), material coupling behavior can be divided into modulus coupling, where the instantaneous elastic stiffness (or compliance) moduli depend on the plastic strain, and dissipative coupling, where the rate of dissipation function depends not only on the plastic strains and their rates of change but also on the stresses (or equivalently the elastic strains). The modulus coupling describes the degradation of stiffness as in for rock and concrete, and is usually modeled by employing a coupled elastic-plastic constitutive model or by introducing damage variables. The dissipative coupling is considered to be one of the main reasons for non-associative behavior in geomaterials Collins and Houlsby (1997), Ziegler (1981).

A number of stability postulates are commonly used to prevent violation of principles of thermodynamics. Stability postulates include Drucker's stability condition Drucker (1956), Drucker (1957), Hill's stability condition Bishop and Hill (1951), Hill (1958), and Il'Iushin's stability postulate Il'Iushin (1961), Lubliner (1990). As summarized in a paper by Lade Lade (2002), theoretical considerations by Nemat–Nasser (1983) and Runesson and Mrǒz (1989) have suggested that they are sufficient but not necessary conditions for stability. These stability postulates can indeed ensure the admissibility of the constitutive models by assuming certain restrictions on incremental plastic work. As demonstrated by Collins (2002), if the plastic strain rate is replaced by the irreversible stain rate in Drucker's postulate, then all the standard interpretations of the classical theory still apply for coupled materials. Dafalias (1977) also modified Il'Iushin's postulate in a similar way and applied it to both coupled and uncoupled materials.

It is important to note that development of inelastic deformation in geomaterials involves large changes in entropy, and significant energy dissipation. It is thus useful to perform energy dissipation (balance) analysis for all models with inelastic deformation. In section we focus on energy dissipation on material level. Focus is on proper modeling that follows thermodynamics. Comparison is made between accumulated plastic dissipation and accumulated plastic work, since these quantities can be quite different in most cases. As a way of verification, the input work, which is introduced by applying external forces, is compared with the stored energy and dissipation in the entire system. Finally, conclusions on plastic energy dissipation are drawn from the verified results.

104.11.2 Theoretical and Computational Formulations

104.11.2.1 Thermo-Mechanical Theory

For energy analysis of elastic-plastic materials undergoing isothermal process, it is beneficial to start from the statement of the first and second laws of thermodynamics:

$$\hat{W} = \dot{\Psi} + \Phi \tag{104.640}$$

where $\Phi \geq 0$ and $\hat{W} \equiv \sigma : \dot{\epsilon} = \sigma_{ij}\dot{\epsilon}_{ij}$ is the rate of work per unit volume. The function Ψ is the Helmholtz free energy, and Φ is the rate of dissipation; both defined per volume. The free energy Ψ is a function of the state variables (also known as internal variables), but Φ and $\hat{W}$ are not the time derivatives of the state functions. The choice of state variables depends on the complexity of constitutive model that is being used, as cyclic loading with certain hardening behaviors usually requires more state variables. This will be elaborated in the following sections as we discuss specific elastic-plastic material models.

For general elastic-plastic materials, the free energy depends on both the elastic and plastic strains. In most material models, it can be assumed that the free energy Ψ can be decomposed into elastic and plastic parts:

$$\Psi = \Psi_{el} + \Psi_{pl} \tag{104.641}$$

The total rate of work associated with the effective stress can be written as the sum of an elastic and plastic component:

$$\hat{W}^{el} \equiv \sigma_{ij}\dot{\epsilon}^{el}_{ij} = \dot{\Psi}_{el} \tag{104.642}$$

and

$$\hat{W}^{pl} \equiv \sigma_{ij}\dot{\epsilon}^{pl}_{ij} = \dot{\Psi}_{pl} + \Phi \tag{104.643}$$

Note that the focus of this section is the energy dissipation caused by material plasticity, which should be distinguished from viscous coupling and other sources of energy dissipation. So the effects of solid-fluid interaction are neglected and all stresses are defined as effective stresses in further derivations. In order to avoid confusion, the common notation $(\sigma^{'}_{ij})$ will not be used. Standard definition of stress from mechanics of materials, i.e. positive in tension, is used.

In the case of a decoupled material, the elastic free energy Ψ_{el} depends only on the elastic strains, and the plastic free energy Ψ_{pl} depends only on the plastic strains, as shown by Collins and Houlsby (1997):

$$\Psi = \Psi_{el}(\epsilon^{el}_{ij}) + \Psi_{pl}(\epsilon^{pl}_{ij}) \tag{104.644}$$

The effective stress can also be decomposed into two parts:

$$\sigma_{ij} = \alpha_{ij} + \chi_{ij} \tag{104.645}$$

lwhere χ_{ij} is a stress-like variable that is related to the dissipative behavior of elastic-plastic material. The difference between the actual stress σ_{ij} and the stress-like variable χ_{ij} is another stress-like term α_{ij}, which is defined from the plastic free energy function Ψ_{pl}. In simple kinematic hardening models, this variable α_{ij} controls the shift behavior of stress under cyclic loading, and thus usually referred to as shift or back stress.

Ziegler's orthogonal postulate Ziegler and Wehrli (1987) ensures the validity of Equation 104.645. It is equivalent to the maximum entropy production criterion, which is necessary to obtain unique formulation. Also, this is a weak assumption so that all the major continuum models of thermo-mechanics are included. Equation 104.643 of plastic work rate can hence be rewritten as:

$$\hat{W}^{pl} \equiv \sigma_{ij}\dot{\epsilon}_{ij}^{pl} = \dot{\Psi}_{pl} + \Phi = \alpha_{ij}\dot{\epsilon}_{ij}^{pl} + \chi_{ij}\dot{\epsilon}_{ij}^{pl} \tag{104.646}$$

The plastic work $\hat{W}^{pl}$ is the product of the actual Cauchy stress σ_{ij} with the plastic strain rate $\dot{\epsilon}_{ij}^{pl}$, while the dissipation rate Φ is the product of the stress variable χ_{ij} with the plastic strain rate $\dot{\epsilon}_{ij}^{pl}$. They are only equal if the rate of plastic free energy $\dot{\Psi}_{pl}$ is zero, or equivalently, if the free energy depends only on the elastic strains.

In kinematic hardening models, where the back stress describes the translation (or rotation) of the yield surface, the decomposition of the true stress (sum of back stress and dissipative stress) is a default assumption. Although such a shift stress is important for anisotropic material models, Collins and Kelly (2002) have pointed out that it is also necessary in isotropic models of geomaterials with different strength in tension and compression.

104.11.2.2 Plastic Free Energy

A popular conceptual model, which focused on particulate materials and demonstrated the physical occurrence of shift stresses, was described by Besseling and Van Der Giessen (1994) and Collins and Kelly (2002). On macro (continuum) scale, every point in a given element is at yield state and deforms plastically. But on meso-scale, only part of this element is undergoing plastic deformations, the remaining part is still within yield surface and respond elastically. The elastic strain energy stored in the elastic part of a plastically deformed macro-continuum element is considered to be locked into the macro-deformation, giving rise to the plastic free energy function Ψ_{pl} and its associated back stress α_{ij}. This energy can be released only when the plastic strains are reversed.

For better explanation, the nature of plastic free energy in particulate materials is illustrated through a finite element simulation combined with considerations of particle rearrangement on mesoscopic scale. Figure 104.80 shows stress-strain response of Drucker-Prager with nonlinear Armstrong-Frederick kinematic hardening, a typical elastic-plastic model for metals and geomaterials. Six states during shear are chosen to represent evolution of micro fabric of the numerical sample. Correspondingly, Figure 104.81 shows the process of particle rearrangement of the 2D granular assembly under cyclic shearing from microscopic level. The square window can be roughly considered as a representative volume (a constitutive level or a finite element) in FEM.

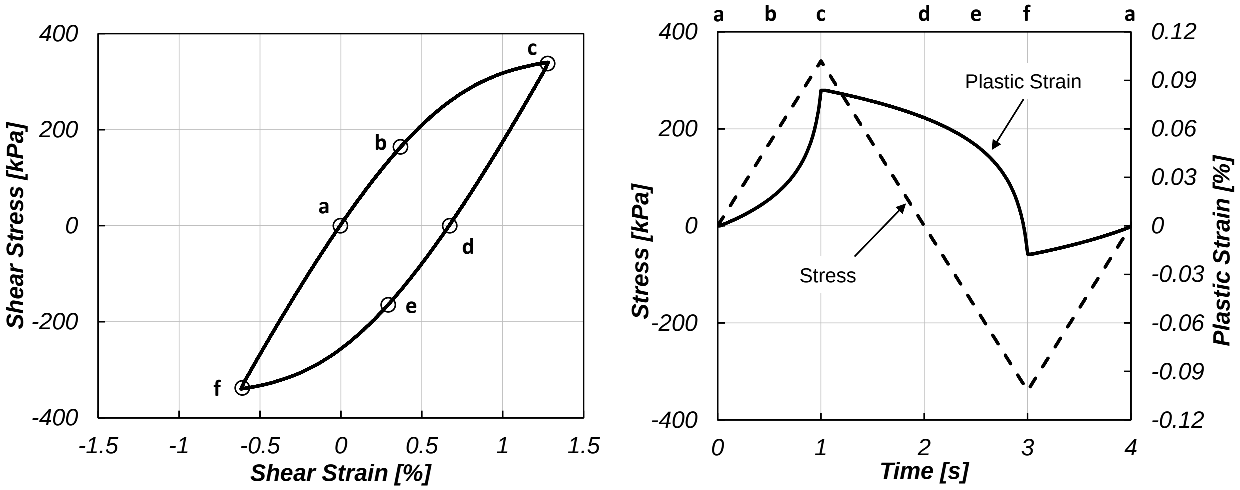

Figure 104.80: Elastic-plastic material modeled with Drucker-Prager yield function and Armstrong-Frederick kinematic hardening under cyclic shear loading: (a) Stress-strain curve; (b) stress and plastic strain versus time.

By discussing movement and energy of particle A in Figure 104.81, the physical nature of plastic free energy is illustrated. At state (a), which is the beginning of deformation, particle A does not bear any load other than its self weight. State (b) is in middle of loading, when particle B pushes downwards to particle A until it makes contact with particle D and E. Load reaches peak at state (c), and there's no space for particle A to move. Then the sample is unloaded to state (d). Particle A is now stuck between particles C, D, and F, which means that certain amount of elastic energy is stored due to particle elastic deformation. Compared with state (a), this part of elastic energy is not released when the sample is unloaded, which indicates that it's not classic strain energy. This part of elastic energy on particle level which can't be released by unloading is defined as the plastic free energy in granular materials. Reverse loading starts at state (e), where particle D pushes particle A upwards, making it squeeze through particle C and F. Elastic energy on particle level, which is now defined as plastic free energy, is released during

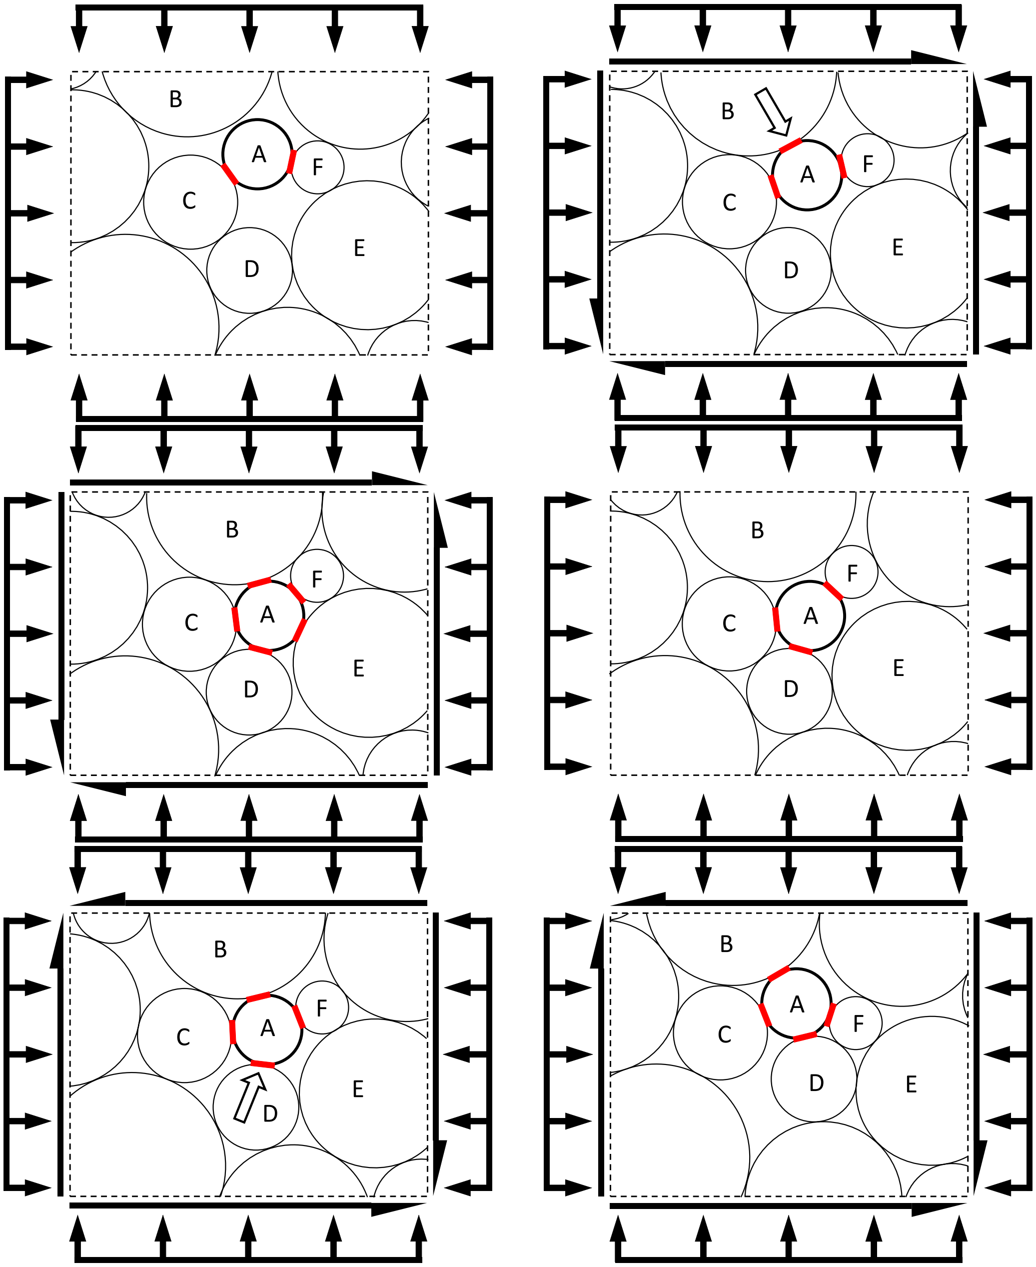

Figure 104.81: Particle rearrangement of a 2D granular assembly under cyclic shearing: (a) Initial state; (b) Loading (accumulating plastic free energy); (c) End of loading (maximum plastic free energy); (d) Unloading (plastic free energy unchanged); (e) Reverse loading (releasing plastic free energy); (f) End of reverse loading (plastic free energy released).

reverse loading.

By analyzing this example, an explanation on particle scale is provided for the origin of plastic free energy in granular materials. It is important to note that the concept of plastic free energy also exists in metals and other materials, as studied by Dafalias et al. (2002) and Feigenbaum and Dafalias (2007). The physical nature of plastic free energy in these materials can be different and probably should be studied on molecular and/or crystalline level.

Collins Collins and Kelly (2002), Collins (2003) suggested that in the case of granular materials, the particle-level plastic energy dissipation during normal compaction, arises from the plastic deformations occurring at the inter-granular contacts on the strong force chains, that are bearing the bulk of the applied loads. Collins also suggested that the locked-in elastic energy is produced in the weak force networks, where the local stresses are not large enough to produce plastic deformation at the grain contacts. The plastic strains can be associated with the irreversible rearrangement of the particles, whilst the elastic energy arises from the elastic compression of the particle contacts. Part of this elastic strain energy will be released during unloading, however other part of this energy will be trapped as a result of the irreversible changes in the particle configuration.

104.11.2.3 Plastic Dissipation

As pointed out, plastic work and energy dissipation are not the same physical quantity. The confusion of these two concepts often leads to incorrect results and conclusions, especially in seismic energy dissipation analysis. Of major concern in this section is the computation of plastic dissipation, as elaborated in this section.

With the decoupling assumption (Equation 104.644), the second law of thermodynamics (positive entropy production) directly leads to the dissipation inequality, which states that the energy dissipated due to the difference of the plastic work rate and the rate of the plastic part of the free energy must be non-negative:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij}^{pl} - \dot{\Psi}_{pl} = \sigma_{ij}\dot{\epsilon}_{ij}^{pl} - \rho\dot{\psi}_{pl} \geq 0 \qquad (104.647)$$

where $\dot{\psi}_{pl}$ is the rate of plastic free energy, per unit mass, and ρ is the mass density. In addition, ψ_{pl} denotes plastic free energy density, which is generally not constant at different locations in a body. This expression is closer to physics and makes it convenient for further derivations.

Now we proceed to consider how to calculate plastic free energy, which can then be used to calculate dissipation. According to Feigenbaum and Dafalias (2007), plastic free energy density ψ_{pl} is assumed to be additively decomposed into parts which correspond to the isotropic, kinematic and distortional hardening mechanisms as follows:

$$\psi_{pl} = \psi_{pl}^{iso} + \psi_{pl}^{ani}; \quad \psi_{pl}^{ani} = \psi_{pl}^{kin} - \psi_{pl}^{dis} \tag{104.648}$$

where ψ_{pl}^{iso}, ψ_{pl}^{ani}, ψ_{pl}^{kin}, and ψ_{pl}^{dis} are the isotropic, anisotropic, kinematic, and distortional parts of the plastic free energy, respectively. The anisotropic part is assumed to decompose into kinematic and distortional parts, which correspond to different hardening models. The subtraction, instead of addition, of ψ_{pl}^{dis} from ψ_{pl}^{kin}, to obtain the overall anisotropic part ψ_{pl}^{ani} of the plastic free energy, is a new concept proposed by Feigenbaum and Dafalias (2007). This expression can better fit experimental data, as well as satisfy the plausible expectations for a limitation of anisotropy development. The distortional part of the plastic free energy ψ_{pl}^{dis} is related to the directional distortion of yield surface and will only be present if the material model incorporates distortional strain hardening, which is not considered in the formulations and examples of this study.

As pointed out by Dafalias et al. (2002), the thermodynamic conjugates to each of the internal variables exist and each part of the plastic free energy can be assumed to be only a function of these conjugates. The explicit expressions for the isotropic and kinematic components of the plastic free energy are:

$$\psi_{pl}^{iso} = \psi_{pl}^{iso}(\bar{k}) = \frac{\kappa_1}{2\rho}\bar{k}^2; \quad \psi_{pl}^{kin} = \psi_{pl}^{kin}(\bar{\alpha}_{ij}) = \frac{a_1}{2\rho}\bar{\alpha}_{ij}\bar{\alpha}_{ij} \tag{104.649}$$

where $\bar{k}$ and $\bar{\alpha}_{ij}$ are the thermodynamic conjugates to k (size of the yield surface) and α_{ij} (deviatoric back stress tensor representing the center of the yield surface), respectively. Material constants κ_1 and a_1 are non-negative material constants whose values depend on the choice of elastic-plastic material models.

According to definition, the thermodynamic conjugates are related to the corresponding internal variables by:

$$k = \rho\frac{\partial\psi_{pl}^{iso}}{\partial\bar{k}} = \kappa_1\bar{k}; \quad \alpha_{ij} = \rho\frac{\partial\psi_{pl}^{kin}}{\partial\bar{\alpha}_{ij}} = a_1\bar{\alpha}_{ij} \tag{104.650}$$

By substituting Equation 104.650 back into Equation 104.649, the plastic free energy can be expressed in terms of the internal variables:

$$\psi_{pl}^{iso} = \frac{1}{2\rho\kappa_1}k^2; \quad \psi_{pl}^{kin} = \frac{1}{2\rho a_1}\alpha_{ij}\alpha_{ij} \tag{104.651}$$

With Equation 104.651, the components of plastic free energy can be computed, as long as the internal variables are provided. Combining Equation 104.647 with 104.651, the plastic dissipation in a given elastic-plastic material can be accurately obtained at any location, at any time. This approach allows engineers and designers to correctly identify energy dissipation in time and space and make appropriate conclusions on material behavior.

104.11.2.4 Energy Computation in Finite Elements

Formulations from the previous section are applied to FEM analysis in order to follow energy dissipation. Energy density is chosen as the physical parameter for energy analysis. Energy density in this study is defined as the amount of energy stored in a given region of space per unit volume.

For FEM simulations, both external forces and displacements can be prescribed. The finite element program accepts either (or both) forces and/or displacements as input and solves for the other. Either way, the rate of input work can be calculated by simply multiplying force and displacement within a time step. Therefor input work of a finite element model is:

$$W_{Input}(t) = \int_0^t \dot{W}_{Input}(T)dT = \int_0^t \sum_i F_i^{ex}(\boldsymbol{x}, T)\dot{u}_i(\boldsymbol{x}, T)dT \tag{104.652}$$

where F_i^{ex} is the external force and u_i is the displacement computed at the location of the applied load, at given time step, for a load controlled analysis. The external load can have many forms, including nodal loads, surface loads, and body loads. All of them are ultimately transformed into nodal forces. As shown in Equation 104.652, input work is computed incrementally at each time step, in order to obtain the evolution of total input work at certain time.

As shown in Figure 104.82, when loads and/or displacements are introduced into a finite element model, the input energy will be converted in a number of different forms as it propagates through the system. Input energy will be converted into kinetic energy, free energy, and dissipation. As mentioned before, free energy can be further separated into elastic part, which is traditionally defined as strain energy, and plastic part, which is defined as the plastic free energy. Kinetic energy and strain energy can be considered as the recoverable portion of the total energy since they are transforming from one to another. Plastic free energy is more complicated in the sense that it is conditionally recoverable during reverse loading, as has been discussed in detail in previous sections. Other than kinetic energy and free energy, the rest of the input energy is dissipated, transformed into heat or other forms of energy that are irrecoverable.

Calculation of kinetic energy and strain energy is rather straight forward:

$$U_K(\boldsymbol{x}, t) = \frac{1}{2}\rho\dot{u}_{ij}(\boldsymbol{x}, t)\dot{u}_{ij}(\boldsymbol{x}, t) \tag{104.653}$$

$$U_S(\boldsymbol{x}, t) = \int_0^t \dot{U}_S(\boldsymbol{x}, T)dT = \int_0^t \sigma_{ij}(\boldsymbol{x}, T)\dot{\epsilon}_{ij}^{el}(\boldsymbol{x}, T)dT \tag{104.654}$$

where U_K and U_S are the kinetic energy density and strain energy density, respectively.

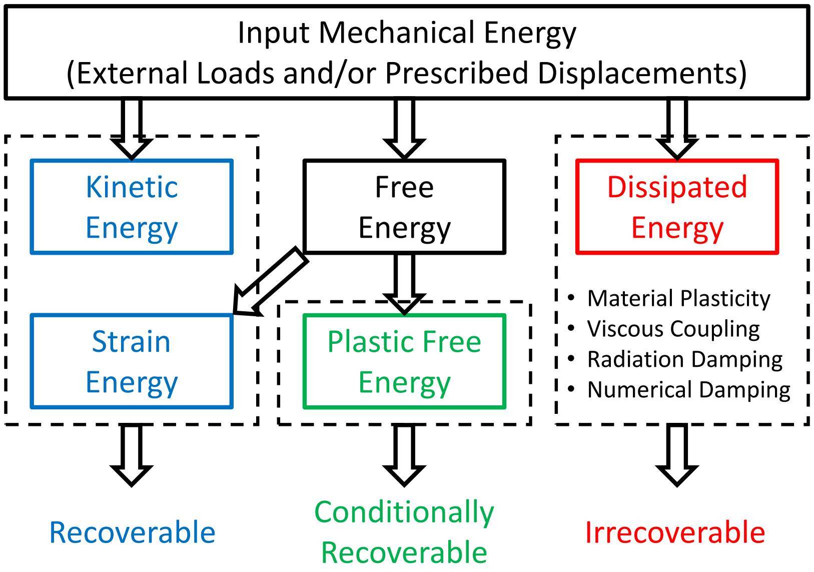

Figure 104.82: Different forms of energy in a dynamic soil-structure system.

Similar to the input energy, strain energy density and plastic free energy are also computed incrementally. Integrating energy density over the entire model, corresponding energy quantities are expressed as:

$$E_K(t) = \int_V U_K(\boldsymbol{x}, t) dV \tag{104.655}$$

$$E_S(t) = \int_V U_S(\boldsymbol{x}, t) dV \tag{104.656}$$

$$E_P(t) = \int_V \Psi_{pl}(\boldsymbol{x}, t) dV \tag{104.657}$$

where E_K, E_S, and E_P are the kinetic energy, strain energy, and plastic free energy of the entire model, respectively. Energy densities, defined in Equations 104.653 and 104.654 are functions of both time and space, while energy components, defined in the above equations (Equation 104.655, 104.656, and 104.657) are only functions of time, since they are integrated over the whole model.

Although the plastic free energy is conditionally recoverable, it is still considered to be stored in the system, rather than dissipated. Summing up all the stored energy E_{Stored}, one obtains:

$$E_{Stored} = E_K + E_S + E_P \tag{104.658}$$

Rate of plastic dissipation, given by Equation 104.647, can be integrated over time and space:

$$D_P(t) = \int_V \int_0^t \Phi(\boldsymbol{x}, T) dT dV \tag{104.659}$$

where D_P is the dissipation due to plasticity of the entire model at certain time.

Finally the energy balance of a finite element model is given by:

$$W_{Input} = E_{Stored} + D_P = E_K + E_S + E_P + D_P \tag{104.660}$$

104.11.3 Numerical Studies

Numerical simulation results presented in this section are performed using the Real-ESSI (Jeremić et al., 1988-2025). Examples in this section focus on constitutive behavior of elastic-plastic material from the perspective of energy dissipation.

All cases are assumed to be static problems. External loads are applied incrementally using load- or displacement-control scheme. System equations are solved using Newton-Raphson iteration algorithm and UMFPACK solver. Standard 8-node-brick elements are used in all cases, in order to eliminate the variation in energy computation caused by different element types.

104.11.3.1 Elastic Material

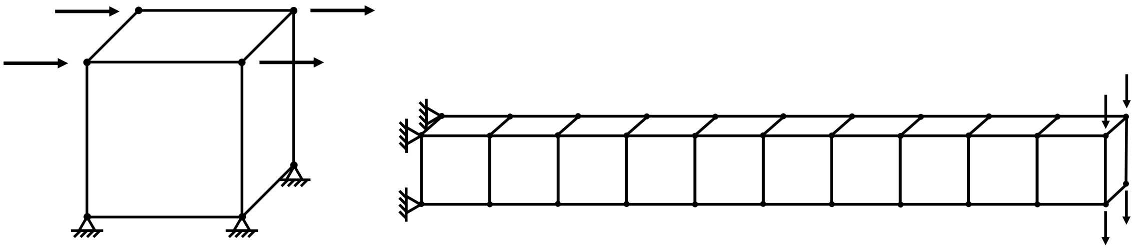

Figure 104.83: Numerical models used in this section: (a) Single brick element; (b) Cantilever with 10 brick elements.

Initial investigation of energy dissipation is focused on linear elastic material. It is noted that linear elastic material does not dissipate energy. Use of linear elastic material model is suitable for preliminary verification of the newly developed energy analysis methodology. In this section, energy balance in a single brick element and a cantilever beam is studied, as shown in Figure 104.83.

It should be mentioned that the bending deformations of cantilever are not accurate due to the use of a single layer of 8-node-brick elements in the direction of stress and strain variation. However, the focus of this example is energy transformation and balance, which are not affected by inaccurate deformations in this example.

The simplest case is a single element model under uniform shear load. The model is constrained appropriately to simulate simple shear test. In order to show the influence of different material parameters and loads, a set of simulations are performed and the results are presented in Table 104.2 and Figure 104.84.

Table 104.2: Energy analysis results for linear elastic materials (single element).

200	0.25	1.25E-5	6.25	0.00	6.25	0.00	6.25	0.00
200	0.30	1.30E-5	6.50	0.00	6.50	0.00	6.50	0.00
200	0.35	1.35E-5	6.75	0.00	6.75	0.00	6.75	0.00
200	0.40	1.40E-5	7.00	0.00	7.00	0.00	7.00	0.00

Since linear elastic material is used with static algorithm, energy components related to dynamics (kinetic energy) and plasticity (plastic free energy and plastic dissipation) are equal to zero. This means that all input work is stored in the system, as observed in all cases.

Figure 104.84 shows that energy stored in the system is inversely proportional to Young's moduli E and proportional to one plus Poisson's ratio $(1+\nu)$. This is expected because of the following equations for strain energy under static shear loading:

$$E_S = \frac{1}{2}\tau\gamma = \frac{1}{2G}\tau^2 = \frac{1+\nu}{E}\tau^2 \tag{104.661}$$

Note that these relationships are only valid at constitutive level. For models with more finite elements, stress and strain are generally not uniform. The computation of energy depends on the distribution of energy density, and nonuniform stress/strain distribution will result in nonuniform energy density distribution.

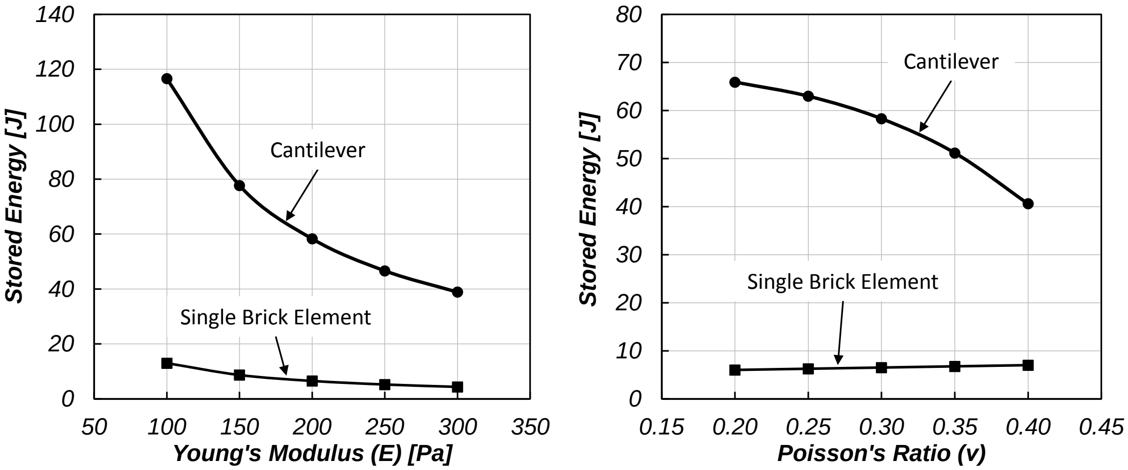

Figure 104.84: Relationships between energy storage and different simulation parameters (single element model): (a) Young's modulus; (b) Poisson's ratio.

In order to study the influence of simulation parameters in larger models, another set of simulations with cantilever model (Figure 104.83b) are performed. Vertical loads are applied to the nodes of the free end. In this case, both shearing and bending occurs, which means that in general a full 3D state of stress and strain is present. The results are presented in Table 104.3 and Figure 104.84. As expected, energy behavior of cantilever is different than the single-element/constitutive example.

For all cases, the energy balance between input and storage is maintained, which gives us confidence on the energy calculation methodology for elastic material. According to results in Figure 104.84, energy stored in the system is still inversely proportional to Young's modulus. This is because the general equation for elastic strain energy density is:

$$E_S = \frac{1}{2E}\left(\sigma_{xx}^2 + \sigma_{yy}^2 + \sigma_{zz}^2 + 2(1+\nu)(\sigma_{xy}^2 + \sigma_{yz}^2 + \sigma_{zx}^2)\right) \tag{104.662}$$

So as long as all the elements have the same Young's modulus, the relationship between stored energy and Young's modulus will remain valid.

104.11.3.2 von Mises Plasticity

Elastic-plastic modeling using von Mises material model has been proven to be effective in modeling pressure-independent materials like steel or other metals. In this section, the energy behavior of models using von Mises plasticity with various hardening rules are examined using the proposed method. The material model parameters used in this section are summarized in Table 104.4.

Note that associated plasticity is used in all models in this section, which means that the plastic flow

direction m_{ij} is equal to the gradient of the yield surface $n_{ij}(= \partial f / \partial \sigma_{ij})$. Since the yield function is of von Mises type, associated plasticity leads to the result that only deviatoric plastic flow will appear in all cases.

No Hardening (Elastic-Perfectly Plastic). In this example, elastic-perfectly plastic material is used. Equations 104.647 and 104.651 indicate that in the case of no hardening the rate of plastic free energy is zero. Then the incremental plastic work is equal to incremental plastic dissipation. Note that this is one of the rare cases where plastic dissipation equals to plastic work.

Figure 104.85 shows stress–strain curve (left) and energy calculated for elastic-perfectly plastic constitutive model (right) used here.

In this case, the plastic dissipation is equal to the plastic work. This means that the plastic free energy does not develop at all during loading and unloading. Zero plastic free energy points out the absence of fabric evolution of a particulate, elastic-plastic material, as all the input work is dissipated through particle to particle friction. Since there is no plastic free energy E_P in this case, the stored energy equals to mechanical energy, which is the combination of strain energy E_S and kinetic energy E_K. Total stored energy E_{Stored} develops nonlinearly and always has the same value at the beginning of every loop after the first one. Plastic dissipation D_P increases linearly when the material yields. This can be

Table 104.4: Model parameters for cases using von Mises plasticity

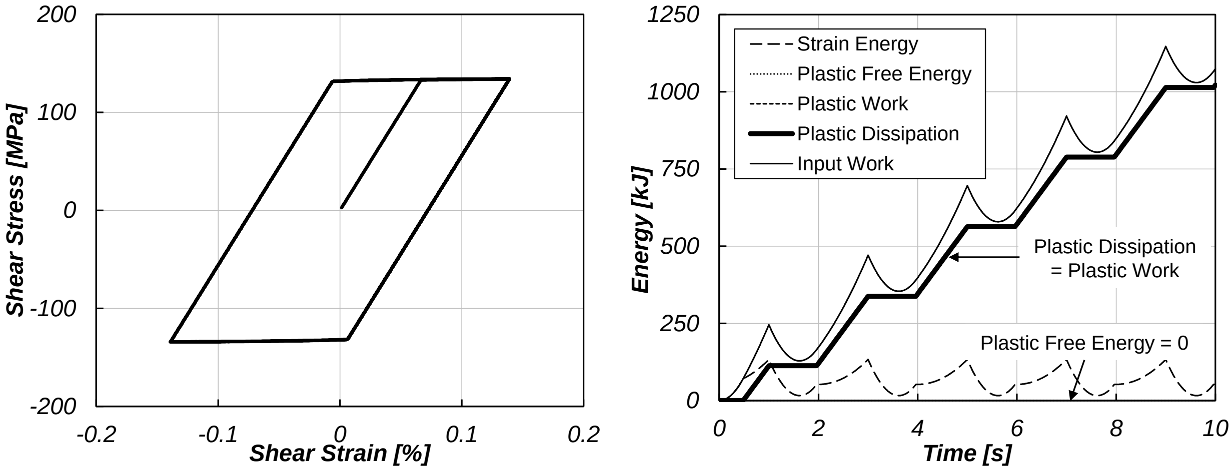

Figure 104.85: Energy analysis of elastic-plastic material modeled using von Mises plasticity with no hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation, strain energy and plastic work.

explained by rewriting Equation 104.647 with $\Psi_{pl} = 0$:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij}^{pl} \tag{104.663}$$

where stress σ_{ij} is constant after elastic perfectly plastic material yields, and rate plastic deformation $\dot{\epsilon}_{ij}^{pl}$ is also constant. Then the rate of plastic dissipation is constant which makes the plastic dissipation D_P increase linearly.

Linear Isotropic Hardening. Next material model used is von Mises plasticity with linear isotropic hardening. First used to model monotonic behavior of elastic-plastic materials, isotropic hardening assumes that the yield surface maintains shape, while isotropically (proportionally) changing its size. Figure 104.86 illustrates the stress–strain response as well as energy balance for elastic-plastic material with isotropic hardening.

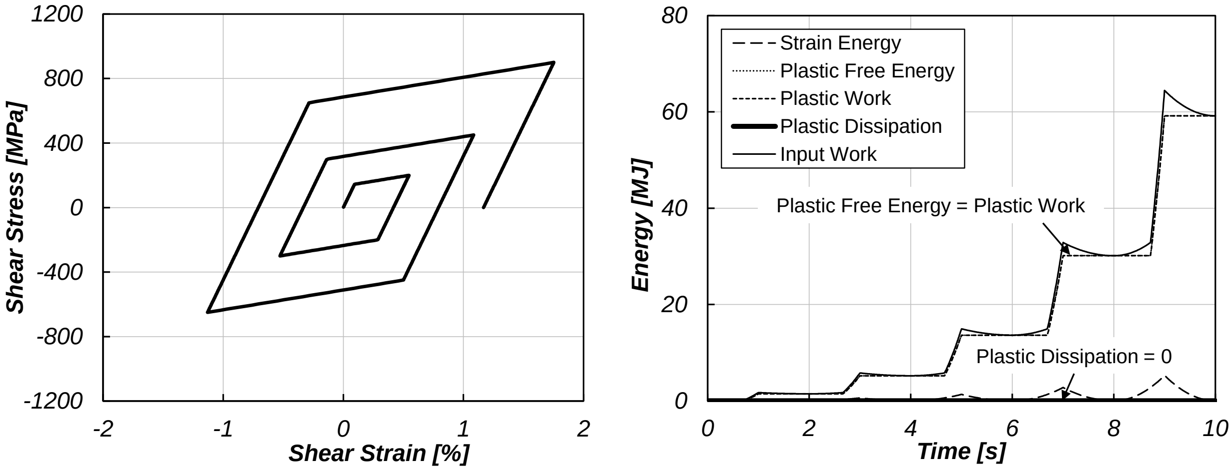

Figure 104.86: Energy analysis of elastic-plastic material modeled using von Mises plasticity with linear isotropic hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation, strain energy, and plastic work.

As can be observed from Figure 104.86, plastic free energy is equal to the plastic work, which means that the plastic dissipation is zero during cycles of loading. Even though this might sound surprising, it can be explained using basic thermodynamics. Linear isotropic hardening, used in this case, can be described through a rate of the internal variable (size of the yield surface) $\dot{k}$ as:

$$\dot{k} = \kappa_1 |\dot{\epsilon}_{ij}^{pl}| \tag{104.664}$$

where $|\dot{\epsilon}_{ij}^{pl}|$ is the magnitude of the rate of plastic strain while κ_1 is a hardening constant. The hardening constant κ_1 is denoted as `isotropic_hardening_rate` in Table 104.4. Substituting previous equation into Equation 104.651 yields:

$$\psi_{pl} = \psi_{pl}^{iso} = \frac{\kappa_1}{2\rho} \epsilon_{ij}^{pl} \epsilon_{ij}^{pl} \tag{104.665}$$

Take the time derivative of the above equation:

$$\dot{\psi}_{pl} = \frac{\kappa_1}{\rho} \epsilon_{ij}^{pl} \dot{\epsilon}_{ij}^{pl} \tag{104.666}$$

Then the rate of dissipation due to plasticity can be expressed as:

$$\Phi = \sigma_{ij}\epsilon_{ij}^{pl} - \rho\dot{\psi}_{pl} = (\sigma_{ij} - \kappa_1\epsilon_{ij}^{pl})\dot{\epsilon}_{ij}^{pl} = (\sigma_{ij} - km_{ij})\dot{\epsilon}_{ij}^{pl} \tag{104.667}$$

where m_{ij} is the plastic flow direction. The plastic flow direction defines the direction of incremental plastic strain, which can be different from the direction of total plastic strain. But in the case of associated von Mises plasticity with only isotropic hardening, the plastic flow direction m_{ij} is the same as the direction of the total plastic strain ϵ_{ij}^{pl}. Thus we have $\kappa_1\epsilon_{ij}^{pl} = km_{ij}$ in the above equation.

Substitute the plastic flow direction m_{ij} with the gradient of yield surface n_{ij}, and also note that $\sigma_{ij}\dot{\epsilon}_{ij}^{pl} = s_{ij}\dot{\epsilon}_{ij}^{pl}$, where $s_{ij}(= \sigma_{ij} - 1/3\delta_{ij}\sigma_{kk})$ is the deviatoric part of the stress tensor, the rate of plastic dissipation can be rewritten as:

$$\Phi = (s_{ij} - kn_{ij})\dot{\epsilon}_{ij}^{pl} = \alpha_{ij}\dot{\epsilon}_{ij}^{pl} \tag{104.668}$$

Realizing that the back stress α_{ij} is always zero since we assume no kinematic hardening, then the rate of plastic dissipation becomes zero, which means there is no energy dissipation during cycles of loading for isotropically hardening material. Obviously, the observed response is not physical from the perspective of energy dissipation. Therefore, isotropic hardening material models cannot properly model energy dissipation, even for monotonic loading.

Prager Linear Kinematic Hardening. Compared with isotropic hardening, kinematic hardening can better describe the constitutive, stress-strain behavior of elastic-plastic materials, particularly for cyclic loading. Elastic-plastic material that relies on kinematic hardening is used to analyze energy dissipation. Both linear and nonlinear kinematic hardening rules are investigated in relation to energy dissipation.

Prager's linear kinematic hardening rule is given as:

$$\dot{\alpha}_{ij} = a_1\dot{\epsilon}_{ij}^{pl} \tag{104.669}$$

where a_1 is a hardening constant. The hardening constant a_1 is denoted as `kinematic_hardening_rate` in Table 104.4.

If only linear kinematic hardening (Equation 104.669) is assumed, the back stress α_{ij} is expressed explicitly, and can be substituted into Equation 104.651 yielding:

$$\psi_{pl} = \psi_{pl}^{kin} = \frac{a_1}{2\rho}\epsilon_{ij}^{pl}\epsilon_{ij}^{pl} \tag{104.670}$$

Take the time derivative of the above equation:

$$\dot{\psi}_{pl} = \frac{a_1}{\rho}\epsilon_{ij}^{pl}\dot{\epsilon}_{ij}^{pl} \tag{104.671}$$

Then the rate of dissipation due to plasticity can be rewritten as:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij}^{pl} - \rho\dot{\psi}_{pl} = (s_{ij} - \alpha_{ij})\dot{\epsilon}_{ij}^{pl} = k m_{ij}\dot{\epsilon}_{ij}^{pl} \tag{104.672}$$

Notice that the term $m_{ij}\dot{\epsilon}_{ij}^{pl}$ denotes the magnitude of the rate of plastic strain. Since only linear kinematic hardening is assumed, the internal variable k will remain constant. So if loads are applied in such a way that the rate of plastic strain is constant, then the rate of dissipation will also remain constant. In other words, the accumulated dissipation will be linearly increasing under the assumption of linear kinematic hardening.

Figure 104.87 shows stress–strain response (left) and energy computation results (right) of an elastic-plastic material modeled using von Mises plasticity with linear kinematic hardening.

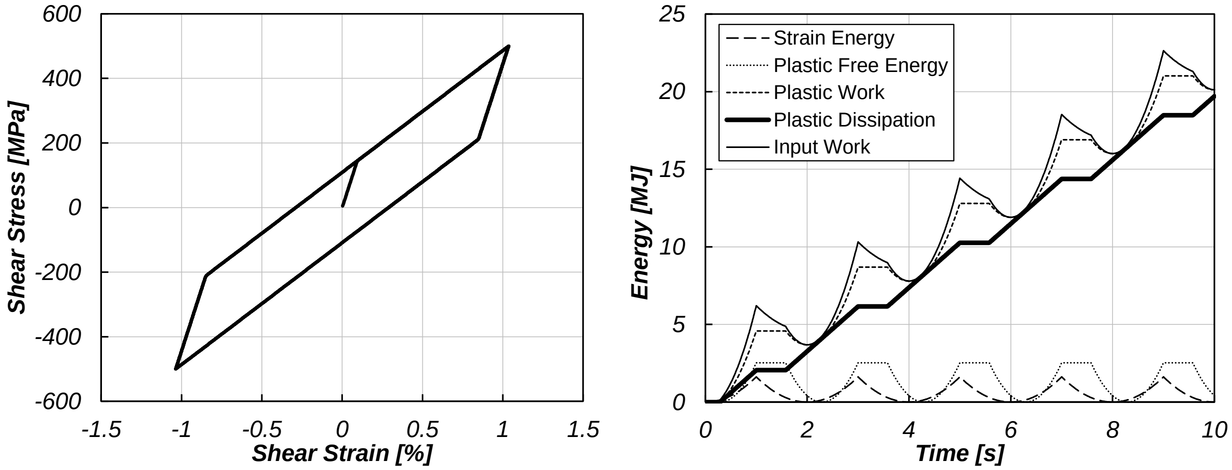

Figure 104.87: Energy analysis of elastic-plastic material modeled using von Mises plasticity with linear kinematic hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation strain energy and plastic work.

As expected, the plastic dissipation increases linearly once the material yields. In contrast to the isotropic hardening case, a significant amount of the input work is dissipated due to material plasticity. The ratio of dissipated energy to input work is largely influenced by the material parameters. However, in general, energy dissipation will be observed if kinematic hardening model is used.

Another important observation is that the plastic work decreases during certain phases of reverse loading, while the actual rate of energy dissipation is always nonnegative. It is important to distinguish plastic work from plastic energy dissipation. Otherwise, one might argue that accumulated energy dissipation can increase or decrease, which is a common mistake observed in a number of publications that violates the second law of thermodynamics.

Armstrong-Frederick Kinematic Hardening. Armstrong-Frederick kinematic hardening model Armstrong and Frederick (1966) is often used to simulate elastic-plastic material behavior under cyclic loading. Material parameters of the Armstrong-Frederick kinematic hardening rule can be derived from basic thermodynamics. The following equation is a general expression for Armstrong-Frederick kinematic hardening rule:

$$\dot{\alpha}_{ij} = a_1 \dot{\epsilon}_{ij}^{pl} - a_2 \dot{\lambda} \alpha_{ij} \tag{104.673}$$

where $\dot{\lambda}$ is a non-negative scalar plastic multiplier and a_2 is a non-negative material hardening constant. It can be proven that a_1/a_2 is related to the limit of back stress magnitude $\left|\alpha_{ij}\right|$. In Table 104.4, the hardening constants a_1 and a_2 correspond to parameters `armstrong_frederick_ha` and `armstrong_frederick_cr`.

Taking the time derivative of the kinematic part of plastic free energy (Equation 104.671), and substituting the expression of back stress α_{ij} (Equation 104.673) gives:

$$\dot{\psi}_{pl}^{kin} = \frac{1}{\rho a_1} \alpha_{ij} \dot{\alpha}_{ij} = \frac{1}{\rho} \alpha_{ij} (\dot{\epsilon}_{ij}^{pl} - \frac{a_2}{a_1} \dot{\lambda} \alpha_{ij}) \tag{104.674}$$

Then the rate of plastic energy dissipation of an Armstrong-Frederick kinematic hardening elastic-plastic material is given by:

$$\Phi = \sigma_{ij} \dot{\epsilon}_{ij}^{pl} - \rho \dot{\psi}_{pl} = s_{ij} \dot{\epsilon}_{ij}^{pl} - \alpha_{ij} \dot{\epsilon}_{ij}^{pl} + \frac{a_2}{a_1} \dot{\lambda} \alpha_{ij} \alpha_{ij} = k m_{ij} \dot{\epsilon}_{ij}^{pl} + \frac{a_2}{a_1} \dot{\lambda} \alpha_{ij} \alpha_{ij} \tag{104.675}$$

Compared with Equation 104.672, the above expression has an additional term which makes the rate of plastic dissipation non-constant even if the rate of plastic strain is constant. As the back stress α_{ij} becomes larger when load increases, the rate of plastic dissipation also increases. This indicates a nonlinear result of total plastic dissipation, which is exactly what we have observed in our computations.

Figure 104.88 shows the energy computation results of an elastic-plastic material modeled using von Mises plasticity with Armstrong-Frederick kinematic hardening. Compared to all previous cases, the material response of this model is more sophisticated and more realistic. Decrease of plastic work is observed, again, while the plastic dissipation is always nonnegative during the entire simulation. For both linear and nonlinear kinematic hardening cases, the plastic free energy is relatively small compared to the plastic dissipation.

104.11.3.3 Drucker–Prager Plasticity

It has been proven that von Mises plasticity generally performs poorly in modeling pressure-sensitive materials like soils. In this section, the thermomechanical formulations presented in earlier sections are

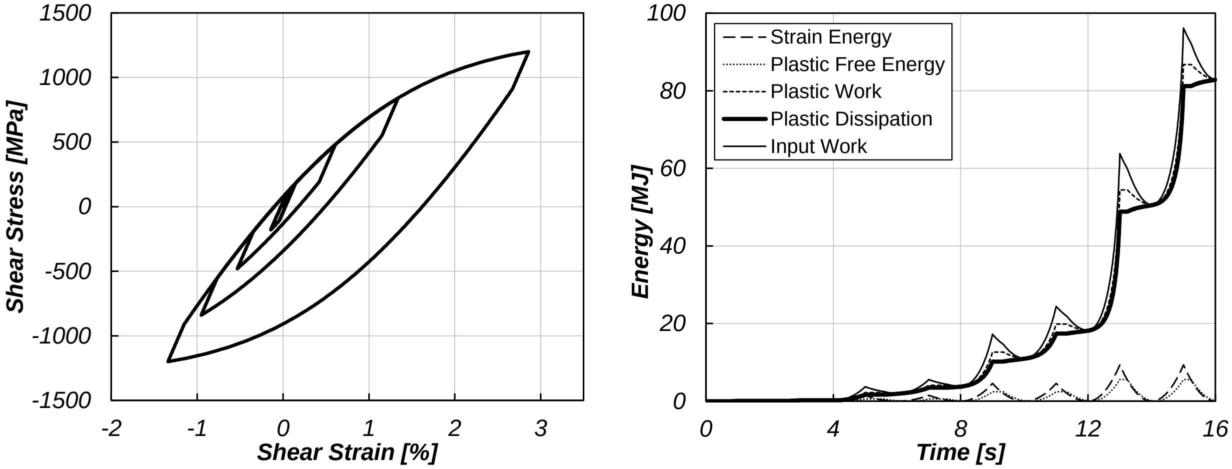

Figure 104.88: Energy analysis of elastic-plastic material modeled using von Mises plasticity with Armstrong–Frederick kinematic hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation, strain energy, and plastic work.

Table 104.5: Model parameters for cases using Drucker–Prager plasticity

Parameter	Unit	Hardening Type

`armstrong_frederick_ha`	MPa			20	20	20
`armstrong_frederick_cr`				100	100	100

applied to models using Drucker–Prager yield criteria with different hardening types. The material model parameters used in this section are summarized in Table 104.5.

The yield function of Drucker–Prager plasticity is:

$$f = [(s_{ij} - p\alpha_{ij})(s_{ij} - p\alpha_{ij})]^{0.5} - \sqrt{\frac{2}{3}}kp \tag{104.676}$$

where $p = (1/3)\delta_{ij}\sigma_{kk}$ is the mean stress (or hydrostatic pressure). Note that in this form of Drucker–Prager plasticity, the internal variables α_{ij} and k, as well as the hardening constants κ_1 and a_1, are dimensionless.

For the computation of plastic free energy in Drucker–Prager plasticity models, Equation 104.651 is modified:

$$\psi_{pl}^{iso} = \frac{1}{2\rho(\kappa_1 p)}(kp)^2 = \frac{1}{2\rho\kappa_1}k^2 p \tag{104.677}$$

$$\psi_{pl}^{kin} = \frac{1}{2\rho(a_1 p)}(\alpha_{ij}p)(\alpha_{ij}p) = \frac{1}{2\rho a_1}\alpha_{ij}\alpha_{ij}p \tag{104.678}$$

All examples presented in this section are using non-associated Drucker–Prager plasticity. The plastic potential function is of von Mises type so that only deviatoric plastic flow exists. In addition, all cases are loaded with constant hydrostatic pressure, which means that the plastic flow direction m_{ij} is the same as the direction of the total plastic strain ϵ_{ij}^{pl}. With the above conditions, Equation 104.663, 104.668, and 104.672 are all still valid for the following examples, as will be observed in their results.

It should be noted that the proposed energy computation approach can also be applied to associated Drucker–Prager plasticity and non-associated Drucker–Prager plasticity with different plastic potential functions. The loading condition can be arbitrary, even with evolving hydrostatic pressures.

Linear Isotropic Hardening. Figure 104.89 shows the stress–strain response and energy computation results of an elastic-plastic material modeled using Drucker–Prager plasticity with linear kinematic hardening.

No plastic dissipation is observed in this case, which have been theoretically proven in Equation 104.668. This example again indicates that isotropic hardening is not capable of proper modeling of energy dissipation in elastic-plastic materials.

Prager Linear Kinematic Hardening. Figure 104.90 shows the stress–strain response and energy computation results of an elastic-plastic material modeled using Drucker–Prager plasticity with linear kinematic hardening.

Plastic dissipation increases linearly when the material yields, while the plastic work decreases during certain phases of reverse loading. This observation is consistent with the theoretical conclusion drawn from Equation 104.672.

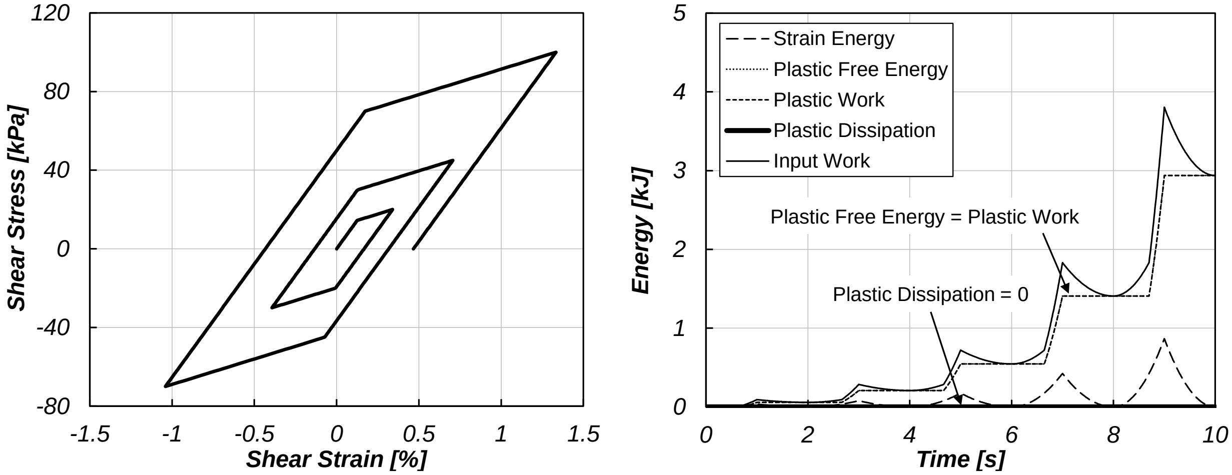

Figure 104.89: Energy analysis of elastic-plastic material modeled using Drucker–Prager plasticity with linear isotropic hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation strain energy and plastic work.

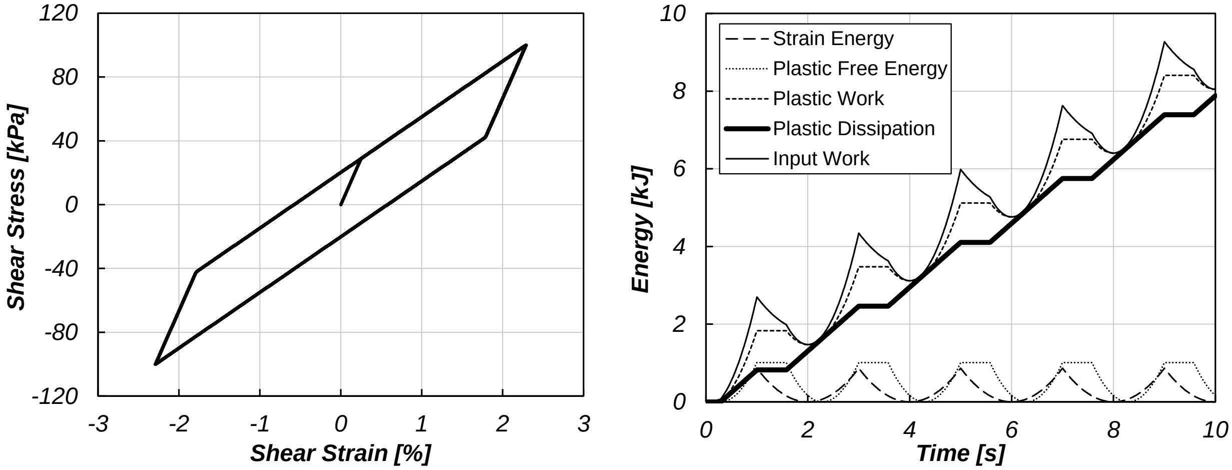

Figure 104.90: Energy analysis of elastic-plastic material modeled using Drucker–Prager plasticity with linear kinematic hardening: (a) Stress–strain curve; (b) Input work, plastic dissipation strain energy and plastic work.

Note that the results of the above two examples share high similarity with those of the cases modeled with associated von Mises plasticity. This is because the hydrostatic pressures were constant during shearing, which makes the pressure-dependent feature of Drucker–Prager plasticity not observed. The energy computation results are expected to be more complicated with different loading conditions. However, the difference between plastic work and plastic dissipation will be observed. And the incremental plastic dissipation should always be nonnegative.

Armstrong–Frederick Kinematic Hardening. In order to illustrate the influence of hydrostatic pressure to the energy dissipation in Drucker–Prager models, three cases with different confining pressures are studied. Armstrong–Frederick kinematic hardening is used here to model the nonlinear hardening response of pressure-dependent material, like soils. Figure 104.91 shows the stress–strain response and energy computation results of these three cases.

As can be observed from Figure 104.91, the slope of stress–strain loop increases, which means the material becomes stiffer, as the confining stress increases. Also, the size of elastic region becomes larger when the confining stress is bigger.

Plastic dissipation and plastic free energy starts to evolve as soon as the material yields. The pattern of evolution of energy components are the same for all three cases, while the value of plastic dissipation decreases as the confining stress increases. This is expected since the material becomes stiffer and harder to plastify with a higher confining stress.

104.11.4 Conclusions

Presented was a methodology for (correct) computation of energy dissipation in elastic-plastic materials based on the second law of thermodynamics. A very important role of plastic free energy was analyzed, with highlights on its physical nature and theoretical formulations. The proposed methodology has been illustrated using a number of elasto-plastic material models.

An analysis of a common misconception that equates plastic work and dissipation, which leads to the violation of the basic principles of thermodynamics, was addressed. A conceptual example, for granular materials, was used to explain the physical meaning of plastic free energy. It was also shown that plastic free energy is responsible for the evolution of internal variables.

It was shown that energy balance is ensured by taking into consideration all energy components, including kinetic and strain energy. Input work was balanced with the stored and dissipated energy, expressed as the summation of all possible components.

Presented approach was illustrated and tested using several elastic-plastic constitutive models with various hardening rules. Elastic materials showed no energy dissipation (as expected), leading to the

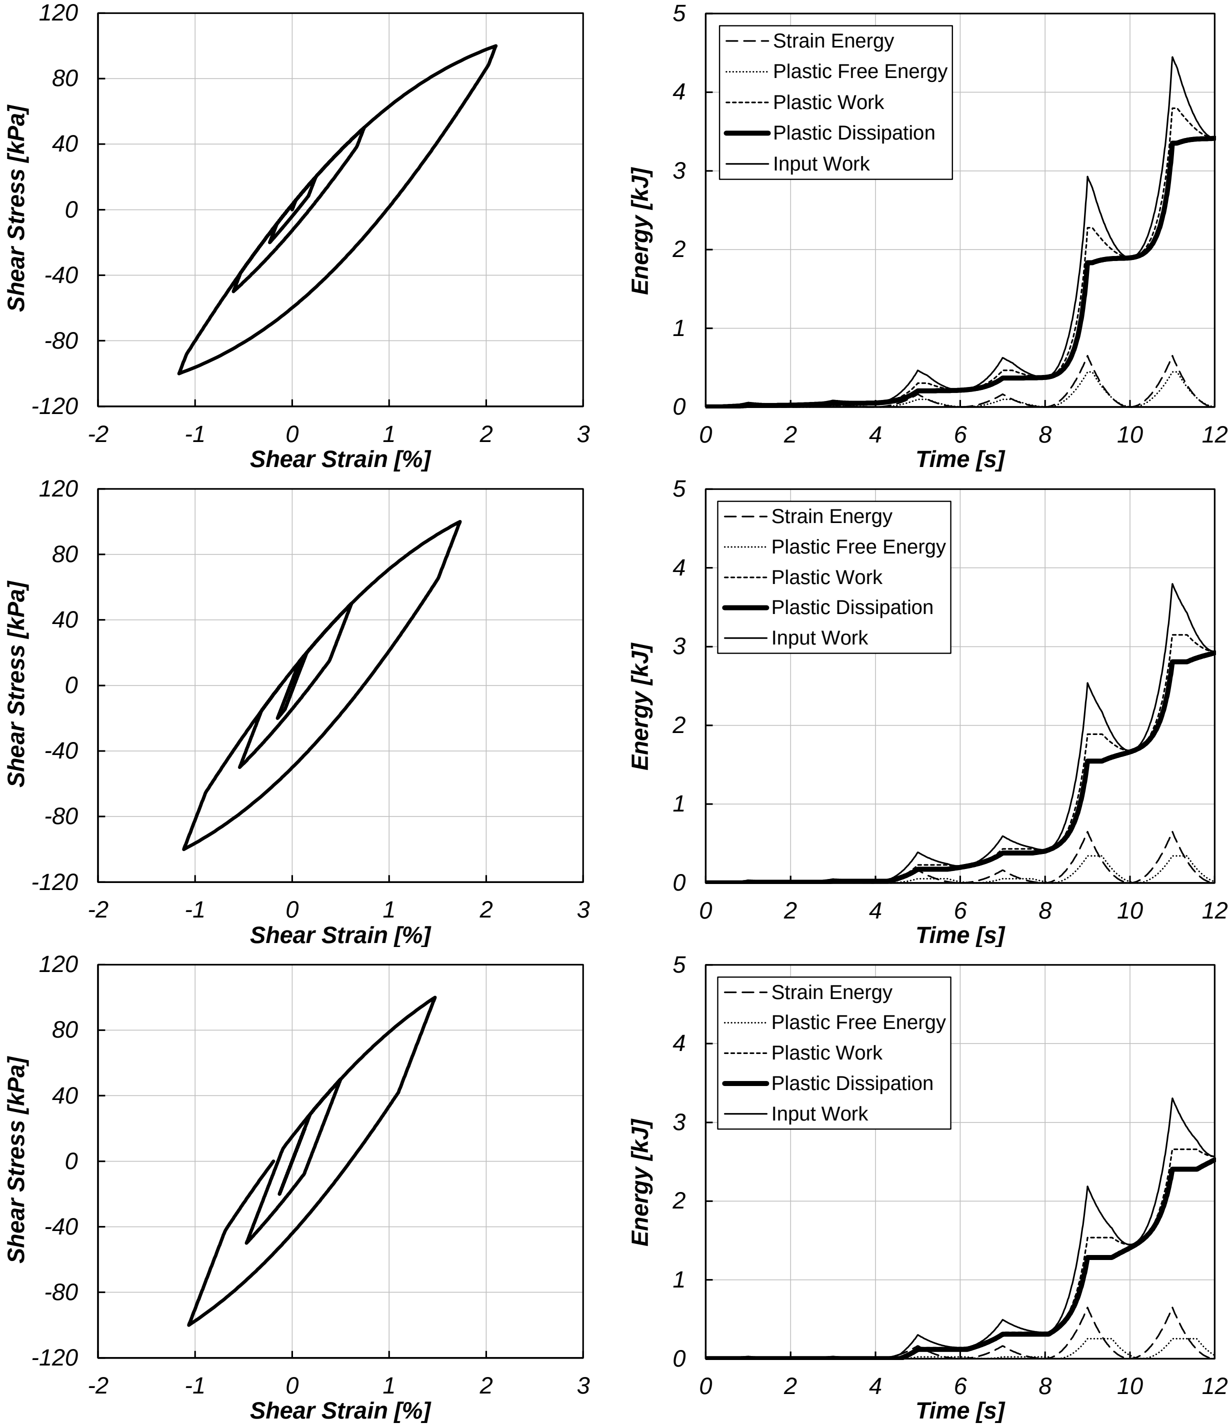

Figure 104.91: Energy analysis of elastic-plastic material modeled using Drucker–Prager plasticity with Armstrong–Frederick kinematic hardening: (a) Confining stress = 100 kPa; (b) Confining stress = 300 kPa; (c) Confining stress = 500 kPa;

input work being equal to the stored energy. Elastic-perfectly plastic materials had no change in plastic free energy, which led to the equality of plastic work and plastic dissipation and indicated no evolution of particle arrangements. The plastic dissipation, in that case, was observed to be increasing linearly. Isotropic hardening materials experienced zero dissipation even after yielding. This observation was surprising, but verified by further derivation of energy equations. This observation also serves as a reminder that the isotropic hardening rules can be used, but only with observed lack of energy dissipation. Prager's linear and Armstrong-Frederick nonlinear kinematic hardening materials both gave significant dissipations, with large fluctuation of plastic free energy as well. In the case with linear kinematic hardening, linear increase of dissipation was derived and observed, while energy was dissipated nonlinearly in the case of nonlinear kinematic hardening. Although the plastic free energy was not significant for some materials, it is noted that it should always be recognized and considered during energy analysis, so that the basic principles of thermodynamics are maintained.

104.12 Energy Dissipation Calculations for Structures

This section is based on Yang et al. (2019a)

104.12.1 Introduction

Mechanical energy in soil structure interaction (SSI) systems are dissipated during the irreversible dissipative process of energy transformation in which entropy of the system increases. Energy dissipation has been used, directly or indirectly, as a key parameter to evaluate damage in elastic-plastic materials. A common misconception of plastic work and energy dissipation due to plasticity has been noticed in a number of publications Uang and Bertero (1990), Léger and Dussault (1992), Symans and Constantinou (1998), Soong and Spencer (2002), Symans et al. (2008), Wong (2008), Nehdi et al. (2010) in which violations of the second law of thermodynamics were observed. As presented in an earlier section (and also by Yang et al. (2018), the correct formulation for energy analysis on elastic-plastic solids has been derived from the second law of thermodynamics. The theoretical and computational framework has been verified through system energy balance in a series of numerical studies on elastic and elastic-plastic material models. The purpose of this section is to present a methodology of correctly evaluating energy dissipation in structural elements, which is crucial in determining the safety and economy of a SSI system.

It has been shown Dafalias et al. (2002), Feigenbaum and Dafalias (2007), Yang et al. (2018) that the difference between plastic work and plastic dissipation is the plastic free energy, or cold work, which can be calculated from material internal variables (or state variables), like radius of yield surface or back stress. This computation can be easily performed on solids modeled with classic elasticity/plasticity constitutive relationships in which internal variables are computed and obtained at every time step. On the other hand, constitutive relationships used to model nonlinear structural elements were proposed mainly based on experimental results Spacone et al. (1996a), Spacone et al. (1996b), Lee and Fenves (1998), Popovics (1973), Mander et al. (1988), Chang and Mander (1994), Waugh (2009), Kolozvari et al. (2015). The internal variables used in these models are different than those used in classic constitutive models for solids. Therefore, a new methodology that can correctly evaluate energy storage and dissipation in structural elements is required.

During the recent few decades, a number of studies have been conducted with focus on energy analysis of SSI systems Uang and Bertero (1990), Léger and Dussault (1992), Kalkan and Kunnath (2007), Kalkan and Kunnath (2008), Symans et al. (2008), Gajan and Saravanathiiban (2011), Moustafa (2011), Moustafa and Mahmoud (2014), Mezgebo and Lui (2017), Deniz et al. (2017). Despite different formulations used, the calculations of energy dissipation due to hysteretic damping (material elasto-plasticity) in these publications were all performed without consideration of plastic free energy, which lead to violations of principles of thermodynamics. It is worth pointing out that such oversight is not rare, especially in literature of civil and geotechnical engineering.

Early work reported by Farren and Taylor (1925) and Taylor and Quinney (1934) showed that plastic free energy could be significant in metals, thus should not be neglected without reasoning. The ratio of plastic work converted into heat, usually referred to as the Quinney–Taylor coefficient, was measured to be between 0.6 to 1.0 Belytschko et al. (1991), Zhou et al. (1996), Dolinski et al. (2010), Osovski et al. (2013). Mason Mason et al. (1994) pointed out that the the Quinney–Taylor coefficient is both strain and strain rate dependent but could be assumed to be a constant in most cases. A constitutive model for metals was presented by Rosakis et al. Rosakis et al. (2000), Hodowany et al. (2000), Ravichandran et al. (2002) based on thermoplasticity, which can model the evolution of energy dissipation and has been validated through experiments. Semnani et al. (2016) presented a thermoplastic framework that could predict strain localization in transversely isotropic materials.

Despite of the existence of sophisticated theories that are capable of modeling the evolution of energy dissipation, including those mentioned earlier, most constitutive relationships used to model structural elements do not involve thermodynamics or thermoplasticity. One commonly used finite element (FE) technique of modeling frame structures is fiber section, in which beams and columns are divided into multiple uniaxial fibers with various constitutive models. This model have been proved to be able to capture nonlinear stress–strain behaviors of structural elements under axial loading and/or bending.

Problems arise when such elements are used to calculate energy dissipation. As observed in many publications Kwan and Billington (2001), Zhu et al. (2006), Gajan and Saravanathiiban (2011), Wang et al. (2012), Zhang et al. (2013), Nikbakht et al. (2014) energy analysis were performed based on the hysteretic stress–strain or force–displacement response of the elements. This indicates that plastic work was confused with plastic energy dissipation, which is the common misconception pointed out earlier. It is also important to point out that various damage indices derived from energy dissipation are used widely to evaluate damage in structures. Such parameters will not be valid if the fundamental formulation of energy dissipation is incorrect.

In order to correctly evaluate energy dissipation in structural elements modeled with fiber sections, the framework of thermo-mechanics must be enforced on the uniaxial constitutive models. Focus of this section is on proper modeling of different forms of energy (storage and dissipation) in uniaxial materials that follows the second law of thermodynamics. Theoretical and computational formulations of energy dissipation in uniaxial concrete and steel fibers are presented. A series of FE simulations are carried out using the Real-ESSI (Jeremić et al., 1988-2025) to illustrate the energy behavior of structural systems. The method is verified by comparing the input work and the energy storage and dissipation in the system. The difference between accumulated plastic work and accumulated plastic dissipation, which can be significant in many cases, is addressed. Finally, conclusions on plastic energy dissipation in structural elements are drawn from the verified results.

104.12.2 Theoretical and Computational Formulations

104.12.2.1 Thermomechanical Framework

The theories of continuum thermo-mechanics have been discussed in a number of earlier publications Lubliner (1972), Rosakis et al. (2000), from which the fundamental framework of this study is derived. General equations of elastoplasticity and thermodynamics are modified with a few plausible assumptions to accommodate the scope of this study. Small deformation theory is assumed, so that the small strain tensor ϵ_{ij} is used to describe deformation of the material body. All equations in this section are expressed in index notation.

The general thermomechanical process is governed by momentum balance and the first and second law of thermodynamics. The localized version of the first law of thermodynamics (energy balance equation) is given in the form:

$$\sigma_{ij}\dot{\epsilon}_{ij} + q_{i,i} + \rho r = \rho \dot{e} \tag{104.679}$$

where the term $\sigma_{ij}\epsilon_{ij}$ is called the stress power, q_i are the components of the heat flux vector, ρ is the mass density of the material, r is the heat supply per unit volume, and e is the internal energy per unit volume. Note that in this section all stresses are defined as effective stresses. In order to avoid confusion, the common notation $(\sigma_{ij}^{'})$ will not be used. Standard definition of stress from mechanics of materials, i.e. positive in tension, is used.

The localized version of the second law of thermodynamics (Clausius–Duhem inequality) is expressed as:

$$\rho\dot{\eta} - (\frac{q_i}{\theta})_{,i} - \frac{1}{\theta}\rho r \geq 0 \tag{104.680}$$

where η is the entropy per unit volume and θ is the absolute temperature.

Substituting the heat supply per unit volume r in Equation 104.680 with the expression from Equation 104.679, and introducing the rate of change of internal dissipation per unit volume Φ gives:

$$\rho\theta\dot{\eta} - \rho\dot{e} + \sigma_{ij}\dot{\epsilon}_{ij} + \frac{1}{\theta}q_i\theta_{,i} = \Phi + \frac{1}{\theta}q_i\theta_{,i} \geq 0 \tag{104.681}$$

Note that the internal dissipation can have many sources, including material plasticity, viscous coupling, radiation damping, and other forms of energy dissipation.

The Helmholtz free energy per unit volume ψ, which is referred to as free energy in this section, is defined as:

$$\psi = e - \theta\eta \tag{104.682}$$

The second law of thermodynamics can be expressed in terms of free energy ψ as:

$$\Phi + \frac{1}{\theta}q_i\theta_{,i} = -\rho\dot{\psi} - \rho\dot{\theta}\eta + \sigma_{ij}\dot{\epsilon}_{ij} + \frac{1}{\theta}q_i\theta_{,i} \geq 0 \tag{104.683}$$

The rate of internal dissipation per unit volume Φ can be written as:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij} - \rho\dot{\psi} - \rho\dot{\theta}\eta \tag{104.684}$$

At this point, a few assumptions are introduced to simplify the governing equations. According to Feigenbaum and Dafalias (2007), Collins and Houlsby (1997), Collins (2002), Collins and Kelly (2002), it can be assumed that the deformation of soil and structural elements under earthquake loading is approximately isothermal, which indicates that the temperature field θ is constant and uniform. This approximation is reasonable considering the fact that seismic energy is mostly carried by the low-frequency components of earthquake ground motion, which allows the heat generated in the materials to be largely dissipated. With this assumption, the rate of internal dissipation Φ is simplified into the form:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij} - \rho\dot{\psi} \geq 0 \tag{104.685}$$

Next, all material models studied in this section is assumed to be decoupled, which means that the (small) strain tensor can be additively decomposed into elastic and plastic parts:

$$\epsilon_{ij} = \epsilon_{ij}^{el} + \epsilon_{ij}^{pl} \tag{104.686}$$

Lubliner (1972) and Collins and Houlsby (1997) showed that this assumption can be deduced if the instantaneous elastic moduli of a material are independent of the internal variables. Under the assumption of decoupled material, the free energy ψ can also be decomposed into elastic and plastic parts as follows:

$$\psi = \psi_{el} + \psi_{pl} \tag{104.687}$$

where the elastic part of the free energy ψ_{el} is also known as the elastic strain energy, which is defined in incremental form as:

$$\dot{\psi}_{el} = \sigma_{ij}\dot{\epsilon}_{ij}^{el} \tag{104.688}$$

By substituting Equation 104.686, Equation 104.687, and Equation 104.688 into Equation 104.685, the rate of internal dissipation Φ can be expressed in terms of the rate of plastic free energy $\dot{\psi}_{pl}$:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij} - \sigma_{ij}\dot{\epsilon}_{ij}^{el} - \rho\dot{\psi}_{pl} \geq 0 \tag{104.689}$$

Equation 504.8 represents two basic principles that should always be upheld in any energy analysis for decoupled material undergoing isothermal process:

- The stress power that is input into a material body by external loading is transformed into elastic strain energy, plastic free energy, and material internal dissipation. All forms of energy must be considered to maintain energy balance of the material body. This principle ensures the first law of thermodynamics.
- The rate of change of material internal dissipation (plastic dissipation) is nonnegative at any time. In other words, accumulated internal dissipation can not decrease during any time period. This principle ensures the second law of thermodynamics.

Note that material internal dissipation can have many sources. Our interest is the energy dissipation caused by material plasticity, so the term plastic dissipation will be used instead, which indicates no other source of energy dissipation is present in the examples that are being analyzed in the remaining part of this section.

104.12.2.2 Plastic Free Energy

The physical nature of plastic free energy is associated with the material micro-structure. For particulate material, like soil, plastic free energy will be accumulated or released if there is evolution of particle arrangement (micro-fabric), which generally happens as soon as the material body is loaded. For other structural and geotechnical materials, like metals, their micro-structures are represented by the shape and arrangement of the crystals, whose evolution will result in change in plastic free energy. Detailed explanations of the evolution of plastic free energy can be found in publications by Besseling and Van Der Giessen (1994), Collins and Kelly (2002), and Yang et al. (2018).

Using Equation 504.8, the energy dissipation of any elastic-plastic material under isothermal loading process can be calculated, if all the terms on the right hand side of the equation is known. For most elastic-plastic constitutive models, the stress tensor σ_{ij} and the elastic strain tensor ϵ_{ij}^{el} are being calculated as simulation progresses. The challenging task is to evaluate the plastic free energy term ψ_{pl}, whose formulation depends on the internal variables used in the constitutive model.

For a decoupled elastic-plastic material model that exhibits both isotropic and kinematic hardening, the plastic free energy is decomposed into isotropic and kinematic parts, which are calculated individually and then added up. The formulation of plastic free energy in this type of material was given by Feigenbaum and Dafalias (2007):

$$\psi_{pl} = \psi_{pl}^{iso} + \psi_{pl}^{kin} = \frac{1}{2\rho\kappa_1}k^2 + \frac{1}{2\rho a_1}\alpha_{ij}\alpha_{ij} \tag{104.690}$$

where ψ_{pl}^{iso} and ψ_{pl}^{kin} are the isotropic and kinematic parts of the plastic free energy, respectively, k is the radius of yield surface, α is the back stress, κ_1 and a_1 are non-negative material constants. Note that Equation 104.690 can be used for a wide range of constitutive models with various yield functions, including von Mises and Drucker-Prager yield criteria whose energy behaviors has been studied and presented by Yang et al. (2018). Such materials are usually used to model soils and parts of the structure that need to be modeled with solid elements in SSI system.

However, frame structures are generally modeled with beam-column elements in combination with fiber sections and uniaxial material models, where Equation 104.690 does not apply. It should be realized that most uniaxial constitutive relationships are capable of modeling the stress–strain behavior but not the energy dissipation features of the material. Therefore, an approach that follows our thermomechanical framework is presented to correctly evaluate energy storage and dissipation in these material models.

104.12.2.3 Energy Dissipation in Beam-Column Element

Beams and columns are modeled with nonlinear displacement-based beam element, which is implemented in the Real-ESSI Simulator. In order to incorporate confined/unconfined concrete and steel reinforcement bars into beam elements, fiber sections are constructed with corresponding uniaxial fibers. A bottom-fixed reinforced concrete column model is shown in Figure 104.92, along with the constitutive relationships used for the concrete and steel fibers.

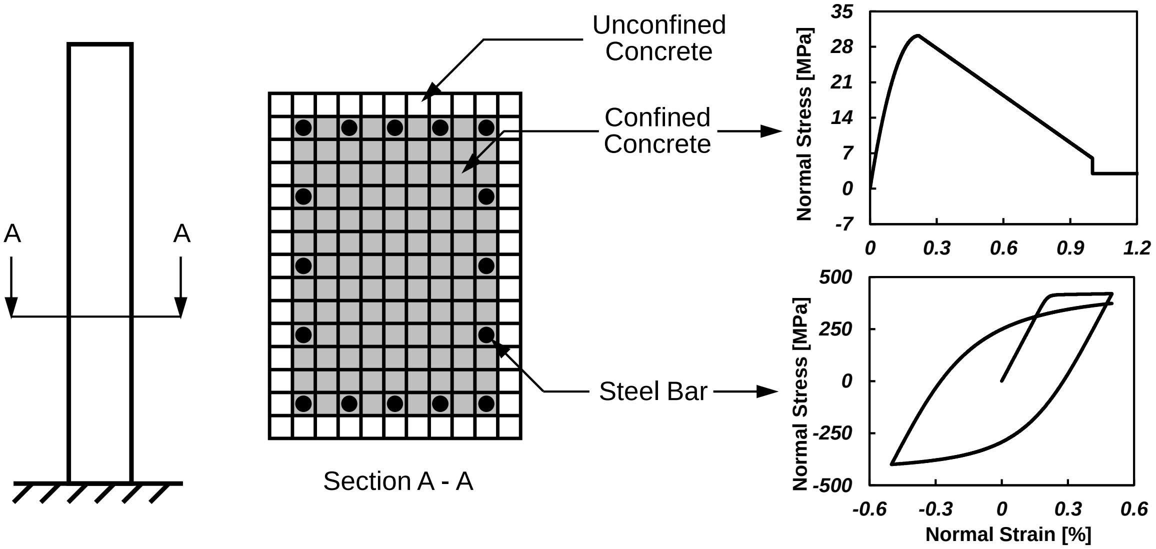

Figure 104.92: Schematic of a bottom-fixed column modeled with concrete and steel fibers.

Uniaxial Steel Fiber. The uniaxial steel material model examined in this study was developed by Menegotto and Pinto (1973) and extended by Filippou et al. (1983), and is capable of capturing the nonlinear hysteretic behavior and isotropic strain-hardening effect of steel. The stress–strain response of this material is shown in Figure 104.93, along with some of the material parameters. The model, as presented in Menegotto and Pinto (1973), takes on the form:

$$\sigma^* = b\epsilon^* + \frac{(1-b)\epsilon^*}{(1+\epsilon^{*R})^{1/R}} \tag{104.691}$$

with

$$\epsilon^* = \frac{\epsilon - \epsilon_r}{\epsilon_0 - \epsilon_r}; \quad \sigma^* = \frac{\sigma - \sigma_r}{\sigma_0 - \sigma_r} \tag{104.692}$$

where b is the strain-hardening ratio, ϵ_r and σ_r are the strain and stress at the point of strain reversal, ϵ_0 and σ_0 are the strain and stress at the point of intersection of the two asymptotes, R is the curvature parameter that governs the shape of the transition curve between the two asymptotes. Note that this model is for uniaxial materials, in which the stresses and strains are scalars instead of tensors.

The expression for the curvature parameter R is suggested by Menegotto and Pinto (1973):

$$R = R_0 - \frac{c_{R_1}\xi}{c_{R_2} + \xi} \tag{104.693}$$

where R_0 is the value of the curvature parameter R during initial loading, c_{R_1} and c_{R_2} are degradation parameters that need to be experimentally determined. The parameter ξ, that is updated after strain

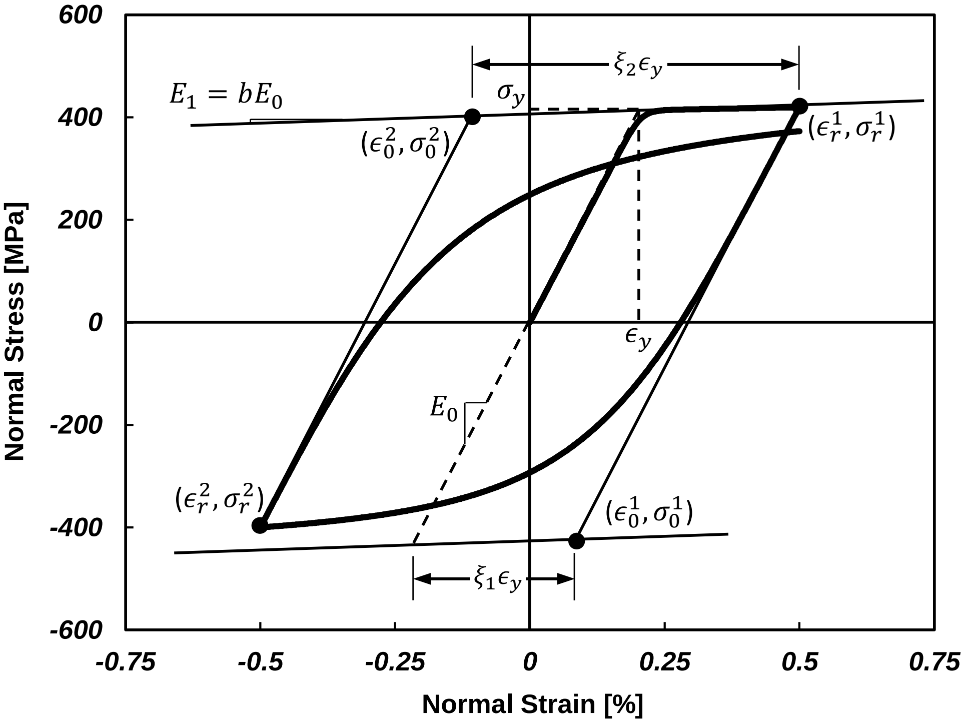

Figure 104.93: Constitutive model for uniaxial steel fiber (Menegotto and Pinto (1973)).

reversal, is defined as:

$$\xi = \left| \frac{(\epsilon_m - \epsilon_0)}{\epsilon_y} \right| \tag{104.694}$$

where ϵ_m is the maximum (or minimum) strain at the previous strain reversal point, depending on the loading direction of the material. If the current incremental strain is positive, the parameter ϵ_m takes the value of the maximum reversal strain. Parameter ϵ_y is the monotonic yield strain.

In order to capture isotropic hardening behavior, Filippou et al. (1983) introduced stress shift mechanism into the original model by Menegotto and Pinto (1973). Note that the hardening rate in compression and tension can be different by choosing different hardening parameters for compression and tension. The proposed relation takes the form:

$$\frac{\sigma_{st}}{\sigma_y} = a_1 \left(\frac{\epsilon_{max}}{\epsilon_y} - a_2 \right) \tag{104.695}$$

where σ_{st} is the shift stress that determines the shift of yield asymptote, ϵ_{max} is the absolute maximum strain at strain reversal, and a_1 and a_2 are hardening parameters in compression that are experimentally determined. In the case of tension, the hardening parameters a_1 and a_2 in Equation 104.695 are changed to a_3 and a_4 that are also determined by experiment or obtained from the literature.

The energy computation procedure for this uniaxial steel model is shown in Figure 507.4, and it follows the thermomechanical framework established earlier in this section.

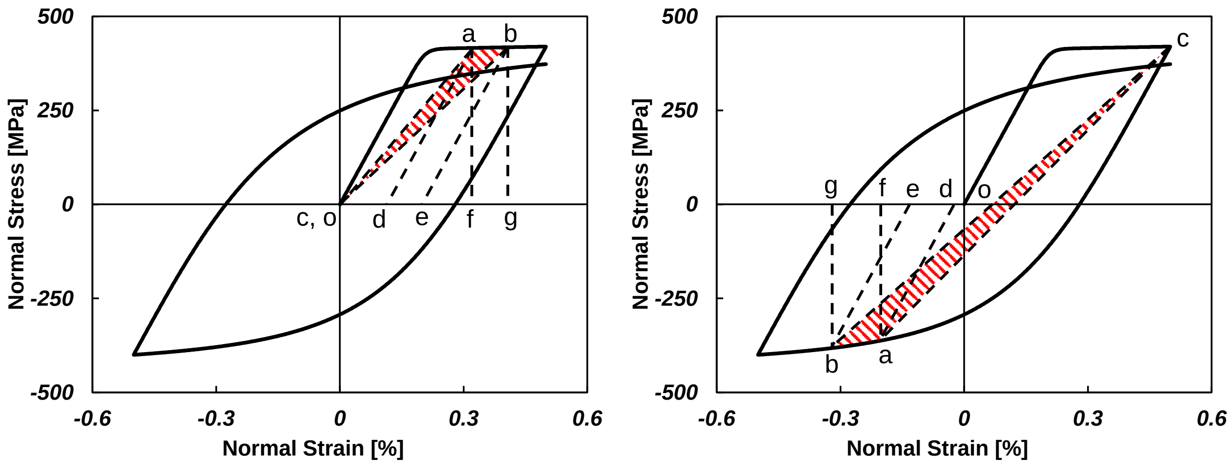

Figure 104.94: Energy computation of uniaxial steel fiber: (a) Monotonic loading branch; (b) Cyclic loading branch.

Note that the only difference between the monotonic loading branch (Figure 507.4(a)) and the cyclic loading branch (Figure 507.4(b)) is that the strain reversal point c is at the origin o in the monotonic case. So the following explanation of the proposed energy computation method applies to both monotonic and cyclic loading scenarios.

Firstly, the elastic strain energy density E_S is defined in accordance with the classic assumption that it is only a function of current stress state of the material, which yields:

$$E_S = E_S(\sigma) = \frac{1}{2E_0}\sigma^2 \tag{104.696}$$

Graphically, the elastic strain energy density of the material shown in Figure 507.4 at states a and b are the triangular areas afd and bge. Then the incremental form of Equation 507.9 is simply:

$$dE_S = \frac{1}{E_0}\sigma d\sigma \tag{104.697}$$

Next, the incremental plastic dissipation density D_P from state a to b is assumed to be the triangular area abc:

$$dD_P = \frac{1}{2}[(\sigma - \sigma_r)d\epsilon - (\epsilon - \epsilon_r)d\sigma] \tag{104.698}$$

This assumption ensures that the incremental plastic dissipation is nonnegative, which is one of the two basic principles of our thermomechanical framework. One special case is when the material exhibits no cyclic softening, which means that perfectly overlapping stress–strain loops will be observed, the energy dissipation calculated using Equation 507.11 for one cyclic is the area of the hysteresis loop. In the proposed thermomechanical framework, the area of hysteresis loop should be equal to the plastic work, rather than plastic dissipation, done in one loading cycle. But in this special case of no cyclic softening, which means no evolution of material state and thus no development of plastic free energy after a complete loading cycle, the plastic work equals to the plastic dissipation in the material in one loading cycle.

For general case where the material does exhibit cyclic softening, plastic free energy density E_P is graphically denoted by the areas $adoc$ and $beoc$ at states a and b, respectively. The formulation representing this assumption is given by:

$$E_P = \frac{1}{2}\left[\sigma\left(\epsilon - \frac{\sigma}{E_0} - \epsilon_r\right) + \sigma_r \epsilon\right] \tag{104.699}$$

The incremental form of Equation 507.12 is:

$$dE_P = \frac{1}{2}\left[(\sigma + \sigma_r)\, d\epsilon + \left(\epsilon - \frac{1}{E_0}\sigma - \epsilon_r\right) d\sigma\right] \tag{104.700}$$

Adding Equation 507.10, 507.11, and 507.13, the incremental form of energy balance is achieved:

$$dE_S + dE_P + dD_P = \sigma d\epsilon \tag{104.701}$$

where the increment of three energy components add up to the increment of stress power during any loading step.

Uniaxial Concrete Fiber. The uniaxial concrete material model used in this study is based on the model proposed by Yassin (1994), which is capable of modeling the nonlinear hysteretic behavior and damage effect of concrete. The material parameters and stress–strain response of this material are shown in Figure 104.95.

The monotonic envelope curve of this model in compression is based on the model of Kent and Park (1971) and later generalized by Scott et al. (1982). For a given strain ϵ_c, the compressive stress σ_c and corresponding tangent stiffness E are given by:

$$\epsilon_c \leq \epsilon_{cs} \qquad \sigma_c = f_{cs}\left[2\left(\frac{\epsilon_c}{\epsilon_{cs}}\right) - \left(\frac{\epsilon_c}{\epsilon_{cs}}\right)^2\right] \qquad E = E_c\left(1 - \frac{\epsilon_c}{\epsilon_{cs}}\right) \tag{104.702}$$

$$\epsilon_{cs} < \epsilon_c \leq \epsilon_{cu} \qquad \sigma_c = \frac{\epsilon_c - \epsilon_{cs}}{\epsilon_{cu} - \epsilon_{cs}}(f_{cu} - f_{cs}) + f_{cs} \qquad E = \frac{f_{cu} - f_{cs}}{\epsilon_{cu} - \epsilon_{cs}} \tag{104.703}$$

$$\epsilon_c > \epsilon_{cu} \qquad \sigma_c = f_{cu} \qquad E = 0 \tag{104.704}$$

where f_{cs} is the maximum compressive strength of the concrete material, ϵ_{cs} is the concrete strain at compressive strength, f_{cu} is the ultimate (crushing) strength of the concrete material, ϵ_{cu} is the concrete

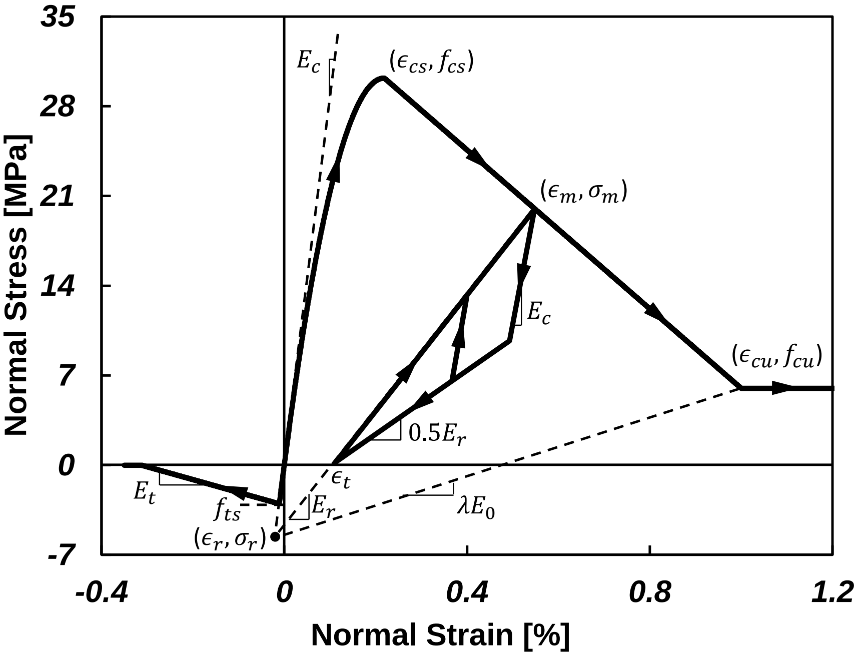

Figure 104.95: Constitutive model for uniaxial concrete fiber (Yassin (1994)).

strain at ultimate strength, and E_c is the initial concrete tangent stiffness that can be calculated using the equation:

$$E_c = \frac{2f_{cs}}{\epsilon_{cs}} \tag{104.705}$$

All material parameters should be determined by experiment or related literature data.

The cyclic behavior of this concrete model in compression is shown in Figure 104.95. One assumption of this model is that all reloading lines intersect at a common point, where the stress σ_r and strain ϵ_r are given by the following expressions:

$$\epsilon_r = \frac{f_{cu} - \lambda E_c \epsilon_{cu}}{E_c(1-\lambda)} \tag{104.706}$$

$$\sigma_r = E_c \epsilon_r \tag{104.707}$$

After unloading from a point on the compressive monotonic envelope, the model response is bounded by two lines that are defined by:

$$\sigma_{max} = \sigma_m + E_r(\epsilon_c - \epsilon_m) \tag{104.708}$$

$$\sigma_{min} = 0.5E_r(\epsilon_c - \epsilon_t) \tag{104.709}$$

where

$$E_r = \frac{\sigma_m - \sigma_r}{\epsilon_m - \epsilon_r} \tag{104.710}$$

$$\epsilon_t = \epsilon_m - \frac{\sigma_m}{E_r} \tag{104.711}$$

where σ_m and ϵ_m are the stress and strain at the unloading point on the compressive monotonic envelope, respectively. If the unloading–reloading cycle is incomplete, the material response will be a straight line with slope E_c, as shown in Figure 104.95.

The tensile behavior of this concrete model considers tension stiffening and the effects of initial cracking. Details of the monotonic and cyclic behavior of this model under tensile stress can be found in Yassin (1994).

Since there are different loading/unloading branches in this model, the energy computation needs to be considered separately for each branch. One energy component that remains the same in all loading cases is the elastic strain energy density E_S, which is only a function of current stress:

$$E_S = E_S(\sigma) = \frac{1}{2E_c}\sigma^2 \tag{104.712}$$

And the incremental form of Equation 104.712 is:

$$dE_S = \frac{1}{E_c}\sigma d\sigma \tag{104.713}$$

In order to calculate plastic dissipation, a few assumptions are made that ensures the energy behavior of the concrete material to follow the proposed thermomechanical framework:

- Majority of energy is dissipated during first monotonic load.
- Subsequent cycles of loading, on an already damaged concrete, do not dissipate much energy.
- No energy is dissipated during unloading in both compressive and tensile conditions.
- When the material is cyclically loaded under compression, energy dissipation only happens when the stress reaches the upper bound σ_{max}.
- No energy is dissipated during cyclic loading when the material is under tension.

For a single loading step from stress state a to b in each subplot of Figure 104.96, the energy dissipation is represented by the shaded area.

If the material is under compression (Figure 104.96 (a), (b), and (c)), the amount of energy dissipated in the concrete fiber D_P is calculated by taking the area $abcdef$, which is generally a hexagon formed by the two unloading paths originated from stress state a and b:

$$dD_P = \frac{1}{2}[(\sigma - \sigma_c)d\epsilon + (\epsilon_c - \epsilon)d\sigma + (\epsilon_c - \epsilon_f)\sigma + (\sigma_f - \sigma_c)(\epsilon - \epsilon_t) + \sigma_c d\epsilon_t] \tag{104.714}$$

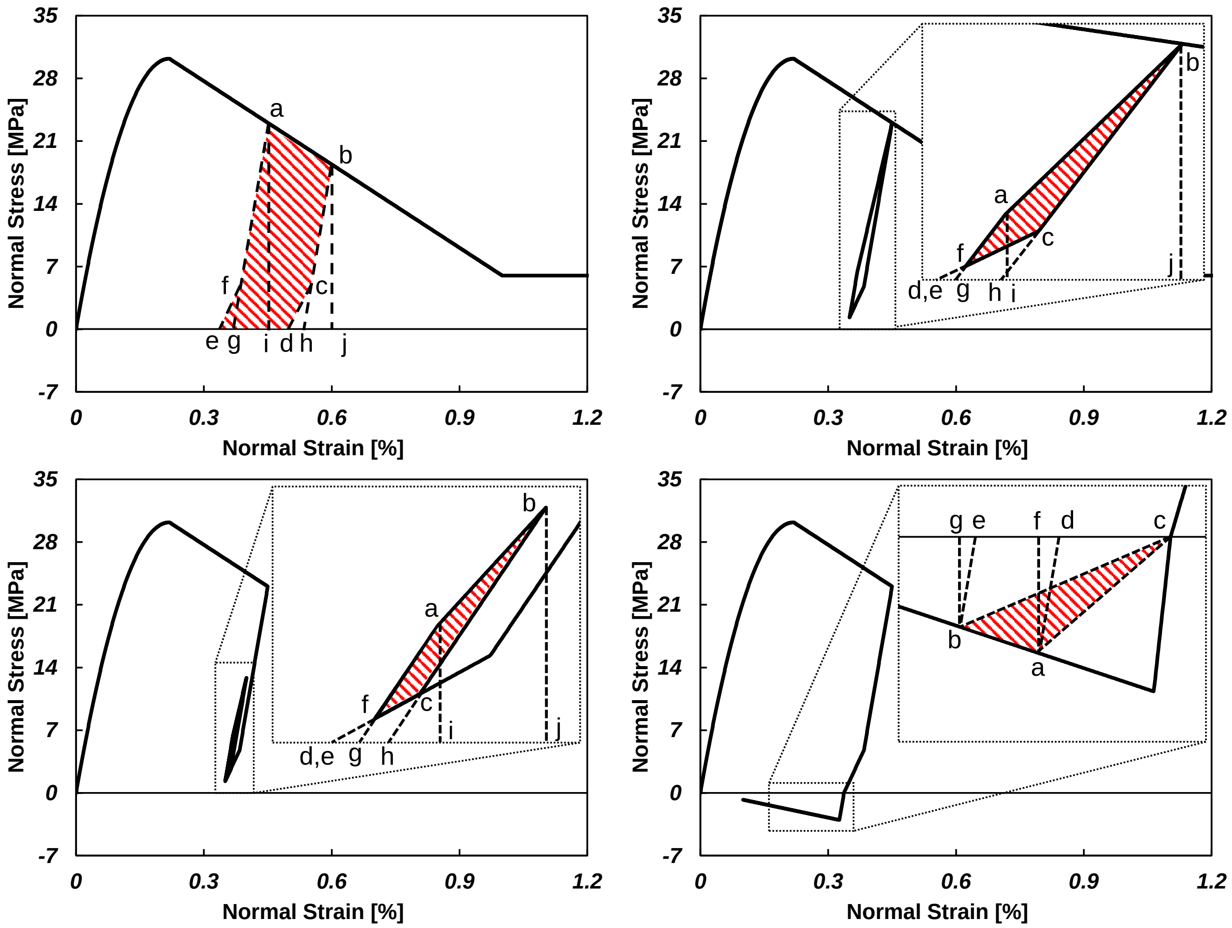

Figure 104.96: Energy computation of uniaxial concrete fiber: (a) Monotonic compression; (b) Single unloading-reloading cycle; (c) Unloading-reloading cycles within monotonic envelope; (d) Tension.

where the stress and strain at point f can be computed using the following expression:

$$\epsilon_f = \frac{\sigma + 0.5 E_r \epsilon_t - E_c \epsilon}{0.5 E_r - E_c} \qquad \sigma_f = 0.5 E_r (\epsilon_f - \epsilon_t) \tag{104.715}$$

Point c can be calculated using the same fashion, but with all variables evaluated at state b.

Note that the hexagon becomes quadrilateral in the cases of cyclic loading within the monotonic envelope, as can be observed in Figure 104.96 (b) and (c). But Equation 104.714 and 104.715 remains valid, obviously.

Plastic free energy E_P in this concrete material is calculated by taking the triangular area fge at state a:

$$E_P = \frac{1}{2}\left[\left(\epsilon - \frac{\sigma}{E_c} - \epsilon_t\right)\sigma_f\right] \tag{104.716}$$

The incremental form of Equation 104.716 is obtained by taking the difference between the plastic free energy at state a and b:

$$dE_P = \frac{1}{2}\left[\left(\sigma_c - \sigma_f - \frac{1}{E_c}\sigma\right)(\epsilon - \epsilon_t) - (d\epsilon - d\epsilon_t)\sigma_c - \frac{1}{E_c}\sigma c d\sigma\right] \tag{104.717}$$

Adding Equation 104.713, 104.714, and 104.717, the incremental form of energy balance is achieved:

$$dE_S + dE_P + dD_P = \sigma d\epsilon \tag{104.718}$$

where the increment of three energy components add up to the increment of stress power during any loading step.

104.12.3 Numerical Studies

Numerical examples presented in this section are performed using the Real-ESSI Simulator Jeremić et al. (1988-2025). Energy dissipation in numerical models consist of fiber section elements and uniaxial steel/concrete fibers are computed and analyzed.

First, numerical simulation of steel and plain concrete columns under various loading conditions are performed to study the energy behavior of uniaxial steel and concrete material models. Then, a model of reinforced concrete column, which consists of both concrete and steel fibers, is constructed and simulated to illustrate the energy dissipation in realistic structural elements. Finally, a bare steel frame structure is modeled with fiber section elements and loaded with seismic motion. Through these examples, it will be shown that the difference between plastic work and plastic energy dissipation can be significant.

External loads are applied incrementally using displacement-control scheme. System equations are solved using Newton-Raphson iteration algorithm and UMFPACK solver, which are available in Real-ESSI. Static integration algorithm is used for the column cases, while Newmark integration is used for the dynamic steel frame case. Note that viscous and numerical damping are excluded from all cases, in order to accurately evaluate energy dissipation due to material elastoplasticity.

104.12.3.1 Steel Column

In order to verify the proposed energy computation approach for uniaxial steel material model, examples of steel columns are studied in this section. As shown in Figure 104.97, the one-meter-long column model is fixed at the bottom, and loads are applied at the top. The size of the cross section is 100 $mm \times$ 100 mm. The parameters for uniaxial steel material used in this section are summarized in Table 104.6.

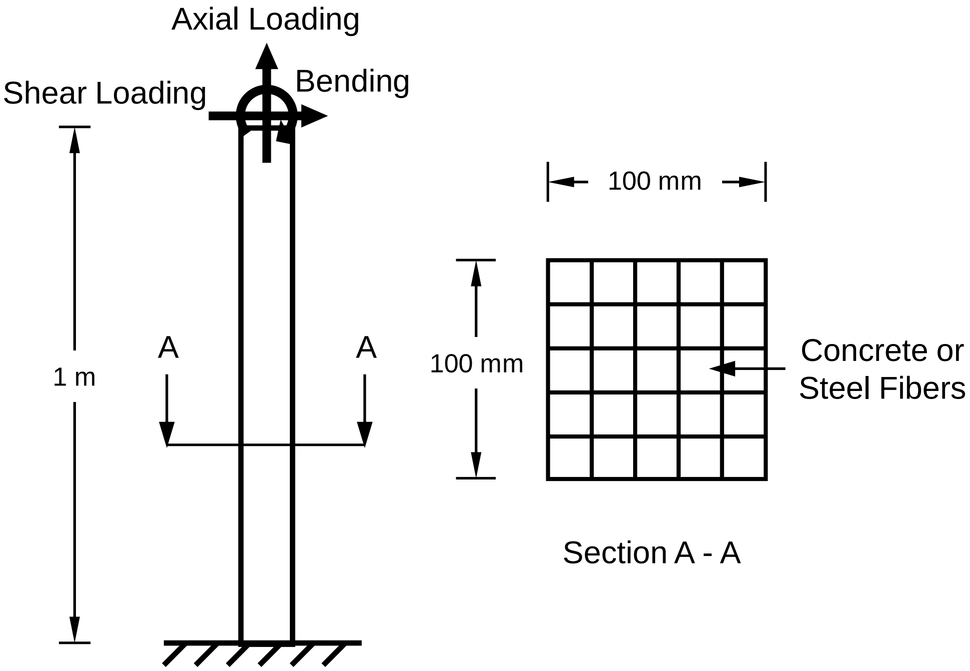

Figure 104.97: Schematic of the steel/plain-concrete column modeled with fiber sections and uniaxial steel/concrete materials.

Table 104.6: Material model parameters used in steel column examples.

σ_y (MPa)	E (GPa)	b	R_0	c_{R_1}	c_{R_2}	a_1	a_2	a_3	a_4
413.8	200.0	0.01	18.0	0.925	0.15	0.0	55.0	0.0	55.0

Cyclic Axial Loading. Since the fiber material model is uniaxial in nature, axial loading case is being investigated first. The evolution of energy parameters for uniaxial steel material are computed using Equation 507.10, 507.11, and 507.13. Figure 104.98 shows the stress–strain response as well as the energy results of the steel column under cyclic axial loading.

As expected, the stress–strain response shown in Figure 104.98 follows the constitutive model presented in Figure 104.93. Due to the choice of hardening parameters (a_1, a_2, a_3, and a_4), isotropic hardening after first loading reversal is relatively small in this case. The evolution of plastic free energy, which is related to the hardening behavior of the constitutive model, is also observed to be insignificant after the first loading reversal. Energy balance in the steel material (Equation 507.14) is maintained during entire simulation.

In this particular case, the difference between plastic dissipation and plastic work is significant during initial loading (or monotonic loading), but then becomes less obvious during cyclic loading, which is

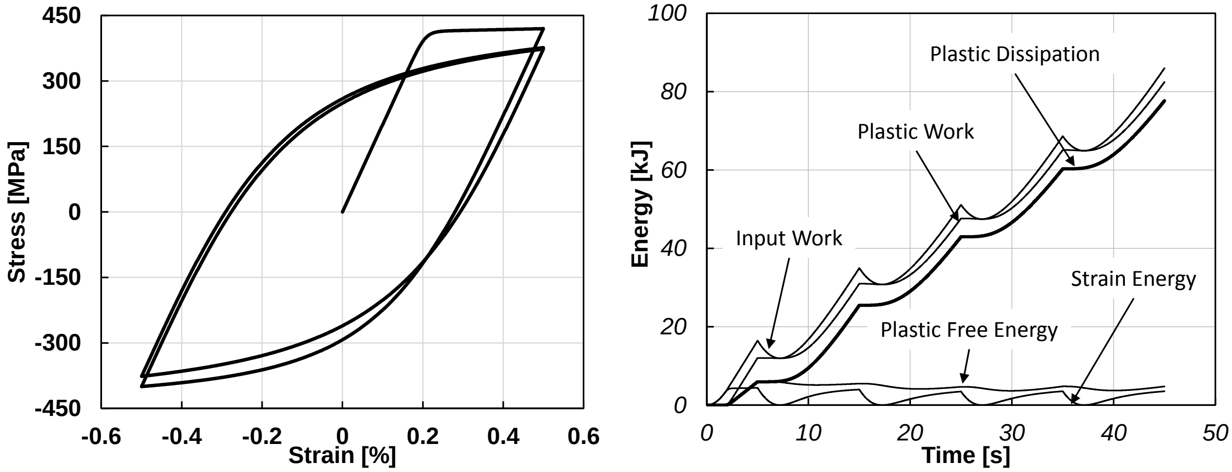

Figure 104.98: Energy analysis of steel column under cyclic axial loading: (a) Stress–strain response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

probably the reason of ignorance of plastic free energy in many studies. It is important to point out that such difference could be significant if different hardening parameters are chosen or complex loading conditions (like seismic loading) are applied.

Another observation made in this example is that the ratio between plastic dissipation and plastic work (the Quinney–Taylor coefficient) changes from 0.5 to 0.9 in just a few loading cycles. Therefore, it is not accurate to prescribe a fixed number to be the Quinney–Taylor coefficient of a material during entire simulation, which is a common assumption made in a number of studies.

Cyclic Bending Loading. It has been proven that fiber section elements perform well under axial- and bending-dominant loading conditions. In this case, a cyclic bending moment is loaded on the top of the steel column. Figure 104.99 shows the moment–rotation response as well as the energy results of the steel column under cyclic bending loading.

Clearly, the moment–rotation response and energy results in this case are very similar to those in the axial loading case. When a beam element is under bending, half of the fibers will be under tension while the other half under compression, and the normal stress distribution on any cross section should be symmetric. Since the fiber material model used in this case has almost the same stress–strain response under tension and compression, the energy results in this bending case are expected to share the same pattern with those in the axial loading case.

Note that in both axial and bending cases, the strain energy accumulated in the material body is much smaller than the plastic dissipation. This means that most of the input work results in plastic

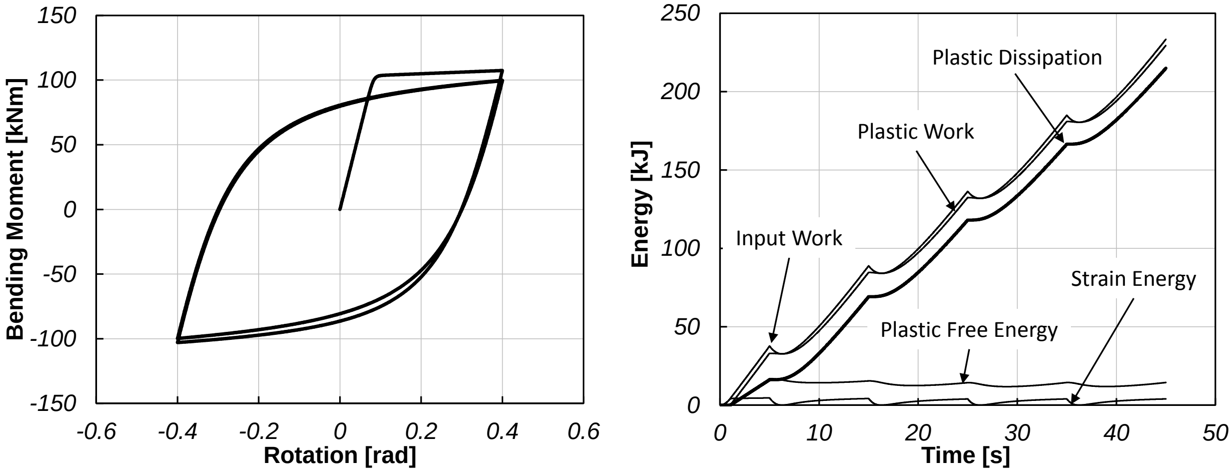

Figure 104.99: Energy analysis of steel column under cyclic bending loading: (a) Moment–rotation response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

deformation of the material, which indicates high possibility of large deformation and material damage.

104.12.3.2 Plain Concrete Column

In order to verify the proposed energy computation approach for uniaxial concrete material model, examples of plain concrete columns are studied in this section. The size and setup of the model are the same as those of the steel column, which has been shown in Figure 104.97. The parameters for uniaxial concrete material used in this section are summarized in Table 104.7.

Table 104.7: Material model parameters used in plain concrete column examples.

f_{cs} (MPa)	ϵ_{cs}	f_{cu} (MPa)	ϵ_{cu}	λ	f_{ts} (MPa)	E_t (GPa)
-30.2	-0.00219	-6.0	-0.00696	0.5	3.02	5.0

Monotonic Axial Loading. As stated in the assumptions for energy dissipation in the uniaxial concrete model, the amount of energy dissipated during monotonic loading is much larger than that during unloading/reloading. Such assumption is made based on the brittle nature of concrete materials, in which fracture is the main source of energy dissipation. In this case, the stress–strain response as well as the energy results of the plain concrete column model under monotonic axial compression is investigated and presented in Figure 104.100.

The stress–strain response shown in Figure 104.100 follows the constitutive model presented in

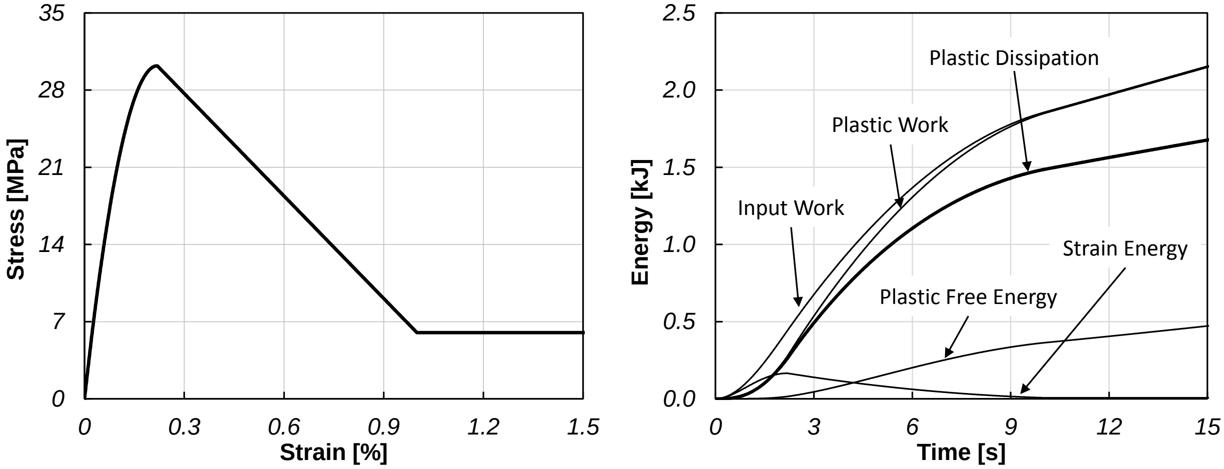

Figure 104.100: Energy analysis of plain concrete column under monotonic axial loading: (a) Stress–strain response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

Figure 104.95, as expected. Energy balance in the model, which is expressed in Equation 507.8, is maintained during entire simulation.

As observed in Figure 104.100, large amount of the input work is dissipated during monotonic compression. It is important to point out that the difference between plastic dissipation and plastic work is significant. Plastic free energy starts to accumulate after maximum compressive strength is reached and continue to increase even after crushing. Such behavior can be explained by considering that the micro-structure of concrete continues to evolve as external loads continues to be applied on the material.

The strain energy starts to drop after maximum compressive strength and gradually decreases to almost zero after crushing. This observation is consistent with the fact that the micro-fractures expand rapidly after maximum strength is reached, which leads to the release of elastic strain energy and energy dissipation caused by fracture and crushing.

Cyclic Axial Loading. Due to the complex unloading–reloading rules of the model, the cyclic behavior of the uniaxial concrete material is much more complicated than that of the steel model. Figure 104.101 presents the stress–strain response as well as the energy results of the plain concrete column under cyclic axial loading.

As shown in Figure 104.101, the majority of plastic dissipation happens during monotonic loading branch. Notice that there are drops in plastic work during unloading, but plastic dissipation never decreases, which means that the second law of thermodynamics (Equation 504.8) is always obeyed.

It should be mentioned that there are certain amount of energy dissipation when the material is in

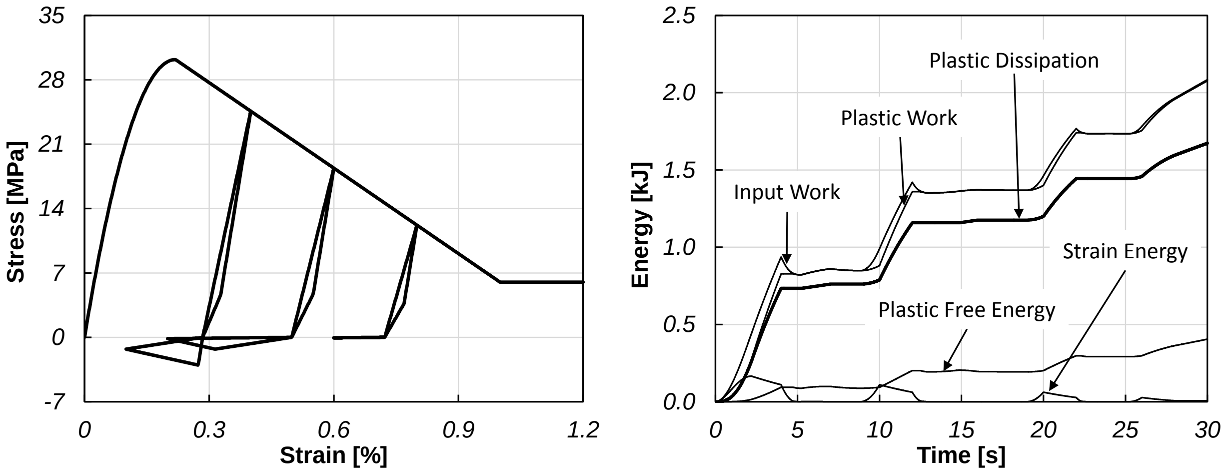

Figure 104.101: Energy analysis of plain concrete column under cyclic axial loading: (a) Stress–strain response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

tension. But it is much smaller than that when the material is in monotonic compression, due to the low tensile strength of concrete material in general.

104.12.3.3 Reinforced Concrete Column

To study the combined influence of concrete and steel fibers, a reinforced concrete column is modeled and tested in this section. The schematic of the model is shown in Figure 104.101, and the material model parameters are summarized in Table 104.8. The cross section of the column is modeled with unconfined concrete, confined concrete, and steel fibers with uniaxial material models discussed in earlier sections.

Cyclic Axial Loading. Figure 104.103 shows the force–displacement response as well as the energy results of the reinforced concrete column under cyclic axial loading.

Since concrete fibers have much higher compressive strength than tensile strength, the stress–strain response of the column is controlled by the concrete part when it is under compression, and by the steel part when under tension. In this case, the initial loading curve clearly resembles the stress–strain response of concrete fiber under monotonic compression. Then the unloading–reloading cycles have the same pattern as those of the steel fiber under cyclic axial loading.

By comparing the energy results shown in Figure 104.103 and those shown in Figure 104.98, it can be seen that the energy dissipation patterns in both cases are very close. This indicates that the majority of input work is dissipated in the steel fibers once the maximum strength of the concrete is exceeded. Again, it can be observed that the difference between plastic work and plastic dissipation is significant

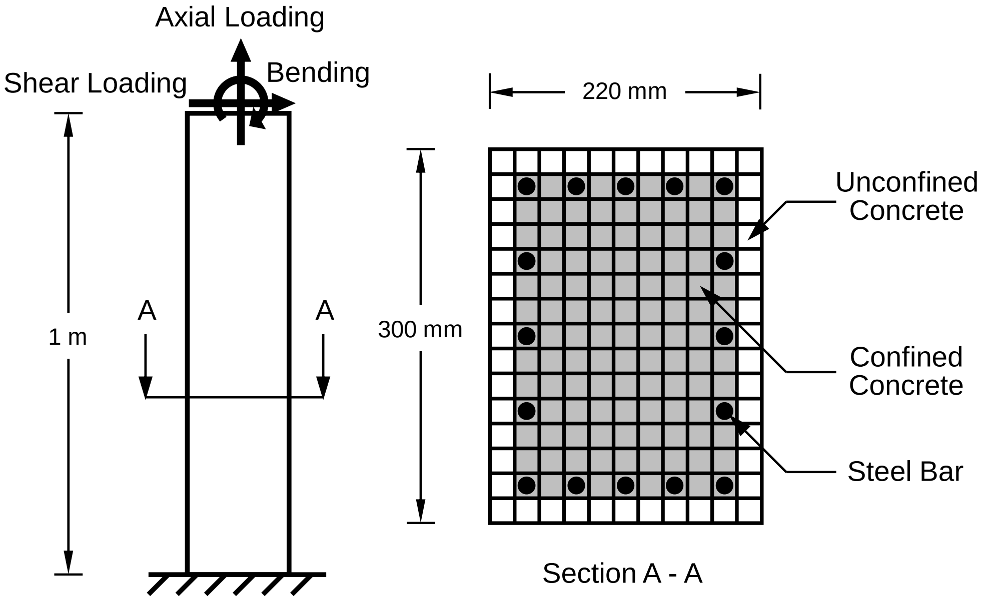

Figure 104.102: Schematic of the reinforced concrete column modeled with fiber sections and uniaxial steel/concrete materials.

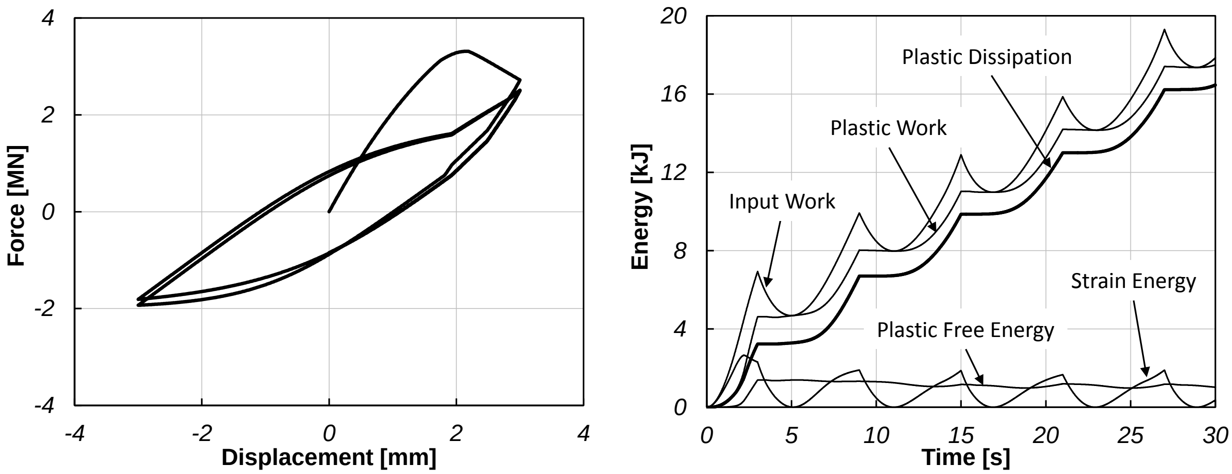

Figure 104.103: Energy analysis of reinforced concrete column under cyclic axial loading: (a) Force–displacement response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

Table 104.8: Material model parameters used in reinforced concrete column examples.

Steel Fiber		Concrete Fiber		
			Confined	Unconfined
σ_y (MPa)	413.8	f_{cs} (MPa)	-30.2	-24.16
E (GPa)	200.0	ϵ_{cs}	-0.00219	-0.001752
b	0.01	f_{cu} (MPa)	-6.0	0.0
R_0	18.0	ϵ_{cu}	-0.00696	-0.005568
c_{R_1}	0.925	λ	0.5	0.5
c_{R_2}	0.15	f_{ts} (MPa)	3.02	0.0
a_1, a_3	0.0	E_t (GPa)	5.0	0.0
a_2, a_4	55.0			

in this case.

Cyclic Bending Loading. Figure 104.104 shows the moment–rotation response as well as the energy results of the reinforced concrete column under cyclic bending loading.

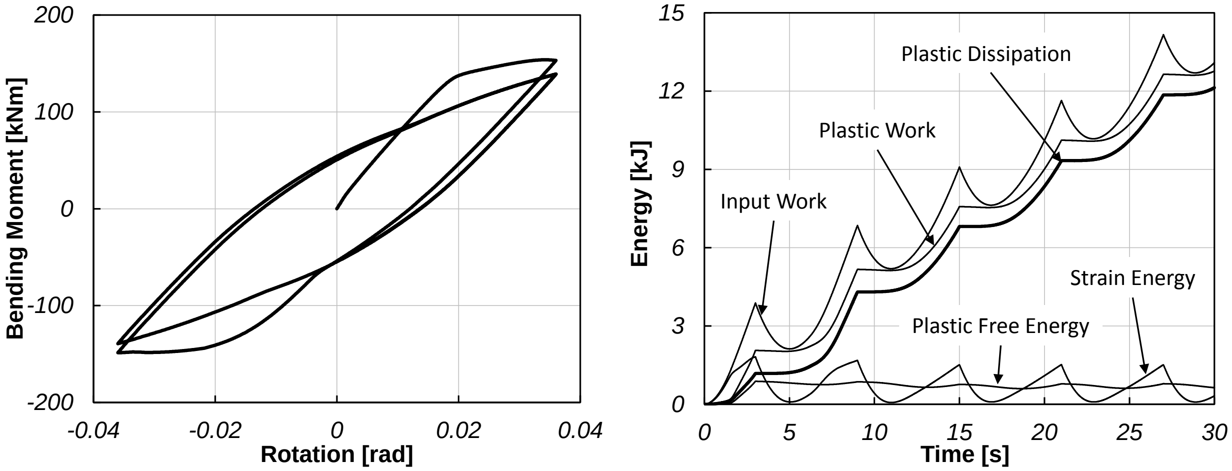

Figure 104.104: Energy analysis of reinforced concrete column under cyclic bending loading: (a) Moment–rotation response; (b) Plastic dissipation, plastic work, plastic free energy, strain energy, and input work.

During initial loading, the concrete fibers on the compressive side of the cross section take most of the compression, then during the first reverse loading, the concrete fibers on the other side of the cross section are compressed and damaged. This process is indicated in the moment–rotation curve where a bump caused by the compressive strength of the concrete fibers during the first reverse loading is observed. The energy computation result also shows that the concrete fibers dissipate large amount of energy and get damaged during the first loading cycle. After that, the response of the reinforced concrete column is controlled by the steel bars.

According to the two cases of reinforced concrete column under cyclic loading, the concrete part of the column can dissipate the majority of the input work if the loading is mainly monotonic compression. For cyclic loading cases, if the loading does not exceed the maximum compressive strength of the concrete, which should not be significantly damaged, energy dissipation would be observed in both the concrete and steel. However, if the cyclic loading does exceed the maximum strength of the concrete, the majority of energy dissipation would be in the steel reinforcing bars after the concrete is damaged. This conclusion is consistent with the engineering experience that reinforcements are crucial to the performance of concrete structure during seismic events, when the beams and columns suffer from cyclic loadings.

104.12.3.4 Steel Frame

All the previous cases are assumed to be static or quasi-static to investigate the energy dissipation on material level without the influence of dynamics. In other words, inertia and kinetic energy were not considered. In this example, a steel frame structure is model using fiber section element with uniaxial steel material, as shown in Figure 104.105, and loaded dynamically with a realistic seismic motion. The peak acceleration of the input motion is 0.76 g.

The energy computation results are shown in Figure 104.106. Strain energy, plastic free energy, and plastic dissipation in different stories are computed using Equation 507.10, 507.11, and 507.13. Input work is computed from the input motion and reaction forces at the base of model. Kinetic energy is computed indirectly by subtracting all other forms of energy from input work.

Note that the kinetic energy of the system is almost zero at certain times, and strain energy reaches a peak value. As can be observed from Figure 104.106, when kinetic energy becomes zero, the combination of strain energy, plastic free energy, and plastic dissipation of the system equals to the total input work. This observation proves that the energy balance of the system is maintained during entire simulation.

At the end of simulation, more than 80% of the total input work is dissipated due to material elasto-plasticity, while about 13% is transformed into plastic free energy which does not result in heating or material damage. In some cases, it might be reasonable to use input work (or energy demand in some literature) as a parameter to evaluate structure safety. However, as shown in this example, correctly computed energy dissipation is more appropriate for evaluation of material damage and structure performance in general.

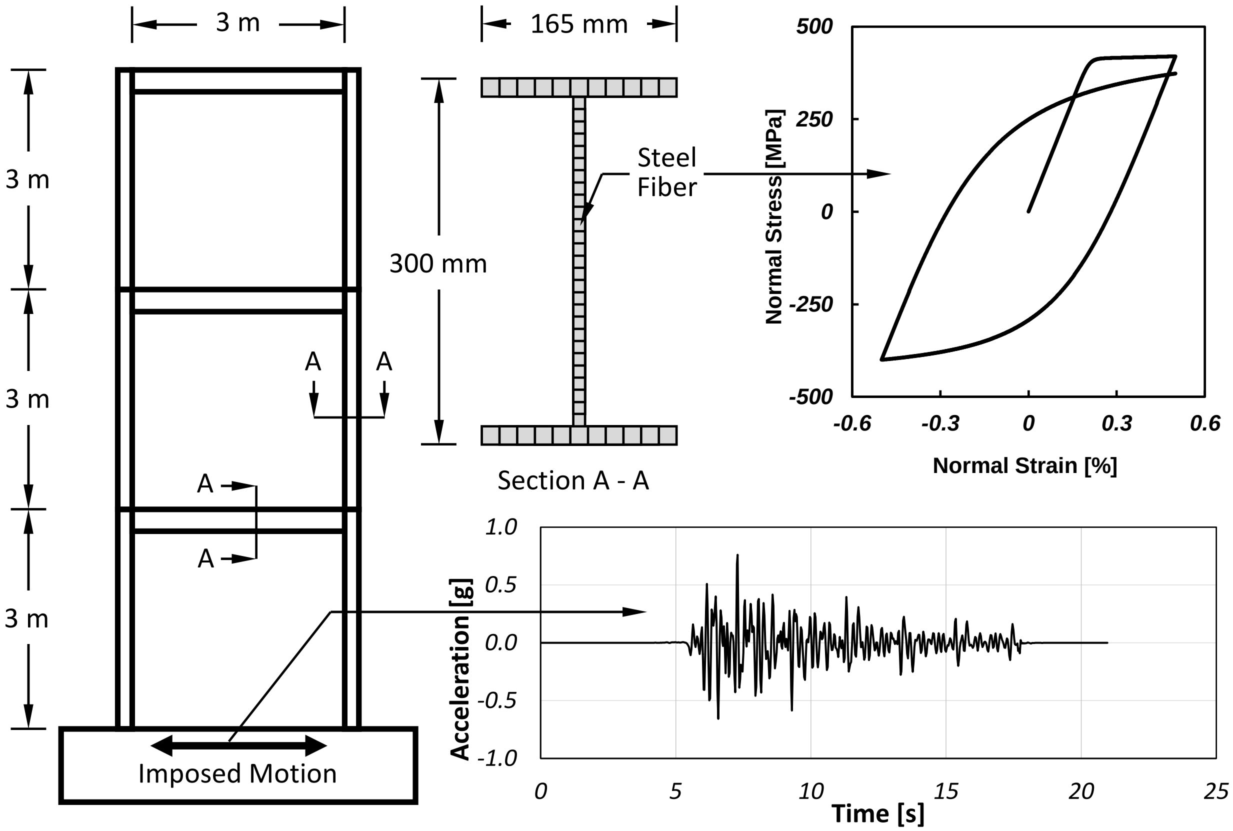

Figure 104.105: Schematic of the steel frame modeled with fiber section elements and uniaxial steel material.

104.12.4 Conclusions

Presented in this section was a thermodynamic-based methodology for (correct) computation of energy dissipation in nonlinear structural elements modeled with fiber section and uniaxial material models. Two popular material models for steel and concrete were examined with focus on their nonlinear cyclic behaviors. Formulations for the energy storage and dissipation in these two material models were derived from the basic principles of thermodynamics, in combination with a few reasonable assumptions. The proposed methodology has been illustrated using a series of numerical simulations on columns and frame modeled with fiber section elements.

The misconception between plastic work and plastic dissipation, which leads to the violation of principles of thermodynamics, was addressed. Theoretical derivation and experimental observation have both proven that plastic free energy is a basic form of energy that should not be neglected without proper reasoning. By taking into account of all possible energy forms, including kinetic energy, strain energy, plastic free energy, and plastic dissipation, the first law of thermodynamics (energy balance) was

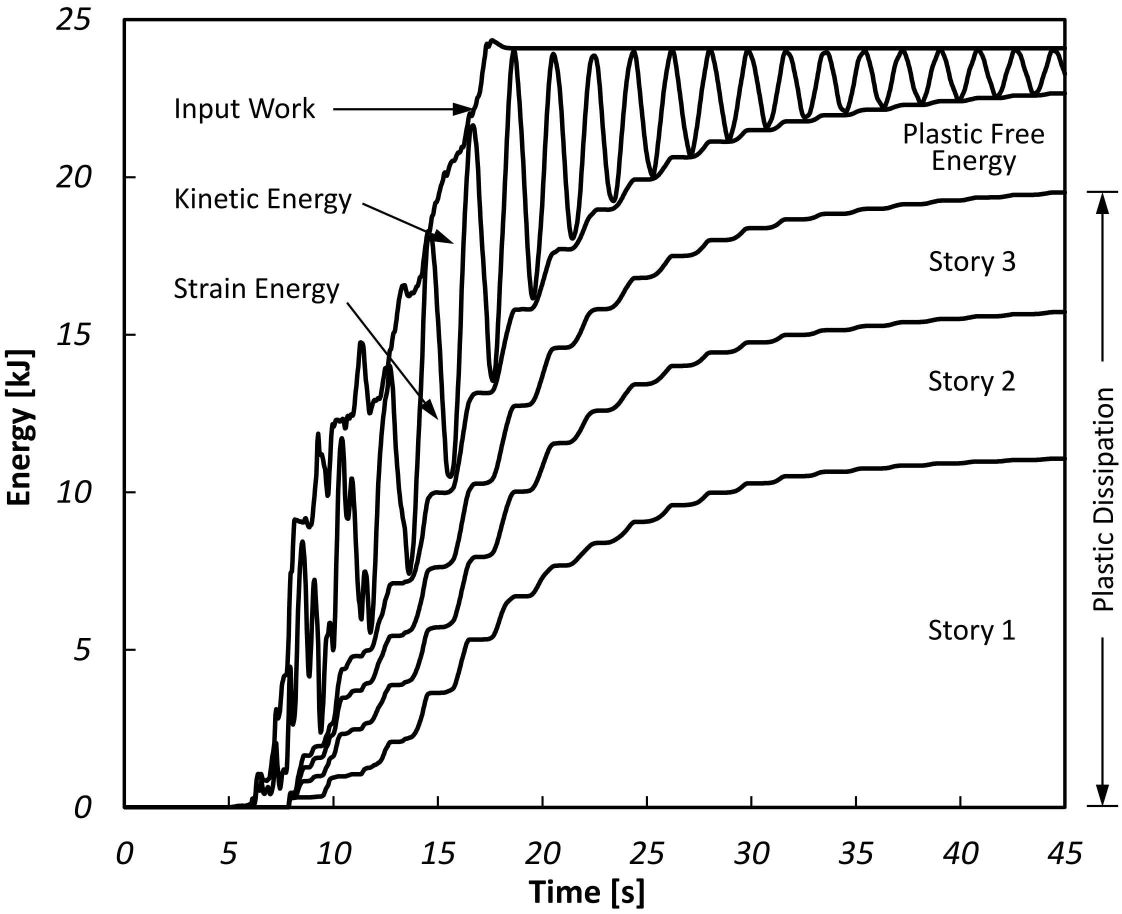

Figure 104.106: Energy analysis of steel frame model under imposed seismic motion.

ensured in the proposed methodology.

Physically, plastic free energy is related to the evolution of material micro-structure, which is not represented by specific parameters (like the internal variables in some elastoplasticity models). According to the experimental behavior of the material models, a few assumptions that ensures their energy behavior to follow the proposed thermomechanical framework were made. Equations for energy computation were derived and implemented in Real-ESSI, which was used to perform numerical simulations in this study.

Presented approach was illustrated and tested using several column and frame models with different loading conditions. As expected, energy balance was maintained during entire simulation in all tested cases. It was shown that plastic work could drop but plastic dissipation always maintained nonnegative during any time period, which is expressed in the second law of thermodynamics. It was also observed that the difference between plastic work and plastic dissipation could be significant in most cases. The ratio between them (Quinney–Taylor coefficient) evolved with time and thus should not be assumed to be constant in general.

105.2 Probabailistic Elasto-Plasticity, 1D FPK Formulation

A second-order exact expression for evolution of Probability Density Function (PDF) of stress is derived for general, one dimensional (1-D) elastic-plastic constitutive rate equations with uncertain material parameters. The Eulerian–Lagrangian (EL) form of Fokker–Planck–Kolmogorov (FPK) equation is used for this purpose. It is also shown that by using EL form of FPK, the so called "closure problem" associated with regular perturbation methods used so far, is resolved too. The use of EL form of FPK also replaces repetitive and computationally expensive deterministic elastic-plastic computations associated with Monte Carlo technique.

The derived general expression are specialized to the particular cases of point location scale linear elastic and elastic–plastic constitutive equations, related to associated Drucker-Prager with linear hardening

In a companion paper, the solution of FPK equations for 1D is presented, discussed and illustrated through a number of examples.

105.2.1 Probabilistic Elasto-Plasticity: Introduction

Advanced elasto–plasticity constitutive models, when properly calibrated, are very accurate in capturing important aspects of material behavior. However, all materials', and in particular geomaterials' (soil, rock, concrete, powder, bone etc.) behavior is uncertain due to inherent spatial and point-wise uncertainties. These uncertainties in material properties could outweigh the advantages gained by using advanced constitutive models. For example, Fig. 105.1 shows a schematic of anticipated influence of material uncertainties on a bi-linear elastic-plastic stress-strain behavior. Depending on uncertainties in material properties and interaction between them, the behavior of the same material could be very different.

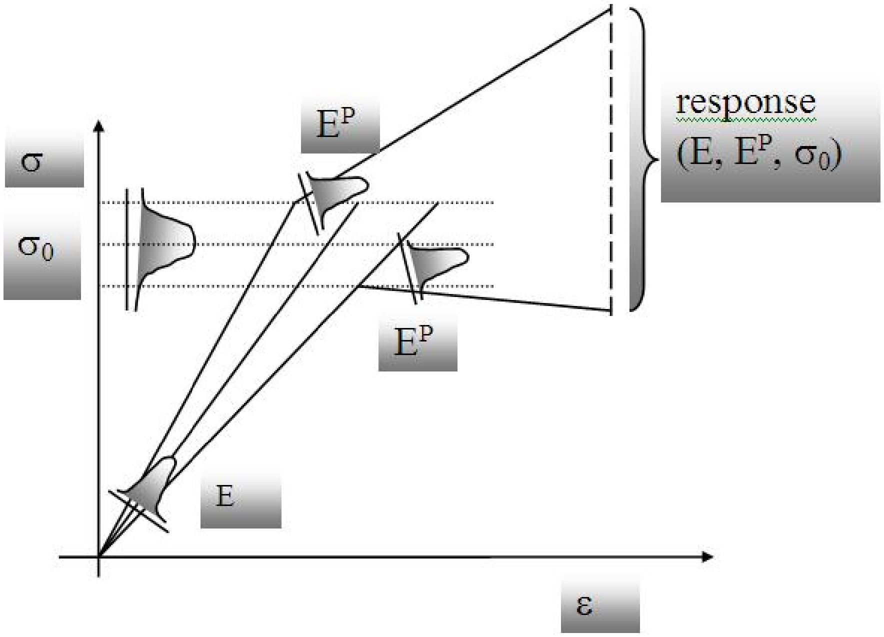

Figure 105.1: Anticipated Influence of Material Fluctuations on Stress-Strain Behavior

The uncertainties in material properties are inevitable in real materials and it is best to account for them in modeling and simulation. In traditional deterministic constitutive modeling, material models are calibrated against set of experimental data. Although those experimental data sets generally exhibit statistical distribution, the models are usually calibrated against the mean of the data and all the information about uncertainties is neglected.

The modeling and simulation of solids and structures with uncertain material properties involves two steps: (a) classification and quantification of uncertainties and (b) propagation of uncertainties through governing differential equations.

The uncertainties can be broadly classified into aleatory and epistemic types. Aleatory uncertainties are associated with the inherent variabilities of nature. This type of uncertainty can not be reduced. Highly developed mathematical theory is available for dealing with aleatory uncertainty. On the other hand, epistemic uncertainties arise due to our lack of knowledge. This type of uncertainty can be reduced by collecting more data but the mathematical tools to deal with them are not highly developed (e.g. fuzzy logic Zadeh (1983), convex models Ben-Haim and Elishakoff (1990), interval arithmetic Moore (1979) etc.). Hence, it proves useful to trade epistemic uncertainties for aleatory uncertainties in order to facilitate their propagation through the governing equations using advanced mathematical tools. It is important to note that in trading-off epistemic uncertainties for aleatory uncertainties, one doesn't reduce the total uncertainties in the system, but assumes that the uncertainties in the system are irreducible. Under the framework of probability theory, uncertain material parameters are modeled as random variables or random fields (Vanmarcke, 1983) depending on whether they are specialized to a fixed location in their continuum or a function of location in their continuum. We note recent works in quantifying the uncertainties in material (soil) properties for geotechnical engineering applications, Lumb (1966), Vanmarcke (1977), Mayerhoff (1993), DeGroot and Baecher (1993), Popescu (1995), Lacasse and Nadim (1996), Popescu et al. (1998), Phoon and Kulhawy (1999a,b), Fenton (1999a,b), Duncan (2000b), Rackwitz (2000), Marosi and Hiltunen (2004), and Stokoe II et al. (2004) The issue of uncertain material properties becomes very pronounced when one starts dealing with the boundary value problems with uncertain material properties (elastic or elastic–plastic).

In mechanics, the equilibrium equation,$A\sigma = \phi(t)$, together with the strain compatibility equation, $Bu = \epsilon$, and the constitutive equation, $\sigma = D\epsilon$, are sufficient[1] to describe the behavior of the solid. Rigorous mathematical theory has been developed for problems where the only random parameter is the external force $\phi(t)$. In this case, the probability distribution function (PDF) of the response variable will satisfy FPK partial differential equation (Soize, 1994) . With appropriate initial and boundary conditions the FPK PDE can be solved for PDF of response variable. The numerical solution method for FPK equation by finite element method (FEM) is described by number of researchers e.g. Langtangen (1991), Masud and Bergman (2005).

The other extreme case, which is of interest in this work, is when the stochasticity of the system is purely due to operator uncertainty. Exact solution of the problems with stochastic operator was attempted by Hopf (1952) using characteristic functional approach. Later, Lee (1974) applied the methodology to the problem of wave propagation in random media and derived a FPK equation satisfied by the characteristic functional of the random wave field. This characteristic functional approach is very complicated for linear problems and becomes even more intractable (and possibly unsolvable) for nonlinear problems and problems with irregular geometries and boundary conditions.

Monte Carlo simulation technique is an alternative to analytical solution of partial differential equation with stochastic coefficient. Nice descriptions of different aspects of formulation of Monte Carlo technique for stochastic mechanics problem is described by Schüeller (1997). Monte Carlo method is very popular

---

[1] Generalized stress is σ, $\phi(t)$ is generalized forces that can be time dependent, u is generalized displacements, ϵ is generalized strain and A, B, and D are operators which could be linear or non-linear.

tool with the advantage that accurate solution can be obtained for any problem whose deterministic solution (either analytical or numerical) is known. Monte Carlo technique has been used by a number of researchers in obtaining probabilistic solution of geotechnical boundary value problems, e.g. Paice et al. (1996); Griffiths et al. (2002); Fenton and Griffiths (2003, 2005). Popescu et al. (1997), Mellah et al. (2000), De Lima et al. (2001), Koutsourelakis et al. (2002), Nobahar (2003). The major disadvantage of Monte Carlo analysis is the repetitive use of the deterministic model until the solution variable become statistically significant. The computational cost associated with it could be very high especially for non–linear problems with multiple uncertain material properties.

Various difficulties in finding analytical solutions and the high computational cost associated with Monte Carlo technique instigated development of numerical method for the solution of stochastic differential equation with random coefficient. For stochastic boundary value problems Stochastic Finite Element Method (SFEM) is the most popular such method. There exist several formulations of SFEM, among which perturbation (Kleiber and Hien (1992); Der Kiureghian and Ke (1988); Mellah et al. (2000); Gutierrez and De Borst (1999)) and Spectral (Ghanem and Spanos (1991); Keese and Matthies (2002); Xiu and Karniadakis (2003); Debusschere et al. (2003); Anders and Hori (2000)) methods are very popular. A nice review on advantages and disadvantages of different formulations of SFEM was provided by Matthies et al. (1997). Mathematical issues regarding different formulations of SFEM was addressed by Deb et al. (2001) and Babuska and Chatzipantelidis (2002). It is important to note that most of the formulations described in the above mentioned references are for linear elastic problems.

A limited number of references is also available related to geometric non–linear problems, Liu and Der Kiureghian (1991); Keese and Matthies (2002) and Keese (2003)). Similarly, there exist only few published references related to material non–linear (elastic–plastic) problems with uncertain material parameters. The major difficulty in extending the available formulations of SFEM to general elastic–plastic problem is the high non–linear coupling in the elastic–plastic constitutive rate equation. First attempt to propagate uncertainties through elastic–plastic constitutive equations considering random Young's modulus was published only recently, e.g. Anders and Hori (1999, 2000). The perturbation expansion at the stochastic mean behavior (considering only the first term of the expansion) was used in the above mentioned references. In computing the mean behavior the Authors took the advantage of bounding media approximation. Although this method doesn't suffer from computational difficulty associated with Monte Carlo method for problems having no closed-form solution, it inherits "closure problem" and the "small coefficient of variation" requirements for the material parameters. Closure problem refers to the need for higher order statistical moments in order to calculate lower order statistical moments Kavvas (2003). The small COV requirement claims that the perturbation method can be used (with reasonable accuracy) for probabilistic simulations of solids and structures with uncertain properties only if their COV < 20 % (Sudret and Der Kiureghian, 2000). For soils and other natural materials, COVs are rarely below 20 % (Lacasse and Nadim (1996); Phoon and Kulhawy (1999a,b)). Furthermore, with bounding media approximation, difficulty arises in computing the mean behavior when one considers uncertainties in internal variable(s) and/or direction(s) of evolution of internal variable(s).

The focus of present work is on development of methodology for the probabilistic simulation of constitutive behavior of elastic–plastic materials with uncertain properties. Recently, Kavvas (2003) obtained a generic Eulerian–Lagrangian (EL) form of FPK equation, exact to second-order, corresponding to any non–linear ordinary differential equation with random coefficients and random forcing. The approach using EL form of the FPK equation doesn't suffer from the drawbacks of Monte Carlo method and perturbation technique. In this paper the authors applied developed EL form of the FPK equation to obtain probabilistic formulation for a general, one-dimensional incremental elastic–plastic constitutive equation with random coefficient. The solution methodology is designed with several applications in mind, namely to

- obtain probabilistic stress–strain behavior from spatial average form (upscaled form) of constitutive equation, when input uncertain material properties to the constitutive equation are random fields; and
- obtain probabilistic stress-strain behavior from point-location scale constitutive equation, when input uncertain material properties to the constitutive equation are random variables.

Application of the developed methodology is demonstrated on a particular point-location scale one-dimensional constitutive equation, namely Drucker–Prager associative linear hardening elastic–plastic material model. In this paper, derivation is made of the EL form of FPK equation that govern the 1D probabilistic elastic–plastic material models with uncertain material parameters. This general formulation is then specialized to a particular 1D Drucker–Prager associative linear hardening material model. In the companion paper the solution methodology of the FPK equation corresponding to Drucker–Prager associative linear hardening material model is described, along with illustrative examples. The methodology is general enough that it allows extension to three-dimensions and incorporation into a general stochastic finite element framework. This work is underway and will be reported in future publications.

105.2.2 Probabilistic Elasto-Plasticity: General Formulation

The incremental form of spatial-average elastic-plastic constitutive equation can be written as

$$\frac{d\sigma_{ij}(x_t,t)}{dt} = D_{ijkl}(x_t,t)\frac{d\epsilon_{kl}(x_t,t)}{dt} \tag{105.1}$$

where the continuum stiffness tensor $D_{ijkl}(x_t, t)$ can be either elastic or elastic-plastic

$$D_{ijkl} = \begin{cases} D^{el}_{ijkl} & ; f < 0 \vee (f = 0 \wedge df < 0) \\ \\ D^{el}_{ijkl} - \dfrac{D^{el}_{ijmn} \dfrac{\partial U}{\partial \sigma_{mn}} \dfrac{\partial f}{\partial \sigma_{pq}} D^{el}_{pqkl}}{\dfrac{\partial f}{\partial \sigma_{rs}} D^{el}_{rstu} \dfrac{\partial U}{\partial \sigma_{tu}} - \dfrac{\partial f}{\partial q_*} r_*} & ; f = 0 \vee df = 0 \end{cases} \tag{105.2}$$

and where D^{el}_{ijkl} is the elastic stiffness tensor, D^{ep}_{ijkl} is the elastic–plastic continuum stiffness tensor, f is the yield function, which is a function of stress (σ_{ij}) and internal variables (q_*), U is the plastic potential function (also a function of stress and internal variables). The internal variables (q_*) could be scalar(s) (for perfectly-plastic and isotropic hardening models), second-order tensor (for translational and rotational kinematic hardening) or fourth-order tensor (for distortional hardening). Therefore, the most general form of incremental constitutive equation in terms of its parameters can be written as

$$\frac{d\sigma_{ij}(x_t, t)}{dt} = \beta_{ijkl}(\sigma_{ij}, D_{ijkl}, q_*, r_*; x_t, t) \frac{d\epsilon_{kl}(x_t, t)}{dt} \tag{105.3}$$

Due to randomnesses in elastic constants (D^{el}_{ijkl}) and internal variables (q_*) and/or rate of evolution of internal variables (r_*) the material stiffness operator β_{ijkl} in Eq. (105.3) becomes stochastic. It follows that the Equation (105.1) becomes a linear/non-linear ordinary differential equations with stochastic coefficients. Similarly, randomness in he forcing term (ϵ_{kl}) of Equation (105.3) results in Equation (105.3) becoming linear/non-linear ordinary differential equations with stochastic forcing. This can be generalized, so that randomnesses in material properties and forcing function of Equation (105.3) results in Equation (105.3) becoming a linear/non-linear ordinary differential equation with stochastic coefficients and stochastic forcing.

In order to gain better understanding of the effects of random material parameters and forcing on response, focus is shifted from a general 3D case to a 1D case. In what follows, the probabilistic formulation for 1-D constitutive elastic–plastic incremental equation with stochastic coefficient and stochastic forcing is derived. In addition to that, the probabilistic formulation for 1-D elastic linear constitutive equation is obtained as a special case of non-linear general derivation.

Focusing on 1-D behavior, the Eq. (105.3) is written as

$$\frac{d\sigma(x_t, t)}{dt} = \beta(\sigma, D, q, r; x_t, t) \frac{d\epsilon(x_t, t)}{dt} \tag{105.4}$$

which is a non-linear ordinary differential equation with stochastic coefficient and stochastic forcing. The right hand side of Eq. (105.4) is replaced with the function η as

$$\eta(\sigma, D, q, r, \epsilon; x, t) = \beta(\sigma, D, q, r; x_t, t) \frac{d\epsilon(x_t, t)}{dt} \tag{105.5}$$

so that now Eq. (105.4) can be written as

$$\frac{\partial \sigma(x_t, t)}{\partial t} = \eta(\sigma, D, q, r, \epsilon; x, t) \tag{105.6}$$

with initial condition,

$$\sigma(x, 0) = \sigma_0 \tag{105.7}$$

In the above Eq. (105.6) σ can be considered to represent a point in the σ-space and hence, the Eq. (105.6) determines the velocity for the point in that σ-space. This may be visualized, from the initial point, and given initial condition σ_0, as a trajectory that describes the corresponding solution of the non-linear stochastic ordinary differential equation (ODE) (Eq. (105.6)). Considering now a cloud of initial points (refer to Fig. 105.2), described by a density $\rho(\sigma, 0)$ in the σ-space.

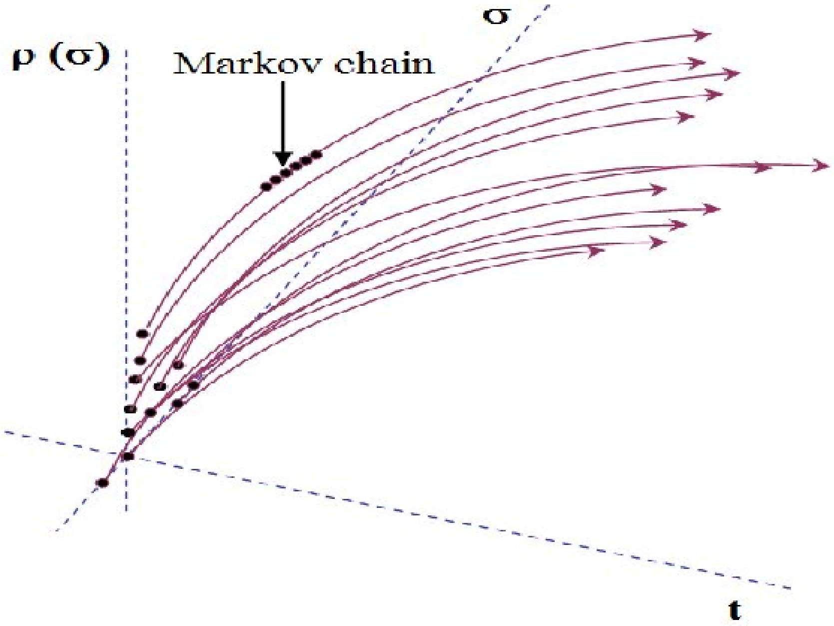

Figure 105.2: Movements of Cloud of Initial Points, described by density $\rho(\sigma, 0)$, in the σ-space

The phase density ρ of $\sigma(x, t)$ (movement of any point dictated by Eq. (105.6)) varies in time according to a continuity equation which expresses the conservation of all these points in the σ-space. This continuity equation can be expressed in mathematical terms, using Kubo's stochastic Liouville equation (Kubo, 1963):

$$\frac{\partial \rho(\sigma(x, t), t)}{\partial t} = -\frac{\partial}{\partial \sigma} \eta[\sigma(x, t), D(x), q(x), r(x), \epsilon(x, t)].\rho[\sigma(x, t), t] \tag{105.8}$$

with an initial condition,

$$\rho(\sigma, 0) = \delta(\sigma - \sigma_0) \tag{105.9}$$

where δ is the Dirac delta function and Eq. (105.9) is the probabilistic restatement in the σ-phase space of the original deterministic initial condition (Eq. (105.7)). Here it proves useful to recall Van Kampen's Lemma (Van Kampen, 1976), which states that the ensemble average of a phase density is the probability density

$$< \rho(\sigma, t) >= P(\sigma, t) \tag{105.10}$$

where, the symbol $< \cdot >$ denotes the expectation operation, and $P(\sigma, t)$ denotes evolutionary probability density of the state variable σ of the constitutive rate equation (Eq. (105.4)).

In order to obtain the deterministic probability density function (PDF) (σ, t) of the state variable, σ, it is necessary to obtain the deterministic partial differential equation (PDE) of the σ-space mean phase density $< \rho(\sigma, t) >$ from the linear stochastic PDE system (Eqs. (105.8) and (105.9)). This necessitates the derivation of the ensemble average form of Eq. (105.8) for $< \rho(\sigma, t) >$. This ensemble average was recently derived by (Kavvas and Karakas, 1996; Kavvas, 2003) as

$$\begin{aligned}
&\frac{\partial \left\langle \rho(\sigma(x_t, t), t) \right\rangle}{\partial t} = \\
&- \quad \frac{\partial}{\partial \sigma} \Bigg\{ \Bigg[\Bigg\langle \eta(\sigma(x_t, t), D(x_t), q(x_t), r(x_t), \epsilon(x_t, t)) \Bigg\rangle \\
&- \quad \int_0^t d\tau Cov_0 \Bigg[\eta(\sigma(x_t, t), D(x_t), q(x_t), r(x_t), \epsilon(x_t, t)); \\
&\qquad \frac{\partial \eta(\sigma(x_{t-\tau}, t-\tau), D(x_{t-\tau}), q(x_{t-\tau}), r(x_{t-\tau}) \epsilon(x_{t-\tau}, t-\tau)}{\partial \sigma} \Bigg] \Bigg] \left\langle \rho(\sigma(x_t, t), t) \right\rangle \Bigg\} \\
&+ \quad \frac{\partial}{\partial \sigma} \Bigg\{ \Bigg[\int_0^t d\tau Cov_0 \left[\eta(\sigma(x_t, t), D(x_t), q(x_t), r(x_t), \epsilon(x_t, t)); \right. \\
&\qquad \left. \eta(\sigma(x_{t-\tau}, t-\tau), D(x_{t-\tau}), q(x_{t-\tau}), r(x_{t-\tau}), \epsilon(x_{t-\tau}, t-\tau)) \right] \Bigg] \frac{\partial \left\langle \rho(\sigma(x_t, t), t) \right\rangle}{\partial \sigma} \Bigg\}
\end{aligned} \tag{105.11}$$

to exact second order (to the order of the covariance time of η). In Eq. (105.11), $Cov_0[\cdot]$ is the time ordered covariance function defined by

$$Cov_0 \left[\eta(x, t_1), \eta(x, t_2) \right] = \left\langle \eta(x, t_1) \eta(x, t_2) \right\rangle - \left\langle \eta(x, t_1) \right\rangle \cdot \left\langle \eta(x, t_2) \right\rangle \tag{105.12}$$

By combining Eqs. (105.11) and (105.10) and rearranging the terms yields the following Fokker-Planck equation (FPE, also known as Forward–Kolmogorov Equation or Fokker–Planck–Kolmogorov

FPK Equation) (Risken (1989), Gardiner (2004), Schüeller (1997)):

$$
\begin{aligned}
&\frac{\partial P(\sigma(x_t,t),t)}{\partial t} = \\
&-\quad \frac{\partial}{\partial \sigma}\Bigg[\Bigg\{\Bigg\langle \eta(\sigma(x_t,t), D(x_t), q(x_t), r(x_t)\epsilon(x_t,t)) \Bigg\rangle \\
&+\quad \int_0^t d\tau Cov_0 \Bigg[\frac{\partial \eta(\sigma(x_t,t), D(x_t), q(x_t), r(x_t)\epsilon(x_t,t))}{\partial \sigma}; \\
&\qquad \eta(\sigma(x_{t-\tau}, t-\tau), D(x_{t-\tau}), q(x_{t-\tau}), r(x_{t-\tau}), \epsilon(x_{t-\tau}, t-\tau)\Bigg]\Bigg\} P(\sigma(x_t,t),t)\Bigg] \\
&+\quad \frac{\partial^2}{\partial \sigma^2}\Bigg[\Bigg\{\int_0^t d\tau Cov_0 \Bigg[\eta(\sigma(x_t,t), D(x_t,t), q(x_t,t), r(x_t,t), \epsilon(x_t,t)); \\
&\qquad \eta_1(\sigma(x_{t-\tau}, t-\tau), D(x_{t-\tau}), q(x_{t-\tau}), r(x_{t-\tau}), \epsilon(x_{t-\tau}, t-\tau))\Bigg]\Bigg\} P(\sigma(x_t,t),t)\Bigg]
\end{aligned}
\tag{105.13}
$$

to exact second order. This is the most general relation for probabilistic behavior of inelastic (non–linear, elastic–plastic) 1-D stochastic incremental constitutive equation. The solution of this deterministic linear FPE (Eq. (105.13)), in terms of the probability density $P(\sigma, t)$, under appropriate initial and boundary conditions will yield the PDF of the state variable σ of the original 1-D non-linear stochastic constitutive rate equation (Eq. (105.4)). It is important to note that while the original equation (Eq. (105.4)) is non-linear, the FPE (Eq. (105.13)) is linear in terms of its unknown, the probability density $P(\sigma, t)$ of the state variable σ. This linearity, in turn, provides significant advantages in the solution of the probabilistic behavior of the incremental constitutive equation (Eq. (105.4)).

One should also note that Eq. (105.13) is a mixed Eulerian-Lagrangian equation. This stems from the fact that while the real space location x_t at time t is known, the location $x_{t-\tau}$ is an unknown. If one assumes small strain theory, one can relate the unknown location $x_{t-\tau}$ from the known location x_t by using the strain rate, $\dot{\epsilon}$ $(=d\epsilon/dt)$ as,

$$x_{t-\tau} = (1 - \dot{\epsilon}\tau)x_t \tag{105.14}$$

Once the probability density function $P(\sigma, t)$ is obtained it can be used to obtain the mean of state variable (σ) by usual expectation operation

$$< \sigma(t) >= \int \sigma(t) P(\sigma(t)) d\sigma(t) \tag{105.15}$$

Another possible way to obtain the mean of state variable is to use the equivalence between FPE and Itô stochastic differential equation (Gardiner, 2004). In this case Itô stochastic differential equation equivalent to Eq. (105.13) is

$$\begin{aligned}
d\sigma(x,t) &= \Bigg\{\Bigg\langle \eta(\sigma(x_t,t),D(x_t),q(x_t),r(x_t),\epsilon(x_t,t))\Bigg\rangle \\
&+ \int_0^t d\tau Cov_0\left[\frac{\partial\eta(\sigma(x_t,t),D(x_t),q(x_t),r(x_t),\epsilon(x_t,t))}{\partial\sigma};\right. \\
&\left.\eta(\sigma(x_{t-\tau},t-\tau),D(x_{t-\tau}),q(x_{t-\tau}),r(x_{t-\tau}),\epsilon(x_{t-\tau},t-\tau))\right]\Bigg\} dt \\
&+ b(\sigma,t)dW(t)
\end{aligned} \tag{105.16}$$

where,

$$\begin{aligned}
b^2(\sigma,t) &= 2\int_0^t d\tau Cov_0\Big[\eta(\sigma(x_t,t),D(x_t),q(x_t),r(x_t),\epsilon(x_t,t)); \\
&\eta(\sigma(x_{t-\tau},t-\tau),D(x_{t-\tau}),q(x_{t-\tau}),r(x_{t-\tau}),\epsilon(x_{t-\tau},t-\tau))\Big]
\end{aligned} \tag{105.17}$$

and, $dW(t)$ is an increment of Wiener process W with $< dW(t) >= 0$. It is also interesting to note that all the stochasticity of the original equation (Eq. (105.4)) are lumped together in the last term (Wiener increment term) of the right-hand-side of Eq. (105.16). By taking advantage of the independent increment property of the Wiener process ($< dW(t) >= 0$), one can derive the differential equation which describes the evolution of mean of state variable (σ) of the nonlinear constitutive rate equation in time and space as, (e.g. (Kavvas, 2003))

$$\begin{aligned}
\frac{< d\sigma(x,t) >}{dt} &= \Bigg\langle \eta(\sigma(x_t,t),D(x_t),q(x_t),r(x_t),\epsilon(x_t,t))\Bigg\rangle \\
&+ \int_0^t d\tau Cov_0\left[\frac{\partial\eta(\sigma(x_t,t),D(x_t),q(x_t),r(x_t),\epsilon(x_t,t))}{\partial\sigma};\right. \\
&\left.\eta(\sigma(x_{t-\tau},t-\tau),D(x_{t-\tau}),q(x_{t-\tau}),r(x_{t-\tau}),\epsilon(x_{t-\tau},t-\tau))\right]
\end{aligned} \tag{105.18}$$

Eq. (105.18) is a nonlocal integro-differential equation in Eulerian-Lagrangian form, since, although the location x_t at time t is known, the Lagrangian location $x_{t-\tau}$ is an unknown which is determined by Eq. (105.14). It is important to note that the state variable appearing within $\eta(\cdot)$ on the right-hand-side of Eq. (105.18) is random and needs to be treated accordingly.

This concludes the development of relation for probabilistic behavior of 1-D elastic–plastic constitutive incremental equation with stochastic coefficients and stochastic forcing in most general form. In the following section the developed general relation is specialized to two particular types of point-location scale constitutive modeling: a) 1-D (shear) linear elastic constitutive behavior, and b) 1-D (shear) elastic-plastic Drucker-Prager associative linear hardening constitutive behavior.

105.2.3 Probabilistic Elasto-Plasticity: Elastic–Plastic Probabilistic 1-D Constitutive Incremental Equation

For materials obeying Drucker-Prager yield criteria (without cohesion), the yield surface can be written as:

$$f = \sqrt{J_2} - \alpha I_1 \tag{105.19}$$

where $J_2 = \frac{1}{2} S_{ij} s_{ij}$ is the second invariant of the deviatoric stress tensor $s_{ij} = \sigma_{ij} - 1/3\delta_{ij}\sigma_{kk}$, and $I_1 = \sigma_{ii}$ is the first invariant of the stress tensor, and α, an internal variable, is a function of friction angle ($\alpha = 2\sin(\phi)/(\sqrt{(}3)(3 - sin\phi)$), where ϕ is the friction angle (e.g. (Chen and Han, 1988b)).

By assuming associative flow rule, so that the yield function has the same derivatives as the plastic flow function

$$\frac{\partial f}{\partial \sigma_{ij}} = \frac{\partial U}{\partial \sigma_{ij}} \tag{105.20}$$

one can expand parts of the tangent constitutive tensor given in Eq. (105.2) (from Page 424), to read[2]

$$\begin{aligned} A_{kl} = \frac{\partial f}{\partial \sigma_{pq}} D_{pqkl} = \quad & A_{kl} \frac{\partial f}{\partial I_1} \left(2G \left(\frac{\partial I_1}{\partial \sigma_{11}} \delta_{1l}\delta_{1k} + \frac{\partial I_1}{\partial \sigma_{22}} \delta_{2l}\delta_{2k} + \frac{\partial I_1}{\partial \sigma_{33}} \delta_{3l}\delta_{3k} \right) \right. \\ + & \left. \left(K - \frac{2}{3}G \right) \frac{\partial I_1}{\partial \sigma_{cd}} \delta_{cd}\delta_{kl} \right) \\ + & \frac{\partial f}{\partial \sqrt{J_2}} \left(2G \frac{\partial \sqrt{J_1}}{\partial \sigma_{ij}} \delta_{ik}\delta_{jl} + \left(K - \frac{2}{3}G \right) \frac{\partial \sqrt{J_2}}{\partial \sigma_{ab}} \delta_{ab}\delta_{kl} \right) \end{aligned} \tag{105.21}$$

and,

$$\begin{aligned} B \;=\; & \frac{\partial f}{\partial \sigma_{rs}} D_{rstu} \frac{\partial f}{\partial \sigma_{tu}} = \\ & \left(\frac{\partial f}{\partial I_1} \right)^2 \left(2G \left(\left(\frac{\partial I_1}{\partial \sigma_{11}} \right)^2 + \left(\frac{\partial I_1}{\partial \sigma_{22}} \right)^2 + \left(\frac{\partial I_1}{\partial \sigma_{33}} \right)^2 \right) \right. \\ + & \left. \left(K - \frac{2}{3}G \right) \left(\frac{\partial I_1}{\partial \sigma_{ij}} \delta_{ij} \right)^2 \right. \\ + & \left(\frac{\partial f}{\partial \sqrt{J_2}} \right)^2 \left(2G \frac{\partial \sqrt{J_2}}{\partial \sigma_{ij}} \frac{\partial \sqrt{J_2}}{\partial \sigma_{ij}} + \left(K - \frac{2}{3}G \right) \left(\frac{\partial \sqrt{J_2}}{\partial \sigma_{ij}} \delta_{ij} \right)^2 \right) \Bigg) \end{aligned} \tag{105.22}$$

where, K and G are the elastic bulk modulus and the elastic shear modulus respectively.

---

[2] A more detailed derivation of this probabilistic differentiation is given in the Appendix.

By further assuming that the evolution of internal variable is a function of equivalent plastic strain[3], $e^p_{eq} = 2/3 e^p_{ij} e^p_{ij}$ then one can write

$$K_P = -\frac{\partial f}{\partial q_n} r_n = -\frac{1}{\sqrt{3}} \frac{\partial f}{\partial \alpha} \frac{d\alpha}{de^p_{eq}} \frac{\partial f}{\partial \sqrt{J_2}} \tag{105.23}$$

It should be noted that since material properties are assumed to be random, the resulting stress tensor will also become random and hence the derivatives of the stress invariants with respect to stress tensor (σ_{ij}) will become random. Therefore, differentiations appearing in Eqs. (105.21), (105.22), and (105.23) can not be carried out in a deterministic sense.

The parameter tensor in Eq. (105.1) then becomes

$$D^{ep}_{ijkl} = \begin{cases} 2G\delta_{ik}\delta_{jl} + \left(K - \frac{2}{3}G\right)\delta_{ij}\delta_{kl} & ; f < 0 \vee (f = 0 \wedge df < 0) \\ \\ 2G\delta_{ik}\delta_{jl} + \left(K - \frac{2}{3}G\right)\delta_{ij}\delta_{kl} - \frac{A_{ij}A_{kl}}{B + K_P} & ; f = 0 \vee df = 0 \end{cases} \tag{105.24}$$

where tensor A_{ij} and scalars B and K_P are defined by Eqs. (105.21), (105.22), and (105.23) respectively. The above equation (Eq. 105.24) represents a probabilistic continuum stiffness tensor for an elastic–plastic material model, in this case Drucker-Prager isotropic linear hardening material with associated plasticity. By focusing our attention on one dimensional point-location scale shear constitutive relationship between σ_{12} and ϵ_{12} for Drucker-Prager material model, one can simplify the function $\eta(\sigma, D, q, r, \epsilon; x, t)$ as defined in Eq. (105.5) (on Page 424) to read

$$\eta = \begin{cases} 2G\frac{d\epsilon_{12}}{dt} & ; f < 0 \vee (f = 0 \wedge df < 0) \\ \left(2G - \frac{4G^2\left(\frac{\partial f}{\partial\sqrt{J_2}}\frac{\sqrt{J_2}}{\partial\sigma_{12}}\right)^2}{B + K_P}\right)\frac{d\epsilon_{12}}{dt} & ; f = 0 \vee df = 0 \end{cases} \tag{105.25}$$

By considering both the material properties (shear modulus G, bulk modulus K, friction angle α, and rate of change of friction angle (linear hardening) α') and the strain rate ($d\epsilon_{12}/dt(t)$) as random, one can substitute η as derived in Eq. (105.13) to obtain the particular FPK equation for the probabilistic behavior of Drucker-Prager associative linear hardening, 1-D point-location scale elastic-plastic shear constitutive rate equation. In particular, two cases are recognized, one for elastic (pre–yield) behavior of

---

[3] This is a fairly common assumption, e.g. (Chen and Han, 1988b)

material $(f < 0 \vee (f = 0 \wedge df < 0))$

$$
\begin{aligned}
&\frac{\partial P(\sigma_{12}(t),t)}{\partial t} = \\
&- \frac{\partial}{\partial \sigma_{12}} \left[\left\langle 2G \frac{d\epsilon_{12}}{dt}(t) \right\rangle P(\sigma_{12}(t),t) \right] \\
&+ \frac{\partial^2}{\partial \sigma_{12}^2} \left[\left\{ \int_0^t d\tau Cov_0 \left[2G \frac{d\epsilon_{12}}{dt}(t); 2G \frac{d\epsilon_{12}}{dt}(t-\tau) \right] \right\} P(\sigma_{12}(t),t) \right]
\end{aligned}
\tag{105.26}
$$

noting that this is the same equation as Eq. (??). In addition to that, the case of elastic–plastic behavior $(f = 0 \vee df = 0)$ is described by the following probabilistic equation

$$
\begin{aligned}
&\frac{\partial P(\sigma_{12}(t),t)}{\partial t} = -\frac{\partial}{\partial \sigma_{12}} \left[\left\{ \left\langle \left(G^{ep}(t) \right) \frac{d\epsilon_{12}}{dt}(t) \right\rangle \right.\right. \\
&+ \left.\left. \int_0^t d\tau Cov_0 \left[\frac{\partial}{\partial \sigma_{12}} \left(G^{ep}(t) \frac{d\epsilon_{12}}{dt}(t) \right); G^{ep}(t-\tau) \frac{d\epsilon_{12}}{dt}(t-\tau) \right] \right\} P(\sigma_{12}(t),t) \right] \\
&+ \frac{\partial^2}{\partial \sigma_{12}^2} \left[\left\{ \int_0^t d\tau Cov_0 \left[G^{ep}(t) \frac{d\epsilon_{12}}{dt}(t); G^{ep}(t-\tau) \frac{d\epsilon_{12}}{dt}(t-\tau) \right] \right\} P(\sigma_{12}(t),t) \right]
\end{aligned}
\tag{105.27}
$$

where $G^{ep}(a)$ is defined as probabilistic elastic–plastic kernel and is introduced to shorten the writing (but will also have other uses later)

$$
G^{ep}(a) = \left(2G - \frac{4G^2 \left(\frac{\partial f}{\partial \sqrt{J_2}(a)} \frac{\partial \sqrt{J_2}(a)}{\partial \sigma_{12}(a)} \right)^2}{B(a) + K_P(a)} \right)
\tag{105.28}
$$

and a assumes values t or $t - \tau$.

It is important to note that the differentiations appearing in the coefficient terms of the FPK PDE (Eq. (105.27)), within the probabilistic elastic–plastic kernel $G^{ep}(a)$ (i.e. Eq. (105.28)), are for fixed values of σ_{12} and hence those differentiations can be carried out in a deterministic sense. After carrying out the differentiations, the probabilistic elastic–plastic kernel becomes

$$
G^{ep}(a)|_{\sigma_{12} \rightarrow const.} = \left(2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}} I_1(a) \alpha'} \right)
\tag{105.29}
$$

which, after substitution, result in simplification of the FPK equation (105.27). Further simplification is possible by noting that the first random process in the covariance term of the first coefficient on the r.h.s of the equation (105.27) is independent of σ_{12}. Furthermore, since the covariance of zero with any random process is zero, the FPK equation (105.27) is further simplified to read

$$\begin{aligned}
&\frac{\partial P(\sigma_{12}(t),t)}{\partial t} = \\
&- \frac{\partial}{\partial \sigma_{12}}\left[\left\langle G^{ep}(t)\frac{d\epsilon_{12}}{dt}(t)\right\rangle P(\sigma_{12}(t),t)\right] \\
&+ \frac{\partial^2}{\partial \sigma_{12}^2}\left[\left\{\int_0^t d\tau Cov_0\left[G^{ep}(t)\frac{d\epsilon_{12}}{dt}(t); G^{ep}(t-\tau)\frac{d\epsilon_{12}}{dt}(t-\tau)\right]\right\} P(\sigma_{12}(t),t)\right]
\end{aligned} \tag{105.30}$$

where the probabilistic elastic–plastic kernel $G^{ep}(a)$ is given by the Eq. (105.29).

The evolution of a mean value of shear stress σ_{12} is obtained by substituting η (derived for Drucker-Prager material in Eq. (105.18)) as

$$\begin{aligned}
&\frac{< d\sigma_{12}(t) >}{dt} = \left\langle G^{ep}(t)\frac{d\epsilon_{12}}{dt}(t)\right\rangle \\
&+ \int_0^t d\tau Cov_0\left[\frac{\partial}{\partial \sigma_{12}}\left(G^{ep}(t)\frac{d\epsilon_{12}}{dt}(t)\right); G^{ep}(t-\tau)\frac{d\epsilon_{12}}{dt}(t-\tau)\right]
\end{aligned} \tag{105.31}$$

It is important to note that the derivatives appearing in the mean and covariance term of the above Eulerian-Lagrangian integro-differential equation (Eq. (105.31) with the probabilistic elastic–plastic kernel defined through the Eq. (105.29)) are random differentiations and need to be treated accordingly. One possible approach to obtaining these differentiations could be perturbation with respect to mean (Anders and Hori, 2000) but the "closure problem" will appear. Hence, in this study the evolution of mean of σ_{12} will be obtained by the expectation operation on the PDF (Eq. (105.15)).

105.2.4 Probabilistic Elasto-Plasticity: Initial and Boundary Conditions for the Probabilistic Elastic–Plastic PDE

The PDE describing the probabilistic behavior of constitutive rate equations can be written in the following general form:

$$\begin{aligned}
\frac{\partial P(\sigma_{12},t)}{\partial t} &= -\frac{\partial}{\partial \sigma_{12}}\left\{P(\sigma_{12},t)N_{(1)}\right\} + \frac{\partial^2}{\partial \sigma_{12}^2}\left\{P(\sigma_{12},t)N_{(2)}\right\} \\
&= -\frac{\partial}{\partial \sigma_{12}}\left[P(\sigma_{12},t)N_{(1)} - \frac{\partial}{\partial \sigma_{12}}\left\{P(\sigma_{12},t)N_{(2)}\right\}\right] \\
&= -\frac{\partial \zeta}{\partial \sigma_{12}}
\end{aligned} \tag{105.32}$$

where, $N_{(1)}$ and $N_{(2)}$ are coefficients[4] of the PDE and represent the expressions within the curly braces of the first and second terms respectively on the right–hand–side of Eqs. (??), (105.26), and (105.27) These terms are called the advection ($N_{(1)}$) and diffusion ($N_{(2)}$) coefficients as the form of Eq. (105.32)

---

[4] Indices in brackets are not used in index summation convention.

closely resembles advection–diffusion equation (Gardiner, 2004). The symbol ζ in Eq. (105.32) can be considered to be the probability current. This follows from Eq. (105.32), which is a continuity equation and the state variable of the equation is probability density.

After introducing initial and boundary conditions, one can solve Eq. (105.32) for probability densities of σ_{12} with evolution of time. The initial condition could be deterministic or stochastic depending on the type of problem. For probabilistic behavior of linear elastic constitutive rate equation (Eq. (??)), one can assume that all the probability mass at time $t = 0$ is concentrated at $\sigma_{12} = 0$ or at some constant value of σ_{12} if there were some initial stresses to begin with (e.g. overburden pressure on a soil mass).

In mathematical term, this translates to,

$$P(\sigma_{12}, 0) = \delta(\sigma_{12}) \tag{105.33}$$

where, $\delta(\cdot)$ is the Dirac delta function.

For the post–yield behavior of probabilistic elastic-plastic constitutive rate Equation[5] (105.30), there will be a distribution of σ_{12}, corresponding to the solution of the pre-yield probabilistic behavior (Eq. (105.26)), to begin with. This probability mass ($P(\sigma_{12}(t), t)$), dictated by Eq. (105.13), will advect and diffuse into the domain (σ_{12}, t space) of the system throughout the evolution (in time/strain) of the simulation. Since it is required that the probability mass within the system is conserved i.e. no leaking is allowed at the boundaries, a reflecting barrier at the boundaries will be the preferred choice. In mathematical term, one can express this condition as (Gardiner, 2004)

$$\zeta(\sigma_{12}, t)\big|_{AtBoundaries} = 0 \tag{105.34}$$

In theory, the stress domain could extend from $-\infty$ to ∞ so that boundary conditions are then

$$\zeta(-\infty, t) = \zeta(\infty, t) = 0 \tag{105.35}$$

With these initial and boundary conditions, the probabilistic differential equation (with random material properties and random strain) for elasto–plasticity, specialized in this case to associated Drucker–Prager material model with linear hardening, and by using FPK transform described above, can be solved for probability densities of shear stress (σ_{12}) as it evolves with time/shear strain (ϵ_{12}).

105.2.5 Probabilistic Elasto-Plasticity: Fokker–Planck–Kolmogorov Equation for Probabilistic Elasticity and Elasto–Plasticity in 1-D

By focusing attention to the randomness of material properties only (i.e. assuming the forcing function (strain rate) as deterministic), partial differential equation (PDE) describing the evolution of probability

---

[5] Specialized to Drucker-Prager associated linear hardening model.

density function (PDF) of stress can be simplified. In particular, for 1D case, and for linear elastic material (but still with probabilistic material properties, in this case shear modulus G) one can write the following PDE

$$\begin{aligned}\frac{\partial P(\sigma_{12}(t))}{\partial t} &= - \left\langle 2G\frac{d\epsilon_{12}}{dt} \right\rangle \frac{\partial P(\sigma_{12}(t))}{\partial \sigma_{12}} \\ &+ \left\{ \int_0^t d\tau Cov_0 \left[2G\frac{d\epsilon_{12}}{dt}; 2G\frac{d\epsilon_{12}}{dt} \right] \right\} \frac{\partial^2 P(\sigma_{12}(t))}{\partial \sigma_{12}^2}\end{aligned} \tag{105.36}$$

Similarly, for elastic–plastic state, again by neglecting the randomness in strain rate, one can write the PDE for evolution of PDF of stress in 1D as

$$\begin{aligned}\frac{\partial P(\sigma_{12}(t))}{\partial t} &= - \left\langle \left(G^{ep}(t)\right) \frac{d\epsilon_{12}}{dt} \right\rangle \frac{\partial P(\sigma_{12}(t))}{\partial \sigma_{12}} \\ + \left\{ \int_0^t d\tau Cov_0 \left[G^{ep}(t)\frac{d\epsilon_{12}}{dt}; G^{ep}(t-\tau)\frac{d\epsilon_{12}}{dt} \right] \right\} &\frac{\partial^2 P(\sigma_{12}(t))}{\partial \sigma_{12}^2}\end{aligned} \tag{105.37}$$

where $G^{ep}(a)$ is the probabilistic elastic–plastic tangent stiffness, (given in Jeremić et al. (2007a))

$$G^{ep}(a) = 2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}} I_1(a)\alpha'} \tag{105.38}$$

where in the previous equation (105.38), a assumes values t or $t - \tau$. With appropriate initial and boundary conditions as described in Jeremić et al. (2007a), one can solve Eqs. (105.36) and (105.37) for evolution of PDF of shear stress with shear strain.

105.2.6 Probabilistic Elasto-Plasticity: Example Problem Statements

The applicability of proposed FPK equations (Eqs. (105.36) and (105.37)) in describing probabilistic elasto-plastic behavior, is verified using the following three example problems.

Problem I. Assume the material is linear elastic, probabilistic, with probabilistic shear modulus (G) given by a normal distribution at a point–location scale with mean of 2.5 MPa and standard deviation of 0.707 MPa. The aim is to calculated the evolution of PDF of shear stress (σ_{12}) with shear strain (ϵ_{12}) for a displacement-controlled test with deterministic shear strain increment. The other parameters are considered deterministic and are as follows: Poisson's ratio ($\nu = 0.2$, and confining pressure $I_1 = 0.03$ MPa.

Problem II. Assume elastic–plastic material model, composed of linear elastic component and Drucker–Prager associative isotropic linear hardening elastic–plastic component. The probabilistic shear modulus

(G) is given through a normal distribution at a point–location scale with mean of 2.5 MPa and standard deviation of 0.707 MPa. The aim is to calculate the evolution of the PDF of shear stress (σ_{12}) with shear strain (ϵ_{12}) for a displacement-controlled test with deterministic shear strain increment. The other parameters are considered deterministic and are as follows: Poisson's ratio $\nu = 0.2$, confining pressure $I_1 = 0.03$ MPa, yield parameter[6] $\alpha = 0.071$, plastic slope[7] $\alpha' = 5.5$.

Problem III. Assume elastic–plastic material model, with linear elastic component and Drucker–Prager associative isotropic linear hardening elastic–plastic component. The probabilistic yield parameter (α) is given through a normal distribution at a point-location scale with mean of 0.52 and standard deviation of 0.1. The aim is to calculate the evolution of the PDF of shear stress (σ_{12}) with shear strain (ϵ_{12}) for a displacement-controlled test with deterministic shear strain increment. The other parameters are considered deterministic and are as follows: shear modulus $G = 2.5$ MPa, Poisson's ratio $\nu = 0.2$, confining pressure $I_1 = 0.03$ MPa, and the plastic slope $\alpha' = 5.5$.

The above three problems will be solved using the proposed FPK equation approach. In addition to that, the solution will verified using either variable transformation method, for linear elastic case or repetitive Monte Carlo type simulations for elastic-plastic case.

105.2.7 Probabilistic Elasto-Plasticity: Determination of Coefficients for Fokker–Planck–Kolmogorov Equation

To solve Problems I, II, and III, the advection and diffusion coefficients $N_{(1)}$ and $N_{(2)}$ must be determined for all three problems. For sake of simplicity, a constant strain rate is assumed and hence, terms containing $d\epsilon_{12}/dt$ in coefficients of Eqs. (105.36) and (105.37) can be substituted by a constant numerical value for the entire simulation of the evolution of PDF. It should be noted that the FPK equation (Eqs. (105.36) or (105.37)) describes the evolution of PDFs of stress with time, while, similarly, strain rate describes the evolution of strain with time. Combining the two, the evolution of PDF of stress with strain can be obtained. Time has been brought in this simulation as an intermediate dimension to help in solution process, and hence, the numerical value of strain rate could be any arbitrary value, which will cancel out once the time evolution of PDF of stress is converted to strain evolution of PDF of stress. For simulation of all the three example problems, an arbitrary value of strain rate of $d\epsilon_{12}/dt = 0.0541/s$ is assumed.

It should also be noted that since the material properties are assumed as random variables at a point-location scale, the covariance terms appearing within the advection and diffusion coefficients become variances of random variables. For estimations of means and variances of functions of random variables

---

[6] The yield parameter α is an internal variable and is a function of friction angle ϕ given by $(\alpha = 2\sin(\phi)/(\sqrt(3)(3 - sin\phi))$ (e.g. (Chen and Han, 1988b))

[7] The plastic slope α' is a rate of change of friction angle governing linear hardening.

(e.g. for Problems II and III) from basic random variables, commercially available statistical software mathStatica Rose and Smith (2002) was used.

Substituting the values of deterministic and random material properties and the strain rate, coefficients $N_{(1)}$ and $N_{(2)}$ of the FPK equations can be obtained for all problems:

Problem I

$$\begin{aligned} N_{(1)} &= \left\langle 2G\frac{d\epsilon_{12}}{dt} \right\rangle \\ &= 2\frac{d\epsilon_{12}}{dt}\langle G \rangle \\ &= 0.27 \quad \text{MPa/s} \end{aligned}$$

$$\begin{aligned} N_{(2)} &= \int_0^t d\tau Var\left[2G\frac{d\epsilon_{12}}{dt}\right] \\ &= 4t\left(\frac{d\epsilon_{12}}{dt}\right)^2 Var[G] \\ &= 0.0058t \quad (\text{MPa/s})^2 \end{aligned}$$

Problem II

For pre-yield linear elastic case, the coefficients $N_{(1)}$ and $N_{(2)}$ will be the same as those for Problem I. For post-yield elastic-plastic case the coefficients are

$$\begin{aligned} N_{(1)} &= \left\langle \left(2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}}I_1\alpha'} \right) \frac{d\epsilon_{12}}{dt} \right\rangle \\ &= \frac{d\epsilon_{12}}{dt}\left\langle 2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}}I_1\alpha'} \right\rangle \\ &= 0.147 \quad \text{MPa/s} \end{aligned}$$

$$\begin{aligned} N_{(2)} &= t\left(\frac{d\epsilon_{12}}{dt}\right)^2 Var\left[2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}}I_1\alpha'}\right] \\ &= 0.00074t \quad (\text{MPa/s})^2 \end{aligned}$$

Problem III

For post-yield elastic-plastic simulation the coefficients $N_{(1)}$ and $N_{(2)}$ are

$$
\begin{aligned}
N_{(1)} &= \left\langle \left(2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}} I_1 \alpha'} \right) \frac{d\epsilon_{12}}{dt} \right\rangle \\
&= \frac{d\epsilon_{12}}{dt} \left\langle 2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}} I_1 \alpha'} \right\rangle \\
&= 0.2365 \quad \mathrm{MPa/s}
\end{aligned}
$$

$$
\begin{aligned}
N_{(2)} &= t \left(\frac{d\epsilon_{12}}{dt} \right)^2 Var \left[2G - \frac{G^2}{G + 9K\alpha^2 + \frac{1}{\sqrt{3}} I_1 \alpha'} \right] \\
&= 0.0001t \quad (\mathrm{MPa/s})^2
\end{aligned}
$$

It should be noted that for Problem III, since the shear modulus is deterministic, the pre-yield elastic case is deterministic.

105.2.8 Probabilistic Elasto-Plasticity: Results and Verifications of Example Problems

In this section results are presented for elastic and elastic–plastic probabilistic 1D problem. The results are obtained by using FPK equation approach described in previous sections and in the companion paper (Jeremić et al., 2007a). In addition to that, the Monte Carlo based verification of developed solutions (results) is presented. The effort to verify developed solutions (that are based on FPK approach) plays a crucial role in presented development of probabilistic elasto–plasticity as there are no previously published solutions which could have been used for verification. In addition to that, verification and validation efforts should always be included in any modeling and simulations work (Oberkampf et al., 2002).

For linear elastic constitutive rate equations (Problem-I and pre-yield case of Problem-II) the verification is performed by comparing solutions obtained through the use of FPK equation approach with high accuracy (exact) solution, using a transformation method of random variables (Montgomery and Runger, 2003). This method is applicable as for rate-independent linear elastic case the 1D shear constitutive equation simplify to a linear algebraic equation of the form,

$$\sigma_{12} = 2G\epsilon_{12} = u(G, \epsilon_{12}) \tag{105.39}$$

Using the definition of strain rate, the above equation can be written in terms of time t as,

$$\sigma_{12} = 2G(0.054t) = v(G, t) \tag{105.40}$$

where, 0.054 $1/\mathrm{s}$ is the arbitrary strain-rate assumed for this example problem. According to the transformation method of random variables (Montgomery and Runger, 2003), and, given the continuous random variable (shear modulus) G, with PDF $g(G)$ and Eqs. (105.39) or (105.40) as one-to-one transformations between the values of random variables of G and σ_{12}, one can obtain the PDF of shear stress (σ_{12}), $P(\sigma_{12})$ as,

$$P(\sigma_{12}) = g(u^{-1}(\sigma_{12}, \epsilon_{12}))\,|J| \tag{105.41}$$

which will allow for predicting the evolution of PDF of σ_{12} with ϵ_{12} or,

$$P(\sigma_{12}) = g(v^{-1}(\sigma_{12}, t))\,|J| \tag{105.42}$$

Eq. (105.42) will predict the evolution of PDF of σ_{12} with t. In Eqs. (105.41) and (105.42), functions $G = u^{-1}(\sigma_{12}, \epsilon_{12})$ or $G = u^{-1}(\sigma_{12}, t)$ are the inverse of functions $\sigma_{12} = u(G, \epsilon_{12})$ or $\sigma_{12} = v(G, t)$ respectively and $J = du^{-1}(\sigma_{12}, \epsilon_{12})/d\sigma_{12}$ and $J = dv^{-1}(\sigma_{12}, t)/d\sigma_{12}$ are their respective Jacobians of transformations.

For non-linear elastic-plastic constitutive rate equations (post-yield cases of Problems II and III) the verification is done using Monte-Carlo simulation technique by generating sample data for material properties from standard normal distribution and by repeating solution of the deterministic elastic-plastic constitutive rate equation for each data generated above. The probabilistic characteristics of resulting random stress variable for each time (or strain) step are then easily computed. A relatively large number of data points (1,000,000) were generated for each material constant random variable for this simulation purpose.

105.2.9 Problem I

The evolution of PDF of shear stress with time and shear strain is shown in Figures 105.3 and 105.4. Presented PDFs are for linear elastic material with random shear modulus, and were obtained using *FPE approach* (Fig. reffigure:ElasticPDF) and *transformation method* (Fig. 105.4).

The contours of evolution of PDFs are compared in Fig. 105.5. Similarly, comparison of the evolution of mean and standard deviations are shown in Fig. 105.6. It can be seen from the comparison figure that even-though the FPK approach predicted the mean behavior exactly, it slightly over-predicted the standard deviation. This is because of the approximation used to represent the Dirac delta function, which was used as the initial condition for the FPK. One may note that at $\epsilon_{12} = 0$, the probability of shear stress σ_{12} should theoretically be 1 i.e. all the probability mass should theoretically be concentrated at $\sigma_{12} = 0$. As such, it would be best described by the Dirac delta function. However, for numerical simulation of FPK, Dirac delta function as initial condition was approximated with a Gaussian function of

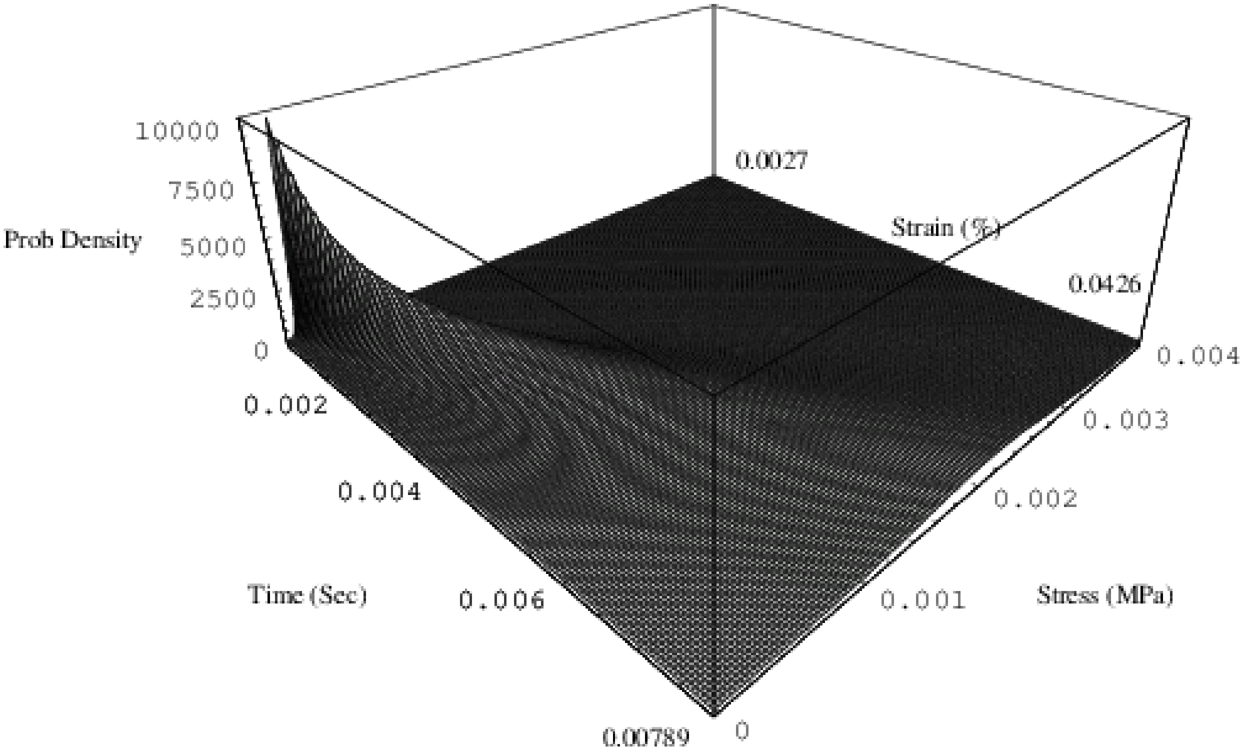

Figure 105.3: Evolution of PDF of shear stress versus strain (or time) for linear elastic material model with random shear modulus (Problem I) obtained using FPK equation approach.

mean zero and standard deviation of 0.00001 MPa, as shown in Fig. ??. This error in the initial condition advected and diffused into the domain with the simulation of the evolution process. This error could be minimized by better approximating the Dirac delta initial condition (but at higher computational cost). The effect of approximating the initial condition of the PDF of shear stress at $\epsilon_{12} = 0.0426$ % is shown in Fig. 105.7. In this figure the actual PDF at $\epsilon_{12} = 0.0426$ % obtained using the transformation method was compared with the PDFs at $\epsilon_{12} = 0.0426$ % obtained using the FPK approach with three different approximate initial conditions - all having zero mean but standard deviations of 0.01 MPa, 0.005 MPa and 0.00001 MPa.

One may also note that finer approximation of initial condition necessitates finer discretization of stress domain close to (or at) σ_{12} =0. The finite difference discretization scheme adopted here uses the same fine discretization uniformly all throughout the entire domain. It is noted that that fine, uniform discretization is not needed (and is quite expensive) in later stages of calculation of evolution of PDF, but is kept the same for simplicity sake. In presented examples, to properly capture the approximate initial condition (as shown in Fig. ??), the stress domain between –0.1 MPa and +0.1 MPa was discretized with a uniform step size of 0.000005 MPa and hence there is a total of $40,000$ nodes. This not only requires

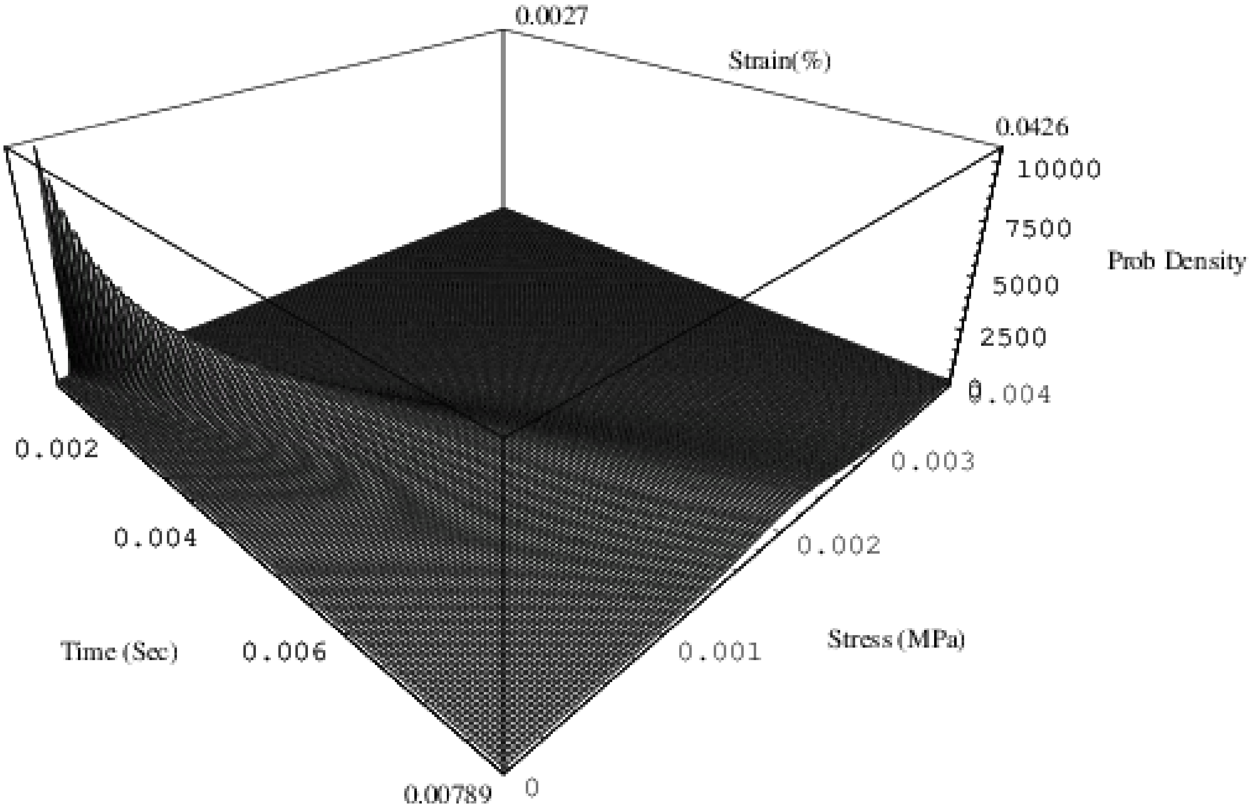

Figure 105.4: Evolution of PDF of shear stress versus strain (or time) for linear elastic material model with random shear modulus (Problem I) obtained using transformation method.

large computational effort but is also very memory sensitive. An adaptive discretization technique will be a much better approach to solving this problem. Current work is going on in formulating an adaptive algorithm for the solution of this type of problem.

105.2.10 Problem II

The solution to this problem involves the solving two FPK equations, one corresponding to the pre-yield elastic part and the other corresponding to the post-yield elastic-plastic part. The elastic part of this problem is identical to Problem–I. The initial condition for the post-yield elastic-plastic part of the problem is random and is shown in Fig. 105.8. It may be noted that this initial condition corresponds to the PDF of shear stress ($P(\sigma_{12})$) at yield obtained from the solution of FPK equation of the pre-yield elastic part. A view of the surface of evolution of the PDF of shear stress versus shear strain (time) is shown in Fig. 105.9. Another view to the PDF of stress–strain surface is shown in Fig. 105.10. It is noted that the yielding of this material occurred at t=0.00789 second (which is equivalent to ϵ_{12}=

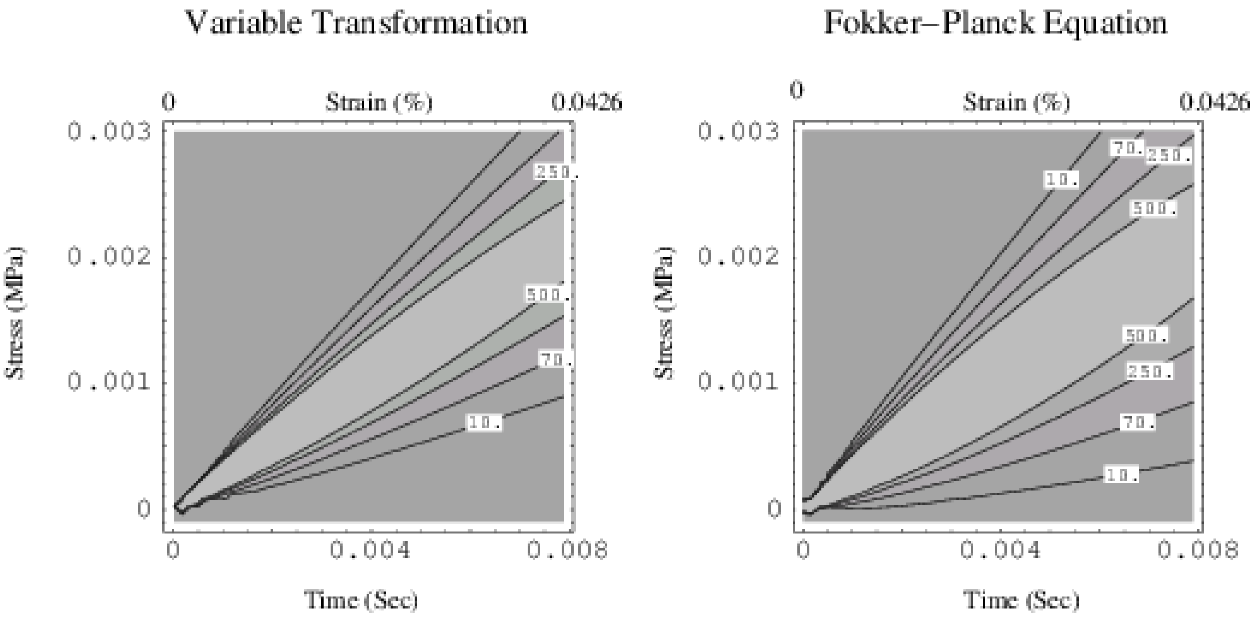

Figure 105.5: Comparison of Contours of Time (or Strain) Evolution of Probability Density Function for Shear Stress for Elastic Constitutive Rate Equation with Random Shear Modulus (Problem–I) for FPE Solution and Variable Transformation Method Solution.

0.0426 %). The evolution contours for PDF of shear stress versus strain (time) along with the mean and standard deviations are shown in Fig. 105.11. It can be seen from that figure that, as expected, the evolution of mean of shear stress changes slope after the material yielded. Another interesting aspect to note is the relative slope of the evolution of standard deviation with respect to the evolution of mean. The relative slope in the pre-yield elastic zone increases at a higher rate during the evolution process when compared with that in the post-yield elastic-plastic zone. In other words, in the evolution process the post-yield elastic–plastic constitutive rate equation did not amplify the initial uncertainty as much as the pre-yield elastic constitutive rate equation did. This can be easily viewed from Fig. 105.12 where the post-yield elastic-plastic evolution of PDF of shear stress was compared with fictitious extension of elastic evolution of PDF. Comparing the PDF of shear stress at $\epsilon_{12} = 0.0804\%$ (which is equivalent to $t = 0.01489s$), one can conclude that the variance of predicted elastic-plastic shear stress is much smaller (i.e. prediction is less uncertain) as compared to the same if the material were modeled as completely elastic.

Fig. 105.13 compares the evolution of means and standard deviations of predicted shear stress obtained using FPK equation approach and transformation method (pre-yield behavior)/Monte-Carlo approach (post-yield behavior). Although in the pre–yield response the FPK equation approach over-predicted the evolution of standard deviations because of reasons discussed earlier, in the post-yield

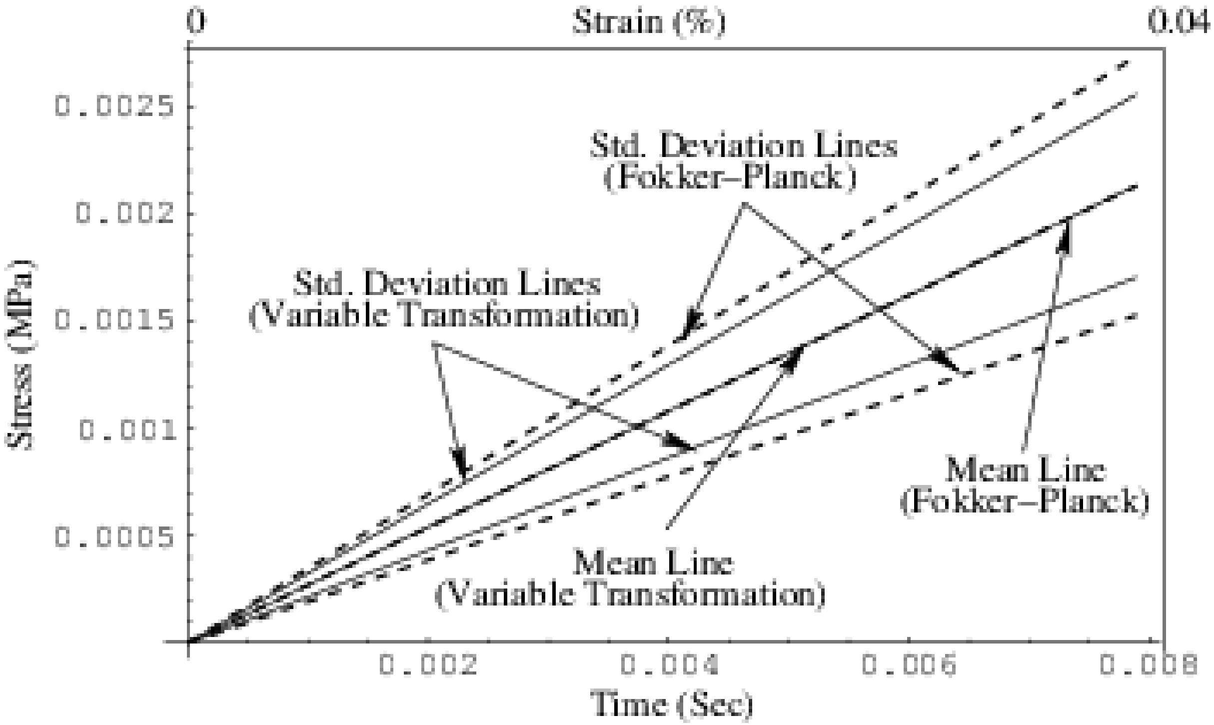

Figure 105.6: Comparison of Mean and Standard Deviation of Shear Stress for Elastic Constitutive Rate Equation with Random Shear Modulus (Problem–I) for FPE Solution and Variable Transformation Method Solution.

response it matched closely at regions further from the yielding region. The somewhat larger difference between FPK equation solution and the verification one (Monte Carlo solution) close to the yielding region is attributed to the fact that the initial condition for solution of post-yield elastic-plastic FPK equation was obtained from the solution of pre-yield elastic FPK equation. One way to better predict the overall probabilistic elastic-plastic behavior, would probably be to obtain the pre-yield elastic behavior through the transformation method and then use the FPK approach to predict post-yield elastic-plastic behavior.

105.2.11 Problem III

In this problem, the pre–yield linear elastic part is deterministic, however, at yield there is a distribution (with very small standard deviation) in shear stress due to assumed distribution in yield parameter α. The distribution in shear stress corresponds to the PDF of the random variable αI_1 (first invariant of the stress tensor or mean confining stress) and is assumed to be deterministic. This PDF of shear stress at yield was assumed to be the initial condition for the solution of post-yield elastic-plastic FPK equation

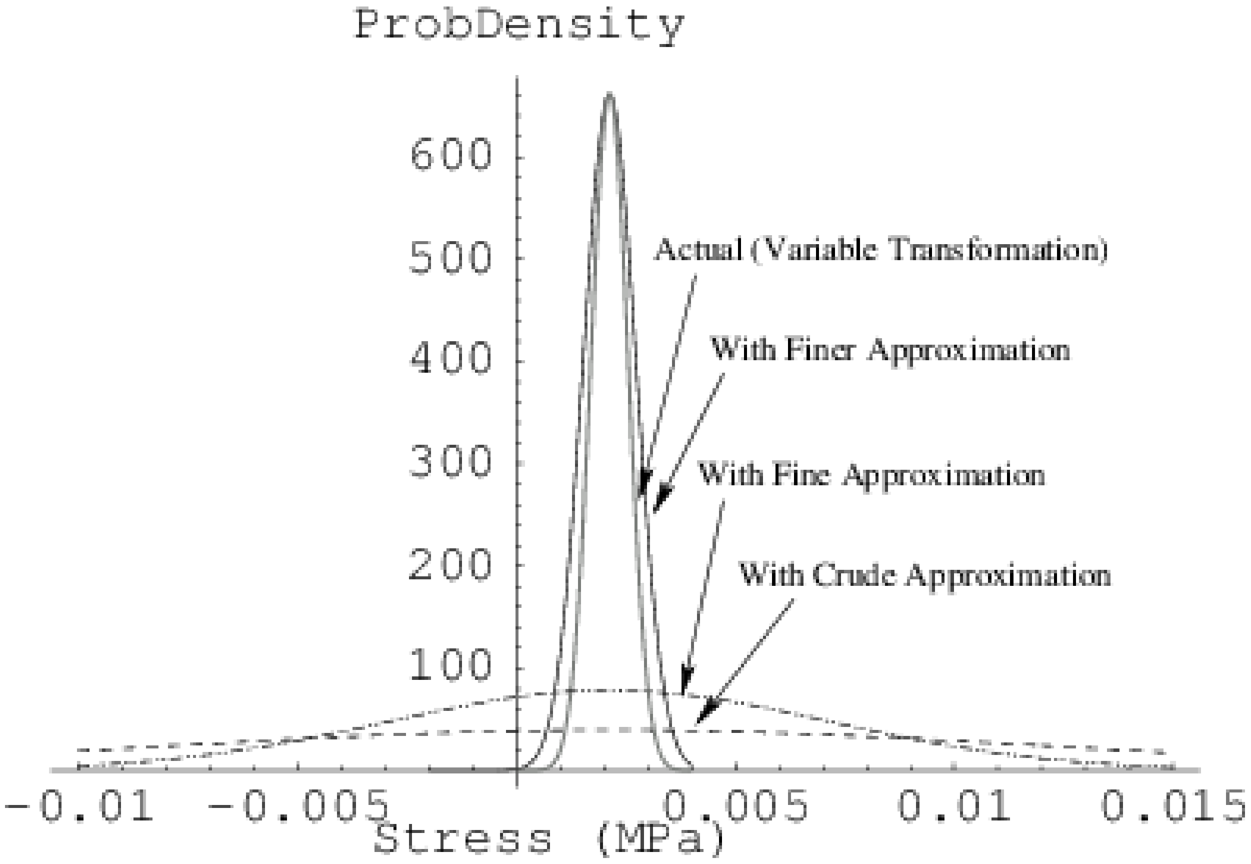

Figure 105.7: Effect of Approximating Function of Dirac Delta Initial Condition : PDF of Stress at Yield for Different Approximation of Initial Condition with Actual (Variable Transformation Method) Solution).

and is shown in Fig. 105.14.

The evolution of PDF for shear stress versus strain (time) is shown in Fig. 105.15. In addition to that the contours (including mean and standard deviation) of the evolution of PDF for shear stress versus strain (time) are shown in Fig. 105.16.

Looking at Fig. 105.16 and comparing the slopes of evolution of mean and standard deviation, one can conclude that the elastic-plastic evolution process didn't amplify the initial uncertainty in yield strength significantly. The initial (at yield) probability density function of shear stress just advected into the domain during the elastic–plastic evolution process without diffusing much. Fig. 105.15 clearly shows this advection process. The evolution of mean and standard deviations of shear stress obtained from the FPK equation approach was compared with those obtained from the Monte Carlo simulation and is shown in Fig. 105.17.

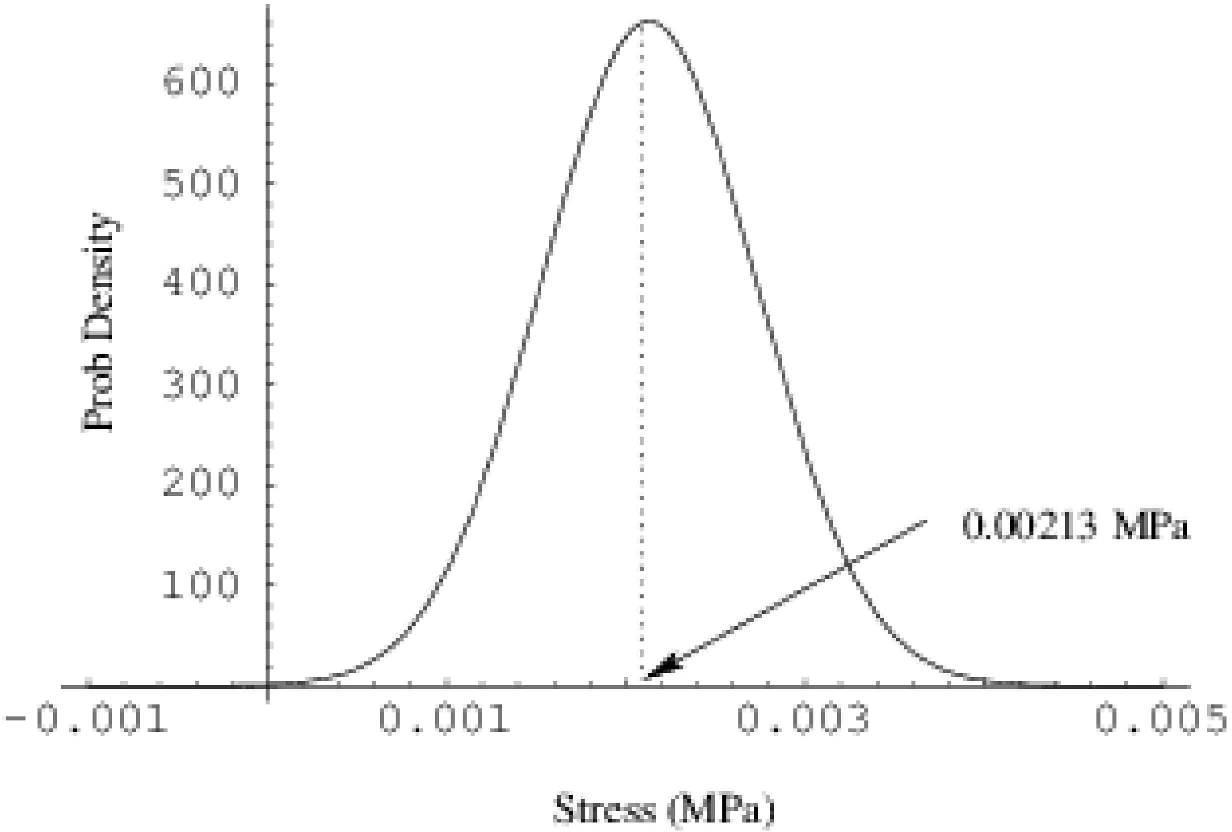

Figure 105.8: Initial condition for FPK equation for elastic–plastic zone (Problem–II).

105.3 Probabilistic Yielding and Cyclic Loading, 1D FPK Formulation

Modeling of geomaterials is inherently uncertain. These uncertainties stem from natural variability of geomaterials (spatial uncertainty), and testing and transformation errors (point uncertainty) (Lacasse and Nadim Lacasse and Nadim (1996), Phoon and Kulhawy Phoon and Kulhawy (1999a)). These uncertainties not only affect the failure characteristics of geomaterials, but also the behavior of geostructures, made with geomaterials. Traditionally, geotechnical engineering community deals with uncertainties in geomaterial by applying (large) factor of safety. However, use of large factors of safety results not only in over-expensive design, but also, sometimes, in unsafe structures (cf. Duncan Duncan (2000b)). Hence, in recent years, the geotechnical community has seen an increasing emphasis on probabilistic characterization of soil and subsequent reliability-based design.

One of the important aspects of probabilistic geomechanics simulation that has received less attention is the probabilistic constitutive problem. Among the few published papers were those by Fenton and Griffiths (Fenton and Griffiths (2002), Fenton and Griffiths (2003), Fenton and Griffiths (2005)) on

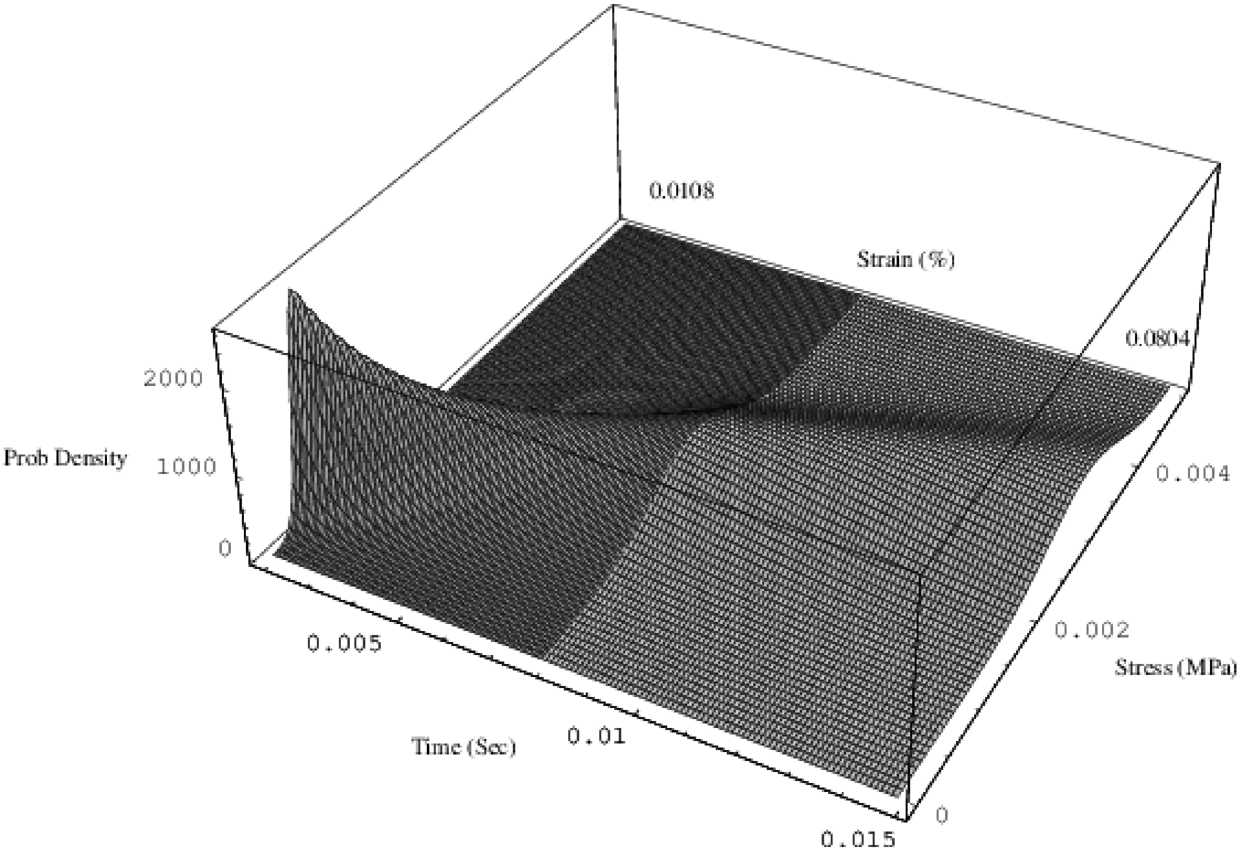

Figure 105.9: Evolution of PDF of shear stress versus strain (time) for elastic-plastic material with random shear modulus (Problem–II). View 1.

probabilistic simulation of spatially random c-ϕ soil using Monte Carlo technique, and those by Anders and Hori (Anders and Hori (1999), Anders and Hori (2000)) on probabilistic simulation of von Mises elastic-perfectly plastic material using perturbation technique. Both Monte Carlo and perturbation techniques have their inherent drawbacks (Matthies et al. Matthies et al. (1997), Keese Keese (2003)) and in dealing with those, recently, Jeremić et al. Jeremić et al. (2007b) proposed Eulerian–Lagrangian form of Fokker–Planck–Kolmogorov equation (FPKE) approach (cf. Kavvas Kavvas (2003)) to modeling and simulation for probabilistic elasto–plasticity. FPKE approach to probabilistic elasto–plasticity not only overcomes the drawbacks associated with other probabilistic simulation techniques, but also is fully compatible with the incremental theory of elasto–plasticity, and hence can easily be applied to probabilistic modeling and simulation of different elastic–plastic constitutive models. Solution strategies for FPK partial differential equation, corresponding to elastic–plastic constitutive rate equation and simulated probabilistic stress-strain responses under monotonic loading, assuming mean stress yielding, were discussed by Sett et al. (Sett et al. (2007c), Sett et al. (2007d)) for both linear and non-linear

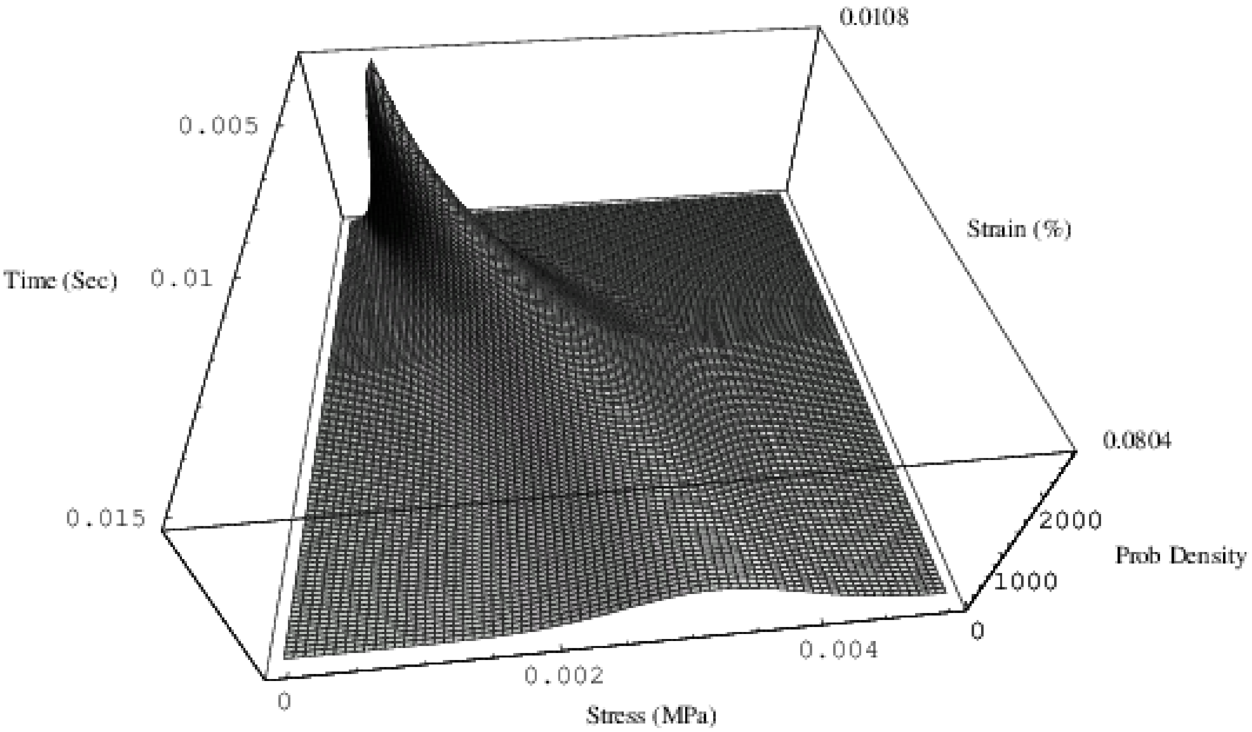

Figure 105.10: Evolution of PDF of shear stress versus strain (time) for elastic-plastic material with random shear modulus (Problem-II). View 2.

hardening models. The concept of probabilistic yielding was introduced and its effect on constitutive simulation under monotonic loading was discussed by Jeremić and Sett Jeremić and Sett (2009b). It was shown that due to uncertainty in yield function (stress), there is always a possibility, depending upon the magnitude of uncertainty, that plastic behavior starts at very very low strain and influence of elastic behavior continues far into plastic domain (at large strains) and hence, the ensemble average (mean) of all the possibilities or the most probable (mode) possibility differ from deterministic behavior. In addition to that, a very realistic, smooth transition between elastic and plastic domains was observed even for elastic perfectly plastic models. Further, nonlinear behavior was observed even for linear hardening models.

In this paper, the concept of probabilistic yielding is extended to 1–D cyclic simulations of geomaterials. Both elastic–perfectly plastic and hardening-type material model are considered. The numerical technique of solving FPKE cyclically with probabilistic yielding is discussed. Simulated responses were discussed in terms of probability density function (PDF) and its statistical moments.

Modeling of geomaterials is inherently uncertain. This uncertainty stems from natural variability of geomaterials (spatial uncertainty), and testing and transformation errors (point uncertainty) (Lacasse

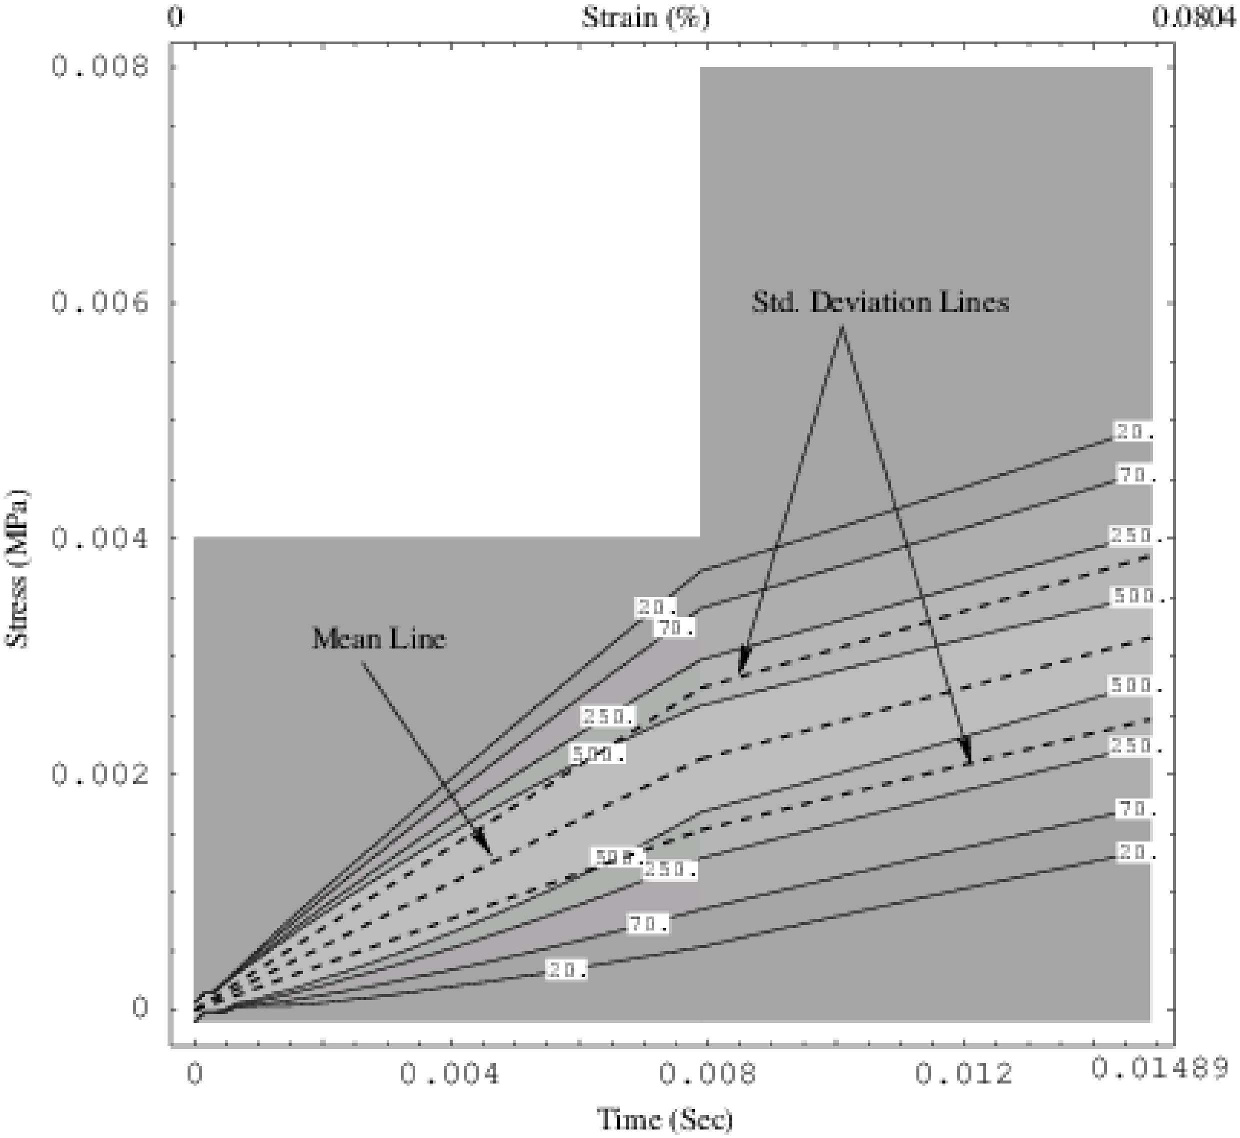

Figure 105.11: Contour of evolution of PDF for shear stress versus strain (time) for elastic-plastic material with random shear modulus (Problem–II).

and Nadim Lacasse and Nadim (1996), Phoon and Kulhawy Phoon and Kulhawy (1999a)). These uncertainties not only affect the failure characteristics of geomaterials, but also the behavior of geostructures, made with geomaterials. Traditionally, geotechnical engineering community deals with uncertainties in geomaterial by applying (large) factor of safety. However, use of large factors of safety results not only in over-expensive design, but also, sometimes, in unsafe structures (cf. Duncan Duncan (2000b)). Hence, in recent years, the geotechnical community has seen an increasing emphasis on probabilistic characterization of soil and subsequent reliability-based design.

105.3.1 Fokker–Planck–Kolmogorov Approach to Probabilistic Elasto–Plasticity

The Eulerian–Lagrangian form Fokker–Planck–Kolmogorov equation (cf. Kavvas Kavvas (2003)) corresponding to generalized 1–D constitutive rate equation can be written as (Jeremić et al. Jeremić et al. (2007b)):

$$
\begin{aligned}
&\frac{\partial P(\sigma(x_t,t),t)}{\partial t} = \\
&\quad \frac{\partial}{\partial \sigma}\left[\left\{\left\langle \eta(\sigma, D, \epsilon; x_t, t)\right\rangle + \int_0^t d\tau Cov_0\left[\frac{\partial \eta(\sigma, D, \epsilon; x_t, t)}{\partial \sigma}; \eta(\sigma, D, \epsilon; x_{t-\tau}, t-\tau)\right]\right\} P(\sigma(x_t,t),t)\right] \\
&\quad + \frac{\partial^2}{\partial \sigma^2}\left[\left\{\int_0^t d\tau Cov_0\left[\eta(\sigma, D, \epsilon; x_t, t); \eta(\sigma, D, \epsilon; x_{t-\tau}, t-\tau)\right]\right\} P(\sigma(x_t,t),t)\right]
\end{aligned}
\tag{105.43}
$$

where, $P(\sigma(x_t,t),t)$ is the probability density of stress (σ) at (pseudo) time t, and η is the operator variable, obtained by collecting together all the operators and variables on the r.h.s of the generalized constitutive rate equation:

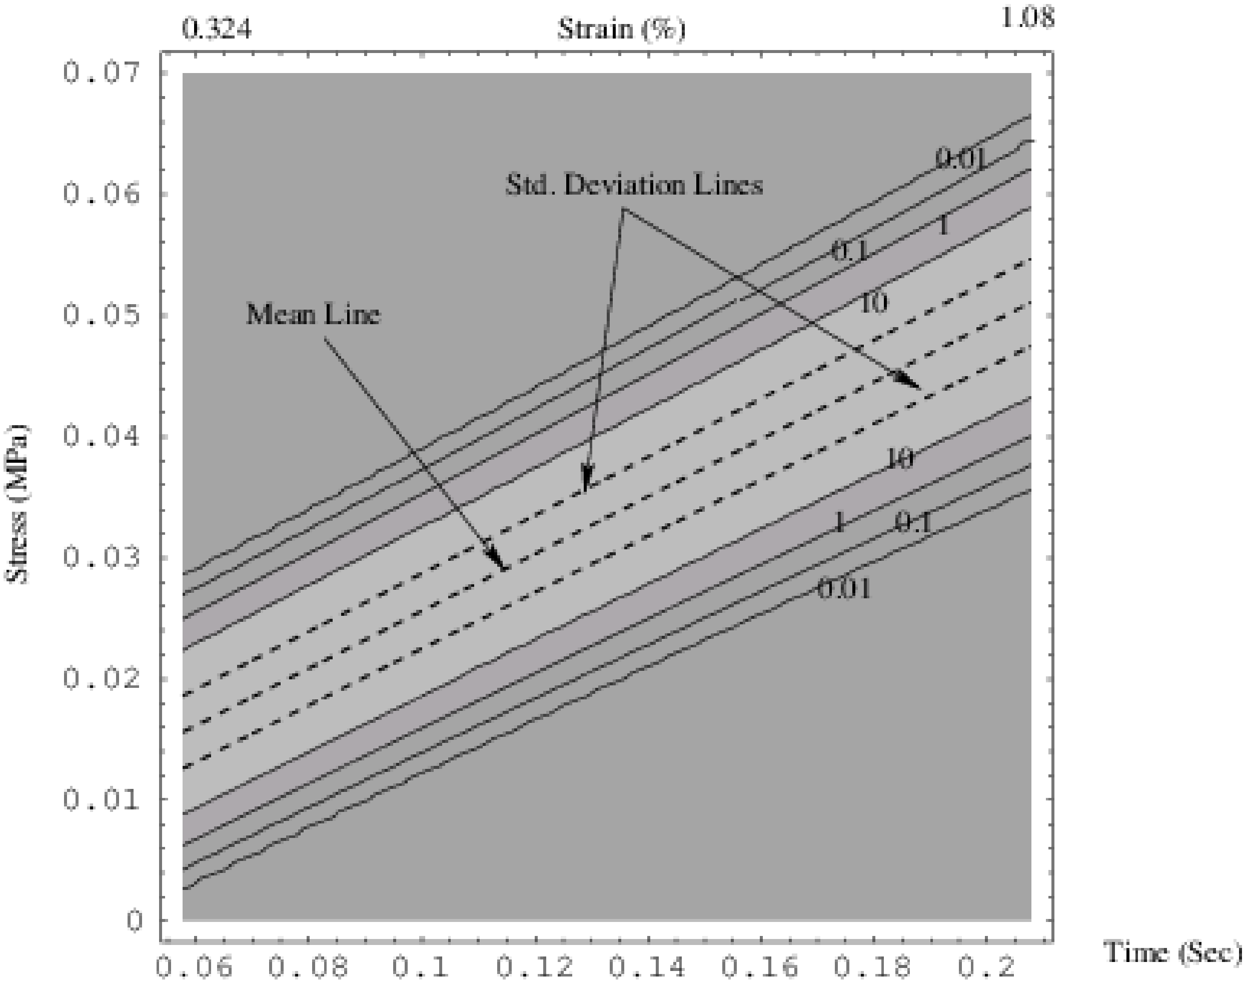

Figure 105.16: Contour PDF for shear stress versus strain (time) for elastic–plastic material with random yield strength (Problem–III).

$$\frac{d\sigma(x_t,t)}{dt} = \eta(\sigma, D, \epsilon; x_t, t) \tag{105.44}$$

In Eq. (105.66), ϵ is the strain, and D is the tangent modulus, which could be elastic or elastic–plastic:

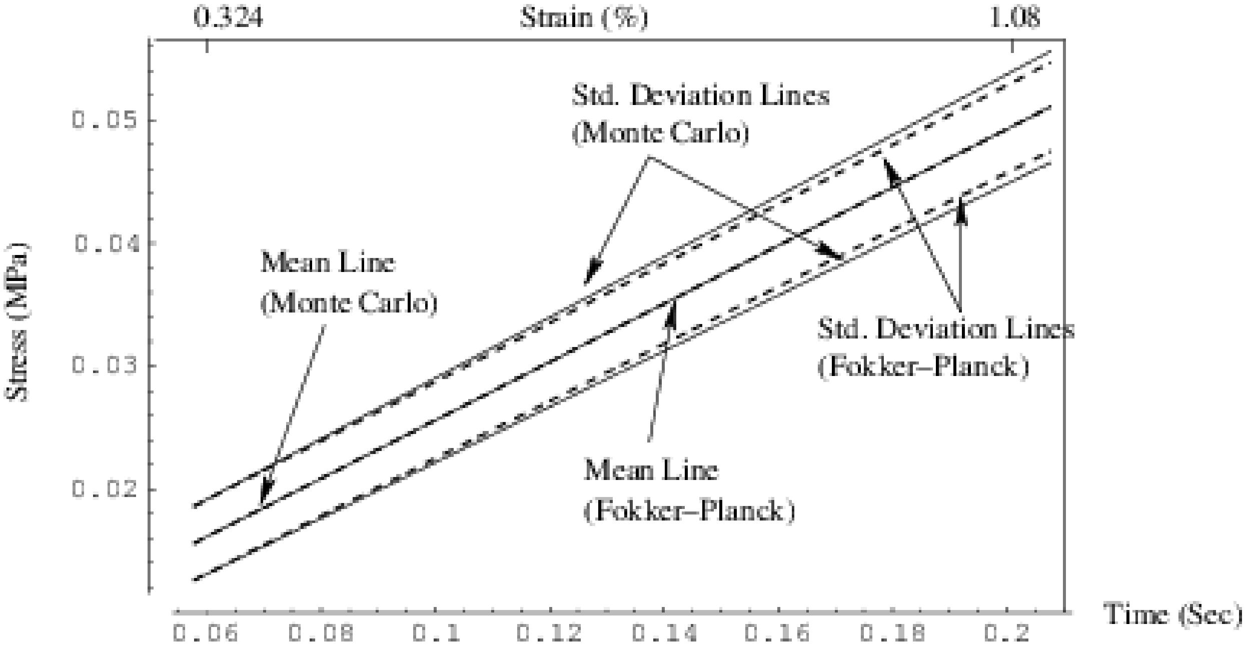

Figure 105.17: Comparison of Mean and Standard Deviation of Shear Stress for Elastic-Plastic Constitutive Rate Equation with Random Yield Strength (Problem-III) for FPE Solution and Monte Carlo Simulation Solution

$$D = \begin{cases} D^{el} & \text{elastic} \\ \\ D^{el} - \dfrac{D^{el} \dfrac{\partial U}{\partial \sigma} \dfrac{\partial f}{\partial \sigma} D^{el}}{\dfrac{\partial f}{\partial \sigma} D^{el} \dfrac{\partial U}{\partial \sigma} - \dfrac{\partial f}{\partial q_*} r_*} & \text{elastic-plastic} \end{cases} \tag{105.45}$$

where, D^{el}, f, U, q_*, and r_* are elastic modulus, yield surface, plastic potential surface, internal variable(s), and rate(s) of evolution of internal variable(s) respectively.

Eq. (105.65) is the most general form of elastic–plastic constitutive rate equation, written in probability density space. This equation (Eq. (105.65)) can be written in a more compact form:

$$\frac{\partial P(\sigma(x_t,t),t)}{\partial t} = \frac{\partial}{\partial \sigma} \left\{ N_{(1)} P(\sigma(x_t,t),t) \right\} + \frac{\partial^2}{\partial \sigma^2} \left\{ N_{(2)} P(\sigma(x_t,t),t) \right\} \tag{105.46}$$

where, $N_{(1)}$ and $N_{(2)}$ are advection and diffusion coefficients respectively, and are material model specific. By specializing Eq. (105.46) to (any) particular constitutive model, the resulting FPKE can be solved to obtain the probability density function of stress response, given uncertainties in material properties and driving strain. However, difference in material behavior in elastic and elastic-plastic regions necessities solution of FPKE twice - one corresponding to elastic constitutive equation (with $N^{el}_{(1)}$ and $N^{el}_{(2)}$, the advection and diffusion coefficients corresponding to elastic constitutive equation) and the other corresponding to elastic–plastic constitutive equation (with $N^{ep}_{(1)}$ and $N^{ep}_{(2)}$, the advection and diffusion coefficients corresponding to elastic–plastic constitutive equation). The switch from elastic to elastic–plastic region (solution) can be controlled using mean stress yielding:

$$\begin{array}{lll} \text{if} & \langle f \rangle < 0 \vee \left(\langle f \rangle = 0 \wedge d \langle f \rangle < 0 \right) & \text{use elastic FPKE} \\ \text{or, if} & \langle f \rangle = 0 \vee d \langle f \rangle = 0 & \text{use elastic–plastic FPKE} \end{array} \tag{105.47}$$

However, difficulty arises if the material yield parameter(s) are uncertain, as the mean yield criteria then does not account for the complete probabilistic yielding of material. For example, such mean yielding will neglect the possibilities of elastic–plastic behavior in the elastic region and vice versa. The concept of probabilistic yielding overcomes this limitation, as it solves Eq. (105.46) once, with equivalent advection and diffusion coefficients, $N^{eq}_{(1)}$ and $N^{eq}_{(2)}$ (Jeremić and Sett Jeremić and Sett (2009b)):

$$\begin{array}{l} N^{eq}_{(1)}(\sigma) = (1 - P[\Sigma_y \leq \sigma])N^{el}_{(1)} + P[\Sigma_y \leq \sigma]N^{ep}_{(1)} \\ N^{eq}_{(2)}(\sigma) = (1 - P[\Sigma_y \leq \sigma])N^{el}_{(2)} + P[\Sigma_y \leq \sigma]N^{ep}_{(2)} \end{array} \tag{105.48}$$

where $(1 - P[\Sigma_y \leq \sigma])$ represents the probability of material being elastic, while $P[\Sigma_y \leq \sigma]$ represents the probability of material being elastic–plastic. The probabilities of material being elastic and the probabilities of material being elastic–plastic can easily be calculated from the cumulative density function of yield function (stress).

It is worth noting that the probabilistic yield criterion (Eq. (105.48)) represents probabilistic restatement of the deterministic yield criteria. The probabilistic yield criteria is introduced (or, the deterministic yield criteria is written in probability space) in order to properly model uncertain (probabilistic) yield strength.

It is also very interesting to note that proposed approach for calculating equivalent advection and diffusion coefficients is similar to the solution strategy of famous Black–Scholes Black and Scholes (1973) equation in financial engineering modeling of European option, where probabilities of exercise of the (European) option, obtained from cumulative density functions, are multiplied with stock price and present value of option strike price to calculate the option price.

105.3.2 Elastic–Perfectly Plastic Material

In this section, the FPKE–approach, along with the concept of probabilistic yielding, is applied to simulate 1–D (shear stress–shear strain) cyclic behavior of elastic–perfectly plastic material. Only von Mises material model has been considered. It may, however, be noted that presented development is general enough to be used with any material model and that von Mises is just one such model we use for illustration purposes.

The von Mises yield criteria can be written as:

$$\sqrt{J_2} - k = 0 \tag{105.49}$$

where, k is a material parameter (yield strength like) and $J_2 = 3/2 s_{ij} s_{ij}$ is the second invariant of deviatoric stress tensor $s_{ij} = \sigma_{ij} - 1/3\sigma_{kk}\delta_{ij}$. For 1–D shear, Eq. (105.49) becomes:

$$|\sigma| - \sigma_y = 0 \quad \text{or} \quad \sigma = \pm\sigma_y \tag{105.50}$$

The yielding occurs at a yield stress of $\pm\sigma_y$. It, however, is important to note that both σ_y and σ are uncertain and are described by their respective probability density functions. For elastic–perfectly plastic material, the distribution of yield stress (σ_y) is given by its experimentally measured initial distribution, and remains constant. The stress (σ), however, evolves according to the governing FPKE (Eq. (105.46)) and its distribution is given by the solution of the governing FPKE (Eq. (105.46)). For 1–D von Mises elastic–perfectly plastic shear constitutive model, the elastic and the elastic–plastic advection and diffusion coefficients of the governing FPKE (Eq. (105.46)), becomes:

$$\begin{aligned} N^{el}_{(1)} &= \frac{d\epsilon_{xy}}{dt}\langle G\rangle \quad ; \quad N^{el}_{(2)} = t\left(\frac{d\epsilon_{xy}}{dt}\right)^2 Var[G] \\ N^{ep}_{(1)} &= 0 \quad ; \quad N^{ep}_{(1)} = 0 \end{aligned} \tag{105.51}$$

where, G is the shear modulus, $d\epsilon_{xy}$ is the (deterministic) incremental shear strain, t is the pseudo time, $\langle\cdot\rangle$ represents expectation operation and $Var[\cdot]$ represents variance operation. The equivalent advection and diffusion coefficients (refer Eq. (105.48)) for von Mises elastic–perfectly plastic material, then, becomes:

$$\begin{aligned} N^{eq}_{(1)}(\sigma) &= (1 - P[\Sigma_y \leq \sigma])\frac{d\epsilon_{xy}}{dt}\langle G\rangle \\ N^{eq}_{(2)}(\sigma) &= (1 - P[\Sigma_y \leq \sigma])t\left(\frac{d\epsilon_{xy}}{dt}\right)^2 Var[G] \end{aligned} \tag{105.52}$$

One may note that, in deriving the elastic and elastic–plastic advection and diffusion coefficients (Eq. (105.51)), it was assumed that spatial random field material properties (G, and σ_y) would be first discretized into random variables, for example at Gauss points, by appropriate tools, for example Karhunen–Loève expansion (Karhunen Karhunen (1947), Loève Loève (1948), Ghanem and Spanos Ghanem and Spanos (1991)). In other words, the solution of FPKE, with advection and diffusion coefficients given by Eq. (105.52), represents point–location scale von Mises elastic–perfectly plastic material behavior, and not the local–average material behavior. The local–average material behavior, if sought for, can then be assembled using polynomial chaos expansion (Wiener Wiener (1938), Ghanem and Spanos Ghanem and Spanos (1991)).

105.3.2.1 Probability Density Function

The FPKE (Eq. (105.46)), with advection and diffusion coefficients given by Eq. (105.52), was solved incrementally with pseudo time steps using method of lines. The stress domain of the Fokker–Planck–Kolmogorov PDE was discretized first on a uniform grid by central differences, and thereby obtaining a series of ODE. The series of ODEs was then solved, after incorporating boundary conditions, simultaneously and incrementally, with n pseudo time steps, using a standard open–source ODE solver, SUNDIALS Hindmarsh et al. (2005), which utilizes ADAMS method and functional iteration.

The yield shear strength (σ_y) of the material was assumed to have a mean value of 60 kPa with a COV of 30%, values typical for clay (Federal Highway Administration Federal Highway Administration (2002), Lacasse and Nadim Lacasse and Nadim (1996)). Also, the yield shear strength was assumed to be either normal or Weibull (with shape parameter of 3.31 and scale parameter of 0.067) distribution as shown in Fig. 105.18. The shear modulus (G) was also assumed to be either normal or Weibull distribution, but

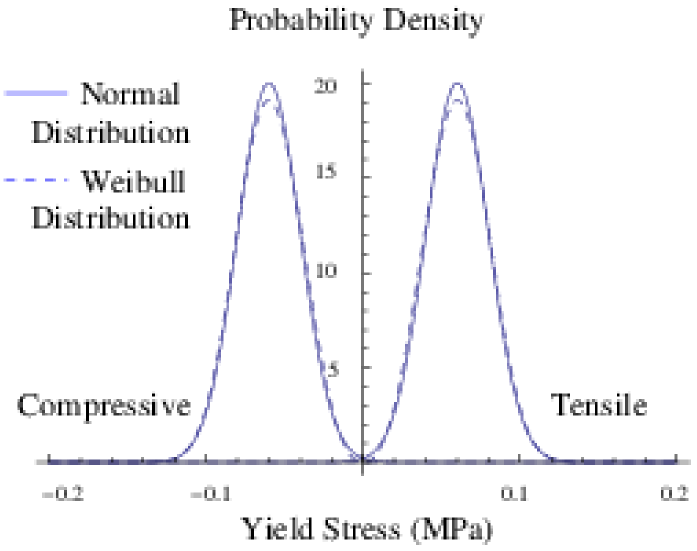

Figure 105.18: Elastic–perfectly plastic probabilistic model: PDF of yield stress

with a mean value of 100 MPa and a COV of 25%. The cyclic probabilistic von Mises, elastic–perfectly plastic shear stress–shear strain response (evolutionary probability density function (PDF) of shear stress), for the case where both yield shear strength (σ_y) and shear modulus (G) are normally distributed, is shown in Fig. 105.19. Two different views of the loading–unloading–reloading cycle are shown, focusing on the

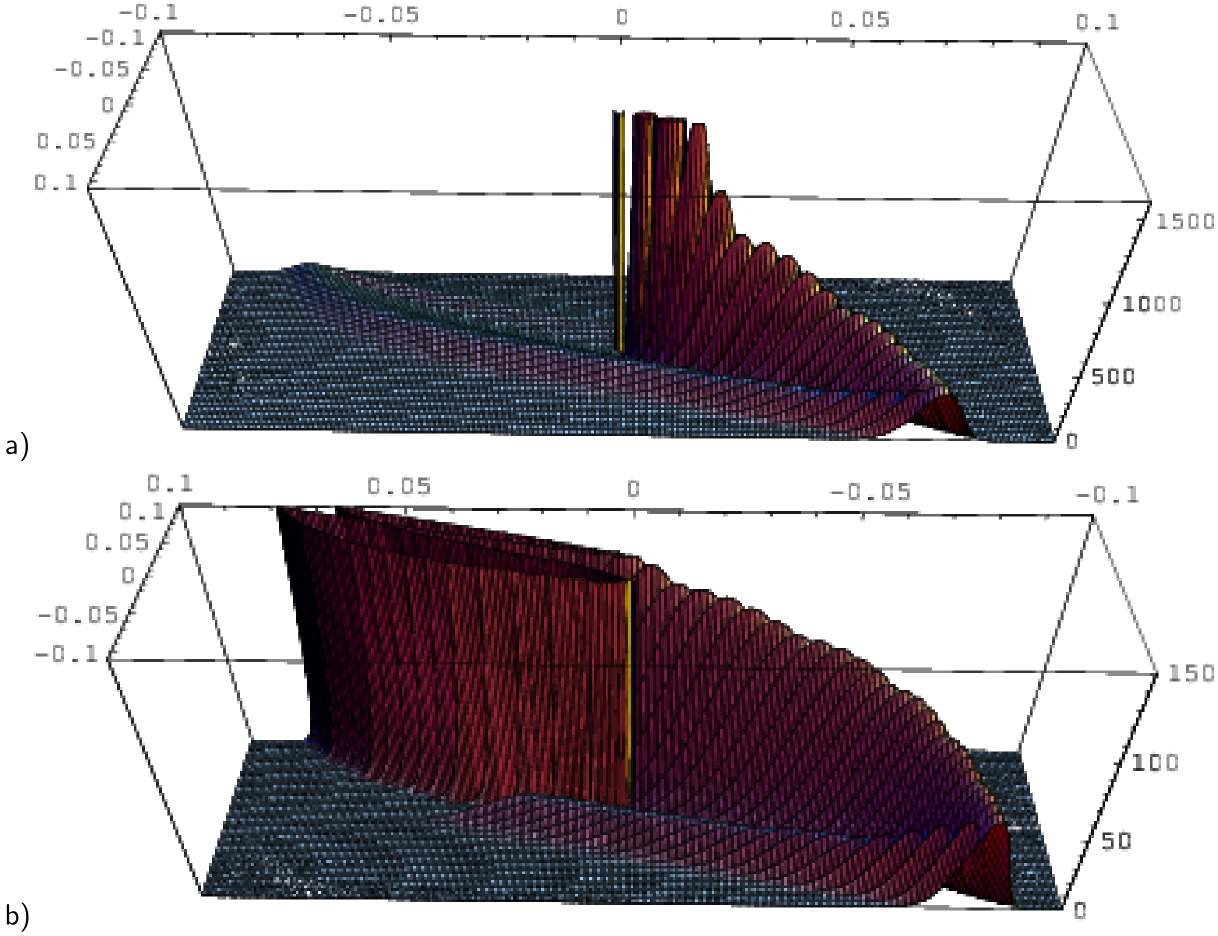

Figure 105.19: Elastic–perfectly plastic probabilistic model under cyclic loading: evolutionary PDF of shear stress (a) view from the junction of loading and unloading branches (probability densities of shear stress are truncated at a value 1500 for clarity of the plot) and (b) view from the junction of unloading and reloading branches (probability densities of shear stress are truncated at a value of 150 for clarity of the plot)

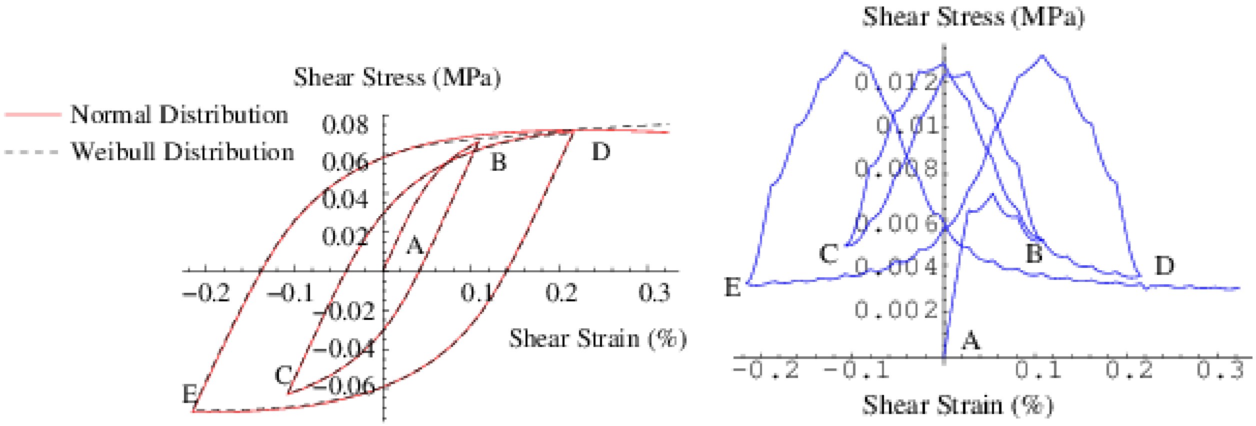
transition between loading and unloading, and unloading and reloading branches. As can be seen from Fig. 105.19, PDF for initial stress (a deterministic Dirac delta function at stress–strain origin) advected and diffused into the domain, governed by the advection and diffusion coefficients (Eq. (105.52)). It is very important to also note that, even–though the deterministic response for von Mises elastic–perfectly plastic material is bi–linear, due to introduced uncertainties in yielding, the probabilistic response is non–linear from the beginning. That is, due to uncertainty in yield strength, there is a (small) possibility that the material becomes elasto–plastic from the very beginning of loading. This possibility has been quantified from the PDF of the yield strength and taken into consideration implicitly during simulation using the equivalent advection and diffusion coefficients ($N^{eq}_{(1)}$ and $N^{eq}_{(2)}$, refer Eq. (105.52)). Those coefficients assigns probability weights to the realizations of stress response based on the probability of material being elastic or elastic–plastic. Initially, in the loading branch, at small strains, the probability of material being elastic–plastic is very small and hence, the initial probabilistic stress response (ensemble of all realizations) is closer (but not fully) to linear, elastic response. However, as strain increases, the probability of elastic–plastic material behaving increases and the probabilistic stress response gradually becomes more elastic–plastic (Fig. 105.19(a)).

Upon unloading, the material behaves as (mostly) elastic since elastic–plastic probability weights from the governing PDF of mirror image (negative) of shear strength (Fig. 105.18) are initially very small. During later stages of unloading (loading in the opposite direction), and similar to the loading branch, the elastic–plastic probability weights increase and gradually transition the response toward elasto–plasticity (Fig. 105.19(b)). Similar to this, in the subsequent reloading branch, the probability weights are again governed the PDF of (positive, loading branch of) shear strength (Fig. 105.18), and hence the probabilistic response is again initially more linear, elastic, while gradually it transitions to full elasto–plasticity.

105.3.2.2 Case of Increasing Strain Loops

In Fig. 105.20, the evolutionary PDF of shear stress for von Mises elastic–perfectly plastic material (refer Fig. 105.19) is plotted in terms of its statistical moments – the evolutionary mean (Fig. 105.20(a)), and standard deviation (Fig. 105.20(b)) of shear stress – for the first couple of cycles with increasing strain loops. The mean response, when both the yield shear strength (σ_y) and the shear modulus (G) are modeled as Weibull distribution, is also shown in Fig. 105.20(a). The oscillations in the evolution of standard deviation of shear stress with shear strain are due to step size issue, inherent to the forward Euler method that has been used in solving the FPKE. Work is underway to implement linearly implicit mid-point rule for solving the FPKE corresponding to elastic-plastic constitutive rate equation.

The very important observation that can be made using Fig. 105.20(a) is that, if one consider uncertainties in geomaterial properties, even the simplest elastic–perfectly model, captures some of the very important features of geomaterial behaviors. For example, reduction of (secant) modulus with cyclic strain, commonly observed in soil (cf. Vucetic and Dobry Vucetic and Dobry (1991)), is fairly nicely captured. If using deterministic models, this feature can only be somewhat successfully modeled with



(a) (b)

Figure 105.20: Elastic–perfectly plastic probabilistic model under cyclic loading with increasing strain loops: evolution of (a) mean and (b) standard deviation of shear stress

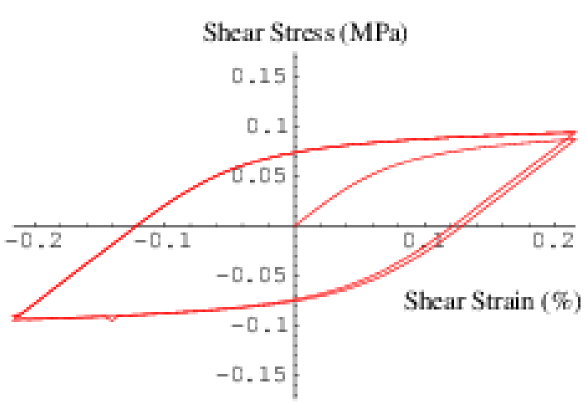
fairly complex models, which require many more parameters. It is important to remark that for our probabilistic modeling, (only) statistical distributions (probability density functions) of shear modulus (G) and shear strength (σ_y), are needed. Expansion of elastic–plastic modeling into probability space seems to have added significant new capabilities to modeling.

105.3.2.3 Case of Constant Strain Loops

This von Mises elastic–plastic material, however, didn't exhibit (secant) modulus degradation, commonly observed in clay (cf. Vucetic and Dobry Vucetic and Dobry (1988)), when the material is cycled repeatedly at the same strain. Fig. 105.21(a) shows such probabilistic response (mean of shear stress). The material was cycled repeatedly up to 0.2% strain. Only first three cycles are shown. It is important to note that the von Mises mean elastic–plastic material behavior is function of both the mean and standard deviation of both shear modulus (G) and yield shear strength (σ_y). The same von Mises elastic–perfectly plastic model with a different set of material properties could, however, be able to capture the degradation of mean (secant) shear modulus. For example, Japanese stiff clay, when modeled as von Mises elastic–perfectly plastic material, exhibited modulus degradation with number of cycles (Sett et al. Sett et al. (2008))

105.3.2.4 Monotonic Loading

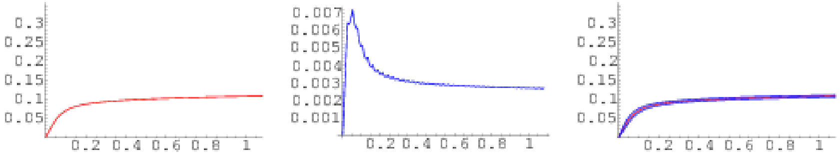
For completeness of comparison, the monotonic behavior of this probabilistic von Mises perfectly plastic material is also shown (refer Fig. 105.22). As can be observed from Fig. 105.22(a), the mean shear



(a) (b)

Figure 105.21: Elastic–perfectly plastic probabilistic model under cyclic loading with all equal loops: evolution of (a) mean and (b) standard deviation of shear stress

stress non–linearly increases with shear strain before reaching the perfectly plastic state.



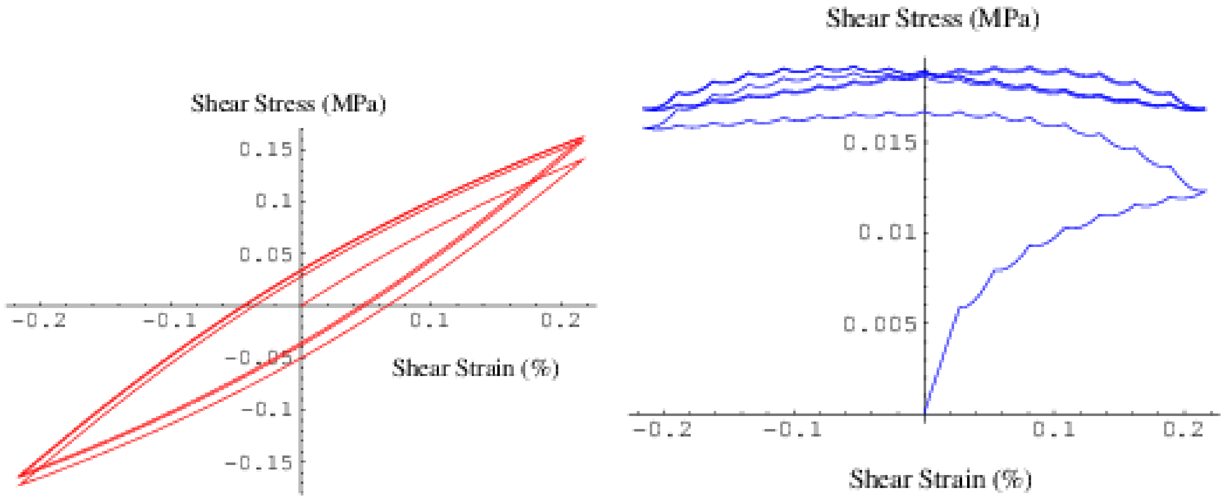
(a) (b)

Figure 105.22: Elastic–perfectly plastic probabilistic model under monotonic loading: evolution of (a) mean, (b) standard deviation, and (c) mean ± standard deviation of shear stress

Physically, one may visualize the probabilistic soil constitutive response as an ensemble of the behaviors of infinite number of soil particles in a representative volume element (RVE), for example, a laboratory soil specimen. The behavior of an individual soil particle in a RVE is governed, in case of elastic–perfectly plastic material, by its modulus and strength. However, if the modulus and strength of each particle are different, for example, governed by their respective PDF, then each particle would behave differently. The PDF of the response behavior then represents the ensemble of all such behaviors, with their respective probability weights. The mean, on the other hand, represents the ensemble average of all such behaviors. In this context, it is important to note that the behaviors presented in this paper do not take into account the correlation between soil particles (scale effect). The scale effect can be accounted for, among others, using stochastic elastic–plastic finite element technique. Sett Sett (2007) proposed one such finite element method by extending the spectral approach to stochastic finite element (cf. Ghanem and Spanos Ghanem and Spanos (1991)) to elastic–plastic problems by updating the material properties at Gauss integration points using the FPKE approach, as the material plastifies.

Further to the promise of an alternate approach to geomaterial modeling, probabilistic approach also quantifies our confidence in the simulated behavior of geomaterials. FPKE based probabilistic elasto–plasticity solves for second-order accurate evolutionary PDF of shear stress (Fig. 105.19). Ability to obtain the PDF of stress accurately is very important in failure simulation of geomaterials, as they often fail at low probabilities (tails of PDF). A full PDF contains enormous amount of information. From the PDF, other than the statistical moments, other useful engineering information, for example, the probability of exceedance, most probable solution, as well as some derivative application like sensitivity analysis can be easily obtained or derived. Figs. 105.20(b) and 105.21(b) show one of the important confidence measuring parameters, the evolutionary standard deviation of shear stress (square-root of second moment of the evolutionary PDF of shear stress (Fig. 105.19)), for cyclic responses with increasing loops and all equal loops, respectively. As can be observed from the above figures (Figs. 105.20(b) and 105.21(b)), inside any branch (loading, unloading, re–loading, re–unloading, ...), as well as in Fig. 105.22(b), where the monotonic response is shown, the standard deviation, first increases and then decreases. This is because, initially, when the material is mostly elastic, both the uncertainties in shear modulus (G) and yield strength (σ_y) are governing. As material becomes mostly elastic–plastic, the influence of uncertainty in shear modulus (G) decreases. However, it is important to note that this type of standard deviation response is not generic to all von Mises elastic–perfectly plastic material. The standard deviation response is very much dependent on the amount uncertainties present in both shear modulus (G) and yield strength (σ_y). For example, Fig. 105.23(b), shows probabilistic response of cyclic behavior of the same material model, except that COV of yield strength (σ_y), is now assumed to be 300%. The standard deviation response shown here is always increasing which is completely different from what was observed in previous case (Figs. 105.20(b), 105.21(b) and 105.22(b))). This is because, for this material, the COV of shear modulus (assumed 30%) is non–significant, compared to the COV of yield strength (assumed 300%), and hence, the standard deviation response (Fig. 105.23(b)) is predominantly influenced by the uncertainty in yield strength (σ_y). Similar standard deviation response can be observed in Fig. 105.24(b), where the material with large COV of yield strength was subjected to monotonic loading.

It is also interesting to compare Figs. 105.21(a) and 105.23(a). Both are mean responses of von Mises elastic–perfectly plastic material model with same material parameters, except with different COV of yield strength. COV of yield strength for simulation in Fig. 105.21(a) was 30% and that for simulation in Fig. 105.23(a) was 300%. It is observed that a completely different responses were obtained. The effect



(a) (b)

Figure 105.24: Elastic–perfectly plastic probabilistic model under monotonic loading (model parameters are exactly the same as used for simulation in Fig. 105.22, but with very large yield uncertainty): evolution of (a) mean, mode, (b) standard deviation, and (c) mean ± standard deviation of shear stress

of COV of yield strength on monotonic mean behavior can, similarly, be compared in Figs. 105.22(a) and 105.24(a).

105.3.2.5 Hardening Material

In this section, the influence of probabilistic yielding is evaluated on cyclic responses of isotropic and kinematic hardening materials. To this end, the same example, as discussed in the previous section (Section 105.3.2) is used but with appropriate hardening rule – isotropic or kinematic.

The main difference between the simulations shown in Section 105.3.2 for elastic–perfectly plastic material is that for a hardening material the internal variables (q_*, refer Eq. (105.45)) will evolve as the material plastifies. Such evolution (change) of internal variables is here assumed to be a function of plastic strain. The FPKE that govern the probabilistic evolution of internal variable (q) can be written, in most the general form, as:

$$\frac{\partial P(q(x_t,t),t)}{\partial t} = \frac{\partial}{\partial q}\left\{N^{eq}_{(1)_{IV}} P(q(x_t,t),t)\right\} + \frac{\partial^2}{\partial q^2}\left\{N^{eq}_{(2)_{IV}} P(q(x_t,t),t)\right\} \tag{105.53}$$

where, $N^{eq}_{(1)_{IV}}$ and $N^{eq}_{(2)_{IV}}$ are the equivalent advection and diffusion coefficients, respectively, for the internal variable. As explained for the case of probabilistic stress response for elastic–perfectly plastic material (refer Section 105.3.2), since point–location scale FPKE will be solved, the equivalent advection and diffusion coefficients for the internal variable, $N^{eq}_{(1)_{IV}}$ and $N^{eq}_{(2)_{IV}}$, can be written as:

$$\begin{aligned} N^{eq}_{(1)_{IV}}(q) &= P[\Sigma_y \leq \sigma(q)]\frac{d\epsilon_{xy}}{dt}\left\langle \frac{Gr}{G+\frac{1}{\sqrt{3}}r}\right\rangle \\ N^{eq}_{(2)_{IV}}(q) &= P[\Sigma_y \leq \sigma(q)]t\left(\frac{d\epsilon_{xy}}{dt}\right)^2 Var\left[\frac{Gr}{G+\frac{1}{\sqrt{3}}r}\right] \end{aligned} \tag{105.54}$$

where, r is the rate of evolution of internal variable (q) with plastic strain. One may note that in the above equivalent advection and diffusion coefficients (Eq. (105.54)), the contributions of probability weights that the material being elastic are absent. This is because the evolution rule of internal variable is governed by the plastic component of strain only. The equivalent advection and diffusion coefficients for shear stress ($N^{eq}_{(1)}$ and $N^{eq}_{(2)}$) for hardening–type materials, will have contributions from both elastic and plastic components, just like the elastic–perfectly plastic case. However, unlike the elastic–perfectly plastic case, those ($N^{eq}_{(1)}$ and $N^{eq}_{(2)}$) will contain the hardening terms:

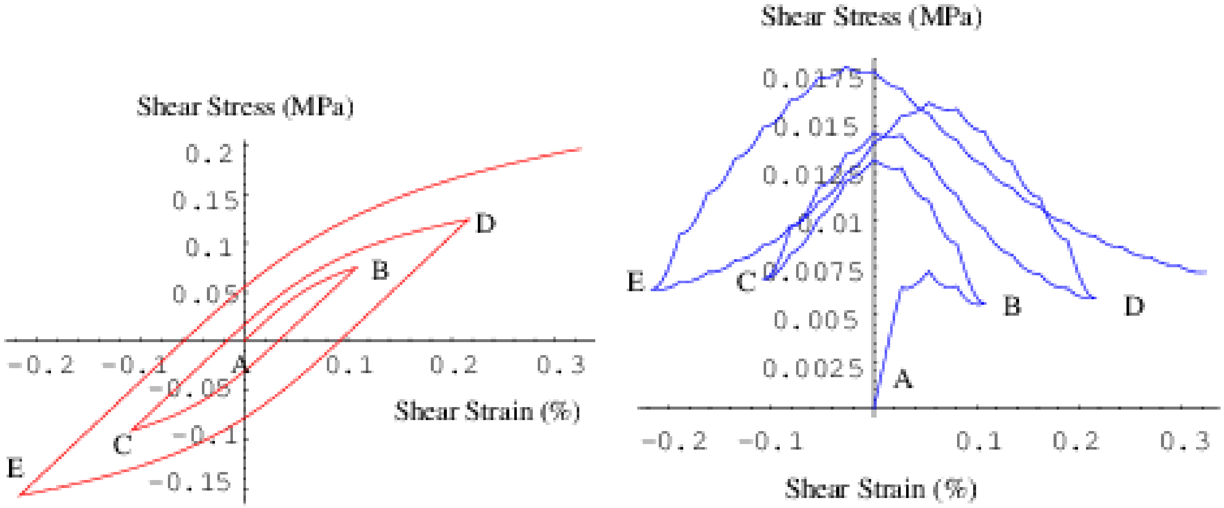
$$\begin{aligned} N^{eq}_{(1)}(\sigma) &= \frac{d\epsilon_{xy}}{dt}\left[(1-P[\Sigma_y \leq \sigma])\langle G\rangle + P[\Sigma_y \leq \sigma]\left\langle G - \frac{G^2}{G+\frac{1}{\sqrt{3}}r}\right\rangle\right] \\ N^{eq}_{(2)}(\sigma) &= t\left(\frac{d\epsilon_{xy}}{dt}\right)^2\left[(1-P[\Sigma_y \leq \sigma])Var[G] + P[\Sigma_y \leq \sigma]Var\left[G - \frac{G^2}{G+\frac{1}{\sqrt{3}}r}\right]\right] \end{aligned} \tag{105.55}$$

To obtain the probabilistic response of von Mises hardening material, the FPKE for probabilistic evolution of internal variable (Eq. (105.53), with advection and diffusion coefficients given by Eq. (105.54)) needs to be solved incrementally. This solution needs to be done simultaneously with the FPKE for probabilistic evolution of shear stress (Eq. (105.46), with advection and diffusion coefficients given by Eq. (105.55)). Those, in turn, need also to be solved incrementally, with the yield strength random variable (Σ_y) in Eqs. (105.54) and (105.55) being updated after each incremental step.

105.3.2.6 Isotropic Hardening

For von Mises isotropic hardening material, the yield strength (σ_y) is the internal variable. Yield strength will evolve probabilistically with plastic strain, following Eq. (105.53), with advection and diffusion coefficients given by Eq. (105.54). The shear stress, on the other hand, evolves in accordance with Eq. (105.46), with advection and diffusion coefficients given by Eq. (105.55).

Fig. 105.25 shows the evolutionary mean and standard deviation of shear stress during first couple of loading–unloading cycles for von Mises isotropic hardening material with a non–dimensional rate of evolution of internal variable (yield strength, in this case) of 10. All other material parameters are assumed to be the same as used for simulation of elastic–perfectly plastic material in the previous section (Section 105.3.2).



(a) (b)

Figure 105.25: Isotropic hardening probabilistic model under cyclic loading with increasing loops: evolution of (a) mean and (b) standard deviation of shear stress

The evolved PDFs of yield strength after each branch (loading, unloading, re–loading, and re–unloading) are shown in Fig. 105.26. The initial PDFs of yield strength (positive for loading branch and negative for unloading branch) are the same as assumed for elastic–perfectly plastic material in Section 105.3.2 (refer Fig. 105.18). As expected (and prescribed by the isotropic hardening model), the yield strength evolved (grew) isotropically. However, it is interesting to note the change in probability distributions of yield strength. The normally distributed initial PDFs of yield strength (Fig. 105.18) evolved into much dispersed non-Gaussian distributions having low kurtosis. In other words, when the material is cycled through loading–unloading cycles, the uncertainty in yield strength increases.

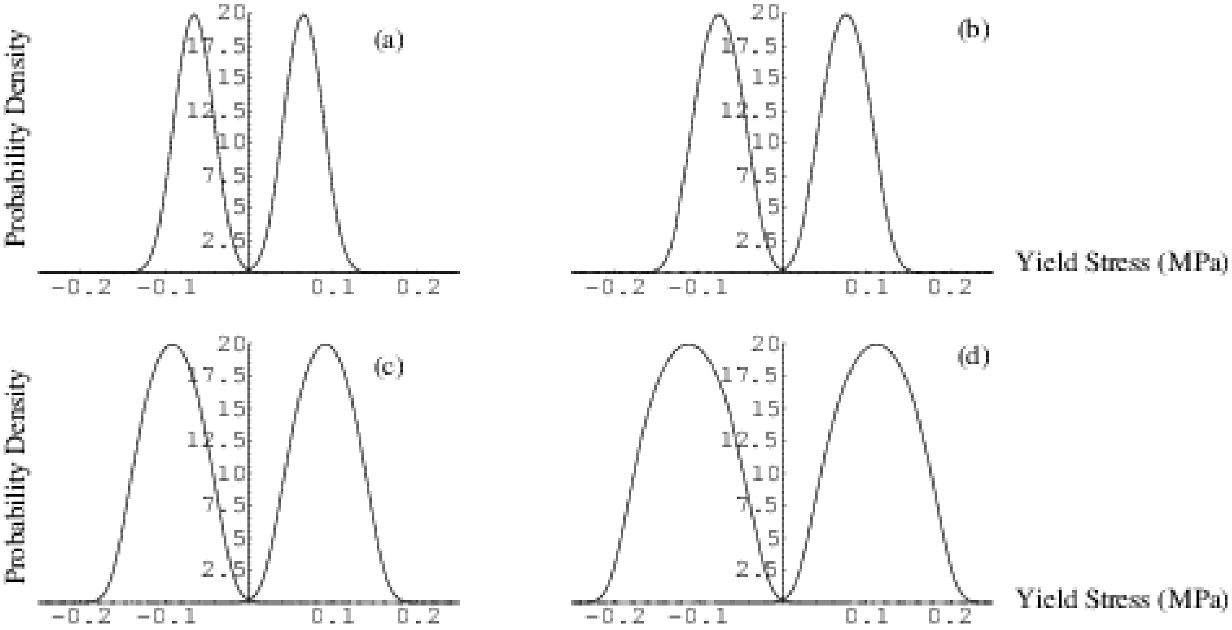


Figure 105.26: Isotropic hardening probabilistic model under cyclic loading with increasing loops: evolved PDF of yield stress after (a) loading branch, (b) unloading branch, (c) re–loading branch, and (d) re–unloading branch

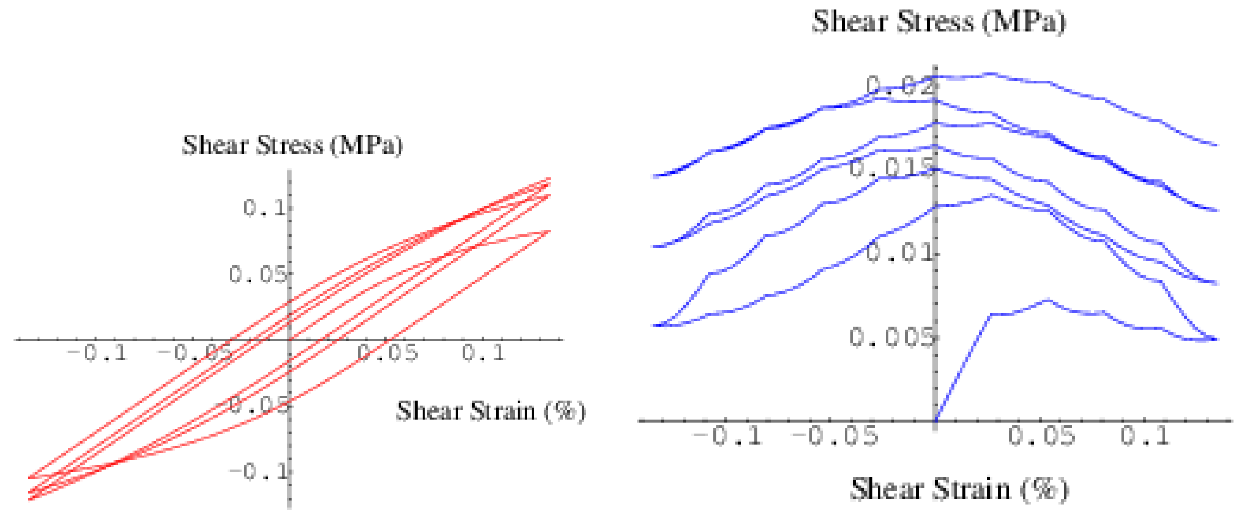
Mathematically, increase in uncertainty of shear strength is due to the nonlinearity in formulation of probabilistic yielding , that is, the state variable q appears in both advection and diffusion equations (refer Eq. (105.54)), and in the evolution equation for internal variable (Eq. (105.53)).

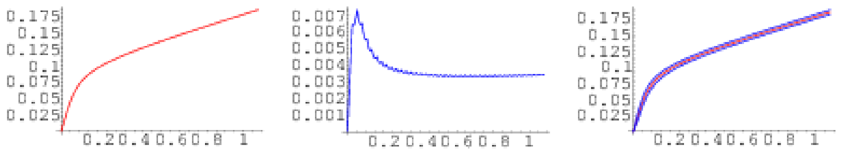
When comparison is made between Figs. 105.25 and 105.20, one can clearly see that, in simulating cyclic behaviors of geomaterials, isotropic hardening model (Fig. 105.25) performed, as expected, poorly. That is, the elastic–perfectly plastic probabilistic model (Fig. 105.20) captures (PDF of) stress–strain loops in a much more realistic way. However, for completeness of comparison, the behavior of isotropic hardening material, when it was cycled to same level (Fig. 105.27) and when loaded monotonically (Fig. 105.28) are also shown.

It is noted that monotonic loading curves for both perfectly plastic probabilistic model (Fig. 105.22) and linear isotropic hardening probabilistic model (Fig. 105.28) do look similar (with a noted difference of more pronounced hardening for a hardening model), but the real difference in stress–strain predictions with both probabilistic models becomes obvious in the case of cyclic loading.



(a) (b)

Figure 105.27: Isotropic hardening probabilistic model under cyclic loading with equal loops: evolution of (a) mean and (b) standard deviation of shear stress



(a) (b)

Figure 105.28: Isotropic hardening probabilistic model under monotonic loading: evolution of (a) mean, (b) standard deviation, and (c) mean ± standard deviation of shear stress

105.3.2.7 Kinematic Hardening

Expanding on elastic–plastic hardening probabilistic models, we now focus on a simple linear kinematic hardening rule based on evolution of back stress (α). By introducing back stress (α) to von Mises yield criteria, one can write:

$$\sqrt{J_\alpha} - k = 0 \tag{105.56}$$

where, k is again material parameter (yield strength like) and $J_\alpha = 3/2(s_{ij}-\alpha_{ij})(s_{ij}-\alpha_{ij})$ is the α–modified second invariant of deviatoric stress tensor (s_{ij}). For 1–D shear, Eq. (105.56) becomes:

$$|\sigma - \alpha| - \sigma_y = 0 \quad \text{or} \quad \sigma = \alpha \pm \sigma_y \tag{105.57}$$

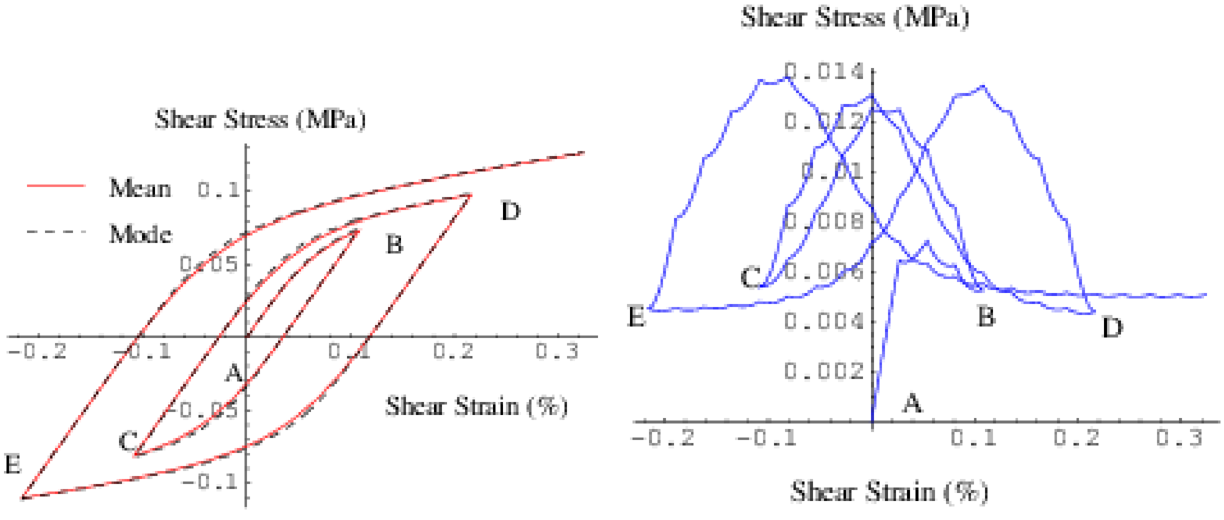
Hence, for kinematic hardening material, the yielding occurs at a stress of $\alpha \pm \sigma_y$, termed in the following as the equivalent yield stress. Initially, α is zero, and σ_y is assumed to have a mean value of 60 kPa with a standard deviation of 20 kPa, resulting in equivalent yield stress of 60 kPa with a COV of 30%, same as the assumed yield stress for the elastic–perfectly plastic material in Section 105.3.2 and isotropic hardening material in Section 105.3.2.6. However, the same distribution of equivalent yield stress will be obtained, if one transfers the initial uncertainty from σ_y to α. In other words, a deterministic σ_y of 60 kPa, and an uncertain α of zero mean and a standard deviation of 20 kPa will result in the same equivalent yield stress. The advantage of keeping σ_y deterministic is that it will simplify the probabilistic addition/subtraction in Eq. (105.57), while estimating the equivalent yield stress after each incremental step of the governing FPKEs, once the back stress (α), the internal variable for kinematic hardening material, starts evolving.

In this study, the back stress (α) is assumed to evolve with plastic strain and hence, it would evolve probabilistically similar to probabilistic evolution of the yield strength for isotropic hardening material. Probabilistic evolution of the back stress will occur according to Eq. (105.53), with advection and diffusion coefficients given by Eq. (105.54). Shear stress evolves according to Eq. (105.46), with advection and diffusion coefficients given by Eq. (105.55). One may note that the yield strength random variable (Σ_y), appearing in Eqs. (105.54) and (105.55), is the equivalent yield strength and is given by Eq. (105.57). Fig. 105.29 shows the probabilistic evolution of shear stress in terms of mean, mode, and standard deviation, when a kinematic hardening material[8], was cycled couple of times with increasing strain loops. All other material parameters are assumed to be the same as for the elastic–perfectly plastic material in Section 105.3.2. The evolved PDFs of the back stress (α) at the beginning and end of each branch (loading, unloading, re–loading, and re–unloading) are shown in Fig. 105.30. The evolved PDFs of equivalent yield stress (refer Eq. (105.57)) after each loading branch are shown in Fig. 105.31. Similar to the isotropic hardening case the uncertainty in (equivalent) yield strength increased as the material was cycled through, but unlike the isotropic hardening model, kinematic hardening model resulted in high kurtosis PDFs of (equivalent) yield strength. It is noted that the cyclic shear stress response of kinematic hardening material (Fig. 105.29), was more realistic than isotropic hardening material (Fig. 105.25), however, it didn't differ much from elastic–perfectly plastic material response (Fig. 105.20). Qualitatively, those, the elastic–perfectly plastic and the kinematic hardening responses, are similar. Like the elastic–perfectly plastic material, for kinematic hardening material, the mean and mode of the evolutionary shear stress (refer Fig. 105.29) are different, although not significantly.

Similarly, when one compares response (mean and standard deviation of shear stress) for loading cycles to the same strain level, for (i) elastic–perfectly plastic, (Fig. 105.21), (ii) isotropic linear hardening

---

[8] with non–dimensional rate of evolution of back stress with plastic strain of 10.



(a) (b)

Figure 105.29: Kinematic hardening probabilistic model under cyclic loading with increasing loops: evolution of (a) mean, mode and (b) standard deviation of shear stress

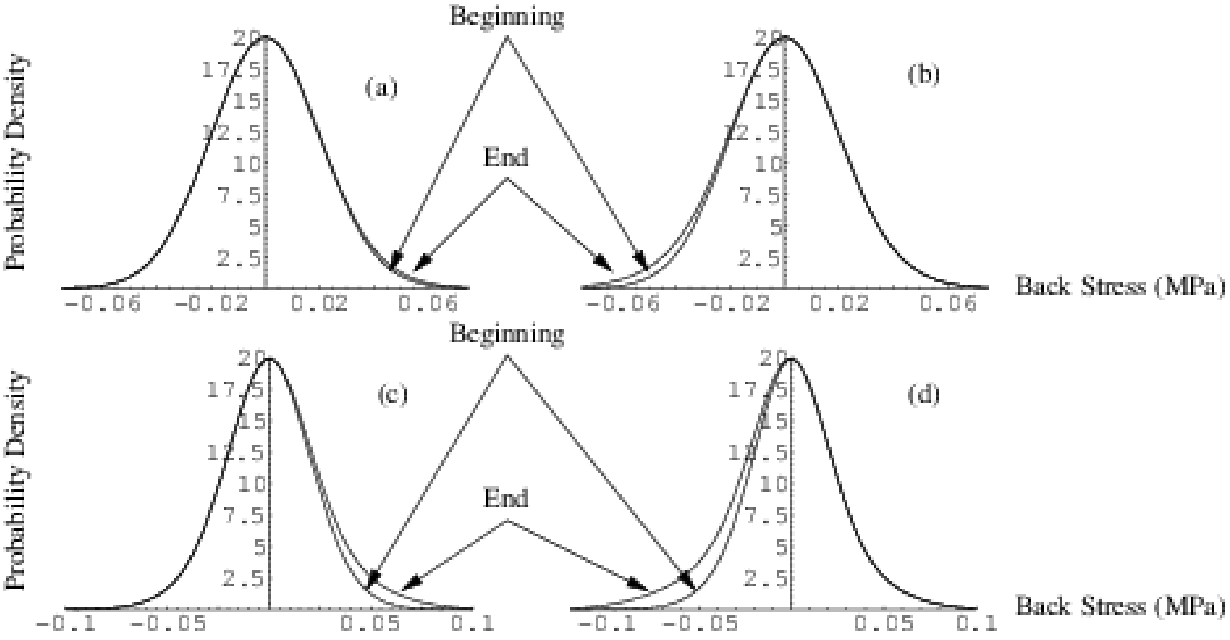


Figure 105.30: Kinematic hardening probabilistic model under cyclic loading with increasing loops: evolved PDF of back stress at the beginning and end of (a) loading branch, (b) unloading Branch, (c) re–loading branch, and (d) re–unloading branch

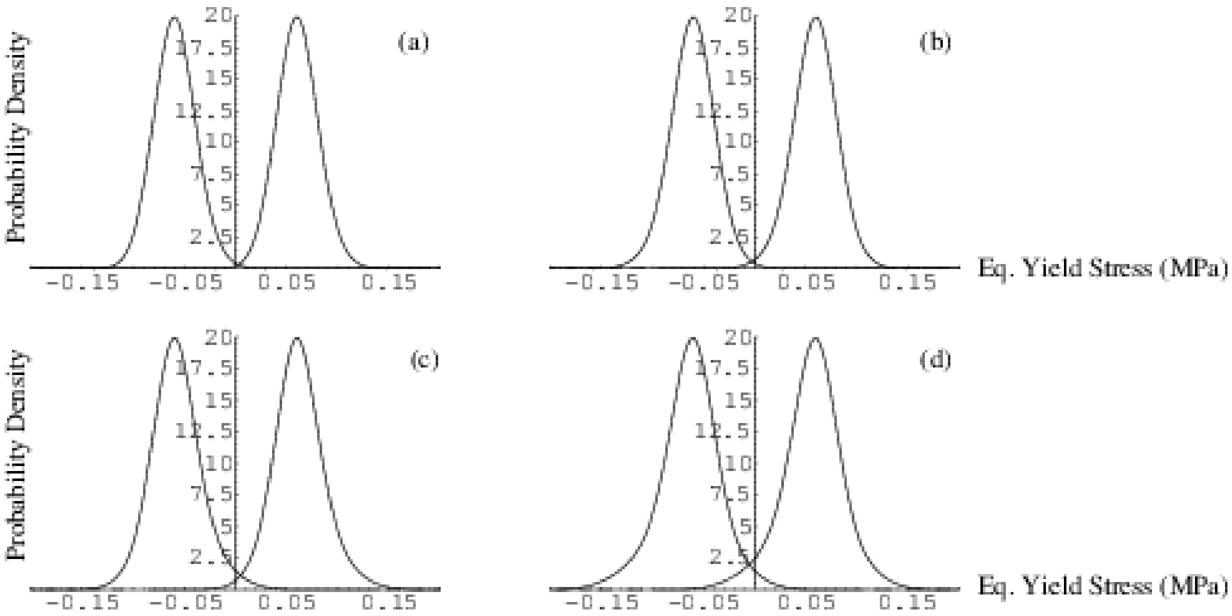

Figure 105.31: Kinematic hardening probabilistic model under cyclic loading with increasing loops: evolved PDF of equivalent yield stress after (a) loading branch, (b) unloading branch, (c) re–loading branch, and (d) re–unloading branch

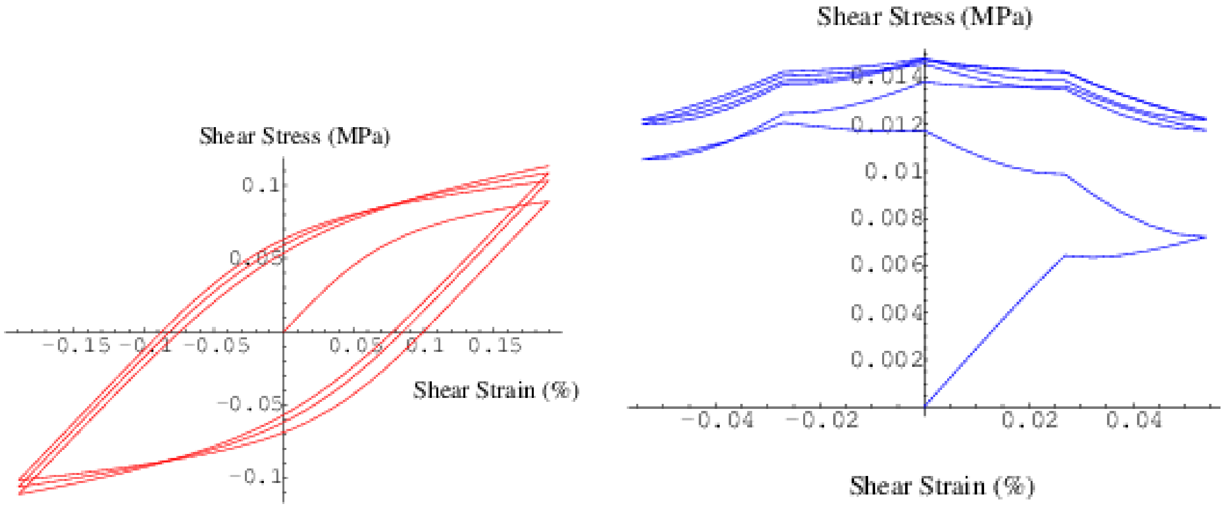
(Fig. 105.27), and (iii) linear kinematic hardening (Fig. 105.32), probabilistic material models, one can easily observe the qualitative similarity between elastic–perfectly plastic (i) and kinematic hardening responses (iii).

Monotonic loading cases, however, for all probabilistic material models ((i) elastic–perfectly plastic, (Fig. 105.22), (ii) isotropic linear hardening (Fig. 105.28), and (iii) linear kinematic hardening (Fig. 105.33)), are qualitatively similar, with expected differences in rate of hardening.

105.4 Hermite Polynomial Chaos Karhunen-Loève Expansion

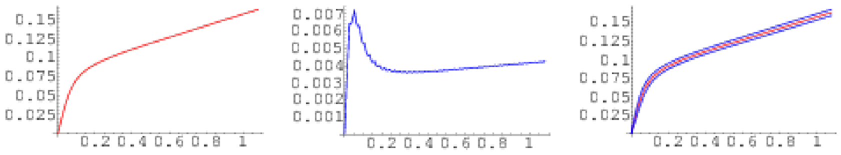
Hermite polynomial chaos Karhunen-Loève (PC-KL) expansion is formulated for the general heterogeneous random field $H(\boldsymbol{x}, \theta)$ of arbitrary marginal distributions. Here θ denotes the uncertainties and $\boldsymbol{x}$ is the general coordinate that can be either temporal as in the case of uncertain random process motions or spatial as in the case of random field material parameters.

Random field $H(\boldsymbol{x}, \theta)$ with any type of marginal distributions can be discretized with orthogonal Hermite polynomial chaos $\Omega_i(\gamma(\boldsymbol{x}, \theta))$ up to a certain order P Sakamoto and Ghanem (2002):



(a) (b)

Figure 105.32: Kinematic hardening probabilistic model under cyclic loading with equal loops: evolution of (a) mean and (b) standard deviation of shear stress



(a) (b)

Figure 105.33: Kinematic hardening probabilistic model under monotonic loading: evolution of (a) mean, (b) standard deviation, and (c) mean ± standard deviation of shear stress

$$H(\boldsymbol{x},\theta) = \sum_{i=0}^{P} H_i(\boldsymbol{x})\Omega_i(\gamma(\boldsymbol{x},\theta)) \tag{105.58}$$

where random functions $\{\Omega_i\}$ are Hermite polynomials constructed from a zero mean, unit variance kernel Gaussian random field $\gamma(\boldsymbol{x},\theta)$. Random functions $\{\Omega_i\}$ are determined by the initial condition $\Omega_0 = 1$ and the recursive relation:

$$\Omega_{i+1}(\gamma) = \gamma\Omega_i(\gamma) - \Omega_i^{'}(\gamma) \tag{105.59}$$

The deterministic PC coefficient field $H_i(\boldsymbol{x})$ can be calculated by projecting random field $H(\boldsymbol{x},\theta)$ onto PC basis Ω_i. Given the input covariance structure $Cov_H(x_1, x_2)$ of the original random field, the underlying

Gaussian covariance kernel $Cov_\gamma(x_1, x_2)$ can then be determined by solving:

$$Cov_H(x_1, x_2) = \sum_{i=1}^{P} H_i(x_1)\, H_i(x_2)\; i\,!\; Cov_\gamma(x_1, x_2)^i \tag{105.60}$$

Following Karhunen-Loève (KL) theorem Ghanem and Spanos (1991), the underlying kernel Gaussian random field $\gamma(\boldsymbol{x}, \theta)$ can be represented as:

$$\gamma(\boldsymbol{x}, \theta) = \sum_{i=1}^{M} \sqrt{\lambda_i} f_i(\boldsymbol{x}) \xi_i(\theta) \tag{105.61}$$

where eigenvalues λ_i and eigenvectors $f_i(\boldsymbol{x})$ of the covariance kernel $Cov_\gamma(x_1, x_2)$ have to satisfy Fredholm's integral equation of the second kind Sakamoto and Ghanem (2002). Zero mean and unit variance Gaussian random variables $\{\xi_i(\theta)\}$ are represented in M independent dimensions.

By combining Equations 105.58 to 105.61, the ultimate PC-KL expansion of the general random field $H(\boldsymbol{x}, \theta)$ into multi-dimensional orthogonal Hermite PC bases $\{\Psi_i\}$ of order P and dimension M can be obtained as:

$$H(\boldsymbol{x}, \theta) = \sum_{i=0}^{K} h_i(\boldsymbol{x}) \Psi_i(\{\xi_j(\theta)\}) \tag{105.62}$$

$$h_i(\boldsymbol{x}) = \frac{p!}{\langle \Psi_i^2 \rangle} H_p(\boldsymbol{x}) \prod_{j=1}^{p} \frac{\sqrt{\lambda_{k(j)}} f_{k(j)}(\boldsymbol{x})}{\sqrt{\sum_{m=1}^{M} (\sqrt{\lambda_m} f_m(\boldsymbol{x}))^2}} \tag{105.63}$$

where K is the total number of multidimensional Hermite PC bases $\{\Psi_i\}$ that depends on order P and dimension M as $K = 1 + \sum_{s=1}^{P} \frac{1}{s!} \prod_{j=0}^{s-1} (M + j)$. The upper product limit p, in equation 105.63 is the order of PC basis $\Psi_i(\{\xi_j(\theta)\})$. The marginal mean, marginal variance, correlation structure and any other statistics of the random field $H(\boldsymbol{x}, \theta)$ can be synthesized from the above Hermite PC-KL expansion. The goodness of the PC-KL expansion can be checked by comparing the PC-synthesized statistics with the input statistics of the random field $H(\boldsymbol{x}, \theta)$.

105.5 Galerkin Stochastic Elastoplastic Finite Element Formulations

105.5.1 Stochastic Elastoplastic Finite Element Method

Within the developed time domain stochastic Galerkin formulations, the uncertain material parameters and the uncertain forcing are modeled as heterogeneous random fields and non-stationary random process, respectively. As a unified probabilistic discretization scheme, Hermite PC-KL expansion is applied to both input uncertainties and output uncertainties, e.g., probabilistic displacement and acceleration responses.

Stochastic Galerkin projection is performed to minimize the error for estimating response PC coefficients. The resulting PC coefficients are used to develop statistics and distributions of the probabilistic response.

The weak form of deterministic, dynamic finite elements Jeremić et al. (1989-2025) can be written as:

$$\int_{D_e} N_m(\boldsymbol{x})\rho(\boldsymbol{x})N_n(\boldsymbol{x})dV\ \ddot{u}_n(t) + \int_{D_e} \nabla N_m(\boldsymbol{x})E(\boldsymbol{x})\nabla N_n(\boldsymbol{x})dV\ u_n(t) - f_m(t) = 0 \tag{105.64}$$

where N_m are the finite element shape functions, and $f_m(t)$ is the nodal force vector, while $\rho(\boldsymbol{x})$ and $E(\boldsymbol{x})$ are the deterministic density and deterministic stiffness fields in the deterministic FEM.

105.5.2 Stochastic Elastoplastic Finite Element Method, 1D Polynomial Chaos Formulation

Considering the tangential stiffness field, $E(\boldsymbol{x})$ to be a heterogeneous random field, and the forcing function, $f_m(t)$ to be a non-stationary random process, both are represented using multidimensional, Hermite PC expansions with known coefficients:

$$E(\boldsymbol{x},\theta) = \sum_{i=0}^{P_1} E_i(\boldsymbol{x})\Psi_i(\{\xi_r(\theta)\}) \tag{105.65}$$

$$f_m(t,\theta) = \sum_{j=0}^{P_2} f_{mj}(t)\psi_j(\{\xi_r(\theta)\}) \tag{105.66}$$

When the system with uncertain properties is excited by uncertain forces, the results, displacement and acceleration responses also become uncertain and can be represented using Hermite PCs with unknown coefficients expanded up to order P_3:

$$u_n(t,\theta) = \sum_{k=0}^{P_3} u_{nk}(t)\phi_k(\{\xi_l(\theta)\}) \tag{105.67}$$

$$\ddot{u}_n(t,\theta) = \sum_{k=0}^{P_3} \ddot{u}_{nk}(t)\phi_k(\{\xi_l(\theta)\}) \tag{105.68}$$

By substituting Eqs. 105.65, 105.66, 105.67, and 105.68 into Eq. 105.64, and denoting the shape function gradients $\nabla N_n(\boldsymbol{x})$ as $B(\boldsymbol{x})$, we obtain:

$$\begin{aligned} &\sum_{k=0}^{P_3} \int_{D_e} N_m(\boldsymbol{x})\rho(\boldsymbol{x})N_n(\boldsymbol{x})dV\ \phi_k\ddot{u}_{nk}(t)\ + \\ &\quad \sum_{k=0}^{P_3}\sum_{i=0}^{P_1} \int_{D_e} B_m(\boldsymbol{x})E_i(\boldsymbol{x})B_n(\boldsymbol{x})dV\ \Psi_i\phi_k u_{nk}(t) - \sum_{j=0}^{P_2} f_{mj}(t)\psi_j = 0 \end{aligned} \tag{105.69}$$

Performing stochastic Galerkin projection by multiplying both sides of Eq. 105.69 with PC basis ϕ_l and taking expectation Ghanem and Kruger (1996), we obtain the following system of ordinary differential equations (ODEs):

$$\sum_{k=0}^{P_3} \langle \phi_k \phi_l \rangle \int_{D_e} N_m(\boldsymbol{x}) \rho(\boldsymbol{x}) N_n(\boldsymbol{x}) dV \; \ddot{u}_{nk}(t) \; + \\ \sum_{k=0}^{P_3} \sum_{i=0}^{P_1} \langle \Psi_i \phi_k \phi_l \rangle \int_{D_e} B_m(\boldsymbol{x}) E_i(\boldsymbol{x}) B_n(\boldsymbol{x}) dV \; u_{nk}(t) = \sum_{j=0}^{P_2} \langle \psi_j \phi_l \rangle f_{mj}(t) \tag{105.70}$$

with $l = 0, 1, 2, ..., P_3$ where P_3 is the PC expansion order, while $m = 1, 2, ..., N$ where N is the number of finite element nodes, and the expectation operator is denoted as $\langle \cdot \rangle$. The expectations of double products $\langle \phi_k \phi_l \rangle$, $\langle \psi_j \phi_l \rangle$ and triple products $\langle \Psi_i \phi_k \phi_l \rangle$ of Hermite PC bases can be analytically computed beforehand and looked up during the stochastic FEM analysis.

Eq. 105.70 can be written into a matrix-vector form as:

$$\boldsymbol{M}\ddot{\boldsymbol{u}} + \boldsymbol{K}\boldsymbol{u} = \boldsymbol{F} \tag{105.71}$$

where $\boldsymbol{M}$, $\boldsymbol{K}$ and $\boldsymbol{F}$ are the stochastic expanded mass matrix, stiffness matrix and force vector, respectively. Vectors of unknown acceleration and displacement PC coefficients are denoted as $\ddot{\boldsymbol{u}}$ and $\boldsymbol{u}$, respectively.

Equation 105.71 is written in index notation, using Einstein summation convention, as:

$$M_{mlnk} \ddot{u}_{nk} + K_{mlnk} u_{nk} = F_{ml} \tag{105.72}$$

where

$$M_{mlnk} = \bigcup_e \langle \phi_k \phi_l \rangle \int_{D_e} N_m(\boldsymbol{x}) \rho(\boldsymbol{x}) N_n(\boldsymbol{x}) dV \tag{105.73}$$

$$K_{mlnk} = \bigcup_e \sum_{i=0}^{P_1} \langle \Psi_i \phi_k \phi_l \rangle \int_{D_e} B_m(\boldsymbol{x}) E_i(\boldsymbol{x}) B_n(\boldsymbol{x}) dV \tag{105.74}$$

$$F_{ml} = \bigcup_e \sum_{j=0}^{P_2} \langle \psi_j \phi_l \rangle f_{mj} \tag{105.75}$$

and $\bigcup_e$ is the assembly operator for elemental mass matrices, stiffness matrices and force vectors. Rayleigh damping can also be added into Eq. 105.71 as:

$$\boldsymbol{M}\ddot{\boldsymbol{u}} + \boldsymbol{C}\dot{\boldsymbol{u}} + \boldsymbol{K}\boldsymbol{u} = \boldsymbol{F} \tag{105.76}$$

The stochastic expanded damping matrix $\boldsymbol{C}$ can be represented as:

$$\boldsymbol{C} = \alpha \boldsymbol{M} + \beta \boldsymbol{K} \tag{105.77}$$

where α and β are Rayleigh damping parameters. The Rayleigh damping would produce the damping ratio ξ dependent on the response frequency ω in a hyperbolic functional form as (Chopra Chopra (2000)):

$$\xi = \frac{1}{2}(\frac{\alpha}{\omega} + \beta\omega) \tag{105.78}$$

Due to the formulation of Rayleigh damping, its uncertainties are inherently considered and modeled through the uncertainties of the mass and stiffness matrix. In Eq. 105.77, both the matrix $\boldsymbol{M}$ and the matrix $\boldsymbol{K}$, are stochastic expanded matrices that reflect the uncertainties from the material density and stiffness. Additional uncertainties could be included through uncertain Rayleigh damping parameters α and β. However, these uncertainties are difficult to calibrate. Therefore, in this study, we consider both the damping parameters α and β to be deterministic. As such, the damping uncertainties come directly as the combination of the mass uncertainties and the stiffness uncertainties. The same Galerkin projection scheme is inherently applied to propagate the damping uncertainties to the probabilistic system response.

The ordinary differential system of equations 105.71 or 105.76 may be solved using any time integration method, for example Newmark method Newmark (1959). Note that the size of the stochastic finite element system of equations is much larger when compared to corresponding deterministic finite element system of equations, depending upon the number of PC terms used to represent the probabilistic displacement and acceleration response. After solving for the unknown PC coefficients for displacements u_{nk} and accelerations $\ddot{u}_{nk}$ from the stochastic FEM analysis, the complete probabilistic dynamic response of the system can be determined. Using the resulting PC coefficients for u_{nk} and $\ddot{u}_{nk}$, any probabilistic measure of the uncertain system response can be obtained. For example, the time-evolving mean and variance of the probabilistic displacement response at node n can be computed as:

$$\langle u_n(t,\theta) \rangle = u_{n0}(t) \tag{105.79}$$

$$\mathrm{Var}(u_n(t,\theta)) = \sum_{k=1}^{P_3} \langle \phi_k^2 \rangle u_{nk}^2(t) \tag{105.80}$$

105.5.3 Probabilistic Elastoplastic Constitutive Modeling, 1D Polynomial Chaos Formulation

In the above stochastic elastoplastic FEM formulation, the probabilistic tangential stiffness $E(\boldsymbol{x},\theta)$ needs to be updated at each incremental step. Probabilistic elastoplastic constitutive modeling is performed at each Gauss point to update the uncertain elastoplastic stiffness and stress. For the one dimensional (1D) stochastic site response analysis in this study, the constitutive behavior of the soil is represented by a 1D elastoplastic material model with a vanishing elastic region and Armstrong-Frederick nonlinear kinematic hardening Armstrong and Frederick (1966). Without considering uncertainties in material properties, the relationship between the stress increment $d\sigma$ and the strain increment $d\epsilon$, in 1D, can be written in the incremental form as:

$$d\sigma = H_a d\epsilon - C_r \sigma |d\epsilon| \tag{105.81}$$

where H_a and C_r are model parameters. The shear strength S_u given by the model becomes $S_u = H_a/C_r$. The elastoplastic tangential stiffness is a function of the stress σ as:

$$E(\sigma) = \frac{d\sigma}{d\epsilon} = H_a - C_r \sigma \; sgn(d\epsilon) \tag{105.82}$$

where $sgn(d\epsilon)$ is the sign function of the strain increment $d\epsilon$. This function returns $sgn(d\epsilon) = 1$ for the positive strain strain increment $d\epsilon > 0$ and $sgn(d\epsilon) = -1$ otherwise, for $d\epsilon < 0$.

Here model parameters H_a and C_r are considered to be uncertain and modeled as random fields $H_a(\boldsymbol{x}, \theta)$ and $C_r(\boldsymbol{x}, \theta)$. Representation of those two model parameters using Hermite PC bases $\varphi_i(\{\xi_r(\theta)\})$ can be written as:

$$H_a(\boldsymbol{x}, \theta) = \sum_{i=0}^{P} H_{ai}(\boldsymbol{x}) \varphi_i(\{\xi_r(\theta)\}) \tag{105.83}$$

$$C_r(\boldsymbol{x}, \theta) = \sum_{i=0}^{P} C_{ri}(\boldsymbol{x}) \varphi_i(\{\xi_r(\theta)\}) \tag{105.84}$$

The strain increments $d\epsilon(\boldsymbol{x}, \theta)$, that represent input to the constitutive driver (Equation 105.81), are also uncertain, since $\epsilon(\boldsymbol{x}, \theta) = B(\boldsymbol{x}) u_n(t, \theta)$:

$$d\epsilon(\boldsymbol{x}, \theta) = \sum_{i=0}^{P} d\epsilon_i(\boldsymbol{x}) \varphi_i(\{\xi_r(\theta)\}) \tag{105.85}$$

As a result, the probabilistic incremental stress $d\sigma(\boldsymbol{x}, \theta)$ and the tangential stiffness $E(\boldsymbol{x}, \theta)$ can be represented using unknown PC coefficients $\{d\sigma_i(\boldsymbol{x})\}$ and $\{E_i(\boldsymbol{x})\}$ as:

$$d\sigma(\boldsymbol{x}, \theta) = \sum_{i=0}^{P} d\sigma_i(\boldsymbol{x}) \varphi_i(\{\xi_r(\theta)\}) \tag{105.86}$$

$$E(\boldsymbol{x}, \theta) = \sum_{i=0}^{P} E_i(\boldsymbol{x}) \varphi_i(\{\xi_r(\theta)\}) \tag{105.87}$$

Substituting Equations 105.83 ∼ 105.87 into Equations 105.81 and 105.82, and applying Galerkin projection on PC basis $\varphi_i\{\xi_r(\theta)\}$ yields:

$$\sum_{m=0}^{P} d\sigma_m \langle \varphi_m \varphi_i \rangle = \sum_{j=0}^{P}\sum_{k=0}^{P} H_{aj} d\epsilon_k \langle \varphi_j \varphi_k \varphi_i \rangle \pm \sum_{l=0}^{P}\sum_{n=0}^{P}\sum_{s=0}^{P} C_{rl}\sigma_n d\epsilon_s \langle \varphi_l \varphi_n \varphi_s \varphi_i \rangle \tag{105.88}$$

$$\sum_{i=0}^{P} E_m \langle \varphi_m \varphi_i \rangle = \sum_{j=0}^{P} H_{aj} \langle \varphi_j \varphi_i \rangle \pm \sum_{l=0}^{P}\sum_{n=0}^{P} C_{rl}\sigma_n \langle \varphi_l \varphi_n \varphi_i \rangle \tag{105.89}$$

Solutions to the unknown PC coefficients of the incremental stress $d\sigma(\boldsymbol{x},\theta)$ and the elastoplastic stiffness $E(\boldsymbol{x},\theta)$ can be computed using the orthogonality of Hermite PC bases $\langle \varphi_i \varphi_j \rangle = \delta_{ij}$:

$$d\sigma_i = \frac{1}{\mathrm{Var}[\varphi_\mathrm{i}]}\left[H_{aj} d\epsilon_k \langle \varphi_j \varphi_k \varphi_i \rangle \pm C_{rl}\sigma_n d\epsilon_s \langle \varphi_l \varphi_n \varphi_s \varphi_i \rangle\right] \tag{105.90}$$

$$E_i = H_{ai} \pm \frac{1}{\mathrm{Var}[\varphi_\mathrm{i}]} C_{rl}\sigma_n \langle \varphi_l \varphi_n \varphi_i \rangle \tag{105.91}$$

where $\mathrm{Var}[\varphi_\mathrm{i}]$ is the scalar variance of PC basis $\varphi_i\{\xi_r(\theta)\}$, that equals to $\langle \varphi_i^2 \rangle$. The Einstein's summation convention is followed in equations 105.90 and 105.91 with index i as a free index. The above formulation for the probabilistic constitutive modeling is implemented in the context of the explicit, forward Euler algorithm Jeremić et al. (1989-2025).

To illustrate the above probabilistic constitutive model, Figure 105.34 shows the stress-strain behavior using uncertain material parameters Ha with mean 10MPa and coefficient of variation (CV) 25%, uncertain shear strength $S_u = H_a/C_r$ with mean 150kPa and coefficient of variation 25%. The material is driven by an uncertain cyclic strain with a mean strain increment 10^{-4} and coefficient of variation of 20%.

It is observed that the probabilistic material response obtained through the intrusive polynomial chaos modeling matches well with Monte Carlo analysis using $10,000$ samples. It is noted that the intrusive probabilistic modeling is around $2,000$ times more computationally efficient, faster than Monte Carlo simulations.

105.5.4 Stochastic Elastoplastic Finite Element Method, 3D Polynomial Chaos Formulation

105.5.5 Probabilistic Elastoplastic Constitutive Modeling, 3D Polynomial Chaos Formulation

105.6 Sobol' Indices Computation Using Polynomial Chaos Expansion

In global sensitivity analysis, the variance of model output is decomposed into a sum of contributions from individual random variable, or groups of random variables. Consider a general mathematical model

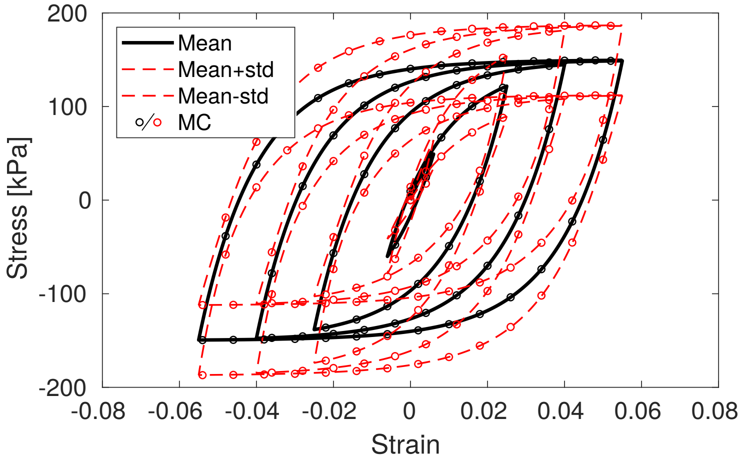


Figure 105.34: The hysteretic behavior of 1-D elastoplastic material with uncertain parameters H_a and H_a/C_r.

with n uncertain inputs represented by vector $\boldsymbol{x}$ and scalar output y as:

$$y = f(\boldsymbol{x}) \quad \boldsymbol{x} \in I^n \tag{105.92}$$

where the input parameters $\boldsymbol{x}$ are defined in n dimensional unit cube I^n without the loss of generality. The ANOVA (ANalysis Of VAriance) representation of $f(x)$ can be written as Sobol (2001):

$$f(x_1, x_2, ..., x_n) = f_0 + \sum_{i=1}^{n} f_i(x_i) + \sum_{1 \le i < j \le n} f_{ij}(x_i, x_j) + ... + f_{1,2,...,n}(x_1, ..., x_n) \tag{105.93}$$

There are 2^n summands in total. Constant f_0 is the mean value of the function:

$$f_0 = \int_{I^n} f(\boldsymbol{x}) d\boldsymbol{x} \tag{105.94}$$

The integral of each summand in Equation 105.93 over any of its independent variable is zero:

$$\int_0^1 f_{i_1,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s}) \; dx_{i_k} = 0 \quad \text{for} \quad 1 \le k \le s \tag{105.95}$$

From Equation 105.95, it can be seen that the summands are orthogonal to each other in the following sense:

$$\int_{I^n} f_{i_1,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s}) f_{j_1,...,j_t}(x_{j_1}, x_{j_2}, ..., x_{j_t}) \; d\boldsymbol{x} = 0 \quad \text{for} \quad \{i_1, ..., i_s\} \neq \{j_1, ..., j_t\} \tag{105.96}$$

For given mathematical model $f(x)$, the above ANOVA representation is unique and can be derived analytically. For example, the univariate terms can be solved as:

$$f_i(x_i) = \int_{I^{n-1}} f(\boldsymbol{x})\ d\boldsymbol{x}_{\sim i} - f_0 \tag{105.97}$$

where $\int_{I^{n-1}}(\cdot)\ d\boldsymbol{x}_{\sim i}$ denotes the integration over all dimensions except x_i. Similarly, the bivariate terms can be derived as follows:

$$f_{ij}(x_i, x_j) = \int_{I^{n-2}} f(\boldsymbol{x})\ d\boldsymbol{x}_{\sim[ij]} - f_i(x_i) - f_j(x_j) - f_0 \tag{105.98}$$

Following this procedure, any summand $f_{i_1,...,i_s}(x_{i_1}, x_{i_2}, ..., x_{i_s})$ can be constructed from some multidimensional integral of $f(\boldsymbol{x})$.

Considering uncertain input parameters $\boldsymbol{X}$ to be independent random variables following uniform distribution in $[0,1]$:

$$\boldsymbol{X} = [X_1, ..., X_n], \quad X_i \sim U(0,1), \quad \text{for} \quad i = 1, ..., n \tag{105.99}$$

Then the total variance of the probabilistic model response $y = f(\boldsymbol{X})$ can be computed as:

$$D = \mathrm{Var}[f(\boldsymbol{X})] = \int_{I^n} f^2(\boldsymbol{x})\ d\boldsymbol{x} - f_0^2 \tag{105.100}$$

Using Equations 105.93 and 105.96, the total variance D can be decomposed as follows:

$$D = \sum_{i=1}^{n} D_i + \sum_{1\le i<j\le n} D_{ij} + ... + D_{1,2,...,n} = \sum_{s=1}^{n} \sum_{i_1<...<i_s} D_{i_1...i_s} \tag{105.101}$$

where the variance contribution from individual summand is given as follows:

$$D_{i_1...i_s} = \int_{I^s} f^2_{i_1...i_s}(x_{i_1}, ..., x_{i_s})\ dx_{i_1}, ...dx_{i_s}, \text{with } 1 \le i_1 < ... < i_s \le n, s = 1, ..., n \tag{105.102}$$

The Sobol' indices $S_{i_1...i_s}$ are defined as:

$$S_{i_1...i_s} = D_{i_1...i_s}/D \tag{105.103}$$

The Sobol' indices $S_{i_1...i_s}$ quantifies the fractional contributions from random inputs $\{X_{i_1}, ..., X_{i_s}\}$ to the total variance D. The first order indices S_i gives the influence of each uncertain input parameter X_i when considered individually. The high order terms describe the mixed influence when a group of uncertain input parameters are considered collectively. Clearly, from Equation 105.101 we have:

$$\sum_{i=1}^{n} S_i + \sum_{1\le i<j\le n} S_{ij} + ... + S_{1,2,...,n} = 1 \tag{105.104}$$

The Sobol' indices for global sensitivity analysis can be used for the following purposes: (1) Ranking of input uncertain parameters $\boldsymbol{X} = [X_1, ..., X_n]$. (2) Neglect of inessential uncertain parameters and high order terms in Equation 105.93. The total sensitivity indices S_i^{total} is defined to evaluate the total influence of a certain input parameter X_i as:

$$S_i^{\text{total}} = \sum_{\mathscr{S}_i} D_{i_1 \ldots i_s} \tag{105.105}$$

where set $\mathscr{S}_i$ contains all the indexes involving index i defined as Equation 105.106 and Sobol' indices set $\{D_{i_1 \ldots i_s}\}$ is the collection of all partial sensitivity indices that are related to parameter X_i.

$$\mathscr{S}_i = \{(i_1, ..., i_s) : \exists k, 1 \leq k \leq s, i_k = i\} \tag{105.106}$$

Using Hermite PC expansion Ghanem and Spanos (1991), the probabilistic model response $y = f(\boldsymbol{X})$ can be represented as:

$$y = \sum_{j=0}^{P-1} y_j \Psi_j(\boldsymbol{\xi}), \quad \boldsymbol{\xi} = \{\xi_1, ..., \xi_M\} \tag{105.107}$$

where $\{\Psi_j\}$ are multi-dimensional, mutually orthogonal Hermite PC bases of order p constructed from M dimension, independent, standard Gaussian random vector $\boldsymbol{\xi}$. The total number of PC bases P is related to the dimension M and order p as:

$$P = \begin{pmatrix} M + p \\ p \end{pmatrix} = \frac{(M+p)!}{M!p!} \tag{105.108}$$

It is noted that the input random vector $\boldsymbol{X}$ of any prescribed joint PDF or any given marginal PDF and correlations can be approximately transformed to standard Gaussian random vector $\boldsymbol{\xi}$ using transformation techniques such as iso-probabilistic transform and Nataf transform Lebrun and Dutfoy (2009):

$$\boldsymbol{X} = T(\boldsymbol{\xi}) \tag{105.109}$$

Therefore, the probabilistic model response can be evaluated and represented with Hermite PC expansion as:

$$y = f(\boldsymbol{X}) = f \circ T(\boldsymbol{\xi}) = \sum_{j=0}^{P-1} y_j \Psi_j(\boldsymbol{\xi}), \quad \boldsymbol{\xi} = \{\xi_1, ..., \xi_M\} \tag{105.110}$$

Here we transform the input random vector $\boldsymbol{X}$ into standard Gaussian random vector $\boldsymbol{\xi}$ and perform Hermite polynomial chaos expansion. We can also transform the input random vector $\boldsymbol{X}$ into other types of basic random variables, e.g., uniform distribution, and represent model response y with associated generalized PC expansion Xiu and Karniadakis (2002).

Since the PC bases $\{\Psi_j(\boldsymbol{\xi})\}$ are zero-mean $(j \geq 1)$ and mutually orthogonal, the mean $\bar{y}$ and total variance of model response D_{PC} can be calculated from its PC representation:

$$\begin{aligned} \bar{y} &= \boldsymbol{E}[f(\boldsymbol{X})] = y_0 \\ D^{PC} &= \text{Var}\left[\sum_{j=0}^{P-1} y_j \Psi_j\right] = \sum_{j=1}^{P-1} y_j^2 \boldsymbol{E}\left[\Psi_j^2\right] \end{aligned} \tag{105.111}$$

To compute the Sobol' indices, the above PC expansion of y should be organized into the ANOVA form Sudret (2008). The multi-dimensional polynomial chaos bases $\{\Psi_j(\boldsymbol{\xi})\}$ can be decomposed into the multiplication of single dimension polynomial chaos bases of different orders:

$$\Psi_j(\boldsymbol{\xi}) = \prod_{i=1}^{n} \phi_{\alpha_i}(\xi_i) \tag{105.112}$$

where $\phi_{\alpha_i}(\xi_i)$ is the single dimensional, order α_i, polynomial function of underlying basic random variable ξ_i. The functional form of the generalized polynomial chaos function $\phi_{\alpha_i}(\xi_i)$ depends on the selected underlying basic random variable ξ_i Xiu and Karniadakis (2002). For example, when the basic random variable ξ_i follows standard Gaussian distribution, Hermite polynomial functions $\phi_{\alpha_i}(\xi_i)$ should be constructed as follows:

$$\phi_0 = 1; \qquad \phi_{k+1}(\xi_i) = \xi_i \phi_k(\xi_i) - \phi_k^{'}(\xi_i) \;\; \text{for all } k \geq 1 \tag{105.113}$$

Each multidimensional polynomial chaos basis can be uniquely characterized by vector $\boldsymbol{\alpha} = (\alpha_1, ..., \alpha_n)$. The connection between the PC expansion and the ANOVA representation of model response y can be established by defining set $\mathscr{S}$ from $\boldsymbol{\alpha}$ as Sudret (2008):

$$\mathscr{S}_{i_1,...,i_s} = \{\boldsymbol{\alpha} : \forall k = 1, ..., n, \text{when } k \in (i_1, ..., i_s),\; \alpha_k > 0,\; \text{otherwise, } \alpha_k = 0\} \tag{105.114}$$

For example, $\mathscr{S}_i$ would correspond to the PC bases depending only on dimension ξ_i. Following Equation 105.114, the PC expansion shown in Equation 105.110 could be written into ANOVA representation:

$$\begin{aligned} y = y_0 &+ \sum_{i=1}^{n} \sum_{\boldsymbol{\alpha} \in \mathscr{S}_i} y_{\boldsymbol{\alpha}} \Psi_{\boldsymbol{\alpha}}(\xi_i) + \sum_{1 \leq i_1 < i_2 \leq n} \sum_{\boldsymbol{\alpha} \in \mathscr{S}_{i_1,i_2}} y_{\boldsymbol{\alpha}} \Psi_{\boldsymbol{\alpha}}(\xi_{i_1}, \xi_{i_2}) + ... \\ &+ \sum_{1 \leq i_1 < ... < i_s \leq n} \sum_{\boldsymbol{\alpha} \in \mathscr{S}_{i_1,...,i_s}} y_{\boldsymbol{\alpha}} \Psi_{\boldsymbol{\alpha}}(\xi_{i_1}, ..., \xi_{i_s}) + ... \\ &+ \sum_{\boldsymbol{\alpha} \in \mathscr{S}_{1,2,...,n}} y_{\boldsymbol{\alpha}} \Psi_{\boldsymbol{\alpha}}(\xi_1, ..., \xi_n) \end{aligned} \tag{105.115}$$

where the term $\sum_{\boldsymbol{\alpha}\in\mathscr{S}_{i_1,...,i_s}} y_{\boldsymbol{\alpha}}\Psi_{\boldsymbol{\alpha}}(\xi_{i_1},...,\xi_{i_s})$ denotes the summation of polynomial chaos expansions depending on all the basic random variables $\{\xi_{i_1},...,\xi_{i_s}\}$ and only on them. From the above ANOVA representation of probabilistic model response, the PC-based Sobol' indices $S^{PC}_{i_1...i_s}$ can be derived as:

$$S^{PC}_{i_1...i_s} = \sum_{\boldsymbol{\alpha}\in\mathscr{S}_{i_1,...,i_s}} y^2_{\boldsymbol{\alpha}}\boldsymbol{E}\left[\Psi^2_{\boldsymbol{\alpha}}\right]/D^{PC} \tag{105.116}$$

The total Sobol' indices $S^{PC,\text{total}}_{j_1..j_t}$ for any group of parameters $\{\xi_{j_1},...,\xi_{j_t}\}$ can then be computed as:

$$S^{PC,\text{total}}_{j_1..j_t} = \sum_{(i_1,...,i_s)\in\mathscr{S}_{j_1,...,j_t}} S^{PC}_{i_1...i_s} \tag{105.117}$$

where set $\mathscr{S}_{j_1,...,j_t}$ is defined as:

$$\mathscr{S}_{j_1,...,j_t} = \{(i_1,...,i_s) : (j_1,...,j_t) \subset (i_1,...,i_s)\} \tag{105.118}$$

From the above formulations, it can be observed that once the PC representation of probabilistic model response is established, Sobol' sensitivity indices can be analytically evaluated with very small computational expense.

Chapter 106

Large Deformation Elasto-Plasticity

(1996-2004-)

(In collaboration with Dr. Zhao Cheng)

106.1 Chapter Summary and Highlights

106.2 Continuum Mechanics Preliminaries: Kinematics

106.2.1 Deformation

In modeling the material nonlinear behavior of solids, plasticity theory is applicable primarily to those bodies that can experience inelastic deformations considerably greater than the elastic deformation. If the resulting total deformation, including both translations and rotations, are small enough, we can apply small deformation theory in solving these problems. If, however strains and rotations are finite, one must resort to the theory of large deformations. In doing so, we will be using two sets of representations[1], namely:

- *Material coordinates* in the undeformed configuration, also called *Lagrangian coordinates*,
- *Spatial coordinates* in the deformed configuration, also called *Eulerian coordinates*.

Figure 106.1 shows the displacement of a particle from its initial position X_I to the current position x_i, defined by the deformation equation:

$$x_i = x_i\,(X_1, X_2, X_3, t) \tag{106.1}$$

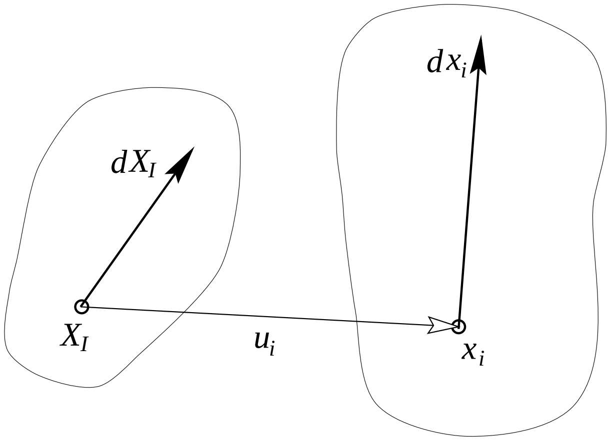

Figure 106.1: Displacement, stretch and rotation of material vector dX_I to new position dx_i.

The initial position X_I of the particle now occupying the position x_i is given by the *Eulerian equation*:

$$X_I = X_I\,(x_1, x_2, x_3, t) \tag{106.2}$$

---

[1] See Malvern (1969).

The two positions are connected by the displacement u_I:

$$x_i = X_I + u_i \qquad ; \qquad X_I = x_i - u_i \tag{106.3}$$

106.2.2 Deformation Gradient

The *deformation gradients* are the gradients of the functions on the right–hand side of equations (106.1) and (106.2). To emphasize the difference between the material, Lagrangian setting and the spatial, Eulerian setting, we will use capital letters for the material coordinate indices and lower case letters for the spatial coordinate indices. We limit our work to the rectangular Cartesian coordinates, thus simplifying the tensor notation to the covariant indices only.

The deformation gradient is defined as the *two–point tensor* whose rectangular Cartesian components are the partial derivatives:

$$F_{kK} = \frac{\partial x_k}{\partial X_K} = x_{k,K} \tag{106.4}$$

The deformation gradient F_{kK} transforms (convects) on an arbitrary infinitesimal material vector dX_I at X_I to associate it with a vector dx_i at x_i:

$$dx_k = F_{kK} dX_K = \frac{\partial x_k}{\partial X_K} dX_K = x_{k,K} dX_K \tag{106.5}$$

The *the spatial deformation gradients* are tensors referred to the deformed, Eulerian configuration:

$$(F_{Kk})^{-1} = \frac{\partial X_K}{\partial x_k} = X_{K,k} \tag{106.6}$$

Similarly to the deformation gradient F_{kK}, *spatial deformation gradient* $(F_{Kk})^{-1}$ operates on an arbitrary infinitesimal material vector dx_i at x_i to associate it with a vector dX_I at X_I:

$$dX_K = (F_{Kk})^{-1} dx_k = \frac{\partial X_K}{\partial x_k} dx_k = X_{K,k} dx_k \tag{106.7}$$

The *spatial deformation gradient* $(F_{Kk})^{-1}$ at x_i is the inverse to the two–point tensor F_{kK} at X_I:

$$F_{iJ} \left(F_{Jk}\right)^{-1} = \delta_{ik} \quad \text{and} \quad \left(F_{Ij}\right)^{-1} F_{jK} = \delta_{IK} \tag{106.8}$$

The Jacobian of the mapping (106.4) can be represented as:

$$J = det\left(F_{kK}\right) = \frac{1}{6} e_{ijk} e_{PQR} F_{iP} F_{jQ} F_{kR} \tag{106.9}$$

The relative deformation gradient f_{km} is the gradient for the relative motion function:

$$\xi = \chi_t \left(x_i , \tau \right) \tag{106.10}$$

and is defined as:

$$f_{km} = \xi_{k,m} \equiv \frac{\partial \xi_k}{\partial x_m} \tag{106.11}$$

If the fixed reference position X_I, the current position x_i and the variable position ξ_i are all referred to the rectangular Cartesian coordinate system, the chain rule of differentiation yields:

$$\frac{\partial \xi_k}{\partial X_I} = \frac{\partial \xi_k}{\partial x_m} \frac{\partial x_m}{\partial X_I} \quad \text{or} \quad F_{kI} = f_{km} \, F_{mI} \tag{106.12}$$

The polar decomposition theorem permits the unique representation[2]:

$$F_{ij} = R_{ik} U_{kj} = v_{ik} R_{kj} \tag{106.13}$$

where U_{kj}, v_{ik} are positive definite symmetric tensors, called *right stretch tensors* and *left stretch tensors*, respectively, and R_{kj} is an *orthogonal tensor* such that:

$$R_{ik} R_{jk} = \delta_{ij} \qquad \text{and also} \qquad R_{ki} R_{kj} = \delta_{ij} \tag{106.14}$$

Equation (106.13), as well as Figure 106.2.2 demonstrate that the motion and deformation of an infinitesimal volume element at X_i consist of consecutive applications of:

- a stretch by U_{kj},
- a rigid body rotation by R_{ik},
- a rigid body translation to x_i

or alternatively:

- a rigid body translation to x_i
- a rigid body rotation by R_{kj},
- a stretch by v_{ik},

---

[2] referring x_i and X_i to the same reference axes and using lower case indices for both. This reference to the same coordinate system will be applied only for the polar decomposition example presented here.

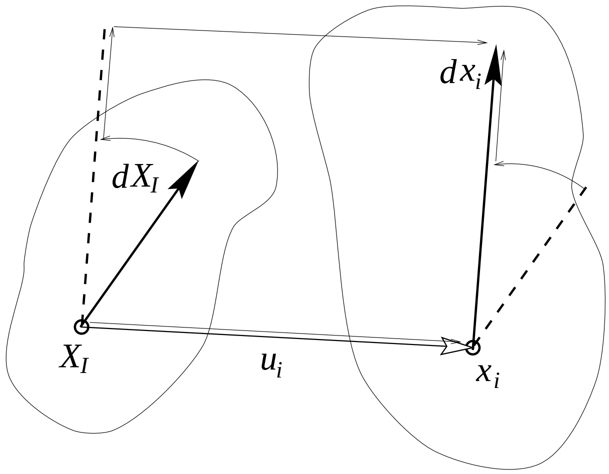

Figure 106.2: Illustration of the equation $F_{ij} = R_{ik}U_{kj} = v_{ik}R_{kj}$.

106.2.3 Strain Tensors, Deformation Tensors and Stretch

The strain tensors E_{IJ} and e_{ij} are defined so that they give the change in the square length of the material vector dX_I. For the Lagrangian formulation we write:

$$(ds)^2 - (dS)^2 = 2dX_I E_{IJ} dX_J \tag{106.15}$$

and for the Eulerian formulation:

$$(ds)^2 - (dS)^2 = 2dx_i e_{ij} dx_j \tag{106.16}$$

The deformation tensors C_{IJ} and c_{ij} are connecting the squared lengths in Lagrangian and Eulerian configurations. The Green deformation tensor[3] C_{IJ}, referred to the undeformed configuration, gives the new squared length $(ds)^2$ of the element into which the given element dX_I is deformed:

$$(ds)^2 = dX_I C_{IJ} dX_J \tag{106.17}$$

The Cauchy deformation tensor c_{ij}, sometimes also denoted as[4] $\left(b_{ij}\right)^{-1}$, gives the initial squared length $(dS)^2$ of an element dx_i identified in the deformed configuration:

$$(dS)^2 = dx_i c_{ij} dx_j \tag{106.18}$$

---

[3] Also called *right Cauchy–Green tensor*.

[4] Another name for b_{ij} is *Finger deformation tensor* or *left Cauchy–Green tensor*.

Substituting equation (106.17) into (106.15) yield:

$$2E_{IJ} = C_{IJ} - \delta_{IJ} \tag{106.19}$$

and similarly, substituting equation (106.18) into (106.16) we obtain:

$$2e_{ij} = \delta_{ij} - c_{ij} \tag{106.20}$$

By using equation (106.5) we can express $(ds)^2$ as:

$$\begin{gathered}(ds)^2 = dx_k dx_k = (F_{kI} dX_I)(F_{kJ} dX_J) = \\ (x_{k,I} dX_I)(x_{k,J} dX_J) = dX_I (F_{kI} F_{kJ}) dX_K = dX_I C_{IJ} dX_K\end{gathered} \tag{106.21}$$

so we have obtained the connection between the deformation tensor C_{IJ} and the deformation gradient F_{kI} in the form:

$$C_{IJ} = (F_{kI} F_{kJ}) = x_{k,I} dX_I x_{k,J} dX_J \tag{106.22}$$

Similarly, by using equation (106.7) and the expression for $(dS)^2$ we can establish the connection between the deformation tensor c_{ij} and the deformation gradient F_{Ki} as:

$$\begin{gathered}(dS)^2 = dS_K dX_K = (F_{Ki} dx_i)(F_{Kj} dx_j) = \\ (X_{K,i} dx_i)(X_{K,j} dx_J) = dx_i (F_{Ki} F_{Kj}) dx_k = dx_i c_{ij} dx_k \Rightarrow \\ c_{ij} = (F_{Ki})^{-1} F^{-1}_{Kj}\end{gathered} \tag{106.23}$$

The expressions for the strain tensors in Lagrangian and Eulerian description[5] is obtained from equations (106.19) and (106.20):

$$\text{L:}\ \ E_{IJ} = \frac{1}{2}\left((F_{kI} F_{kJ}) - \delta_{IJ}\right) \qquad ; \qquad \text{E:}\ \ e_{ij} = \frac{1}{2}\left(\delta_{ij} - (F_{Ki})^{-1} \left(F_{Kj}\right)^{-1}\right) \tag{106.24}$$

If one starts from the displacement equation (106.3), referenced to the same axes for both X_I and x_i

$$x_I = X_I + u_I \quad ; \quad X_I = x_I - u_I$$

the general expression for the Lagrangian strain tensor E_{IJ} in terms of displacements is:

$$\begin{gathered}E_{IJ} = \frac{1}{2}\left((F_{KI} F_{KJ}) - \delta_{IJ}\right) = \\ \frac{1}{2}\left(\left(\delta_{KI} + u_{K,I}\right)\left(\delta_{KJ} + u_{K,J}\right) - \delta_{IJ}\right) = \\ \frac{1}{2}\left(\delta_{KI}\delta_{KJ} + \delta_{KI} u_{K,J} + u_{K,I}\delta_{KJ} + u_{K,I} u_{K,J} - \delta_{IJ}\right) = \\ \frac{1}{2}\left(\delta_{IJ} + u_{I,J} + u_{J,I} + u_{K,I} u_{K,J} - \delta_{IJ}\right) = \\ \frac{1}{2}\left(u_{I,J} + u_{J,I} + u_{K,I} u_{K,J}\right)\end{gathered} \tag{106.25}$$

---

[5] Lagrangian format will be denoted by L: while Eulerian format by E:.

Similarly, the general expression for the Eulerian strain tensor e_{ij} in terms of displacements is:

$$\begin{aligned} e_{ij} = \frac{1}{2}\left(\delta_{ij} - (F_{ki})^{-1}\left(F_{kj}\right)^{-1}\right) = \\ \frac{1}{2}\left(\delta_{ij} - \left(\delta_{ki} - u_{k,i}\right)\left(\delta_{kj} - u_{k,j}\right)\right) = \\ \frac{1}{2}\left(\delta_{ij} - \delta_{ki}\delta_{kj} + \delta_{ki}u_{k,j} + u_{k,i}\delta_{kj} - u_{k,i}u_{k,j}\right) = \\ \frac{1}{2}\left(\delta_{ij} - \delta_{ij} + u_{i,j} + u_{j,i} - u_{k,i}u_{k,j}\right) = \\ \frac{1}{2}\left(u_{i,j} + u_{j,i} - u_{k,i}u_{k,j}\right) \end{aligned} \tag{106.26}$$

It is worthwhile noting that equations (106.25) and (106.26) represent the complete finite strain tensor. They involve only linear and quadratic terms in the components of displacement gradients.

The stretch is a measure of extension of an infinitesimal element and is a function of direction of an element, in either deformed or undeformed configuration. By denoting N_I a unit vector in the undeformed configuration and n_i a unit vector in the deformed configuration, we denote material stretch as $\Lambda_{(N)}$ of those elements whit initial direction N_I and spatial stretch $\lambda_{(n)}$ of those elements with initial direction n_i. By dividing equations (106.15) and (106.16) by $(ds)^2$ and $(dS)^2$ respectively and by using:

$$N_I = \frac{dX_I}{dS} \qquad \text{and} \qquad n_i = \frac{dx_i}{ds} \tag{106.27}$$

we obtain the Cartesian form of stretch in the Lagrangian and Eulerian descriptions:

$$\text{L:}\ \ \Lambda^2_{(N)} = \frac{dX_I}{dS} C_{IJ} \frac{dX_J}{dS} \qquad \text{and} \qquad \text{E:}\ \ \lambda^2_{(n)} = \frac{dx_i}{ds} c_{ij} \frac{dx_j}{ds} \tag{106.28}$$

General strain tensors can be defined by considering a scale function (Hill, 1978) for the stretch. Scale function is any smooth, monotonic function of stretch $f(\lambda)$ such that:

$$f(\lambda)\ \ ;\ \ \lambda \in [0, \infty)\ \ \text{subject to}\ \ f(1) = 0, f'(1) = 1 \tag{106.29}$$

Scale function is often taken in the form $(\lambda^{2m} - 1)/2m$, where m may have any value. If we choose m to be an integer, the corresponding strain tensor is:

$$E_{IJ} = \frac{\left(U^{2m}_{IJ} - \delta_{IJ}\right)}{2m} \quad \text{where} \quad F_{IJ} = R_{IK}U_{KJ} = v_{IK}R_{KJ} \tag{106.30}$$

Table 106.1 shows different Lagrangian strain measures obtained for a particular choice of parameter m.

In the Eulerian setting, generalized strain tensor is defined as

$$e_{ij} = \frac{\left(\delta_{ij} - v^{2m}_{ij}\right)}{2m} \quad ; \quad F_{IJ} = R_{IK}U_{KJ} = v_{IK}R_{KJ} \tag{106.31}$$

Table 106.1: Different Lagrangian strain measures.

Strain measure name	parameter m	expression for E^{m}_{IJ}
Green–Lagrange	1	$E^{GL}_{IJ} = \left(U^{2}_{IJ} - \delta_{IJ}\right)/2$
Almansi	-1	$E^{A}_{IJ} = \left(\delta_{IJ} - U^{-2}_{IJ}\right)/2$
Biot	1/2	$E^{B}_{IJ} = \left(U_{IJ} - \delta_{IJ}\right)$
Hencky	0	$E^{H}_{IJ} = \ln\left(U_{IJ}\right)$

106.2.4 Rate of Deformation Tensor

The *rate of deformation tensor*[6] describes the *tangent motion* in terms of velocity components $v_i = dx_i/dt$. The spatial coordinates are:

$$v_i = v_i\left(x_1, x_2, x_3, t\right) \tag{106.32}$$

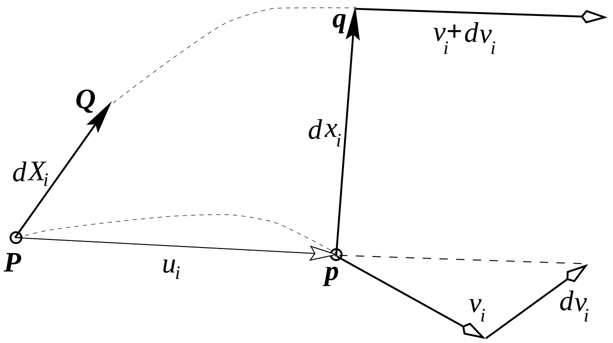

Figure 106.3: Relative velocity dv_i of particle *Q* at point *q* relative to particle *P* at point *p*.

In Figure 106.3 the dashed lines represents the trajectories of particles *P* and *Q*. The velocity vectors v_i at *p* and $v_i + dv_i$ at *q* are tangent to the two trajectories. The relative velocity components dv_i of particle at *q* relative to the particle at *p* are given by:

$$dv_k = \frac{\partial v_k}{\partial x_m} dx_m = v_{k,m} dx_m = L_{km} dx_m \tag{106.33}$$

---

[6] Also called *stretch tensor* or *velocity strain*.

The *spatial gradient of the velocity* L_{km} can be decomposed as the sum of the symmetric, *rate of deformation tensor* D_{km}, and a skew symmetric *spin tensor* W_{km} as follows:

$$L_{km} = \frac{1}{2}\left(L_{km} + L_{mk}\right) + \frac{1}{2}\left(L_{km} - L_{mk}\right) = D_{km} + W_{km} \tag{106.34}$$

where:

$$D_{km} = \frac{1}{2}\left(L_{km} + L_{mk}\right) = D_{mk} \qquad \text{and} \qquad W_{km} = \frac{1}{2}\left(L_{km} - L_{mk}\right) = -W_{mk} \tag{106.35}$$

An alternate way of deriving the rate of deformation tensor goes as follows. The rate of change of squared length $(ds)^2$ is given as:

$$\frac{d\,(ds)^2}{dt} = 2\frac{d\,(ds)}{dt}ds \tag{106.36}$$

since $(ds)^2 = dx_k dx_k$ it follows:

$$\frac{d\,(ds)^2}{dt} = 2\frac{d\,(dx_k)}{dt}dx_k \tag{106.37}$$

and with $dx_k = (\partial x_k / \partial X_m) dX_m$ it follows:

$$\frac{d\,(dx_k)}{dt} = \frac{d\left(\frac{\partial x_k}{\partial X_m}dX_m\right)}{dt} = \frac{d\left(\frac{\partial x_k}{\partial X_m}\right)}{dt}dX_m + \frac{d\,(dX_m)}{dt}\frac{\partial x_k}{\partial X_m} = \frac{d\left(\frac{\partial x_k}{\partial X_m}\right)}{dt}dX_m \tag{106.38}$$

since $d\,(dX_m)/dt \equiv 0$, because the initial relative position vector dX_m does not change with time. By interchanging the order of differentiation we get:

$$\frac{d\,(dx_k)}{dt} = dv_k = \frac{d\left(\frac{\partial x_k}{\partial X_M}\right)}{dt}dX_m = \frac{\partial v_k}{\partial X_m}dX_m \qquad \text{where} \qquad v_k = \frac{\partial x_k}{dt} \tag{106.39}$$

From equation (106.33) $dv_k = L_{km} dx_m$ and equation (106.39) it follows that:

$$\frac{\partial v_k}{\partial X_m}dX_m = L_{km}dx_m \qquad \Rightarrow \qquad \frac{d\,(dx_k)}{dt} = dv_k = L_{km}dx_m = v_{k,m}dx_m \tag{106.40}$$

and then the equation (106.37) becomes:

$$\begin{aligned}\frac{d\,(ds)^2}{dt} &= 2\frac{d\,(dx_k)}{dt}dx_k = 2dx_k v_{k,m} dx_m dx_k = 2dx_k L_{km} dx_m dx_k = \\ &= 2dx_k D_{km} dx_m dx_k + 2dx_k W_{km} dx_m dx_k = 2dx_k D_{km} dx_m dx_k\end{aligned} \tag{106.41}$$

since $dx_k dx_m \equiv dx_m dx_k$ and W_{km} is skew symmetric such that $W_{km} = -W_{mk}$. Finally we obtain:

$$\frac{d\,(ds)^2}{dt} = 2dx_k D_{km} dx_m \tag{106.42}$$

and thus it follows that the rate of change of the squared length $(ds)^2$ of the material instantaneously occupying any infinitesimal relative position dx_k at point *p* is determined by the tensor D_{km} at point *p*.

In order to compare the strain rate to the rate of deformation, we differentiate equation (106.15) with respect to time:

$$\frac{d\left((ds)^2-(dS)^2\right)}{dt} = 2\frac{d\left(dX_I E_{IJ} dX_J\right)}{dt} =$$

$$= \frac{d\left((ds)^2\right)}{dt} = 2dX_I \frac{d\left(E_{IJ}\right)}{dt} dX_J \qquad (106.43)$$

since $(dS)^2$ and dX_I are constant through time. From the equations (106.42) and (106.43) it follows that:

$$\frac{d\,(ds)^2}{dt} = 2dx_k D_{km} dx_m d = 2\left(dX_I F_{Ik}\right) D_{km}\left(F_{mJ} dX_J\right) = 2dX_I\left(F_{Ik} D_{km} F_{mJ}\right) dX_J \qquad (106.44)$$

and from equations (106.43) and (106.44) it follows that:

$$\frac{dE_{IJ}}{dt} = F_{Ik} D_{km} F_{mJ} \qquad (106.45)$$

or inversely:

$$D_{km} = \left(F_{Ik}\right)^{-1} \frac{dE_{IJ}}{dt}\left(F_{mJ}\right)^{-1} \qquad (106.46)$$

To obtain the rate of change of the deformation gradient we start from equations (106.4) and differentiate it with respect to time:

$$\frac{dF_{kK}}{dt} = \frac{d\left(\frac{\partial x_k}{\partial X_K}\right)}{dt} = \frac{\partial\left(\frac{dx_k}{dt}\right)}{\partial X_K} = \frac{\partial v_k}{\partial X_K} = \frac{\partial v_k}{\partial x_m}\frac{\partial x_m}{\partial X_K} = v_{k,m} x_{m,K} = \frac{dx_{k,K}}{dt} =$$

$$= L_{km} F_{mK} = \dot{F}_{kK} \qquad (106.47)$$

or inversely:

$$v_{k,m} = \frac{dx_{k,K}}{dt} X_{K,m} = \frac{dF_{kK}}{dt}\left(F_{Km}\right)^{-1} =$$

$$= \dot{F}_{kK}\left(F_{Km}\right)^{-1} = L_{km} \qquad (106.48)$$

106.3 Constitutive Relations: Hyperelasticity

106.3.1 Introduction

A material is called *hyperelastic* or *Green elastic*, if there exists an *elastic potential function* W, also called the *strain energy function per unit volume of the undeformed configuration*, which represents a scalar function of strain of deformation tensors, whose derivatives with respect to a strain component determines the corresponding stress component. The most general form of the elastic potential function, is described in equation 106.49, with restriction to pure mechanical theory, by using the *axiom of locality* and the *axiom of entropy production*[7]:

$$W = W\left(X_K, F_{kK}\right) \tag{106.49}$$

By using the *axiom of material frame indifference*[8], we conclude that W depends only on X_K and C_{IJ}, that is:

$$W = W\left(X_K, C_{IJ}\right) \quad \text{or:} \quad W = W\left(X_K, c_{ij}\right) \tag{106.50}$$

By assuming hyperelastic response, the following are the constitutive equations for the material stress tensors:

- 2. Piola–Kirchhoff stress tensor:

$$S_{IJ} = 2\frac{\partial W}{\partial C_{IJ}} \tag{106.51}$$

- Mandel stress tensor:

$$T_{IJ} = C_{IK} S_{KJ} = 2 C_{IK} \frac{\partial W}{\partial C_{KJ}} \tag{106.52}$$

- 1. Piola–Kirchhoff stress tensor

$$P_{iJ} = S_{IJ}(F_{iI})^t = 2\frac{\partial W}{\partial C_{IJ}}(F_{iI})^t \tag{106.53}$$

and the spatial, Kirchhoff stress tensor is defined as:

- Kirchhoff stress tensor

$$\tau_{ij} = 2\,\frac{\partial W}{\partial b_{ij}} = 2\,F_{iA}(F_{jB})^t \frac{\partial W}{\partial C_{AB}} = F_{iA}(F_{jB})^t S_{AB} \tag{106.54}$$

---

[7] See Marsden and Hughes (1983) pp. 190.

[8] See Marsden and Hughes (1983) pp. 194.

Material tangent stiffness relation is defined from:

$$dS_{IJ} = 2\,\frac{\partial^2 W}{\partial C_{IJ}\,\partial C_{KL}}\,dC_{KL} = \frac{1}{2}\,\mathcal{L}_{IJKL}\,dC_{KL} \tag{106.55}$$

where

$$\mathcal{L}_{IJKL} = 4\,\frac{\partial^2 W}{\partial C_{IJ}\,\partial C_{KL}} \tag{106.56}$$

The spatial tangent stiffness tensor $\mathcal{E}_{ijkl}$ is obtained by the following *push–forward* operation with the deformation gradient:

$$\mathcal{E}_{ijkl} = F_{iI}F_{jJ}(F_{kK})^t(F_{lL})^t\mathcal{L}_{IJKL} \tag{106.57}$$

106.3.2 Isotropic Hyperelasticity

In the case of material isotropy, the strain energy function $W\left(X_K, C_{IJ}\right)$ belongs to the class of isotropic, invariant scalar functions. It satisfies the relation:

$$W\left(X_K, C_{KL}\right) = W\left(X_K, Q_{KI}C_{IJ}\left(Q_{JL}\right)^t\right) \tag{106.58}$$

where Q_{KI} is the proper orthogonal transformation. If we choose $Q_{KI} = R_{KI}$, where R_{KI} is the orthogonal rotation transformation, defined by the polar decomposition theorem in equation (106.13), then:

$$W\left(X_K, C_{KL}\right) = W\left(X_K, U_{KL}\right) = W\left(X_K, v_{kl}\right) \tag{106.59}$$

Right and left stretch tensors, U_{KL}, v_{kl} have the same principal values[9] $\lambda_i \;\; ; \;\; i = \overline{1,3}$ so the strain energy function W can be represented in terms of principal stretches, or similarly in terms of principal invariants of deformation tensor:

$$W = W\left(X_K, \lambda_1, \lambda_2, \lambda_3, \right) = W\left(X_K, I_1, I_2, I_3\right) \tag{106.60}$$

where:

$$\begin{aligned} I_1 &\overset{\text{def}}{=} C_{II} \\ I_2 &\overset{\text{def}}{=} \frac{1}{2}\left(I_1^2 - C_{IJ}C_{JI}\right) \\ I_3 &\overset{\text{def}}{=} \det\left(C_{IJ}\right) = \frac{1}{6}e_{IJK}e_{PQR}C_{IP}C_{JQ}C_{KR} = J^2 \end{aligned} \tag{106.61}$$

Left and right Cauchy–Green tensors were defined by equations (106.22) and (106.23), respectively as:

$$C_{IJ} = (F_{kI})^t F_{kJ} \quad ; \quad (c^{-1})_{ij} = b_{ij} = F_{iK}(F_{jK})^t \tag{106.62}$$

---

[9] Principal stretches.

The spectral[10] decomposition theorem for symmetric positive definite tensors[11] states that:

$$C_{IJ} = \lambda_A^2 \left(N_I^{(A)} N_J^{(A)} \right)_A \qquad \text{where} \qquad A = \overline{1,3} \tag{106.63}$$

and N_I are the eigenvectors[12] of C_{IJ}. Values λ_A^2 are the roots of the characteristic polynomial

$$P(\lambda_A^2) \stackrel{\text{def}}{=} -\lambda_A^6 + I_1\ \lambda_A^6 - I_2\ \lambda_A^4 + I_3 = 0 \tag{106.64}$$

It should be noted that no summation is implied over indices in parenthesis[13].

The mapping of the eigenvectors can be deduced from equation (106.5) and is given by

$$\lambda_{(A)}\ n_i^{(A)} = F_{iJ}\ N_J^{(A)} \tag{106.65}$$

where $\|n_i^{(A)}\| \equiv 1$. The spectral decomposition of F_{iJ}, R_{iJ} and b_{ij} is then given by

$$F_{iJ} = \lambda_A \left(n_i^{(A)} N_J^{(A)} \right)_A \tag{106.66}$$

$$R_{iJ} = \sum_{A=1}^{3} n_i^{(A)} N_J^{(A)} \tag{106.67}$$

$$b_{ij} = \lambda_A^2 \left(n_i^{(A)} n_j^{(A)} \right)_A \tag{106.68}$$

Spectral decomposition from equation (106.63) is valid for the case of non–equal principal stretches, i.e. $\lambda_1 \neq \lambda_2 \neq \lambda_3$. If two or all three principal stretches are equal, we shall introduce a small perturbation to the numerical values for principal stretches in order to make them distinct. The case of two or all three values of principal stretches being equal is theoretically possible and results for example from standard triaxial tests or isotropic compression tests. However, we are never certain about equivalence of two numerical numbers, because of the finite precision arithmetics involved in calculation of these numbers. From the numerical point of view, two number are equal if the difference between them is smaller than the machine precision ($macheps$) specific to the computer platform on which computations are performed. Our perturbation will be a function of the $macheps$.

The characteristic polynomial $P(\lambda_A^2)$ from equation (106.64) can be solved[14] for λ_A:

$$\lambda_A = \frac{1}{\sqrt{3}} \sqrt{I_1 + 2\sqrt{I_1^2 - 3I_2} \cos\left(\frac{\Theta + 2\pi A}{3} \right)} \tag{106.69}$$

---

[10] See Simo and fTaylor (1991).

[11] Cauchy–Green tensor C_{IJ} for example.

[12] So that $\|N_I\| = 1$.

[13] For example, in the present case $N_I^{(A)}$ is the Ath eigenvector with members $N_1^{(A)}$, $N_2^{(A)}$ and $N_3^{(A)}$, so that the actual equation $C_{IJ} = \lambda_A^2 \left(N_I^{(A)} N_J^{(A)} \right)_A$ can also be written as $C_{IJ} = \sum_{A=1}^{A=3} \lambda_{(A)}^2 N_I^{(A)} N_J^{(A)}$. In order to follow the consistency of indicial notation in this work, we shall make an effort to represent all the tensorial equations in indicial form.

[14] See also Morman (1986) and Schellekens and Schellekens and Parisch (1994).

where

$$\Theta = \arccos \frac{2I_1^3 - 9I_1I_2 + 27I_3}{2\sqrt{\left(I_1^2 - 3I_2\right)^3}} \tag{106.70}$$

Recently, Ting (1985) and Morman (1986) have used Serrin's representation theorem in order to devise a useful representation for generalized strain tensors[15] E_{IJ} and e_{ij} through C^m_{IJ} and b^m_{ij}. Morman (1986) has shown that b^m_{ij} can be stated as

$$b^m_{ij} = \lambda_A^{2m} \left(\frac{(b^2)_{ij} - \Big((I_1 - \lambda^2_{(A)} \Big) b_{ij} + I_3 \lambda^{-2}_{(A)} \delta_{ij}}{2\lambda^4_{(A)} - I_1 \lambda^2_{(A)} + I_3 \lambda^{-2}_{(A)}} \right)_A \tag{106.71}$$

By comparing equations (106.71) and (106.68) it follows that the Eulerian eigendiad $n_i^{(A)} n_j^{(A)}$ can be written as

$$n_i^{(A)} n_j^{(A)} = \frac{(b^2)_{ij} - \left(I_1 - \lambda^2_{(A)} \right) b_{ij} + I_3 \lambda^{-2}_{(A)} \delta_{ij}}{2\lambda^4_{(A)} - I_1 \lambda^2_{(A)} + I_3 \lambda^{-2}_{(A)}} \tag{106.72}$$

The Lagrangian eigendiad $N_I^{(A)} N_J^{(A)}$, from equation (106.63), can be derived, if one substitutes mapping of the eigenvectors, (106.65), into equation (106.72) to get:

$$N_I^{(A)} N_J^{(A)} = \lambda^2_{(A)} \frac{C_{IJ} - \left(I_1 - \lambda^2_{(A)} \right) \delta_{IJ} + I_3 \lambda^{-2}_{(A)} (C^{-1})_{IJ}}{2\lambda^4_{(A)} - I_1 \lambda^2_{(A)} + I_3 \lambda^{-2}_{(A)}} \tag{106.73}$$

where it was used that:

$$C_{IJ} = (F_{iI})^{-1} \; (b^2)_{ij} \; (F_{jJ})^{-t} \tag{106.74}$$

$$\delta_{IJ} = (F_{iI})^{-1} \; b_{ij} \; (F_{jJ})^{-t} \tag{106.75}$$

$$(C^{-1})_{IJ} = (F_{iI})^{-1} \; \delta_{ij} \; (F_{jJ})^{-t} \tag{106.76}$$

It should be noted that the denominator in equations (106.72) and (106.73) can be written as:

$$2\lambda^4_{(A)} - I_1 \lambda^2_{(A)} + I_3 \lambda^{-2}_{(A)} = \left(\lambda^2_{(A)} - \lambda^2_{(B)} \right) \left(\lambda^2_{(A)} - \lambda^2_{(C)} \right) \overset{\text{def}}{=} D_{(A)} \tag{106.77}$$

where indices A, B, C are cyclic permutations of $1, 2, 3$. It follows directly from the definition of $D_{(A)}$ in equation (106.77) that $\lambda_1 \neq \lambda_2 \neq \lambda_3 \Rightarrow D_{(A)} \neq 0$ for equations (106.72) and (106.73) to be valid. Similarly to equations (106.63) and (106.68) we can obtain:

$$(C^{-1})_{IJ} = \lambda_A^{-2} \left(N_I^{(A)} N_J^{(A)} \right)_A \tag{106.78}$$

$$(b^{-1})_{ij} = \lambda_A^{-2} \left(n_i^{(A)} n_j^{(A)} \right)_A \tag{106.79}$$

---

[15] Defined by equations (106.30) and (106.31).

106.3.3 Volumetric–Isochoric Decomposition of Deformation

It proves useful to separate deformation in volumetric and isochoric parts by a multiplicative split of a deformation gradient as

$$F_{iI} = \tilde{F}_{i\beta} \, {}^{vol}F_{\beta I} \qquad \text{where} \qquad \tilde{F}_{i\beta} = F_{iI} J^{-\frac{1}{3}} \quad ; \quad {}^{vol}F_{\beta I} = J^{\frac{1}{3}} \delta_{\beta I} \tag{106.80}$$

where x_β represents an intermediate configuration such that deformation $X_I \rightarrow x_\beta$ is purely volumetric and $x_\beta \rightarrow x_i$ is purely isochoric. It also follows from equation (106.80) that $\tilde{F}_{\beta I}$ and F_{iI} have the same eigenvectors.

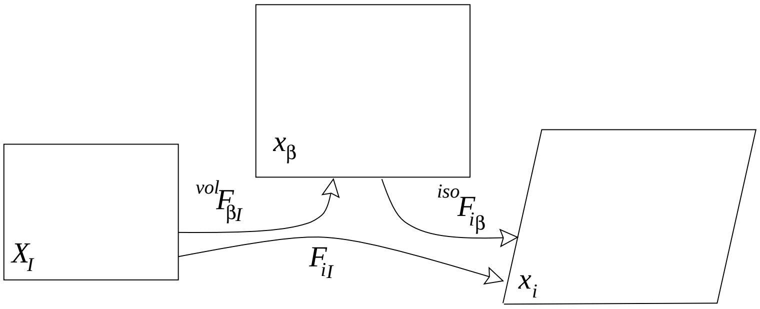

Figure 106.4: Volumetric isochoric decomposition of deformation.

The isochoric part of the Green deformation tensor C_{IJ}, defined in equation (106.63) can be defined as

$$\tilde{C}_{IJ} = J^{-\frac{2}{3}} C_{IJ} = \tilde{\lambda}_A^2 \left(N_I^{(A)} N_J^{(A)} \right)_A \tag{106.81}$$

while the isochoric part of the Finger deformation tensor b_{ij} can be defined similarly as

$$\tilde{b}_{ij} = J^{-\frac{2}{3}} b_{ij} = \tilde{\lambda}_A^2 \left(n_i^{(A)} n_j^{(A)} \right)_A \tag{106.82}$$

where the isochoric principal stretches are defined as

$$\tilde{\lambda}_A = J^{-\frac{1}{3}} \lambda_A = (\lambda_1 \lambda_2 \lambda_3)^{-\frac{1}{3}} \lambda_A \tag{106.83}$$

The free energy W is then decomposed additively as:

$$W \left(X_K, \lambda_{(A)} \right) = {}^{iso}W \left(X_K, \tilde{\lambda}_{(A)} \right) + {}^{vol}W \left(X_K, J \right) \tag{106.84}$$

106.3.4 Simo–Serrin's Formulation

In Section (106.3.2) we have presented the most general form of the isotropic strain energy function W in terms of of principal stretches:

$$W = W \left(X_K, \lambda_1, \lambda_2, \lambda_3, \right) \tag{106.85}$$

It was also shown in Section (106.3.1) that it is necessary to calculate the gradient $\partial W / \partial C_{IJ}$ in order to obtain 2. Piola–Kirchhoff stress tensor S_{IJ} and accordingly other stress measures. Likewise, it was shown that the material tangent stiffness tensor $\mathcal{L}_{IJKL}$ (as well as the spatial tangent stiffness tensor $\mathcal{E}_{ijkl}$) requires second order derivatives of strain energy function $\partial^2 W/(\partial C_{IJ}\,\partial C_{KL})$. In order to obtain these quantities we introduce[16] a second order tensor $M^{(A)}_{IJ}$

$$\begin{aligned} M^{(A)}_{IJ} &\overset{\text{def}}{=} \lambda^{-2}_{(A)}\, N^{(A)}_I\, N^{(A)}_J \\ &= (F_{iI})^{-1} \left(n^{(A)}_i n^{(A)}_j\right) (F_{jJ})^{-t} \\ &= \frac{1}{D_{(A)}} \left(C_{IJ} - \left(I_1 - \lambda^2_{(A)}\right)\delta_{IJ} + I_3\lambda^{-2}_{(A)}(C^{-1})_{IJ}\right) \quad \text{from (106.73)} \end{aligned} \tag{106.86}$$

where $D_{(A)}$ was defined by equation (106.77). With $M^{(A)}_{IJ}$ defined by equation (106.86), we get from equation (106.63) that:

$$C_{IJ} = \lambda^4_A \left(M^{(A)}_{IJ}\right)_A \tag{106.87}$$

and also from equation (106.78) it follows that:

$$(C^{-1})_{IJ} = M^{(1)}_{IJ} + M^{(2)}_{IJ} + M^{(3)}_{IJ} \tag{106.88}$$

It can also be concluded that:

$$\delta_{IJ} = \lambda^2_{(1)}M^{(1)}_{IJ} + \lambda^2_{(2)}M^{(2)}_{IJ} + \lambda^2_{(3)}M^{(3)}_{IJ} = \lambda^2_A \left(M^{(A)}_{IJ}\right)_A \tag{106.89}$$

since, from the orthogonal properties of eigenvectors

$$\delta_{IJ} = \sum_{A=1}^{3} N^{(A)}_I\, N^{(A)}_J = \left(N^{(A)}_I\right)_A \left(N^{(A)}_J\right)_A \tag{106.90}$$

We are now in a position to define the *Simo–Serrin* fourth order tensor $\mathcal{M}_{IJKL}$ as:

$$\begin{aligned} \mathcal{M}^{(A)}_{IJKL} \overset{\text{def}}{=} & \frac{\partial M^{(A)}_{IJ}}{\partial C_{KL}} = \\ & \frac{1}{D_{(A)}} \left(I_{IJKL} - \delta_{KL}\delta_{IJ} + \lambda^2_{(A)} \left(\delta_{IJ}\, M^{(A)}_{KL} + M^{(A)}_{IJ}\,\delta_{KL}\right) + \right. \\ + \; & I_3\lambda^{-2}_{(A)} \left((C^{-1})_{IJ}(C^{-1})_{KL} + \frac{1}{2}\left((C^{-1})_{IK}(C^{-1})_{JL} + (C^{-1})_{IL}(C^{-1})_{JK}\right)\right) - \\ - \; & \left. \lambda^{-2}_{(A)}\, I_3 \left((C^{-1})_{IJ}\, M^{(A)}_{KL} + M^{(A)}_{IJ}\,(C^{-1})_{KL}\right) - D'_{(A)}\, M^{(A)}_{IJ}\, M^{(A)}_{KL}\right) \end{aligned} \tag{106.91}$$

Complete derivation of $\mathcal{M}_{IJKL}$ is given in Appendix (704.2).

---

[16] See Runesson (1996).

106.3.5 Stress Measures

In Section (106.3.1) we have defined various stress measures in terms of derivatives of the free energy function W. With the free energy function decomposition, as defined in equation (106.84) we can appropriately decompose all the previously defined stress measures:

- 2. Piola–Kirchhoff stress tensor:

$$\begin{aligned} S_{IJ} &= 2\frac{\partial W}{\partial C_{IJ}} = 2\frac{\partial^{iso} W}{\partial C_{IJ}} + 2\frac{\partial^{vol} W}{\partial C_{IJ}} \\ &= {}^{iso}S_{IJ} + {}^{vol}S_{IJ} \end{aligned} \tag{106.92}$$

- Mandel stress tensor:

$$\begin{aligned} T_{IJ} &= C_{IK}S_{KJ} = 2C_{IK}\frac{\partial W}{\partial C_{KJ}} = 2C_{IK}\frac{\partial^{iso} W}{\partial C_{KJ}} + 2C_{IK}\frac{\partial^{vol} W}{\partial C_{KJ}} \\ &= {}^{iso}T_{IJ} + {}^{vol}T_{IJ} \end{aligned} \tag{106.93}$$

- 1. Piola–Kirchhoff stress tensor

$$\begin{aligned} P_{iJ} &= S_{IJ}(F_{iI})^t = 2\frac{\partial W}{\partial C_{IJ}}(F_{iI})^t = 2\frac{\partial^{iso} W}{\partial C_{IJ}}(F_{iI})^t + 2\frac{\partial^{vol} W}{\partial C_{IJ}}(F_{iI})^t \\ &= {}^{iso}P_{iJ} + {}^{vol}P_{iJ} \end{aligned} \tag{106.94}$$

- Kirchhoff stress tensor

$$\begin{aligned} \tau_{ab} &= 2\frac{\partial W}{\partial e_{ij}} = F_{aI}(F_{bJ})^t S_{IJ} = 2F_{aI}(F_{bJ})^t\frac{\partial^{iso} W}{\partial C_{IJ}} + 2F_{aI}(F_{bJ})^t\frac{\partial^{vol} W}{\partial C_{IJ}} \\ &= F_{aI}(F_{bJ})^{t\,iso}S_{IJ} + F_{aI}(F_{bJ})^{t\,vol}S_{IJ} \\ &= {}^{iso}\tau_{ab} + {}^{vol}\tau_{ab} \end{aligned} \tag{106.95}$$

The derivative of the volumetric part of the free energy function is

$$\frac{\partial^{vol}W(J)}{\partial C_{IJ}} = \frac{\partial^{vol}W(J)}{\partial J}\,\frac{\partial J}{\partial C_{IJ}} = \frac{1}{2}\,\frac{\partial^{vol}W(J)}{\partial J}\;J\;(C^{-1})_{IJ} \tag{106.96}$$

where equation (704.9) was used, while the derivative of the isochoric part of the free energy function yields

$$\frac{\partial^{iso}W(\tilde{\lambda}_{(A)})}{\partial C_{IJ}} = \frac{\partial^{iso}W(\tilde{\lambda}_{(A)})}{\partial \lambda_{(A)}}\,\frac{\partial \lambda_{(A)}}{\partial C_{IJ}} = \frac{1}{2}\frac{\partial^{iso}W(\lambda_{(A)})}{\partial \lambda_{(A)}}\lambda_{(A)}(M^{(A)}_{IJ})_A = \frac{1}{2}w_A(M^{(A)}_{IJ})_A \tag{106.97}$$

where equation (704.7) was used and w_A is derived in Appendix 704.5 as:

$$w_A = \frac{\partial^{iso}W(\lambda_{(A)})}{\partial \tilde{\lambda}_B}\,\frac{\partial \tilde{\lambda}_B}{\partial \lambda_{(A)}}\;\tilde{\lambda}_{(A)} = -\frac{1}{3}\,\frac{\partial^{iso}W(\tilde{\lambda}_{(A)})}{\partial \tilde{\lambda}_B}\;\tilde{\lambda}_B + \frac{\partial^{iso}W(\tilde{\lambda}_{(A)})}{\partial \tilde{\lambda}_{(A)}}\;\tilde{\lambda}_{(A)} \tag{106.98}$$

The decomposed 2. Piola–Kirchhoff stress tensor is

$$\begin{aligned} S_{IJ} &= {}^{vol}S_{IJ} + {}^{iso}S_{IJ} \\ &= \frac{\partial^{vol}W(J)}{\partial J}\;J\;(C^{-1})_{IJ} + w_A\;(M^{(A)}_{IJ})_A \end{aligned} \tag{106.99}$$

The derivative of the free energy is then:

$$\begin{aligned} \frac{\partial W(\lambda_{(A)})}{\partial C_{IJ}} &= \frac{\partial^{vol}W(\lambda_{(A)})}{\partial C_{IJ}} + \frac{\partial^{iso}W(\lambda_{(A)})}{\partial C_{IJ}} \\ &= \frac{1}{2}\,\frac{\partial^{vol}W(J)}{\partial J}\;J\;(C^{-1})_{IJ} + \frac{1}{2}\;w_A\;(M^{(A)}_{IJ})_A \end{aligned} \tag{106.100}$$

It is obvious that the only material dependent parts are derivatives in the form $\partial^{vol}W/\partial J$ and w_A, while the rest is independent of which hyperelastic material model we choose.

106.3.6 Tangent Stiffness Operator

The free energy function decomposition (106.84) is used together with the appropriate definitions made in section (106.3.1) toward the tangent stiffness operator decomposition

$$\mathcal{L}_{IJKL} = {}^{vol}\mathcal{L}_{IJKL} + {}^{iso}\mathcal{L}_{IJKL} = 4\,\frac{\partial^2\left({}^{vol}W\right)}{\partial C_{IJ}\;\partial C_{KL}} + 4\,\frac{\partial^2\left({}^{iso}W\right)}{\partial C_{IJ}\;\partial C_{KL}} \tag{106.101}$$

The volumetric part $\partial^2\left({}^{vol}W\right)/(\partial C_{IJ}\;\partial C_{KL})$ can be written as:

$$\frac{\partial^{2\,vol}W}{\partial C_{IJ}\;\partial C_{KL}} = \frac{1}{4}\left(J^2\frac{\partial^2\left({}^{vol}W\right)}{\partial J \partial J} + J\frac{\partial\left({}^{vol}W\right)}{\partial J}\right)(C^{-1})_{KL}(C^{-1})_{IJ} + \frac{1}{2}J\frac{\partial\left({}^{vol}W\right)}{\partial J}I^{(C^{-1})}_{IJKL} \tag{106.102}$$

and the complete derivation is again given in appendix 704.3.

The isochoric part $\partial^2 \left({}^{iso}W\right)/(\partial C_{IJ}\ \partial C_{KL})$ can be written in the following form:

$$\frac{\partial^{2\,iso}W(\lambda_{(A)})}{\partial C_{IJ}\partial C_{KL}} = \frac{1}{4}\ Y_{AB}\ (M^{(B)}_{KL})_B\ (M^{(A)}_{IJ})_A + \frac{1}{2}\ w_A\ (\mathcal{M}^{(A)}_{IJKL})_A \tag{106.103}$$

and the complete derivation is given in the appendix (704.4).

Finally, one can write the volumetric and isochoric parts of the tangent stiffness tensors as:

$${}^{vol}\mathcal{L}_{IJKL} =$$

$$J^2 \frac{\partial^{2\,vol}W(J)}{\partial J \partial J}(C^{-1})_{KL}(C^{-1})_{IJ} + J\frac{\partial^{vol}W(J)}{\partial J}(C^{-1})_{KL}(C^{-1})_{IJ} + 2J\frac{\partial^{vol}W(J)}{\partial J} I^{(C^{-1})}_{IJKL} \tag{106.104}$$

$$\mathcal{L}^{iso}_{IJKL} = Y_{AB}\ (M^{(B)}_{KL})_B\ (M^{(A)}_{IJ})_A + 2\ w_A\ (\mathcal{M}^{(A)}_{IJKL})_A \tag{106.105}$$

In a similar manner to the stress definitions it is clear that the only material model dependent parts are Y_{AB} and w_A. The remaining second and fourth order tensors $M^{(A)}_{IJ}$ and $\mathcal{M}^{(A)}_{IJKL}$ are independent of the choice of the material model. This observation has a practical consequence in that it is possible to create a *template derivations* for various hyperelastic isotropic material models. Only first and second derivatives of strain energy function with respect to isochoric principal stretches ($\tilde{\lambda}_A$) and Jacobian (J) are needed in addition to the independent tensors, for the determination of various stress and tangent stiffness tensors.

106.3.7 Isotropic Hyperelastic Models

The strain energy function for isotropic solid in terms of principal stretches is represented as:

$$W = W(\lambda_1, \lambda_2, \lambda_3) \tag{106.106}$$

The only restriction is that W is a symmetric function of $\lambda_1, \lambda_2, \lambda_3$, although an appropriate natural configuration condition requires that:

$$W(1,1,1) = 0 \qquad \text{and} \qquad \frac{\partial W(1,1,1)}{\partial \lambda_i} = 0 \tag{106.107}$$

The strain energy function W can either be regarded as a function of principal stretches or the principal invariants of stretches[17]:

$$\begin{aligned} I_1 &= \lambda_1^2 + \lambda_2^2 + \lambda_3^2 \\ I_2 &= \lambda_2^2\lambda_3^2 + \lambda_3^2\lambda_1^2 + \lambda_1^2\lambda_2^2 \\ I_3 &= \lambda_1^2\lambda_2^2\lambda_3^2 \end{aligned} \tag{106.108}$$

---

[17] See also equation (106.61).

A slightly more general formulation is obtained by using principal stretches in the strain energy function definition. A widely exploited family of compressible hyperelastic models[18] are defined (Ogden, 1984) as an infinite series in powers of $(I_1 - 3), (I_2 - 3)$ and $(I_3 - 1)$ as:

$$W = \sum_{p,q,r=0}^{N \to \infty} c_{pqr} \; (I_1 - 3)^p \, (I_2 - 3)^q \, (I_3 - 1)^r \tag{106.109}$$

The regularity condition that W is continuously differentiable an infinitely number of times is satisfied. The requirement that energy vanishes in the reference configuration is met provided $c_{000} = 0$. Reference configuration is stress free iff $c_{100} + 2c_{010} + c_{001} = 0$. Isochoric deviatoric decoupling is possible by setting $c_{pqr} = 0 \;\; (r = 1, 2, 3, ...)$ and $c_{pqr} = 0 \;\; (p, q = 1, 2, 3, ..)$ to obtain:

$$W = {}^{iso}W + {}^{vol}W \tag{106.110}$$

where:

$$\begin{aligned} {}^{iso}W &= \sum_{p,q=0}^{N \to \infty} c_{pq0} \; (I_1 - 3)^p \, (I_2 - 3)^q \\ {}^{vol}W &= \sum_{r=0}^{N \to \infty} c_{00r} \; (I_3 - 1)^r \end{aligned} \tag{106.111}$$

In what follows, we will present a number of widely used strain energy functions for isotropic elastic solids.

106.3.7.1 Ogden Model

A very general set of hyperelastic models was defined by Ogden (1984). The strain energy is expressed as a function of principal stretches as:

$$W = \sum_{r=1}^{N \to \infty} \frac{c_r}{\mu_r} \left(\lambda_1^{\mu_r} + \lambda_2^{\mu_r} + \lambda_3^{\mu_r} - 3 \right) \tag{106.112}$$

The isochoric strain energy function can be written as:

$${}^{iso}W = \sum_{r=1}^{N \to \infty} \frac{c_r}{\mu_r} \left(\tilde{\lambda}_1^{\mu_r} + \tilde{\lambda}_2^{\mu_r} + \tilde{\lambda}_3^{\mu_r} - 1 \right) \tag{106.113}$$

where the following was used $\tilde{\lambda}_i = J^{-\frac{1}{3}} \lambda_i$.

Derivatives needed for building tensors w_A and Y_{AB} are given by the following formulae:

$$\frac{\partial\, {}^{iso}W}{\partial \tilde{\lambda}_A} = \sum_{r=1}^{N \to \infty} c_r \left(\tilde{\lambda}_A \right)^{\mu_r - 1} \tag{106.114}$$

---

[18] Used mainly for rubber–like materials.

$$\frac{\partial^2 \left({}^{iso}W\right)}{\partial \tilde{\lambda}_A^2} = \sum_{r=1}^{N\to\infty} c_r \;\; (\mu_r - 1) \;\; \left(\tilde{\lambda}_A\right)^{\mu_r - 2} \tag{106.115}$$

$$\frac{\partial^2 \left({}^{iso}W\right)}{\partial \tilde{\lambda}_A \partial \tilde{\lambda}_B} = 0 \tag{106.116}$$

106.3.7.2 Neo–Hookean Model

The general isotropic hyperelastic model defined in terms of invariants of principal stretches contains the Neo–Hookean model as special cases. The isochoric part of Neo–Hookean isotropic elastic model can be obtained by selecting $N = 1$, $q = 0$, $c_{p00} = G/2$, to get:

$${}^{iso}W = \frac{G}{2} \left(\tilde{\lambda}_1^2 + \tilde{\lambda}_2^2 + \tilde{\lambda}_3^2 - 3\right) \tag{106.117}$$

while the volumetric part can be defined by choosing $N = 2$, $c_{001} = 0$, $c_{002} = K_b/2$, as:

$${}^{vol}W = \frac{K_b}{2} \left(\lambda_1^2 \lambda_2^2 \lambda_3^2 - 1\right)^2 = \frac{K_b}{2} \left(J^2 - 1\right)^2 \tag{106.118}$$

where G and K_b are the shear and bulk moduli respectively.

Derivatives needed for building tensors w_A and Y_{AB} are given by the following formulae:

$$\frac{\partial^{iso}W}{\partial \tilde{\lambda}_A} = G \; \tilde{\lambda}_A \tag{106.119}$$

$$\frac{\partial^2 \left({}^{iso}W\right)}{\partial \tilde{\lambda}_A^2} = G \tag{106.120}$$

$$\frac{\partial^2 \left({}^{iso}W\right)}{\partial \tilde{\lambda}_A \partial \tilde{\lambda}_B} = 0 \tag{106.121}$$

106.3.7.3 Mooney–Rivlin Model

Mooney proposed a strain energy function for isochoric behavior of the form:

$$\begin{aligned} {}^{iso}W &= \sum_{n=0}^{N\to\infty} \left(a_n \left(\tilde{\lambda}_1^{2n} + \tilde{\lambda}_2^{2n} + \tilde{\lambda}_3^{2n} - 3\right) + a_n \left(\tilde{\lambda}_1^{-2n} + \tilde{\lambda}_2^{-2n} + \tilde{\lambda}_3^{-2n} - 3\right)\right) \\ &= \sum_{n=0}^{N\to\infty} \left(a_n \left(\tilde{\lambda}_1^{2n} + \tilde{\lambda}_2^{2n} + \tilde{\lambda}_3^{2n} - 3\right)\right. \\ &\quad \left. + \, a_n \left(\left(\tilde{\lambda}_2 \tilde{\lambda}_3\right)^{-2n} + \left(\tilde{\lambda}_3 \tilde{\lambda}_1\right)^{-2n} + \left(\tilde{\lambda}_1 \tilde{\lambda}_2\right)^{-2n} - 3\right)\right) \end{aligned} \tag{106.122}$$

with a_n and b_n being the material parameters and a volume preserving constrain $\lambda_a = 1/(\lambda_b \lambda_c$, and a, b, c are cyclic permutations of $(1, 2, 3)$. A more general form was proposed by Rivlin:

$${}^{iso}W = \sum_{p,q=0}^{N\to\infty} c_{pq} \;\; (I_1 - 3)^p \, (I_2 - 3)^q \tag{106.123}$$

which is actually quite similar to the isochoric part of the general isotropic representation from equation (106.111). Both Mooney and Rivlin strain energy functions become similar, if one chooses to set $N = 1$ and $c_{10} = C_1$ and $c_{01} = C_2$ to obtain:

$$\begin{aligned} {}^{iso}W &= \left(C_1 \left(\tilde{\lambda}_1^2 + \tilde{\lambda}_2^2 + \tilde{\lambda}_3^2 - 3 \right) + C_2 \left(\tilde{\lambda}_1^{-2} + \tilde{\lambda}_2^{-2} + \tilde{\lambda}_3^{-2} - 3 \right) \right) \\ &= \left(C_1 \left(\tilde{I}_1 - 3 \right) + C_2 \left(\tilde{I}_2 - 3 \right) \right) \end{aligned} \tag{106.124}$$

Derivatives needed for building tensors w_A and Y_{AB} are given by the following formulae:

$$\frac{\partial {}^{iso}W}{\partial \tilde{\lambda}_A} = 2\, C_1\, \tilde{\lambda}_A - 2\, C_2\, \tilde{\lambda}_A^{-3} \tag{106.125}$$

$$\frac{\partial^2 \left({}^{iso}W \right)}{\partial \tilde{\lambda}_A^2} = 2\, C_1 + 6\, C_2\, \tilde{\lambda}_A^{-4} \tag{106.126}$$

$$\frac{\partial^2 \left({}^{iso}W \right)}{\partial \tilde{\lambda}_A \partial \tilde{\lambda}_B} = 0 \tag{106.127}$$

106.3.7.4 Logarithmic Model

By choosing an alternative set of isochoric principal stretch invariants in the form:

$$\begin{aligned} \tilde{I}_1^{ln} &= 2 \left(\ln \tilde{\lambda}_1 \right)^2 + 2 \left(\ln \tilde{\lambda}_2 \right)^2 + 2 \left(\ln \tilde{\lambda}_3 \right)^2 \\ &= \left(\tilde{\lambda}_1^{\ln} \right)^2 + \left(\tilde{\lambda}_2^{\ln} \right)^2 + \left(\tilde{\lambda}_3^{\ln} \right)^2 \\[1em] \tilde{I}_2^{ln} &= 4 \left(\ln \tilde{\lambda}_2 \right)^2 \left(\ln \tilde{\lambda}_3 \right)^2 + 4 \left(\ln \tilde{\lambda}_3 \right)^2 \left(\ln \tilde{\lambda}_1 \right)^2 + 4 \left(\ln \tilde{\lambda}_1 \right)^2 \left(\ln \tilde{\lambda}_2 \right)^2 \\ &= \left(\tilde{\lambda}_2^{\ln} \right)^2 \left(\tilde{\lambda}_3^{\ln} \right)^2 + \left(\tilde{\lambda}_3^{\ln} \right)^2 \left(\tilde{\lambda}_1^{\ln} \right)^2 + \left(\tilde{\lambda}_1^{\ln} \right)^2 \left(\tilde{\lambda}_2^{\ln} \right)^2 \end{aligned} \tag{106.128}$$

where the isochoric logarithmic stretch $\tilde{\lambda}_i^{\ln}$ was used:

$$\tilde{\lambda}_i^{\ln} = \sqrt{2} \ln \tilde{\lambda}_i = \frac{1}{\sqrt{2}} \ln \tilde{\lambda}_i^2 \tag{106.129}$$

The general representation of the isochoric part of the strain energy function in terms of $\tilde{I}_1^{ln}$ and $\tilde{I}_2^{ln}$ was proposed by Simo and Miehe (1992). A somewhat simpler isochoric strain energy function can be presented in the form:

$${}^{iso}W = G \left(\left(\ln \tilde{\lambda}_1 \right)^2 + \left(\ln \tilde{\lambda}_2 \right)^2 + \left(\ln \tilde{\lambda}_3 \right)^2 \right) \tag{106.130}$$

while the volumetric part is suggested in the form:

$${}^{vol}W = \frac{K_b}{2} \left(\ln J \right)^2 \tag{106.131}$$

Derivatives needed for building tensors w_A and Y_{AB} are given by the following formulae:

$$\frac{\partial^{iso} W}{\partial \tilde{\lambda}_A} = 2\ G\ \left(\tilde{\lambda}_A\right)^{-1} \tag{106.132}$$

$$\frac{\partial^2\left({}^{iso}W\right)}{\partial \tilde{\lambda}_A^2} = -2\ G\ \left(\tilde{\lambda}_A\right)^{-2} \tag{106.133}$$

$$\frac{\partial^2\left({}^{iso}W\right)}{\partial \tilde{\lambda}_A \partial \tilde{\lambda}_B} = 0 \tag{106.134}$$

$$\frac{d\left({}^{vol}W\right)}{dJ} = K_b\ J^{-1} \ln J \tag{106.135}$$

$$\frac{d^2\left({}^{vol}W\right)}{dJ^2} = K_b\ J^{-2} - K_b\ J^{-2} \ln J \tag{106.136}$$

106.3.7.5 Simo–Pister Model

Another form or a volumetric part of strain energy function was proposed by Simo and Pister (1984) in the form:

$$W_{vol}(J) = \frac{1}{4}\ K_b\ \left(J^2 - 1 - 2 \ln J\right) \tag{106.137}$$

The first and second derivatives with respect to J are then given as:

$$\frac{d^{vol}W(J)}{dJ} = \frac{\left(\frac{-2}{J} + 2\,J\right)\ K_b}{4} \tag{106.138}$$

$$\frac{d^{2\,vol}W(J)}{dJ^2} = \frac{\left(2 + \frac{2}{J^2}\right)\ K_b}{4} \tag{106.139}$$

106.4 Finite Deformation Hyperelasto–Plasticity

106.4.1 Introduction

The mathematical structure and numerical analysis of classical small deformation elasto–plasticity is generally well established. However, development of large deformation elastic–plastic algorithms for isotropic and anisotropic material models is still a research area. Here, we present a new integration algorithm, based on the multiplicative decomposition of the deformation gradient into elastic and plastic parts. The algorithm is novel in that it is designed to be used with isotropic as well as anisotropic material models. Consistent derivation is based on the idea from the infinitesimal strain algorithm developed earlier by Jeremić and Sture (1997). The algorithm is not an extension of earlier developments, but rather a novel development which consistently utilizes Newton's method for numerical solution scheme for integrating pertinent constitutive equations. It is also shown that in the limit, the proposed algorithm reduces to the small strain counterpart.

In what follows, we briefly introduce the multiplicative decomposition of the deformation gradient and pertinent constitutive relations. We then proceed to present the numerical algorithm and the algorithmic tangent stiffness tensor consistent with the presented algorithm.

106.4.2 Kinematics

An appropriate generalization of the additive strain decomposition is the multiplicative decomposition of displacement gradient. The motivation for the multiplicative decomposition can be traced back to the early works of Bilby et al. (1957), and Kröner (1960) on micromechanics of crystal dislocations and application to continuum modeling. In the context of large deformation elastoplastic computations, the work by Lee and Liu (1967), Fox (1968) and Lee (1969) stirred an early interest in multiplicative decomposition.

The appropriateness of multiplicative decomposition technique for soils may be justified from the particulate nature of the material. From the micromechanical point of view, plastic deformation in soils arises from slipping, crushing, yielding and plastic bending[19] of granules comprising the assembly[20]. It can certainly be argued that deformations in soils are predominantly plastic, however, reversible deformations could develop from the elasticity of soil grains, and could be relatively large when particles are locked in high density specimens.

The reasoning behind multiplicative decomposition is a rather simple one. If an infinitesimal neighborhood of a body $x_i, x_i + dx_i$ in an inelastically deformed body is cut–out and unloaded to an unstressed configuration, it would be mapped into $\hat{x}_i, \hat{x}_i + d\hat{x}_i$. The transformation would be comprised of a rigid body displacement[21] and purely elastic unloading. The elastic unloading is a fictitious one, since materials with a strong Baushinger's effect, unloading will lead to loading in an other stress direction, and, if there are residual stresses, the body must be cut–out in small pieces and then every piece relieved of stresses. The unstressed configuration is thus incompatible and discontinuous. The position $\hat{x}_i$ is arbitrary, and we may assume a linear relationship between dx_i and $d\hat{x}_i$, in the form[22]:

---

[19] For plate like clay particles.

[20] See also Lambe and Whitman (1979) and Sture (1993).

[21] Translation and rotation.

[22] referred to same Cartesian coordinate system.

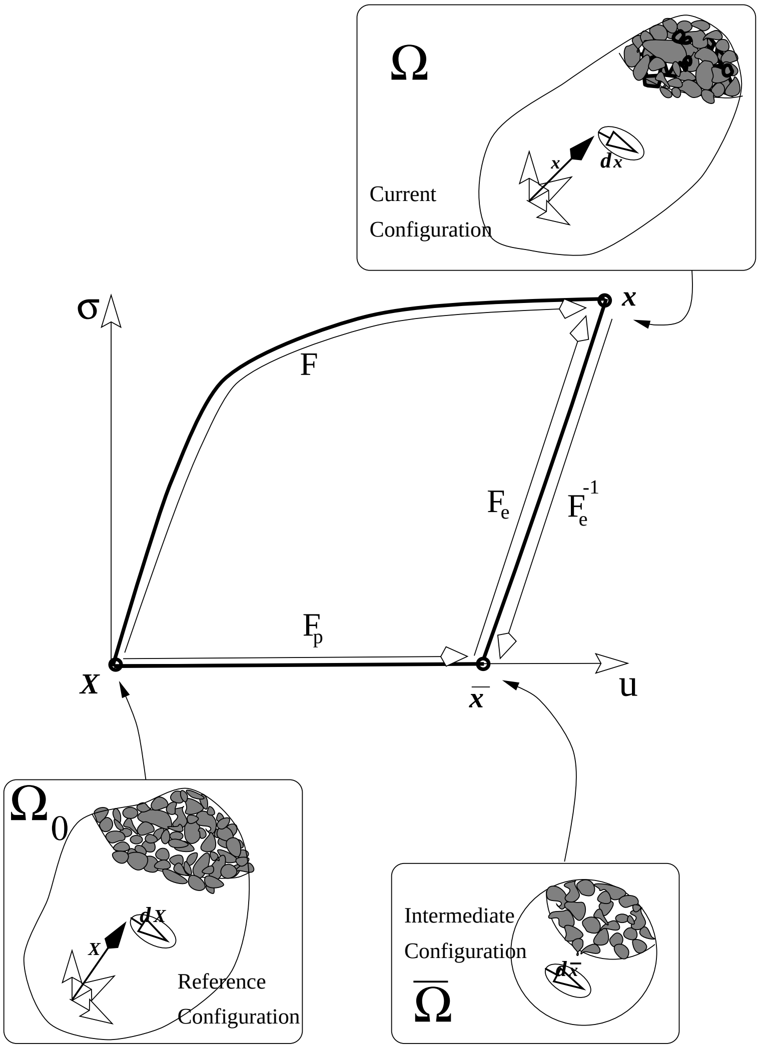

Figure 106.5: Multiplicative decomposition of deformation gradient: schematics.

$$d\hat{x}_k = \left(F^e_{ik}\right)^{-1} dx_i \tag{106.140}$$

where $\left(F^e_{ik}\right)^{-1}$ is not to be understood as a deformation gradient, since it may represent the incompatible, discontinuous deformation of a body. By considering the reference configuration of a body dX_i, then the connection to the current configuration is[23]:

$$dx_k = F_{ki} dX_i \Rightarrow d\hat{x}_k = \left(F^e_{ik}\right)^{-1} F_{ij} dX_j \tag{106.141}$$

---

[23] See section 106.2.2.

so that one can define:

$$F^p_{kj} \overset{def}{=} \left(F^e_{ik}\right)^{-1} F_{ij} \Rightarrow F_{ij} \overset{\text{def}}{=} F^e_{ki} F^p_{kj} \tag{106.142}$$

The plastic part of the deformation gradient, F^p_{kj} represents micro–mechanically, the irreversible process of slipping, crushing dislocation and macroscopically the irreversible plastic deformation of a body. The elastic part, F^e_{ki} represents micro–mechanically a pure elastic reversal of deformation for the particulate assembly, macroscopically a linear elastic unloading toward a stress free state of the body, not necessarily a compatible, continuous deformation but rather a fictitious elastic unloading of small cut outs of a deformed particulate assembly or continuum body.

106.4.3 Constitutive Relations

We propose the free energy density W, which is defined in $\bar{\Omega}$, as follows

$$\rho_0 W(\bar{C}^e_{ij}, \kappa_\alpha) = \rho_0 W^e(\bar{C}^e_{ij}) + \rho_0 W^p(\kappa_\alpha) \tag{106.143}$$

where $W^e(\bar{C}^e_{ij})$ represents a suitable hyperelastic model in terms of the elastic right deformation tensor $\bar{C}^e_{ij}$, whereas $W^p(\kappa_\alpha)$ represents the hardening. It has been shown elsewhere (Runesson, 1996), that the pertinent dissipation inequality becomes

$$D = \bar{T}_{ij}\ \bar{L}^p_{ij} + \sum_\alpha \bar{K}_\alpha\ \dot{\kappa}_\alpha \geq 0 \tag{106.144}$$

where $\bar{T}_{ij}$ is the Mandel stress[24] and $\bar{L}^p_{ij}$ is the plastic velocity gradient defined on $\bar{\Omega}$.

We now define elastic domain $\mathcal{B}$ as

$$\mathcal{B} = \{\bar{T}_{ij}, \bar{K}_\alpha \mid \Phi(\bar{T}_{ij}, \bar{K}_\alpha) \leq 0\} \tag{106.145}$$

When Φ is isotropic in $\bar{T}_{ij}$ (which is the case here) in conjunction with elastic isotropy, we can conclude that $\bar{T}_{ij}$ is symmetrical and we may replace $\bar{T}_{ij}$ by τ_{ij} in Φ.

As to the choice of elastic law, it is emphasized that this is largely a matter of convenience since we shall be dealing with small elastic deformations. Here, the Neo–Hookean elastic law is adopted. The generic situation is $\bar{T}_{ij} = \bar{T}_{ij}(\tilde{\bar{U}}^e_{kl}, \bar{J}^e)$, where we have used the isochoric/volumetric split of the elastic right stretch tensor as $\bar{U}^e_{kl} = \tilde{\bar{U}}^e_{kl}\ (\bar{J}^e)^{1/3}$.

The constitutive relations can now be written as

$$\bar{T}_{ij} = \bar{T}_{ij}(\tilde{\bar{U}}^e_{kl}, \bar{J}^e) \tag{106.146}$$

$$\bar{L}^p_{ij} := \dot{F}^p_{ik}\ \left(F^p_{jk}\right)^{-1} = \dot{\mu}\frac{\partial \Phi^*}{\partial \bar{T}_{ij}} = \dot{\mu}\bar{M}_{ij} \tag{106.147}$$

---

[24] See section 106.3.1.

$$\bar{K}_\alpha = \bar{K}_\alpha(\bar{\kappa_\beta}) \tag{106.148}$$

$$\dot{\bar{\kappa}}_\beta = \dot{\mu} \, \frac{\partial \Phi^*}{\partial K_\beta} \quad , \quad \kappa_\beta(0) = 0 \tag{106.149}$$

where $F^p_{ik} = (\bar{F}^e_{li})^{-1} F_{lk}$ is the plastic part of the deformation gradient.

106.4.4 Implicit Integration Algorithm

The incremental deformation and plastic flow are governed by the system of evolution equations (106.147) and (106.149):

$$\dot{F}^p_{ik} \, \left(F^p_{jk}\right)^{-1} = \dot{\mu}\bar{M}_{ij} \tag{106.150}$$

$$\dot{\bar{\kappa}}_\beta = \dot{\mu} \, \frac{\partial \Phi^*}{\partial K_\beta} \quad , \quad \kappa_\beta(0) = 0 \tag{106.151}$$

The flow rule from equation (106.150) can be integrated to give

$$^{n+1}F^p_{ij} = \exp\left(\Delta\mu^{n+1}\bar{M}_{ik}\right) {}^nF^p_{kj} \tag{106.152}$$

By using the multiplicative decomposition

$$F_{ij} = \bar{F}^e_{ik} \, F^p_{kj} \Rightarrow \bar{F}^e_{ik} = F_{ij} \, \left(F^p_{kj}\right)^{-1} \tag{106.153}$$

and equation (106.152) we obtain

$$\begin{aligned} {}^{n+1}\bar{F}^e_{ij} &= {}^{n+1}F_{im} \, \left({}^nF^p_{mk}\right)^{-1} \exp\left(-\Delta\mu^{n+1}\bar{M}_{kj}\right) \\ &= {}^{n+1}\bar{F}^{e,tr}_{ik} \exp\left(-\Delta\mu^{n+1}\bar{M}_{kj}\right) \end{aligned} \tag{106.154}$$

where we used that

$$^{n+1}\bar{F}^{e,tr}_{ik} = {}^{n+1}F_{im} \, \left({}^nF^p_{km}\right)^{-1} \tag{106.155}$$

The elastic deformation is then

$$\begin{aligned} {}^{n+1}\bar{C}^e_{ij} &\overset{\text{def}}{=} \left({}^{n+1}\bar{F}^e_{im}\right)^T \, {}^{n+1}\bar{F}^e_{mj} \\ &= \exp\left(-\Delta\mu^{n+1}\bar{M}^T_{ir}\right) \, \left({}^{n+1}\bar{F}^{e,tr}_{rk}\right)^T \, {}^{n+1}\bar{F}^{e,tr}_{kl} \, \exp\left(-\Delta\mu^{n+1}\bar{M}_{lj}\right) \\ &= \exp\left(-\Delta\mu^{n+1}\bar{M}^T_{ir}\right) \, {}^{n+1}\bar{C}^{e,tr}_{rl} \, \exp\left(-\Delta\mu^{n+1}\bar{M}_{lj}\right) \end{aligned} \tag{106.156}$$

By recognizing that the exponent of a tensor can be expanded in Taylor series[25]

$$\exp\left(-\Delta\mu^{n+1}\bar{M}_{lj}\right) = \delta_{lj} - \Delta\mu^{n+1}\bar{M}_{lj} + \frac{1}{2}\left(\Delta\mu^{n+1}\bar{M}_{ls}\right)\left(\Delta\mu^{n+1}\bar{M}_{sj}\right) + \cdots \tag{106.157}$$

---

[25] See for example Pearson (1974).

and by using the first order expansion in the equation (106.156), we obtain

$$\begin{aligned} {}^{n+1}\bar{C}^{e}_{ij} &= \left(\delta_{ir} - \Delta\mu^{n+1}\bar{M}_{ir}\right) {}^{n+1}\bar{C}^{e,tr}_{rl} \left(\delta_{lj} - \Delta\mu^{n+1}\bar{M}_{lj}\right) \\ &= \left({}^{n+1}\bar{C}^{e,tr}_{il} - \Delta\mu^{n+1}\bar{M}_{ir}\;{}^{n+1}\bar{C}^{e,tr}_{rl}\right)\left(\delta_{lj}-\Delta\mu^{n+1}\bar{M}_{lj}\right) \\ &= {}^{n+1}\bar{C}^{e,tr}_{ij} - \Delta\mu^{n+1}\bar{M}_{ir}\;{}^{n+1}\bar{C}^{e,tr}_{rj} - \Delta\mu\;{}^{n+1}\bar{C}^{e,tr}_{il}\;{}^{n+1}\bar{M}_{lj} \\ &\quad +\Delta\mu^2\;{}^{n+1}\bar{M}_{ir}\;{}^{n+1}\bar{C}^{e,tr}_{rl}\;{}^{n+1}\bar{M}_{lj} \end{aligned} \tag{106.158}$$

Remark 106.4.1 The Taylor's series expansion from equation (106.157) is a proper approximation for the general nonsymmetric tensor $\bar{M}_{lj}$. That is, the approximate solution given by equation (106.158) is valid for a general anisotropic solid. This contrasts with the spectral decomposition family of solutions[26] which are restricted to isotropic solids.

Remark 106.4.2 Taylor's series expansion[27] is proper for "small" values of plastic flow tensor $\Delta\mu^{n+1}\bar{M}_{lj}$. This is indeed the case for small increments, when $\Delta\mu \to 0$ which are required for following the equilibrium path for path–dependent solids.

Remark 106.4.3 In the limit, when the displacements are sufficiently small, the solution (106.158) collapses to

$$\begin{aligned} \lim_{F_{ij}\to\delta_{ij}} \delta_{ij} + 2^{n+1}\epsilon_{ij} = &+ \;\delta_{ij} + 2^{n+1}\epsilon^{e,tr}_{ij} \\ &- \;\Delta\mu^{n+1}\bar{M}_{ir}\left(\delta_{rj} + 2^{n+1}\epsilon^{e,tr}_{rj}\right) \\ &- \;\Delta\mu\left(\delta_{il} + 2^{n+1}\epsilon^{e,tr}_{il}\right)\;{}^{n+1}\bar{M}_{lj} \\ &+ \;\Delta\mu^2\;{}^{n+1}\bar{M}_{ir}\left(\delta_{rl} + 2^{n+1}\epsilon^{e,tr}_{rl}\right)\;{}^{n+1}\bar{M}_{lj} \\ = &+ \;\delta_{ij} + 2^{n+1}\epsilon^{e,tr}_{ij} \\ &- \;\Delta\mu^{n+1}\bar{M}_{ij} - 2\Delta\mu^{n+1}\bar{M}_{ir}{}^{n+1}\epsilon^{tr}_{rj} \\ &- \;\Delta\mu\;{}^{n+1}\bar{M}_{ij} - 2\Delta\mu\;{}^{n+1}\epsilon^{tr}_{il}\;{}^{n+1}\bar{M}_{lj} \\ &+ \;\Delta\mu^2\;{}^{n+1}\bar{M}_{il}\;{}^{n+1}\bar{M}_{lj} + 2\Delta\mu^2\;{}^{n+1}\bar{M}_{ir}\;{}^{n+1}\epsilon^{tr}_{rl}{}^{n+1}\bar{M}_{lj} \\ &= \;\delta_{ij} + 2^{n+1}\epsilon^{e,tr}_{ij} - 2\Delta\mu\;{}^{n+1}\bar{M}_{ij} \\ \Rightarrow {}^{n+1}\epsilon_{ij} &= \;{}^{n+1}\epsilon^{tr}_{ij} - \Delta\mu\;{}^{n+1}\bar{M}_{ij} \end{aligned} \tag{106.159}$$

which is a small deformation elastic predictor–plastic corrector equation in strain space. In working out

---

[26] See Simo (1992).

[27] It should be called MacLaurin's series expansion, since expansion is about zero plastic flow state (no incremental plastic deformation).

the small deformation counterpart (106.159) it was used that

$$\begin{aligned}
\lim_{F_{ij}\to\delta_{ij}} {}^{n+1}\bar{C}^{e}_{ij} &= \delta_{ij} + 2\,{}^{n+1}\epsilon_{ij} \\
2\Delta\mu\ {}^{n+1}\epsilon^{tr}_{il}\ {}^{n+1}\bar{M}_{lj} &\ll {}^{n+1}\bar{M}_{ij} \\
\Delta\mu &\ll 1
\end{aligned} \tag{106.160}$$

By neglecting the higher order term with $\Delta\mu^2$ in equation (106.158), the solution for the right elastic deformation tensor ${}^{n+1}\bar{C}^{e}_{ij}$ can be written as

$$ {}^{n+1}\bar{C}^{e}_{ij} = {}^{n+1}\bar{C}^{e,tr}_{ij} - \Delta\mu \left({}^{n+1}\bar{M}_{ir}\ {}^{n+1}\bar{C}^{e,tr}_{rj} + {}^{n+1}\bar{C}^{e,tr}_{il}\ {}^{n+1}\bar{M}_{lj} \right) \tag{106.161}$$

The hardening rule (106.151) can be integrated to give

$$ {}^{n+1}\kappa_{\alpha} = {}^{n}\kappa_{\alpha} + \Delta\mu \left. \frac{\partial\Phi^{*}}{\partial K_{\alpha}} \right|_{n+1} \tag{106.162}$$

Remark 106.4.4 It is interesting to note that equation (106.161) resembles the *elastic predictor–plastic corrector* equation for small deformation elastic–plastic incremental analysis. That resemblance will be used to build an iterative solution algorithm in the next section.

The incremental problem is defined by equations (106.161), (106.162), and the constitutive relations

$$ {}^{n+1}\bar{S}_{IJ} = 2 \left. \frac{\partial W}{\partial C_{IJ}} \right|_{n+1} \tag{106.163}$$

$$ {}^{n+1}K_{\alpha} = - \left. \frac{\partial W}{\partial \kappa_{\alpha}} \right|_{n+1} \tag{106.164}$$

and the Karush–Kuhn–Tucker (KKT) conditions

$$ \Delta\mu < 0 \quad ; \quad {}^{n+1}\Phi \leq 0 \quad ; \quad \Delta\mu\ {}^{n+1}\Phi = 0 \tag{106.165}$$

where

$$ \Phi = \Phi(\bar{T}_{ij}, K_{\alpha}) \tag{106.166}$$

Remark 106.4.5 The Mandel stress tensor $\bar{T}_{ij}$ can be obtained from the second Piola–Kirchhoff stress tensor $\bar{S}_{kj}$ and the right elastic deformation tensor $\bar{C}^{e}_{ik}$ as

$$ \bar{T}_{ij} = \bar{C}^{e}_{ik}\ \bar{S}_{kj} \tag{106.167}$$

This set of nonlinear equations will be solved with a Newton type procedure, described in the next section. For a given ${}^{n+1}F_{ij}$, or ${}^{n+1}\bar{C}^{e,tr}_{ij}$, the upgraded quantities ${}^{n+1}\bar{S}_{IJ}$ and ${}^{n+1}K_{\alpha}$ can be found, then the appropriate pull–back to B_0 or push–forward to B will give ${}^{n+1}S_{IJ}$ and ${}^{n+1}\tau_{ij}$

$$ {}^{n+1}S_{IJ} = \left({}^{n+1}F^{p}_{iI}\right)^{-1} \; {}^{n+1}\bar{S}_{IJ} \; \left({}^{n+1}F^{p}_{jJ}\right)^{-T} \tag{106.168}$$

$$ {}^{n+1}\tau_{ij} = {}^{n+1}\bar{F}^{e}_{iI} \; {}^{n+1}\bar{S}_{IJ} \; \left({}^{n+1}F^{e}_{jJ}\right)^{-1} \tag{106.169}$$

The elastic predictor, plastic corrector equation

$$\begin{aligned} {}^{n+1}\bar{C}^{e}_{ij} &= {}^{n+1}\bar{C}^{e,tr}_{ij} - \Delta\mu \left({}^{n+1}\bar{M}_{ir} \; {}^{n+1}\bar{C}^{e,tr}_{rj} + {}^{n+1}\bar{C}^{e,tr}_{il} \; {}^{n+1}\bar{M}_{lj}\right) \\ &= {}^{n+1}\bar{C}^{e,tr}_{ij} - \Delta\mu \; {}^{n+1}Z_{ij} \end{aligned} \tag{106.170}$$

is used as a starting point for a Newton iterative algorithm. In previous equation, we have introduced tensor Z_{ij} to shorten writing. The trial right elastic deformation tensor is defined as

$$\begin{aligned} {}^{n+1}\bar{C}^{e,tr}_{ij} = \; & \left({}^{n+1}\bar{F}^{e,tr}_{ri}\right)^{T} \left({}^{n+1}\bar{F}^{e,tr}_{rj}\right) \\ & \left({}^{n+1}F_{rM} \; \left({}^{n}F^{p}_{iM}\right)^{-1}\right)^{T} \left({}^{n+1}F_{rS} \; \left({}^{n}F^{p}_{jS}\right)^{-1}\right) \end{aligned} \tag{106.171}$$

We introduce a tensor of deformation residuals

$$ R_{ij} = \underbrace{\bar{C}^{e}_{ij}}_{current} - \underbrace{\left({}^{n+1}\bar{C}^{e,tr}_{ij} - \Delta\mu \; {}^{n+1}Z_{ij}\right)}_{BackwardEuler} \tag{106.172}$$

Tensor R_{ij} represents the difference between the current right elastic deformation tensor and the Backward Euler right elastic deformation tensor. The trial right elastic deformation tensor ${}^{n+1}\bar{C}^{e,tr}_{ij}$ is maintained fixed during the iteration process. The first order Taylor series expansion can be applied to the equation (106.172) in order to obtain the iterative change, the new residual R^{new}_{ij} from the old R^{old}_{ij}

$$ R^{new}_{ij} = R^{old}_{ij} + d\bar{C}^{e}_{ij} + d(\Delta\mu) \; {}^{n+1}Z_{ij} + \Delta\mu \frac{\partial \, {}^{n+1}Z_{ij}}{\partial \bar{T}_{mn}} \; d\bar{T}_{mn} + \Delta\mu \frac{\partial \, {}^{n+1}Z_{ij}}{\partial K_{\alpha}} \; dK_{\alpha} \tag{106.173}$$

By using that

$$ \bar{T}_{mn} = \bar{C}^{e}_{mk} \; \bar{S}_{kn} \qquad \Rightarrow \qquad \left(\bar{C}^{e}_{sk}\right)^{-1} \; \bar{T}_{sn} = \bar{S}_{kn} \tag{106.174}$$

we can write

$$\begin{aligned} d\bar{T}_{mn} &= d\bar{C}^{e}_{mk} \; \bar{S}_{kn} + \bar{C}^{e}_{mk} \; d\bar{S}_{kn} \\ &= d\bar{C}^{e}_{mk} \; \bar{S}_{kn} + \frac{1}{2} \; \bar{C}^{e}_{mk} \; \bar{\mathcal{L}}^{e}_{knpq} \; d\bar{C}^{e}_{pq} \qquad \text{from (106.55)} \\ &= d\bar{C}^{e}_{mk} \; \left(\bar{C}^{e}_{sk}\right)^{-1} \; \bar{T}_{sn} + \frac{1}{2} \; \bar{C}^{e}_{mk} \; \bar{\mathcal{L}}^{e}_{knpq} \; d\bar{C}^{e}_{pq} \qquad \text{from (106.174)} \end{aligned} \tag{106.175}$$

and the equation (106.173) can be rewritten as

$$
\begin{aligned}
R^{new}_{ij} = \quad & R^{old}_{ij} + d\bar{C}^e_{ij} + d(\Delta\mu)\ {}^{n+1}Z_{ij} + \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial \bar{T}_{mn}} \left(d\bar{C}^e_{mk}\ \left(\bar{C}^e_{sk}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq}\ d\bar{C}^e_{pq} \right) + \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\ dK_\alpha \\
\\
= \quad & R^{old}_{ij} + d\bar{C}^e_{ij} + d(\Delta\mu)\ {}^{n+1}Z_{ij} + \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial \bar{T}_{mn}}\ d\bar{C}^e_{mk}\ \left(\bar{C}^e_{sk}\right)^{-1}\ \bar{T}_{sn} + \\
+ \quad & \frac{1}{2}\ \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq}\ d\bar{C}^e_{pq} + \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\ dK_\alpha \\
\\
= \quad & R^{old}_{ij} + d\bar{C}^e_{ij} + d(\Delta\mu)\ {}^{n+1}Z_{ij} + \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{ik}} \left(\bar{C}^e_{sj}\right)^{-1}\ \bar{T}_{sk}\ d\bar{C}^e_{ij} + \qquad \text{dummy indices rearrangement} \\
+ \quad & \frac{1}{2}\ \Delta\mu \frac{\partial\, {}^{n+1}Z_{pq}}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knij}\ d\bar{C}^e_{ij} + \qquad \text{dummy indices rearrangement} \\
+ \quad & \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\ dK_\alpha
\end{aligned}
\tag{106.176}
$$

The goal is to have $R^{new}_{ij} = 0$ so one can write

$$
\begin{aligned}
0 \;=\;& R^{old}_{ij} + d\bar{C}^e_{ij} + d(\Delta\mu)\; {}^{n+1}Z_{ij} + \\
+\;& \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{ik}} \left(\bar{C}^e_{sj}\right)^{-1} \; \bar{T}_{sk}\; d\bar{C}^e_{ij} + \\
+\;& \frac{1}{2}\,\Delta\mu \frac{\partial\, {}^{n+1}Z_{pq}}{\partial \bar{T}_{mn}}\; \bar{C}^e_{mk}\; \bar{\mathcal{L}}^e_{knij}\; d\bar{C}^e_{ij} + \\
+\;& \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\; dK_\alpha \\
\\
=\;& R^{old}_{ij} + d(\Delta\mu)\; {}^{n+1}Z_{ij} \\
+\;& \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\; dK_\alpha + \\
+\;& d\bar{C}^e_{ij} + \\
+\;& \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{ik}} \left(\bar{C}^e_{sj}\right)^{-1} \; \bar{T}_{sk}\; d\bar{C}^e_{ij} + \\
+\;& \frac{1}{2}\,\Delta\mu \frac{\partial\, {}^{n+1}Z_{pq}}{\partial \bar{T}_{mn}}\; \bar{C}^e_{mk}\; \bar{\mathcal{L}}^e_{knij}\; d\bar{C}^e_{ij} \\
\\
=\;& R^{old}_{ij} + d(\Delta\mu)\; {}^{n+1}Z_{ij} + \Delta\mu \frac{\partial\, {}^{n+1}Z_{ij}}{\partial K_\alpha}\; dK_\alpha + \\
+\;& \left(\delta_{im}\delta_{nj} + \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{ik}} \left(\bar{C}^e_{sj}\right)^{-1} \; \bar{T}_{sk} + \frac{1}{2}\,\Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{pq}}\; \bar{C}^e_{pk}\; \bar{\mathcal{L}}^e_{kqij}\;\right) d\bar{C}^e_{ij}
\end{aligned}
\tag{106.177}
$$

Upon introducing notation

$$
\mathcal{T}_{mnij} = \delta_{im}\delta_{nj} + \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{ik}} \left(\bar{C}^e_{sj}\right)^{-1} \; \bar{T}_{sk} + \frac{1}{2}\,\Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial \bar{T}_{pq}}\; \bar{C}^e_{pk}\; \bar{\mathcal{L}}^e_{kqij}
\tag{106.178}
$$

we can solve (106.177) for $d\bar{C}^e_{ij}$

$$
d\bar{C}^e_{ij} = \left(\mathcal{T}_{mnij}\right)^{-1} \left(-R^{old}_{mn} - d(\Delta\mu)\; {}^{n+1}Z_{mn} - \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial K_\alpha}\; dK_\alpha \right)
\tag{106.179}
$$

or, by rearranging indices

$$
d\bar{C}^e_{pq} = \left(\mathcal{T}_{mnpq}\right)^{-1} \left(-R^{old}_{mn} - d(\Delta\mu)\; {}^{n+1}Z_{mn} - \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial K_\alpha}\; dK_\alpha \right)
\tag{106.180}
$$

By using that

$$
dK_\alpha = \frac{\partial K_\alpha}{\partial \kappa_\beta}\; d\kappa_\beta = -d(\Delta\mu)\; \frac{\partial K_\alpha}{\partial \kappa_\beta}\; \frac{\partial Q}{\partial K_\beta} = -d(\Delta\mu)\; H_{\alpha\beta}\; \frac{\partial Q}{\partial K_\beta}
\tag{106.181}
$$

it follows from (106.180)

$$d\bar{C}^e_{pq} = \left(\mathcal{T}_{mnpq}\right)^{-1} \left(-R^{old}_{mn} - d(\Delta\mu)\ {}^{n+1}Z_{mn} + \Delta\mu \frac{\partial\, {}^{n+1}Z_{mn}}{\partial K_\alpha}\ d(\Delta\mu)\ H_{\alpha\beta}\ \frac{\partial Q}{\partial K_\beta} \right) \tag{106.182}$$

A first order Taylor series expansion of a yield function yields

$$\begin{aligned}
{}^{new}\Phi(\bar{T}_{ij}, K_\alpha) = & \quad {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}}\ d\bar{T}_{mn} \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\ dK_\alpha \\
= & \quad {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}} \left(d\bar{C}^e_{mk}\ \left(\bar{C}^e_{sk}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq}\ d\bar{C}^e_{pq} \right) \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\ dK_\alpha \\
= & \quad {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{pn}} \left(\bar{C}^e_{sq}\right)^{-1}\ \bar{T}_{sn}\ d\bar{C}^e_{pq} \qquad \text{dummy indices rearrangement} \\
+ & \quad \frac{1}{2}\ \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq}\ d\bar{C}^e_{pq} \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\ dK_\alpha \\
= & \quad {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ & \quad \left(\frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{pn}} \left(\bar{C}^e_{sq}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq} \right)\ d\bar{C}^e_{pq} \\
+ & \quad \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\ dK_\alpha
\end{aligned} \tag{106.183}$$

By using (106.181), equation (106.183) becomes

$$\begin{aligned}
{}^{new}\Phi(\bar{T}_{ij}, K_\alpha) = & \quad {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ & \quad \left(\frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{pn}} \left(\bar{C}^e_{sq}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq} \right)\ d\bar{C}^e_{pq} \\
- & \quad d(\Delta\mu)\ \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\ H_{\alpha\beta}\ \frac{\partial\Phi^*}{\partial K_\beta}
\end{aligned} \tag{106.184}$$

Upon introducing the following notation

$$\mathcal{F}_{pq} = \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{pn}} \left(\bar{C}^e_{sq}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \frac{\partial\Phi(\bar{T}_{ij}, K_\alpha)}{\partial \bar{T}_{mn}}\ \bar{C}^e_{mk}\ \bar{\mathcal{L}}^e_{knpq} \tag{106.185}$$

and with the solution for $d\bar{C}^e_{pq}$ from (106.182), (106.184) becomes

$$\begin{aligned}
& {}^{new}\Phi(\bar{T}_{ij}, K_\alpha) = {}^{old}\Phi(\bar{T}_{ij}, K_\alpha) + \\
+ \quad & \mathcal{F}_{pq} \left(\left(\mathcal{T}_{mnpq}\right)^{-1} \left(-R^{old}_{mn} - d(\Delta\mu)\; {}^{n+1}Z_{mn} + d(\Delta\mu)\; \Delta\mu\; \frac{\partial\, {}^{n+1}Z_{mn}}{\partial K_\alpha}\; H_{\alpha\beta}\; \frac{\partial \Phi^*}{\partial K_\beta} \right) \right) \\
- \quad & d(\Delta\mu)\; \frac{\partial \Phi(\bar{T}_{ij}, K_\alpha)}{\partial K_\alpha}\; H_{\alpha\beta}\; \frac{\partial \Phi^*}{\partial K_\beta}
\end{aligned} \tag{106.186}$$

After setting ${}^{new}\Phi(\bar{T}_{ij}, K_\alpha) = 0$ we can solve for the incremental inconsistency parameter $d(\Delta\mu)$

$$\begin{aligned}
& d(\Delta\mu) = \\
& \frac{{}^{old}\Phi - \mathcal{F}_{pq}\; \left(\mathcal{T}_{mnpq}\right)^{-1}\; R^{old}_{mn}}{\mathcal{F}_{pq}\; \left(\mathcal{T}_{mnpq}\right)^{-1}\; {}^{n+1}Z_{mn} - \Delta\mu\; \mathcal{F}_{pq}\; \left(\mathcal{T}_{mnpq}\right)^{-1}\; \frac{\partial\, {}^{n+1}Z_{mn}}{\partial K_\alpha}\; H_{\alpha\beta}\; \frac{\partial \Phi^*}{\partial K_\beta} + \frac{\partial \Phi}{\partial K_\alpha}\; H_{\alpha\beta}\; \frac{\partial \Phi^*}{\partial K_\beta}}
\end{aligned} \tag{106.187}$$

Remark 106.4.6 In the perfectly plastic case, the increment inconsistency parameter $d(\Delta\mu)$ is

$$d(\Delta\mu) = \frac{{}^{old}\Phi - \mathcal{F}_{pq}\; \left(\mathcal{T}_{mnpq}\right)^{-1}\; R^{old}_{mn}}{\mathcal{F}_{pq}\; \left(\mathcal{T}_{mnpq}\right)^{-1}\; {}^{n+1}Z_{mn}} \tag{106.188}$$

Remark 106.4.7 In the limit, for small deformations, isotropic response, the increment inconsistency parameter $d(\Delta\mu)$ becomes

$$d(\Delta\mu) = \frac{{}^{old}\Phi - \left(n_{mn}\; E_{mnpq}\right)\; \left(\delta_{pm}\delta_{nq} + \Delta\mu\; \frac{\partial m_{mn}}{\partial \sigma_{ij}}\; E_{ijpq}\right)^{-1}\; R^{old}_{mn}}{n_{mn}\; E_{mnpq}\; \left(\delta_{mp}\delta_{qn} + \Delta\mu\; \frac{\partial m_{pq}}{\partial \sigma_{ij}}\; E_{ijmn}\right)^{-1}\; {}^{n+1}m_{mn} + \frac{\partial \Phi}{\partial K_\alpha}\; H_{\alpha\beta}\; \frac{\partial \Phi^*}{\partial K_\beta}} \tag{106.189}$$

since in the limit, as deformations are getting small

$$\begin{aligned}
\mathcal{T}_{mnpq} & \rightarrow \delta_{pm}\delta_{nq} + \Delta\mu\; \frac{\partial m_{mn}}{\partial \sigma_{ij}}\; E_{ijpq} \\
\mathcal{F}_{pq} & \rightarrow \frac{1}{2}\; \frac{\partial \Phi}{\partial \sigma_{mn}}\; E_{mnpq} \\
Z_{pq} & \rightarrow 2\; m_{pq} \\
R_{pq} & \rightarrow 2\; \epsilon_{pq}
\end{aligned} \tag{106.190}$$

Upon noting that residual R_{pq} is defined in strain space, the increment inconsistency parameter $d(\Delta\mu)$ compares exactly with it's small strain counterpart (Jeremić and Sture, 1997).

The procedure described below summarizes the implementation of the return algorithm.

Trial State Given the right elastic deformations tensor ${}^{n}\bar{C}^{e}_{pq}$ and a set of hardening variables ${}^{n}K_{\alpha}$ at a specific quadrature point in a finite element, compute the relative deformation gradient ${}^{n+1}f_{ij}$ for a given displacement increment $\Delta^{n+1}u_i$, and the right deformation tensor

$$ {}^{n+1}f_{ij} = \delta_{ij} + u_{i,j} \tag{106.191}$$

$$ {}^{n+1}\bar{C}^{e,tr}_{ij} = \left({}^{n+1}f_{ir}\ {}^{n}F^{e}_{rk}\right)^{T} \left({}^{n+1}f_{kl}\ {}^{n}F^{e}_{lj}\right) = \left({}^{n}F^{e}_{rk}\right)^{T} \left({}^{n+1}f_{ir}\right)^{T} \left({}^{n+1}f_{kl}\ {}^{n}F^{e}_{lj}\right) \tag{106.192}$$

Compute the trial elastic second Piola–Kirchhoff stress and the trial elastic Mandel stress tensor

$$ {}^{n+1}\bar{S}^{e,tr}_{ij} = 2\frac{\partial W}{\partial^{n+1}\bar{C}^{e,tr}_{ij}} \tag{106.193}$$

$$ {}^{n+1}\bar{T}^{e,tr}_{ij} = {}^{n+1}\bar{C}^{e,tr}_{il}\ {}^{n+1}\bar{S}^{e,tr}_{lj} \tag{106.194}$$

Evaluate the yield function ${}^{n+1}\Phi^{tr}(\bar{T}^{e,tr}_{ij}, K_{\alpha})$. If ${}^{n+1}\Phi^{tr} \leq 0$ there is no plastic flow in current increment

$$\begin{aligned} {}^{n+1}\bar{C}^{e}_{ij} &= {}^{n+1}\bar{C}^{e,tr}_{ij} \\ {}^{n+1}K_{\alpha} &= {}^{n}K_{\alpha} \\ {}^{n+1}T_{ij} &= {}^{n}T^{e,tr}_{ij} \end{aligned}$$

and exit constitutive integration procedure.

Return Algorithm If yield criteria has been violated $({}^{n+1}\Phi^{tr} > 0)$ proceed to step 1.

step 1. k^{th} iteration. Known variables

$$ {}^{n+1}\bar{C}^{e(k)}_{ij} \quad ; \quad {}^{n+1}\kappa^{(k)}_{\alpha} \quad ; \quad {}^{n+1}K^{(k)}_{\alpha} \quad ; \quad {}^{n+1}T^{(k)}_{ij} \quad ; \quad {}^{n+1}\Delta\mu^{(k)}$$

evaluate the yield function and the residual

$$\begin{aligned} \Phi^{(k)} &= \Phi({}^{n+1}\bar{T}^{e(k)}_{ij}, {}^{n+1}K^{(k)}_{\alpha}) \\ R^{(k)}_{ij} &= {}^{n+1}\bar{C}^{e,(k)}_{ij} - \left({}^{n+1}\bar{C}^{e,tr}_{ij} - {}^{n+1}\Delta\mu^{(k)n+1}Z^{(k)}_{ij}\right) \end{aligned}$$

step 2. Check for convergence, $\Phi^{(k)} \leq NTOL$ and $\|R^{(k)}_{ij}\| \leq NTOL$. If convergence criteria is satisfied set

$$\begin{aligned} {}^{n+1}\bar{C}^{e}_{ij} &= {}^{n+1}\bar{C}^{e(k)}_{ij} \\ {}^{n+1}\kappa_{\alpha} &= {}^{n+1}\kappa^{(k)}_{\alpha} \\ {}^{n+1}K_{\alpha} &= {}^{n+1}K^{(k)}_{\alpha} \\ {}^{n+1}T_{ij} &= {}^{n+1}T^{(k)}_{ij} \\ {}^{n+1}\Delta\mu &= {}^{n+1}\Delta\mu^{(k)} \end{aligned}$$

Exit constitutive integration procedure.

step 3.[28] If convergence is not achieved, i.e. $\Phi^{(k)} > NTOL$ or $\|R^{(k)}_{ij}\| > NTOL$ then compute the elastic stiffness tensor $\mathcal{L}_{ijkl}$

$$\bar{\mathcal{L}}^{(k)}_{ijkl} = 4 \; \frac{\partial^2 W}{\partial \bar{C}^{e(k)}_{ij} \; \partial \bar{C}^{e(k)}_{kl}} \tag{106.195}$$

step 4. Compute the incremental inconsistency parameter $d(\Delta\mu^{(k+1)})$

$$d(\Delta\mu^{(k+1)}) = \frac{\Phi^{(k)} - \bar{\mathcal{F}}^{(k)}_{mn} \; R_{mn}{}^{(k)}}{\bar{\mathcal{F}}^{(k)}_{mn} \; Z_{mn}{}^{(k)} - \Delta\mu^{(k)} \; \bar{\mathcal{F}}_{mn}{}^{(k)} \; \dfrac{\partial Z_{mn}{}^{(k)}}{\partial K_\alpha} \; \bar{H}_\alpha{}^{(k)} + \dfrac{\partial \Phi^{(k)}}{\partial K_\alpha} \; \bar{H}_\alpha{}^{(k)}} \tag{106.196}$$

where

$$\bar{H}_\alpha{}^{(k)} = H_{\alpha\beta}{}^{(k)} \; \frac{\partial \Phi^{*,(k)}}{\partial K_\beta} \quad ; \quad \bar{\mathcal{F}}_{mn}{}^{(k)} = \mathcal{F}_{pq}{}^{(k)} \; \left(\mathcal{T}_{mnpq}{}^{(k)}\right)^{-1}$$

$$\mathcal{F}_{pq} = \frac{\partial \Phi(\bar{T}^{(k)}_{ij}, K^{(k)}_\alpha)}{\partial \bar{T}_{pn}} \; \left(\bar{C}^{e,(k)}_{sq}\right)^{-1} \; \bar{T}^{(k)}_{sn} + \frac{1}{2} \; \frac{\partial \Phi(\bar{T}^{(k)}_{ij}, K^{(k)}_\alpha)}{\partial \bar{T}_{mn}} \; \bar{C}^{e,(k)}_{mk} \; \bar{\mathcal{L}}^{e,(k)}_{knpq}$$

$$\mathcal{T}_{mnij} = \delta_{im}\delta_{nj} + \Delta\mu^{(k)} \; \frac{\partial Z^{(k)}_{mn}}{\partial \bar{T}^{(k)}_{ik}} \; \left(\bar{C}^{e,(k)}_{sj}\right)^{-1} \; \bar{T}^{(k)}_{sk} + \frac{1}{2} \; \Delta\mu^{(k)} \; \frac{\partial Z^{(k)}_{mn}}{\partial \bar{T}_{pq}} \; \bar{C}^{e,(k)}_{pk} \; \bar{\mathcal{L}}^{e,(k)}_{kqij}$$

step 5. Updated the inconsistency parameter $\Delta\mu^{(k+1)}$

$$\Delta\mu^{(k+1)} = \Delta\mu^{(k)} + d(\Delta\mu^{(k+1)}) \tag{106.197}$$

step 6. Updated the right deformation tensor, the hardening variable and the Mandel stress

$$d\bar{C}^{e,(k+1)}_{pq} = \left(\mathcal{T}^{(k)}_{mnpq}\right)^{-1} \left(-R^{(k)}_{mn} - d(\Delta\mu^{(k+1)}) \; {}^{n+1}Z^{(k)}_{mn} + \Delta\mu^{(k)} \; \frac{\partial Z^{(k)}_{mn}}{\partial K_\alpha} \; d(\Delta\mu^{(k+1)}) \; \bar{H}^{(k)}_\alpha \right) \tag{106.198}$$

$$d\kappa^{(k+1)}_\alpha = d(\Delta\mu^{(k+1)}) \; \frac{\partial \Phi^{*,(k)}}{\partial K_\beta} \tag{106.199}$$

$$dK^{(k+1)}_\alpha = -d(\Delta\mu^{(k+1)}) \; H^{(k)}_{\alpha\beta} \; \frac{\partial \Phi^{*,(k)}}{\partial K_\beta} \tag{106.200}$$

---

[28] From step 3. to step 9. all of the variables are in intermediate $n+1$ configuration. For the sake of brevity we are omitting superscript $n+1$.

$$d\bar{T}_{mn}^{(k+1)} = d\bar{C}_{mk}^{e,(k+1)} \left(\bar{C}_{sk}^{e,(k)}\right)^{-1} \bar{T}_{sn}^{(k)} + \frac{1}{2}\,\bar{C}_{mk}^{e,(k)}\,\bar{\mathcal{L}}_{knpq}^{e,(k)}\,d\bar{C}_{pq}^{e,(k+1)} \tag{106.201}$$

step 7. Update right deformation tensor $\bar{C}_{pq}^{e,(k+1)}$, hardening variable $K_\alpha^{(k+1)}$ and Mandel stress $\bar{T}_{mn}^{(k+1)}$

$$\begin{aligned}
\bar{C}_{pq}^{e,(k+1)} &= \bar{C}_{pq}^{e,(k)} + d(\bar{C}_{pq}^{e,(k+1)})\\
\kappa_\alpha^{(k+1)} &= \kappa_\alpha^{(k)} + d(\kappa_\alpha^{(k+1)})\\
K_\alpha^{(k+1)} &= K_\alpha^{(k)} + d(K_\alpha^{(k+1)})\\
\bar{T}_{mn}^{(k+1)} &= \bar{T}_{mn}^{(k)} + d(\bar{T}_{mn}^{(k+1)})
\end{aligned} \tag{106.202}$$

step 8. evaluate the yield function and the residual

$$\Phi^{(k+1)} = \Phi(\bar{T}_{ij}^{e(k+1)}, K_\alpha^{(k+1)}) \;\; ; \;\; R_{ij}^{(k+1)} = \bar{C}_{ij}^{e,(k+1)} - \left(\bar{C}_{ij}^{e,tr} - \Delta\mu^{(k+1)} Z_{ij}^{(k+1)}\right) \tag{106.203}$$

step 9. Set $k = k + 1$

$$\begin{aligned}
\Delta\mu^{(k)} &= \Delta\mu^{(k+1)}\\
\bar{C}_{pq}^{e,(k)} &= \bar{C}_{pq}^{e,(k+1)}\\
\kappa_\alpha^{(k)} &= \kappa_\alpha^{(k+1)}\\
K_\alpha^{(k)} &= K_\alpha^{(k+1)}\\
\bar{T}_{mn}^{(k)} &= \bar{T}_{mn}^{(k+1)}
\end{aligned} \tag{106.204}$$

and return to step 2.

106.4.5 Algorithmic Tangent Stiffness Tensor

Starting from the elastic predictor–plastic corrector equation

$${}^{n+1}\bar{C}_{ij}^{e} = {}^{n+1}\bar{C}_{ij}^{e,tr} - \Delta\mu\;{}^{n+1}Z_{ij} \tag{106.205}$$

and taking the first order Taylor series expansion we obtain

$$\begin{aligned}
d\bar{C}_{ij}^{e} &= d\bar{C}_{ij}^{e,tr} - d(\Delta\mu)\,Z_{ij} - \Delta\mu\,\frac{\partial Z_{ij}}{\partial \bar{T}_{mn}}\,d\bar{T}_{mn} - \Delta\mu\,\frac{\partial Z_{ij}}{\partial K_\alpha}\,dK_\alpha\\
&= d\bar{C}_{ij}^{e,tr} - d(\Delta\mu)\,Z_{ij}\\
&\quad -\Delta\mu\,\frac{\partial Z_{ij}}{\partial \bar{T}_{mn}}\left(d\bar{C}_{mk}^{e}\,\left(\bar{C}_{sk}^{e}\right)^{-1}\,\bar{T}_{sn} + \frac{1}{2}\,\bar{C}_{mk}^{e}\,\bar{\mathcal{L}}_{knpq}^{e}\,d\bar{C}_{pq}^{e}\right) \quad \text{from (106.175)}\\
&\quad -\Delta\mu\,\frac{\partial Z_{ij}}{\partial K_\alpha}\,dK_\alpha
\end{aligned} \tag{106.206}$$

Previous equation can be written as

$$\begin{aligned}
&d\bar{C}_{ij}^{e} + \Delta\mu\,\frac{\partial Z_{ij}}{\partial \bar{T}_{mn}}\,\left(\bar{C}_{sk}^{e}\right)^{-1}\,\bar{T}_{sn}\,d\bar{C}_{mk}^{e} + \Delta\mu\,d(\Delta\mu)\,\frac{\partial Z_{ij}}{\partial \bar{T}_{mn}}\,\frac{1}{2}\,\bar{C}_{mk}^{e}\,\bar{\mathcal{L}}_{knpq}^{e}\,d\bar{C}_{pq}^{e}\\
&\qquad = d\bar{C}_{ij}^{e,tr} - d(\Delta\mu)\,Z_{ij} + \Delta\mu\,d(\Delta\mu)\,\frac{\partial Z_{ij}}{\partial K_\alpha}\,H_{\alpha\beta}\,\frac{\partial \Phi^*}{\partial K_\beta}
\end{aligned} \tag{106.207}$$

or as

$$d\bar{C}^{e}_{ij}\ \left(\mathcal{T}_{mnij}\right) = d\bar{C}^{e,tr}_{ij} - d(\Delta\mu)\, Z_{ij} + \Delta\mu\ d(\Delta\mu)\ \frac{\partial Z_{ij}}{\partial K_{\alpha}}\ H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}} \tag{106.208}$$

where

$$\mathcal{T}_{mnij} = \delta_{im}\delta_{nj} + \Delta\mu^{(k)}\ \frac{\partial Z^{(k)}_{mn}}{\partial \bar{T}^{(k)}_{ik}}\ \left(\bar{C}^{e,(k)}_{sj}\right)^{-1}\ \bar{T}^{(k)}_{sk} + \frac{1}{2}\ \Delta\mu^{(k)}\ \frac{\partial Z^{(k)}_{mn}}{\partial \bar{T}_{pq}}\ \bar{C}^{e,(k)}_{pk}\ \bar{\mathcal{L}}^{e,(k)}_{kqij}$$

The solution for the increment in right elastic deformation tensor is then

$$d\bar{C}^{e}_{ij}\ = \left(\mathcal{T}_{mnij}\right)^{-1}\ \left(d\bar{C}^{e,tr}_{ij} - d(\Delta\mu)\, Z_{ij} + \Delta\mu\ d(\Delta\mu)\ \frac{\partial Z_{ij}}{\partial K_{\alpha}}\ H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}}\right) \tag{106.209}$$

We next use the first order Taylor series expansion of yield function $d\Phi(\bar{T}_{ij}, K_{\alpha}) = 0$

$$\begin{aligned}
\frac{\partial \Phi}{\partial \bar{T}_{mn}}\ d\bar{T}_{mn} + \frac{\partial \Phi}{\partial K_{\alpha}}\ dK_{\alpha} &= \\
\frac{\partial \Phi}{\partial \bar{T}_{mn}}\ \left(d\bar{C}^{e}_{mk}\ \left(\bar{C}^{e}_{sk}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \bar{C}^{e}_{mk}\ \bar{\mathcal{L}}^{e}_{knpq}\ d\bar{C}^{e}_{pq}\right) + \frac{\partial \Phi}{\partial K_{\alpha}}\ dK_{\alpha} &= \\
\frac{\partial \Phi}{\partial \bar{T}_{pn}}\ \left(\bar{C}^{e}_{sq}\right)^{-1}\ \bar{T}_{sn}\ d\bar{C}^{e}_{pq} + \frac{1}{2}\ \frac{\partial \Phi}{\partial \bar{T}_{mn}}\ \bar{C}^{e}_{mk}\ \bar{\mathcal{L}}^{e}_{knpq}\ \ d\bar{C}^{e}_{pq} + \frac{\partial \Phi}{\partial K_{\alpha}}\ dK_{\alpha} &= \\
\left(\frac{\partial \Phi}{\partial \bar{T}_{pn}}\ \left(\bar{C}^{e}_{sq}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \frac{\partial \Phi}{\partial \bar{T}_{mn}}\ \bar{C}^{e}_{mk}\ \bar{\mathcal{L}}^{e}_{knpq}\right)\ d\bar{C}^{e}_{pq} - \frac{\partial \Phi}{\partial K_{\alpha}}\ d(\Delta\mu)\, H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}} &= \\
\mathcal{F}_{pq}\ d\bar{C}^{e}_{pq} - \frac{\partial \Phi}{\partial K_{\alpha}}\ d(\Delta\mu)\, H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}} &= \ \ 0
\end{aligned} \tag{106.210}$$

where

$$\mathcal{F}_{pq} = \frac{\partial \Phi}{\partial \bar{T}_{pn}}\ \left(\bar{C}^{e}_{sq}\right)^{-1}\ \bar{T}_{sn} + \frac{1}{2}\ \frac{\partial \Phi}{\partial \bar{T}_{mn}}\ \bar{C}^{e}_{mk}\ \bar{\mathcal{L}}^{e}_{knpq} \tag{106.211}$$

By using solution for $d\bar{C}^{e}_{ij}$ from 106.209 we can write

$$\begin{aligned}
\mathcal{F}_{pq}\ \left(\mathcal{T}_{mnpq}\right)^{-1}\ \left(d\bar{C}^{e,tr}_{mn} - d(\Delta\mu)\, Z_{mn} + \Delta\mu\ d(\Delta\mu)\ \frac{\partial Z_{mn}}{\partial K_{\alpha}}\ H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}}\right)& \\
-\frac{\partial \Phi}{\partial K_{\alpha}}\ d(\Delta\mu)\, H_{\alpha\beta}\ \frac{\partial \Phi^{*}}{\partial K_{\beta}} &= \ \ 0
\end{aligned} \tag{106.212}$$

We are now in the position to solve for the incremental inconsistency parameter $d(\Delta\mu)$

$$d(\Delta\mu) = \frac{\mathcal{F}_{pq}\ \left(\mathcal{T}_{mnpq}\right)^{-1}\ d\bar{C}^{e,tr}_{mn}}{\Gamma} \tag{106.213}$$

where we have used Γ to shorten writing

$$\Gamma = \mathcal{F}_{pq}\left(\mathcal{T}_{mnpq}\right)^{-1}\, {}^{n+1}Z_{mn} - \Delta\mu\mathcal{F}_{pq}\left(\mathcal{T}_{mnpq}\right)^{-1}\ \frac{\partial^{n+1}Z_{mn}}{\partial K_{\alpha}} H_{\alpha\beta} \frac{\partial \Phi^{*}}{\partial K_{\beta}} + \frac{\partial \Phi}{\partial K_{\alpha}} H_{\alpha\beta} \frac{\partial \Phi^{*}}{\partial K_{\beta}} \tag{106.214}$$

Since

$$d\bar{S}_{kn} = \frac{1}{2}\,\bar{\mathcal{L}}^{e}_{knpq}\,d\bar{C}^{e}_{pq} \tag{106.215}$$

and by using 106.209 we can write

$$\begin{aligned}
&d\bar{C}^{e}_{pq} = \\
&\left(\mathcal{T}_{mnpq}\right)^{-1}\left(\delta_{mv}\,\delta_{nt} - \frac{\mathcal{F}_{op}\,\left(\mathcal{T}_{rsop}\right)^{-1}\,\delta_{rv}\,\delta_{st}}{\Gamma}\,Z_{mn} + \right. \\
&\left.\Delta\mu\,\frac{\mathcal{F}_{op}\,\left(\mathcal{T}_{rsop}\right)^{-1}\,\delta_{rv}\,\delta_{st}}{\Gamma}\,\frac{\partial Z_{ij}}{\partial K_{\alpha}}\,H_{\alpha\beta}\,\frac{\partial \Phi^{*}}{\partial K_{\beta}}\right)\,d\bar{C}^{e,tr}_{vt}
\end{aligned} \tag{106.216}$$

Then

$$d\bar{C}^{e}_{pq} = \bar{\mathcal{P}}_{pqvt}\,d\bar{C}^{e,tr}_{vt} \tag{106.217}$$

where

$$\begin{aligned}
\bar{\mathcal{P}}_{pqvt} \;&=\; \left(\mathcal{T}_{mnpq}\right)^{-1}\,\delta_{mv}\,\delta_{nt} - \frac{\mathcal{F}_{op}\,\left(\mathcal{T}_{rsop}\right)^{-1}\,\delta_{rv}\,\delta_{st}}{\Gamma}\,Z_{mn} \\
&+\;\Delta\mu\,\frac{\mathcal{F}_{op}\,\left(\mathcal{T}_{rsop}\right)^{-1}\,\delta_{rv}\,\delta_{st}}{\Gamma}\,\frac{\partial Z_{ij}}{\partial K_{\alpha}}\,H_{\alpha\beta}\,\frac{\partial \Phi^{*}}{\partial K_{\beta}} \\
&=\; (\mathcal{T}_{mnpq})^{-1}\left(\delta_{mv}\delta_{nt} - \frac{\mathcal{F}_{ab}(\mathcal{T}_{vtab})^{-1}}{\Gamma}\left(Z_{mn} - \Delta\mu\,\frac{\partial^{n+1}Z_{mn}}{\partial K_{\alpha}}H_{\alpha\beta}\frac{\partial \Phi^{*}}{\partial K_{\beta}}\right)\right)
\end{aligned} \tag{106.218}$$

Algorithmic tangent stiffness tensor $\bar{\mathcal{L}}_{ijkl}$ (in intermediate configuration $\bar{\Omega}$) is then defined as

$$\bar{\mathcal{L}}^{ATS}_{knvt} = \bar{\mathcal{L}}^{e}_{knpq}\,\bar{\mathcal{P}}_{pqvt} \tag{106.219}$$

Pull–back to the reference configuration Ω_0 yields the algorithmic tangent stiffness tensor $\mathcal{L}_{ijkl}$ in reference configuration Ω_0

$${}^{n+1}\mathcal{L}^{ATS}_{ijkl} = {}^{n+1}F^{p}_{im}\;{}^{n+1}F^{p}_{jn}\;{}^{n+1}F^{p}_{kr}\;{}^{n+1}F^{p}_{ls}\;{}^{n+1}\bar{\mathcal{L}}^{ATS}_{mnrs} \tag{106.220}$$

Remark 106.4.8 In the limit, for small deformations, isotropic response, the Algorithmic Tangent Stiffness tensor $\mathcal{L}^{ATS}_{ijkl}$ becomes

$$\begin{aligned}
\lim \bar{\mathcal{L}}^{ATS}_{vtpq} = E^{ATS}_{vtpq} = \;&\; E_{knpq}\left(\Upsilon^{-1}_{mnpq}\left(\delta_{mv}\delta_{nt} - \frac{n_{cd}E_{cdab}\Upsilon^{-1}_{vtab}\mathcal{H}_{mn}}{\Gamma}\right)\right) \\
=\;&\; E_{knpq}\left(\Upsilon^{-1}_{vtpq} - \frac{\Upsilon^{-1}_{mrpq}n_{cd}E_{cdab}\Upsilon^{-1}_{vtab}\mathcal{H}_{mr}}{\Gamma}\right) \\
=\;&\; E_{knpq}\Upsilon^{-1}_{vtpq} - \frac{E_{knpq}\Upsilon^{-1}_{mrpq}n_{cd}E_{cdab}\Upsilon^{-1}_{vtab}\mathcal{H}_{mr}}{\Gamma} \\
=\;&\; \mathcal{R}_{knvt} - \frac{n_{cd}\mathcal{R}_{cdvt}\mathcal{R}_{knmr}\mathcal{H}_{mr}}{\Gamma}
\end{aligned} \tag{106.221}$$

since

$$\begin{aligned} \lim \bar{\mathcal{T}}_{mnpq} = \Upsilon_{mnpq} = \quad & \delta_{pm}\delta_{nq} + \Delta\mu \frac{\partial Z_{mn}}{\partial \bar{T}_{pk}} \left(\bar{C}^e_{sq}\right)^{-1} \bar{T}_{sk} + \frac{1}{2}\Delta\mu \frac{\partial Z_{mn}}{\partial \bar{T}_{rs}} \bar{C}^e_{rk} \bar{\mathcal{L}}^e_{kspq} \\ = \quad & \delta_{pm}\delta_{nq} + \Delta\mu \frac{\partial m_{mn}}{\partial \sigma_{rs}} E^e_{kspq} \end{aligned} \tag{106.222}$$

$$\begin{aligned} \lim \mathcal{F}_{ab} = \quad & \lim \left(\frac{\partial \Phi}{\partial \bar{T}_{ad}} \left(\bar{C}^e_{sb}\right)^{-1} \bar{T}_{sd} + \frac{1}{2} \frac{\partial \Phi}{\partial \bar{T}_{cd}} \bar{C}^e_{ck} \bar{\mathcal{L}}^e_{kdab} \right) \\ = \quad & \frac{1}{2} n_{cd} E^e_{cdab} \end{aligned} \tag{106.223}$$

$$\mathcal{H}_{mn} = m_{mn} - \Delta\mu \frac{\partial m_{mn}}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \tag{106.224}$$

$$\begin{aligned} \lim \Gamma = \quad & \lim \left(\mathcal{F}_{pq} \left(\mathcal{T}_{mnpq}\right)^{-1} {}^{n+1}Z_{mn} - \Delta\mu \mathcal{F}_{pq} \left(\mathcal{T}_{mnpq}\right)^{-1} \frac{\partial^{n+1} Z_{mn}}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} + \frac{\partial \Phi}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \right) \\ = \quad & n_{ab} E_{abpq} \Upsilon^{-1}_{mnpq} m_{mn} - \Delta\mu n_{ab} E_{abpq} \Upsilon^{-1}_{mnpq} \frac{\partial m_{mn}}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} + \frac{\partial \Phi}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \\ = \quad & n_{ab} E_{abpq} \Upsilon^{-1}_{mnpq} \left(m_{mn} - \Delta\mu \frac{\partial m_{mn}}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \right) + \frac{\partial \Phi}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \\ = \quad & n_{ab} \mathcal{R}_{abmn} \mathcal{H}_{mn} + \frac{\partial \Phi}{\partial K_\alpha} H_{\alpha\beta} \frac{\partial \Phi^*}{\partial K_\beta} \end{aligned} \tag{106.225}$$

It is noted that the Algorithmic Tangent Stiffness tensor given by 106.221 compares exactly with it's small strain counterpart (Jeremić and Sture, 1997).

Chapter 107

Solution of Static Equilibrium Equations

(1994-2016-)

(In collaboration with Dr. Yuan Feng)

107.1 Chapter Summary and Highlights

107.2 The Residual Force Equations

This chapter is based on Felippa (1993).

In previous Chapters we have derived the basic equations for (material and/or geometric) nonlinear analysis of solids. Discretization of such problems by finite element methods results in a set of nonlinear algebraic equations called *residual force equations*:

$$\mathbf{r}(\mathbf{u}, \lambda) = \mathbf{f}_{int}(\mathbf{u}) - \lambda \mathbf{f}_{ext} = 0 \tag{107.1}$$

where $\mathbf{f}_{int}(\mathbf{u})$ are the internal forces which are functions of the displacements, $\mathbf{u}$, the vector $\mathbf{f}_{ext}$ is a fixed external loading vector and the scalar λ is a load–level parameter that multiplies $\mathbf{f}_{ext}$. Equation (107.1) describes the case of proportional loading in which the loading pattern is kept fixed.

All solution procedures of practical importance are strongly rooted in the idea of "advancing the solution" by *continuation*. Except in very simple problems, the continuation process is *multilevel* and involves hierarchical breakdown into stages, incremental steps and iterative steps. Processing a complex nonlinear problem generally involves performing a series of analysis stages. Multiple control parameters are not varied independently in each stage and may therefore be characterized by a single stage control parameter λ. Stages are only weakly coupled in the sense that end solution of one may provide the starting point for another.

107.3 Constraining the Residual Force Equations

Various forms of path following methods[1] have stemmed from the original work of Riks (1972), Riks (1979) and Wempner (1971). They aimed at finding the intersection of equation (107.1) with $s = constant$ where s is the arc-length , defined as[2]:

$$s = \int ds \tag{107.2}$$

where:

$$ds = \sqrt{\frac{\psi_u^2}{u_{ref}^2} d\mathbf{u}^T \mathbf{S} d\mathbf{u} + d\lambda^2 \psi_f^2} \tag{107.3}$$

---

[1] also called arc-length methods with various methods of approximating the exact length of an arc.

[2] A bit different form in that it is scaled with scaling matrix $\mathbf{S}$, introduced by Felippa (1984).

Differential form (107.3) can be replaced with an incremental form:

$$a = (\Delta s)^2 - (\Delta l)^2 = \left(\frac{\psi_u^2}{u_{ref}^2} \Delta \mathbf{u}^T \mathbf{S} \Delta \mathbf{u} + \Delta\lambda^2 \psi_f^2 \right) - (\Delta l)^2 \tag{107.4}$$

where Δl is the radius of the desired intersection[3] and represents an approximation to the incremental arc length. Scaling matrix $\mathbf{S}$ is usually diagonal non-negative matrix that scales the state vector $\Delta\mathbf{u}$ and u_{ref} is a reference value with the dimension of $\sqrt{\Delta\mathbf{u}^T\mathbf{S}\Delta\mathbf{u}}$. It is important to note that the vector $\Delta\mathbf{u}$ and scalar $\Delta\lambda$ are incremental and not iterative values, and are starting from the last converged equilibrium state.

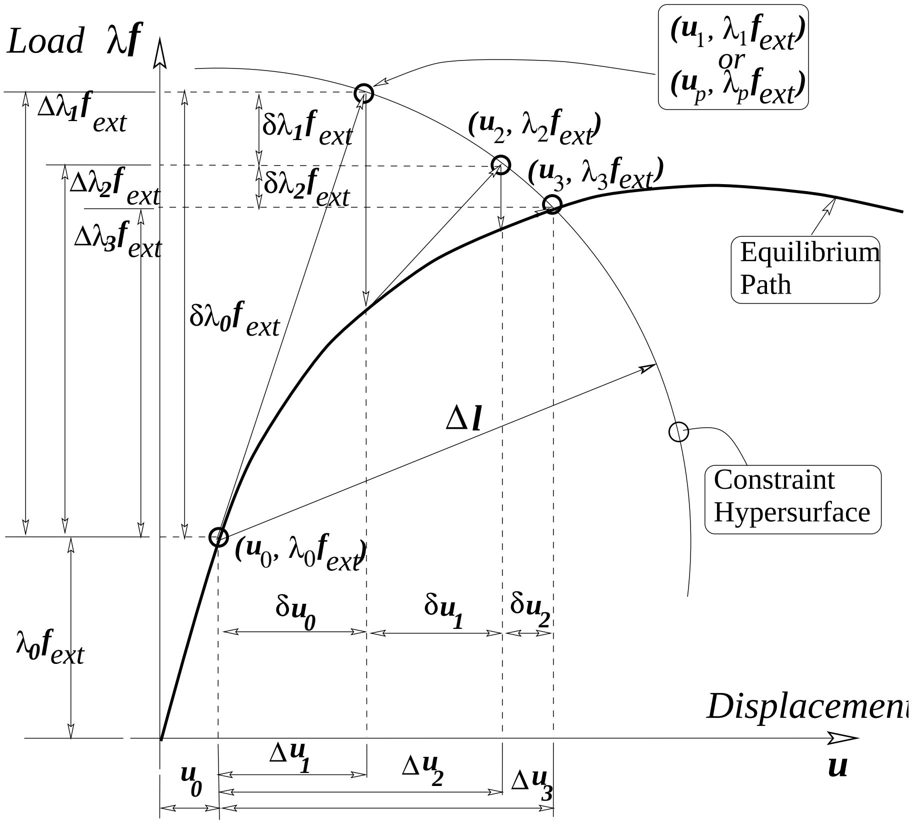

Figure 107.1: Spherical arc-length method and notation for one DOF system.

The main essence of the arc-length methods is that the load parameter λ becomes a variable. With load parameter λ variable we are dealing with $n+1$ unknowns[4]. In order to solve this problem we have n equilibrium equations (107.1) and the one constraint equation (107.4). We can solve the augmented

---

[3] See Figure (107.1).

[4] n unknown displacement variables and on extra unknown in the form of load parameter.

system of $n + 1$ equations by applying the Newton-Raphson[5] method to equations (107.1) and (107.4)

$$
\begin{aligned}
\mathbf{r}^{new}(\mathbf{u}, \lambda) &= \mathbf{r}^{old}(\mathbf{u}, \lambda) + \frac{\partial \mathbf{r}(\mathbf{u}, \lambda)}{\partial \mathbf{u}} \, \delta \mathbf{u} + \frac{\partial \mathbf{r}(\mathbf{u}, \lambda)}{\partial \lambda} \, \delta \lambda = \\
&= \mathbf{r}^{old}(\mathbf{u}, \lambda) + \mathbf{K}_t \, \delta \mathbf{u} - \mathbf{f}_{ext} \, \delta \lambda = \\
&= 0 \qquad (107.5)
\end{aligned}
$$

$$
a^{new} = a^{old} + 2 \frac{\psi_u^2}{u_{ref}^2} \Delta \mathbf{u}^T \mathbf{S} \delta \mathbf{u} + 2 \Delta \lambda \delta \lambda \, \psi_f^2 = 0 \qquad (107.6)
$$

where $\mathbf{K}_t = \frac{\partial \mathbf{r}(\mathbf{u},\lambda)}{\partial \mathbf{u}}$ is the tangent stiffness matrix. The aim is to have $\mathbf{r}^{new}(\mathbf{u}, \lambda) = 0$ and $a^{new} = 0$ so the previous system can be written as:

$$
\begin{bmatrix} \mathbf{K}_t & -\mathbf{f}_{ext} \\ 2 \frac{\psi_u^2}{u_{ref}^2} \Delta \mathbf{u}^T \mathbf{S} & 2 \Delta \lambda \, \psi_f^2 \end{bmatrix} \begin{bmatrix} \delta \mathbf{u} \\ \delta \lambda \end{bmatrix} = - \begin{bmatrix} \mathbf{r}^{old} \\ a^{old} \end{bmatrix} \qquad (107.7)
$$

One can solve previous system of two equations for $\delta \mathbf{u}$ and $\delta \lambda$:

$$
\begin{bmatrix} \delta \mathbf{u} \\ \delta \lambda \end{bmatrix} = - \begin{bmatrix} \mathbf{K}_t & -\mathbf{f}_{ext} \\ 2 \frac{\psi_u^2}{u_{ref}^2} \Delta \mathbf{u}^T \mathbf{S} & 2 \Delta \lambda \, \psi_f^2 \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{r}^{old} \\ a^{old} \end{bmatrix} \qquad (107.8)
$$

or by defining the augmented stiffness matrix[6] $\mathcal{K}$ as:

$$
\mathcal{K} = \begin{bmatrix} \mathbf{K}_t & -\mathbf{f}_{ext} \\ 2 \frac{\psi_u^2}{u_{ref}^2} \Delta \mathbf{u}^T \mathbf{S} & 2 \Delta \lambda \, \psi_f^2 \end{bmatrix} \qquad (107.9)
$$

the equation (107.8) can be written as:

$$
\begin{bmatrix} \delta \mathbf{u} \\ \delta \lambda \end{bmatrix} = - \mathcal{K}^{-1} \begin{bmatrix} \mathbf{r}^{old} \\ a^{old} \end{bmatrix} \qquad (107.10)
$$

It should be mentioned that the augmented stiffness matrix remains non-singular even if $\mathbf{K}_t$ is singular.

---

[5] By using a truncated Taylor series expansion.

[6] Or augmented Jacobian.

107.4 Load Control

107.5 Displacement Control

107.6 Generalized, Hyper–Spherical Arc-Length Control

In section (107.3) we have introduced an constraining equation that is intended to reduce the so called drift error in the incremental nonlinear finite element procedure. The constraining equation was given in a rather general form. Some further comments and observations are in order. By assigning various numbers to parameters ψ_u, ψ_f, $\mathbf{S}$ and u_{ref} one can obtain different constraining schemes from (107.4).

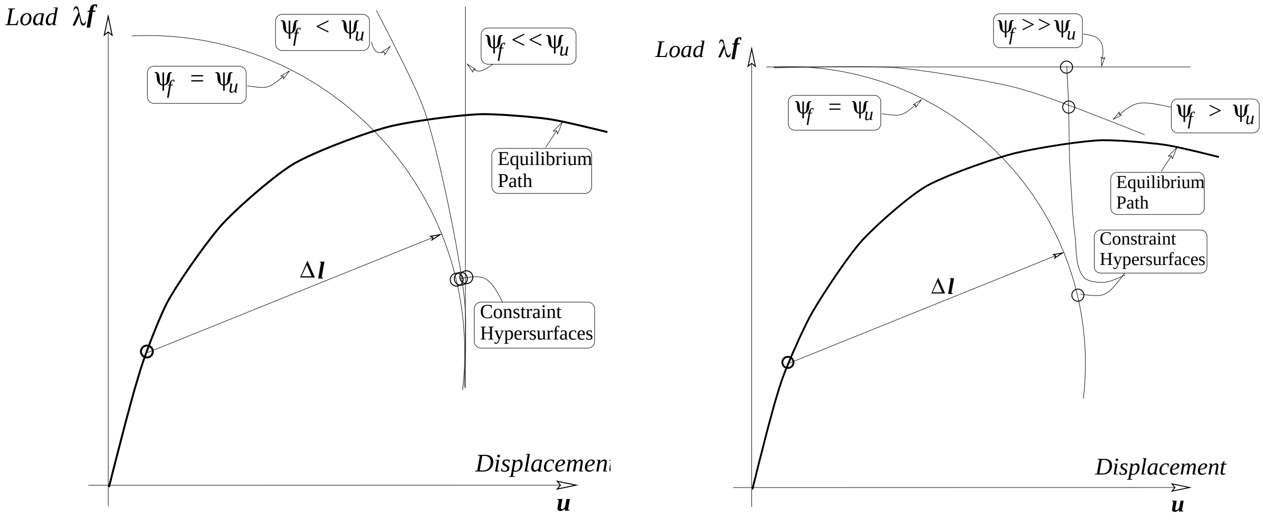

Figure 107.2: Influence of ψ_u and ψ_f on the constraint surface shape.

Coefficients ψ_u and ψ_f may not be simultaneously zero. Useful choices for $\mathbf{S}$ are $\mathbf{I}$, $\mathbf{K}_t$ and $diag\left(\mathbf{K}_t\right)$. If $\mathbf{S} = \mathbf{I}$ and $u_{ref} = 1$ the method is called the arclength method[7]. If we choose $\mathbf{S} = diag\left(\mathbf{K}_t\right)$ nice scaling is obtained[8] but otherwise no physical meaning can be attributed to this scaling type. With $\mathbf{S} = \mathbf{K}_t$ and $\psi_f \equiv 0$ one ends up with something very similar to the external work constraint of Bathe and Dvorkin (1983). A rather general equation (107.4) can be further specialized to load (λ) control with $\psi_u \equiv 0; \psi_f \equiv 1$ and state control[9] with $\psi_u \equiv 1; \psi_f \equiv 0$ and $\mathbf{S} = \mathbf{I}$. In the finite element literature, the term displacement control has been traditionally associated with the case in which only one of the components of the displacement vector $\mathbf{u}$[10] is specified. This may be regarded either as a variant of state

---

[7] It actually reduces to the original work of fRiks (1972), Riks (1979) and Wempner (1971).

[8] For example if FEM model includes both translational and rotational DOFs.

[9] That is the cylindrical constraint, or general displacement control.

[10] Say $\mathbf{u}_i$.

control, in which a norm that singles out the ith component is used, or as a variant of the λ control if the control parameter is taken as $\lambda \mathbf{u}_i$. It is, of course, possible to make the previous parameters variable, functions of different unknowns. For example if one defines $u_{ref} = \Delta\mathbf{u}^T\mathbf{S}\Delta\mathbf{u}$ then close to the limit point $\Delta\mathbf{u} \to 0 \Rightarrow \frac{\psi_u^2}{u_{ref}^2} \gg \psi_f^2$ that makes our constraint from equation (107.4) behave like state control. One important aspect of scaling constraint equations by using $\mathbf{S} = diag\left(\mathbf{K}_t\right)$ or $\mathbf{S} = \mathbf{K}_t$ is the possibility of non–positive definite stiffness matrix $\mathbf{K}_t$. It usually happens that after the limit point is passed, at least one of the eigenvalues of $\mathbf{K}_t$ is non–positive, thus rendering the constraint hypersurface non–convex.

In order to get better control of the solution to the system of equations (107.10) one may directly introduce the constraint from equation (107.6) by following the approach proposed by Batoz and Dhatt (1979), as described by Crisfield (1991) and Felippa (1993).

The iterative displacement $\delta\mathbf{u}$ is split into two parts, and with the Newton change at the new unknown load level:

$$\lambda^{new} = \lambda^{old} + \delta\lambda \tag{107.11}$$

becomes:

$$\begin{aligned}
\delta\mathbf{u} &= -\mathbf{K}_t^{-1}\mathbf{r}\left(\mathbf{u}^{old}, \lambda\right) = -\mathbf{K}_t^{-1}\left(\mathbf{f}_{int}(\mathbf{u}^{old}) - \lambda^{new}\mathbf{f}_{ext}\right) \\
&= -\mathbf{K}_t^{-1}\left(\mathbf{f}_{int}(\mathbf{u}^{old}) - \left(\lambda^{old} + \delta\lambda\right)\mathbf{f}_{ext}\right) = -\mathbf{K}_t^{-1}\left(\left(\mathbf{f}_{int}(\mathbf{u}^{old}) - \lambda^{old}\mathbf{f}_{ext}\right) - \delta\lambda\mathbf{f}_{ext}\right) \\
&= -\mathbf{K}_t^{-1}\left(\mathbf{r}\left(\mathbf{u}^{old}, \lambda^{old}\right) - \delta\lambda\mathbf{f}_{ext}\right) = -\mathbf{K}_t^{-1}\mathbf{r}^{old} + \delta\lambda\mathbf{K}_t^{-1}\mathbf{f}_{ext} = \delta\bar{\mathbf{u}} + \delta\lambda\delta\mathbf{u}_t
\end{aligned} \tag{107.12}$$

where $\delta\mathbf{u}_t = \mathbf{K}_t^{-1}\mathbf{f}_{ext}$ is the displacement vector corresponding to the fixed load vector $\mathbf{f}_{ext}$, and $\delta\bar{\mathbf{u}}$ is an iterative change that would stem from the standard load-controlled Newton-Raphson, at a fixed load level λ^{old}. With the solution[11] for the $\delta\mathbf{u}$ from (107.12), the new incremental displacements are:

$$\Delta\mathbf{u}^{new} = \Delta\mathbf{u}^{old} + \delta\mathbf{u} = \Delta\mathbf{u}^{old} + \delta\bar{\mathbf{u}} + \delta\lambda\delta\mathbf{u}_t \tag{107.13}$$

where $\delta\lambda$ is the only unknown. The constraint from equation (107.4) can be used here, and by rewriting it as:

$$\left(\frac{\psi_u^2}{u_{ref}^2}\left(\Delta\mathbf{u}^{new}\right)^T\mathbf{S}\left(\Delta\mathbf{u}^{new}\right) + \left(\Delta\lambda^{new}\right)^2\psi_f^2\right) = (\Delta l)^2 \tag{107.14}$$

---

[11] But having in mind that $\delta\lambda$ is still unknown!

then by substituting $\Delta \mathbf{u}^{new}$ from equation (107.13) into equation (107.14) and by recalling that $\lambda^{new} = \lambda^{old} + \delta\lambda$ one ends up with the following quadratic scalar equation:

$$\left(\frac{\psi_u^2}{u_{ref}^2} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} + \delta\lambda \delta \mathbf{u}_t \right)^T \mathbf{S} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} + \delta\lambda \delta \mathbf{u}_t \right) + \left(\Delta\lambda^{old} + \delta\lambda \right)^2 \psi_f^2 \right) = (\Delta l)^2 \tag{107.15}$$

or, by collecting terms:

$$\begin{array}{rcl} \left(\frac{\psi_u^2}{u_{ref}^2} \delta \mathbf{u}_t^T \mathbf{S} \delta \mathbf{u}_t + \psi_f^2 \right) & \delta\lambda^2 & + \\ +2 \left(\frac{\psi_u^2}{u_{ref}^2} \delta \mathbf{u}_t^T \mathbf{S} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right) + \Delta\lambda^{old} \psi_f^2 \right) & \delta\lambda & + \\ + \left(\frac{\psi_u^2}{u_{ref}^2} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right)^T \mathbf{S} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right) - \Delta l^2 + \left(\Delta\lambda^{old} \right)^2 \psi_f^2 \right) & & = 0 \end{array} \tag{107.16}$$

or:

$$a_1 \delta\lambda^2 + 2 a_2 \delta\lambda + a_3 = 0 \tag{107.17}$$

where:

$$\begin{array}{rcl} a_1 & = & \frac{\psi_u^2}{u_{ref}^2} \delta \mathbf{u}_t^T \mathbf{S} \delta \mathbf{u}_t + \psi_f^2 \\ 2a_2 & = & 2 \left(\frac{\psi_u^2}{u_{ref}^2} \delta \mathbf{u}_t^T \mathbf{S} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right) + \Delta\lambda^{old} \psi_f^2 \right) \\ a_3 & = & \frac{\psi_u^2}{u_{ref}^2} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right)^T \mathbf{S} \left(\Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} \right) - \Delta l^2 + \left(\Delta\lambda^{old} \right)^2 \psi_f^2 \end{array}$$

The quadratic scalar equation (107.17) can be solved for $\delta\lambda$:

$$\delta\lambda = \delta\lambda_1 = \frac{-a_2 + \sqrt{a_2^2 - a_1 a_3}}{a_1} \quad ; \quad \delta\lambda = \delta\lambda_2 = \frac{-a_2 - \sqrt{a_2^2 - a_1 a_3}}{a_1} \tag{107.18}$$

or, if $a_1 = 0$, then:

$$\delta\lambda = -\frac{a_3}{2a_2} \tag{107.19}$$

and then the complete change is defined from equation (107.13):

$$\Delta \mathbf{u}^{new} = \Delta \mathbf{u}^{old} + \delta \bar{\mathbf{u}} + \delta\lambda \delta \mathbf{u}_t \tag{107.20}$$

An ambiguity is introduced in the solution for $\delta\lambda$ from (107.18). The tangent at the regular point on the equilibrium path has two possible directions, which generally intersect the constraint hypersurface at two points. However, some exceptions from that rule are possible, so the solutions from (107.18) can be categorized as:

- Real roots of opposite signs. This occurs when the iteration process converges normally and there is no limit or turning point enclosed by the constraint hypersurface. The root is chosen by applying one of the schemes proposed below.
- Real roots of equal sign opposite to that of $\Delta\lambda^{old}$. This usually happens when going over a "flat" limit point.
- Real roots of equal sign same as that of $\Delta\lambda^{old}$. This is an unusual case. It may signal a turning point or be triggered by erratic iteration behavior.
- Complex roots. This is an unusual case too. It may signal a sharp turning point, a bifurcation point, erratic or divergent iterates.

For the first two cases, the correct $\Delta\lambda$ can be chosen by applying one of the following schemes.

107.6.1 Traversing Equilibrium Path in Positive Sense

107.6.1.1 Positive External Work

The simplest rule requires that the external work expenditure over the predictor step be positive:

$$\Delta W = \mathbf{f}_{ext}^T \Delta \mathbf{u} = \mathbf{f}_{ext}^T \mathbf{K}_t^{-1} \mathbf{f}_{ext} \delta\lambda > 0 \tag{107.21}$$

The simple conclusion is that $\delta\lambda$ should have the sign of $\mathbf{f}_{ext}^T \mathbf{K}_t^{-1} \mathbf{f}_{ext}$. This condition is particularly effective at limit points. However, it fails when $\mathbf{f}_{ext}$ and $\mathbf{K}_t^{-1}\mathbf{f}_{ext}$ are orthogonal:

$$\mathbf{f}_{ext}^T \mathbf{K}_t^{-1} \mathbf{f}_{ext} = 0 \tag{107.22}$$

This can happen at:

- Bifurcation points,

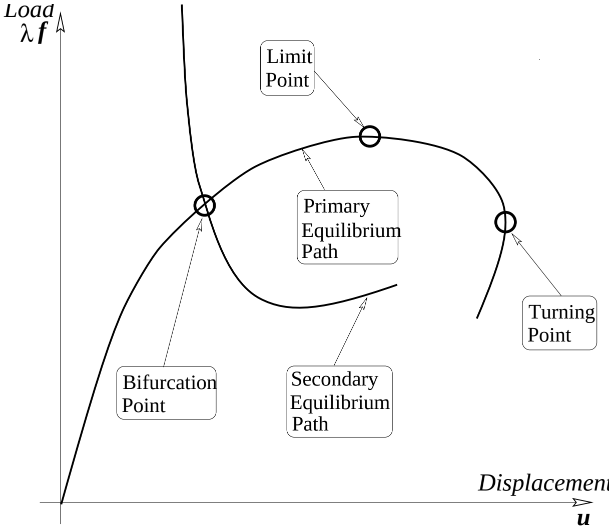

Figure 107.3: Simple illustration of Bifurcation and Turning point.

- Turning points,

The treatment of bifurcation points is of a rather special nature and is left for the near future. Turning points[12] can be traversed by a modification of a previous rule, as described in the next section.

107.6.1.2 Angle Criterion

Near a turning point application of the positive work rule (107.21) causes the path to double back upon itself. When it crosses the turning point it reverses so the turning point becomes impassable. Physically, a positive work rule is incorrect because in passing a turning point the structure releases external work until another turning point is encountered.

To pass a turning point imposing a condition on the angle of the prediction vector proves more effective. The idea is to compute both solutions $\delta\lambda_1$ and $\delta\lambda_2$ and then both $\Delta\mathbf{p}_1^{new}$ and $\Delta\mathbf{u}_1^{new}$:

$$\Delta\mathbf{u}_1^{new} = \Delta\mathbf{u}^{old} + \delta\bar{\mathbf{u}} + \delta\lambda_1\delta\mathbf{u}_t \tag{107.23}$$

$$\Delta\mathbf{u}_2^{new} = \Delta\mathbf{u}^{old} + \delta\bar{\mathbf{u}} + \delta\lambda_2\delta\mathbf{u}_t \tag{107.24}$$

---

[12] One might ask "why treating turning points in a material nonlinear analysis?". The answer is rather simple: "try to prevent all unnecessary surprises". For a good account of some of surprises in material nonlinear analysis one might take a look at some examples in Crisfield (1991) pp. 270.

The one that lies closest to the old incremental step direction $\Delta\mathbf{u}^{old}$ is the one sought. This should prevent the solution from double backing. The procedure can be implemented by finding the solution with the minimum angle between $\Delta\mathbf{u}^{old}$ and $\Delta\mathbf{p}^{new}$, and hence the maximum cosine of the angle:

$$\cos\phi = \frac{\left(\Delta\mathbf{u}^{old}\right)^T \left(\Delta\mathbf{u}^{new}\right)}{\|\Delta\mathbf{u}^{old}\| \, \|\Delta\mathbf{u}^{new}\|} = \frac{\left(\Delta\mathbf{u}^{old}\right)^T \left(\Delta\mathbf{u}^{old} + \delta\bar{\mathbf{u}} + \delta\lambda\delta\mathbf{u}_t\right)}{\|\Delta\mathbf{u}^{old}\| \, \|\Delta\mathbf{u}^{old} + \delta\bar{\mathbf{u}} + \delta\lambda\delta\mathbf{u}_t\|} \tag{107.25}$$

where $\delta\bar{\mathbf{u}} = -\mathbf{K}_t^{-1}\mathbf{r}^{old}$ and $\delta\mathbf{u}_t = \mathbf{K}_t^{-1}\mathbf{f}_{ext}$. Once the turning point has been crossed, the work criterion should be reversed so the external work is negative.

By directly introducing the constraint from equation (107.6) and following the method through equations (107.12) to (107.25) a limitation is introduced. Precisely at the limit point, $\mathbf{K}_t$ is singular and the equations cannot be solved. However, Batoz and Dhatt (1979) and Crisfield (1991) report that no such problem has occurred, because one appears never to arrive precisely at limit point.

107.6.2 Predictor step

The predictor solution is achieved by applying one forward Euler, explicit step from the last obtained equilibrium point:

$$\Delta\mathbf{u}_p = \mathbf{K}_t^{-1}\Delta\mathbf{q}_e = \Delta\lambda_p\mathbf{K}_t^{-1}\mathbf{f}_{ext} = \Delta\lambda_p\delta\mathbf{u}_t \tag{107.26}$$

where $\mathbf{K}_t$ is the tangent stiffness matrix at the beginning of increment. Substituting equation (107.26) into the constraint equation (107.14) one obtains:

$$\begin{aligned}
\left(\frac{\psi_u^2}{u_{ref}^2}\left(\Delta\mathbf{u}^{new}\right)^T \mathbf{S}\left(\Delta\mathbf{u}^{new}\right) + \left(\Delta\lambda^{new}\right)^2\psi_f^2\right) &= \\
\left(\frac{\psi_u^2}{u_{ref}^2}\Delta\lambda_p^2\delta\mathbf{u}_t^T\mathbf{S}\delta\mathbf{u}_t\right) + \left(\Delta\lambda_p\right)^2\psi_f^2 &= \\
\Delta\lambda_p^2\left(\frac{\psi_u^2}{u_{ref}^2}\delta\mathbf{u}_t^T\mathbf{S}\delta\mathbf{u}_t + \psi_f^2\right) &= (\Delta l)^2
\end{aligned} \tag{107.27}$$

The solution for $\Delta\lambda_p$ is readily found:

$$\Delta\lambda_p = \pm\frac{\Delta l}{\sqrt{\frac{\psi_u^2}{u_{ref}^2}\left|\delta\mathbf{u}_t^T\mathbf{S}\delta\mathbf{u}_t\right| + \psi_f^2}} \tag{107.28}$$

where $\Delta l > 0$ is the given increment length. The absolute value of $|\delta \mathbf{u}_t^T \mathbf{S} \delta \mathbf{u}_t|$ is needed if the stiffness matrix is chosen as a scaling matrix, i.e. $\mathbf{S} = \mathbf{K}_t$, since, after passing limit point, the stiffness matrix is non–positive definite so $\delta \mathbf{u}_t^T \mathbf{S} \delta \mathbf{u}_t \leq 0$. The question of choosing the right sign + or – in (107.28) is still a vigorous research topic. In the simplified procedure[13] the negative sign – is chosen with respect to the occurrence of one negative pivot during factorization of the tangent stiffness matrix $\mathbf{K}_t$. If more than one pivot happens to be negative, one is advised[14] to stop the analysis and try to restart from previously converged solution with smaller step size.

107.6.3 Automatic Increments

A number of workers have advocated different strategies for controlling the step length size. In this work we will follow the strategy advocated by Crisfield (1991). The idea is to find the new incremental length by applying:

$$\Delta l^{new} = \Delta l^{old} \left(\frac{I_{desired}}{I_{old}} \right)^n \tag{107.29}$$

where Δl^{old} is the old incremental factor for which I_{old} iterations were required, $I_{desired}$ is the input, desired number of iterations[15] and the parameter n is set to $\frac{1}{2}$ as suggested by Ramm (1982) Ramm (1981).

107.6.4 Convergence Criteria

Introduction of an iterative scheme calls for the introduction of an iteration termination test. There are several convergence criteria that can be applied.

- Absolute Displacement Convergence Criteria. The change in the last correction $\delta \mathbf{u}$ of the state vector $\mathbf{u}$, measured in an appropriate norm, should not exceed a given tolerance ϵ_u. For example, if we use Euclidean norm[16] the termination criteria can be written as:

  $$||\delta \mathbf{u}||_{absolute} = \sqrt{(\delta \mathbf{u})^T \mathbf{S} (\delta \mathbf{u})} \leq \epsilon_u \tag{107.30}$$

  Scaling matrix $\mathbf{S}$ is used in order to ensure that for a problem involving mixed units[17], all parameters have the same unit. Here, an obvious choice for the scaling matrix is $\mathbf{S} = diag(\mathbf{K}_t^{-1})$. If, on the

---

[13] Which is not guaranteed to work if one takes into account bifurcation phenomena.

[14] For more details see Crisfield (1991).

[15] Say $I_{desired} \approx 3$.

[16] The so called 2–norm.

[17] For example, if rotations and displacements are involved.

other hand we don't have mixed variables in state vector $\mathbf{u}$ then the simplest choice for scaling matrix is $\mathbf{S} = \mathbf{I}$.

Currently used within FEI and the Real-ESSI program is an absolute convergence criteria with unit scaling matrix $\mathbf{S} = \mathbf{I}$. This means that absolute tolerance criteria mixes units for different Degrees of Freedom (DoFs). Supplied tolerance is converted to basic units of the system (meter and Newton) and that is used for comparison and convergence decisions.

- Relative Displacement Convergence Criteria. It is beneficial to use the relative convergence criteria in order to relax convergence criteria for problems where one or few displacements dominate. In order to to that, use of ratio of Euclidean norm of iterative displacement $||\delta\mathbf{u}||_{scaled}$ and Euclidean norm of total displacement $||\mathbf{u}||_{scaled}$ is recommended:

$$\frac{||\delta\mathbf{u}||_{relative}}{||\mathbf{u}||_{scaled}} \leq \epsilon_u \tag{107.31}$$

Again it is important to note that currently used within FEI and the Real-ESSI program is an absolute convergence criteria with unit scaling matrix $\mathbf{S} = \mathbf{I}$. This means that relative tolerance criteria mixes units for different Degrees of Freedom (DoFs). Supplied tolerance is converted to basic units of the system (meter and Newton) and that is used for comparison and convergence decisions.

- Average Displacement Convergence Criteria. The change in the last correction $\delta\mathbf{u}$ of the state vector $\mathbf{u}$, measured in an appropriate norm, should not exceed a given tolerance ϵ_u, divided by the total number of DoFs:

$$||\delta\mathbf{u}||_{average} = \frac{\sqrt{(\delta\mathbf{u})^T\,\mathbf{S}\,(\delta\mathbf{u})}}{nDoFs} \leq \epsilon_u \tag{107.32}$$

This is important in order to preserve objectivity of displacement convergence criteria for similar (same) models that are discretized with a different number of finite elements (and therefor feature different number of nodes and DoFs). For example, a cantilever (simplest model) can be discretized using 5 DoFs and 5,000,000 DoFs. Since equation 107.32 essentially sums up absolute values of all displacements, it is expected that in the case of larger number of DoFs, larger norm will be calculated. This will create a problem since specified tolerance will then be a function of a number of DoFs a model features. Hence, a norm of all iterative displacements is divided by the total number of DoFs.

One more time, it is important to note that currently used within FEI and the Real-ESSI program is an absolute convergence criteria with unit scaling matrix $\mathbf{S} = \mathbf{I}$. Therefor average tolerance criteria mixes units. Supplied tolerance is converted to basic units of the system (meter and Newton) and that is used for comparison and convergence decisions.

- Absolute Residual Force Convergence Criteria. Since the residual $\mathbf{r}(\mathbf{u}, \lambda)$ measures the departure from the equilibrium path, an appropriate convergence test would be to compare Euclidean norm of residual with some predefined tolerance:

  $$\|\mathbf{r}(\mathbf{u}, \lambda)\|_{scaled} = \sqrt{(\mathbf{r})^T \, \mathbf{S} \, (\mathbf{r})} \leq \epsilon_r \tag{107.33}$$

  Here, an obvious choice for scaling matrix is $\mathbf{S} = diag(\mathbf{K}_t)$

  Much the same as for displacement based convergence criteria, currently used within FEI and the Real-ESSI program is a convergence criteria with unit scaling matrix $\mathbf{S} = \mathbf{I}$. This means that absolute tolerance criteria mixes units for different Degrees of Freedom (DoFs). Supplied tolerance is converted to basic units of the system (meter and Newton) and that is used for comparison and convergence decisions.

- Relative Residual Force Convergence Criteria. In order to provide scaling of residual forces that are used to tolerance criteria, (previously defined) absolute residual force norm is divided (scaled) by a a norm of residual forces at the beginning of the iterative step:

  $$\|\mathbf{r}(\mathbf{u}, \lambda)\|_{relative} = \frac{\sqrt{(\mathbf{r})^T \, \mathbf{S} \, (\mathbf{r})}}{\sqrt{(\mathbf{r}_0)^T \, \mathbf{S} \, (\mathbf{r}_0)}} \leq \epsilon_r \tag{107.34}$$

  Here, an obvious choice for scaling matrix is $\mathbf{S} = diag(\mathbf{K}_t)$, however, within FEI and the Real-ESSI program, for this convergence criteria, a unit scaling matrix $\mathbf{S} = \mathbf{I}$ is used, therefor relative tolerance criteria will feature mixed units.

- Average Residual Force Convergence Criteria. With the residual $\mathbf{r}(\mathbf{u}, \lambda)$, which measures the departure from the equilibrium path, there is a need to take into the account number of DoFs, in order to reduce the influence of a model discretization (number of DoFs) on norm of the residual force vector:

  $$\|\mathbf{r}(\mathbf{u}, \lambda)\|_{scaled} = \frac{\sqrt{(\mathbf{r})^T \, \mathbf{S} \, (\mathbf{r})}}{nDoFs} \leq \epsilon_{average} \tag{107.35}$$

  Here, an obvious choice for scaling matrix is $\mathbf{S} = diag(\mathbf{K}_t)$ however, again, as noted avove, within FEI and the Real-ESSI program, for this convergence criteria, a unit scaling matrix $\mathbf{S} = \mathbf{I}$ is used, therefor relative tolerance criteria will feature mixed units.

- Energy Based Convergence Criteria. The previous convergence criteria can be combined in a single work change criterion:

  $$\| \, (\delta \mathbf{u})^T \, (\mathbf{r}) \, \| = \sqrt{(\delta \mathbf{u})^T \, (\mathbf{r})} \leq \epsilon_u \epsilon_r \tag{107.36}$$

  A word of caution is appropriate at this point. As pointed out by Crisfield (1991), it follows that:

  $$\| \, (\delta \mathbf{u})^T \, (\mathbf{r}) \, \| = \| \, (\delta \mathbf{u})^T \left(\mathbf{K}_t^{-1} \mathbf{K}_t \right) (\mathbf{r}) \, \| = \| - (\delta \mathbf{u})^T \, \mathbf{K}_t \, (\delta \mathbf{u}) \, \| \leq \epsilon_u \epsilon_r \tag{107.37}$$

  where the iterative change was $(\delta \mathbf{u}) = -\mathbf{K}_t^{-1} \mathbf{r}$. It should be noted that equations (107.37) give a measure of the "stiffness" of $\mathbf{K}_t$. This merely implies that a stationary energy position has been reached in the current iterative direction, $\delta \mathbf{u}$. This can occur when the solution is still far away from equilibrium.

Since $\mathbf{u}$ and $\mathbf{r}$ usually have physical unites, so do necessarily ϵ_u and ϵ_r. For a general purpose implementation of Newton–Raphson iteration this dependency on physical units is undesirable and it is more convenient to work with ratios that render the ϵ_u and ϵ_r dimensionless. Displacement Convergence Criteria can be rendered dimensionless by using ratio of scaled Euclidean norm of iterative displacement $\|\delta \mathbf{u}\|_{scaled}$ and scaled Euclidean norm of total displacement $\|\mathbf{u}\|_{scaled}$:

$$\frac{\|\delta \mathbf{u}\|_{scaled}}{\|\mathbf{u}\|_{scaled}} \leq \epsilon_u \tag{107.38}$$

The similar approach can be used for Residual Convergence Criteria:

$$\frac{\|\mathbf{r}\|_{scaled}}{\|\mathbf{r}^{predictor}\|_{scaled}} \leq \epsilon_r \tag{107.39}$$

Another important thing to be considered is Divergence. The Newton–Raphson scheme is not guaranteed to converge. Some sort of divergence detection scheme is therefor necessary in order to interrupt an erroneous iteration cycle. Divergence can be diagnosed if either of following inequalities occur:

$$\frac{\|\delta \mathbf{u}\|_{scaled}}{\|\mathbf{u}\|_{scaled}} \geq g_u \tag{107.40}$$

$$\frac{\|\mathbf{r}\|_{scaled}}{\|\mathbf{r}^{predictor}\|_{scaled}} \geq g_r \tag{107.41}$$

where g_u and g_r are dangerous growth factors that can be set to, for example $g_u = g_r = 100$.

In some cases, the Newton–Raphson iteration scheme will neither diverge nor converge, but rather exhibit oscillatory behavior. To avoid excessive bouncing around, a good practice is to put upper limit to the number of iterations performed in one iteration cycle. Typical limits to the iteration number are 20 to 50.

107.6.5 The Algorithm Progress

The progress of the scheme will be briefly described, in relation with the Figure (107.1). The procedure starts from a previously converged solution $(\mathbf{u}_0, \lambda_0 \mathbf{f}_{ext})$. An incremental, tangential predictor step $\Delta\mathbf{u}_1, \Delta\lambda_1$ is obtained[18] and the next point obtained is $(\mathbf{u}_1, \lambda_1 \mathbf{f}_{ext})$. The first iteration would then use quadratic equation 107.17 where constants a_1, a_2 and a_3 should be computed with $\Delta\mathbf{u}^{old} = \Delta\mathbf{u}_1$ and $\Delta\lambda^{old} = \Delta\lambda_1$, to calculate $\delta\lambda_1$ and[19] $\delta\mathbf{u}_1 = -\mathbf{K}_t^{-1}\mathbf{r}(\mathbf{u}_1, \lambda_1) + \delta\lambda_1 \mathbf{K}_t^{-1}\mathbf{f}_{ext}$. After these values are calculated, the updating procedure[20] would lead to:

$$\Delta\lambda_2 = \Delta\lambda_1 + \delta\lambda_1 \qquad \text{and} \qquad \Delta\mathbf{u}_2 = \Delta\mathbf{u}_1 + \delta\mathbf{u}_1 \tag{107.42}$$

When added to the displacements $\mathbf{u}_0$ and load level λ_0, at the end of the previous increment this process would lead to the next point $(\mathbf{u}_2, \lambda_2 \mathbf{f}_{ext})$.

The next iteration would then again use quadratic equation 107.17 where constants a_1, a_2 and a_3 should be computed with $\Delta\mathbf{u}^{old} = \Delta\mathbf{u}_2$ and $\Delta\lambda^{old} = \Delta\lambda_2$, to calculate $\delta\lambda_3$ and $\delta\mathbf{u}_3 = \delta\bar{\mathbf{u}} + \delta\lambda_2 \delta\mathbf{u}_t$. After these values are calculated, the updating procedure would lead to:

$$\Delta\lambda_3 = \Delta\lambda_2 + \delta\lambda_2 \qquad \text{and} \qquad \Delta\mathbf{u}_3 = \Delta\mathbf{u}_2 + \delta\mathbf{u}_2 \tag{107.43}$$

When added to the displacements $\mathbf{u}_0$ and load level λ_0, at the end of the previous increment this process would lead to the next point $(\mathbf{u}_3, \lambda_3 \mathbf{f}_{ext})$.

108.2 The Principle of Virtual Displacements in Dynamics

(see section 102.2 on page 100).

Great reading on this subject is a book by Argyris and Mlejnek (1991).

108.3 Direct Integration Methods for the Equations of Dynamic Equilibrium

This section follows Argyris and Mlejnek (1991) and Hughes (1987).

need to rewrite and improve! BJ

108.3.1 Newmark Integrator

The Newmark time integration method (Newmark, 1959) uses two parameters, β and γ, and is defined by the following two equations:

$$
\begin{aligned}
{}^{n+1}x &= {}^{n}x + \Delta t\ {}^{n}\dot{x} + \Delta^2 t\ [(\frac{1}{2}-\beta)\ {}^{n}\ddot{x} + \beta\ {}^{n+1}\ddot{x}] && (108.1)\\
{}^{n+1}\dot{x} &= {}^{n}\dot{x} + \Delta t\ [(1-\gamma)\ {}^{n}\ddot{x} + \gamma\ {}^{n+1}\ddot{x}] && (108.2)
\end{aligned}
$$

These equatons give relationship between knowns variables at time step n to the unknown variables at next time step $n+1$. Method is in general an implicit one, except when $\beta = 0$ and $\gamma = 1/2$.

There are several possible implementation methods for Newmark Integrator. One possible approach to integrating equations of motion using Newmark algorithm is to use displacement as the basic unknowns, and the following difference relations are used to relate ${}^{n+1}\dot{x}$ and ${}^{n+1}\ddot{x}$ to ${}^{n+1}x$ and the response quantities are

$$
\begin{aligned}
{}^{n+1}\dot{x} &= \frac{\gamma}{\beta\Delta t}\left({}^{n+1}x - {}^{n}x\right) + \left(1-\frac{\gamma}{\beta}\right){}^{n}\dot{x} + \left(1-\frac{\gamma}{2\beta}\right){}^{n}\ddot{x} && (108.3)\\
{}^{n+1}\ddot{x} &= \frac{1}{\beta\Delta t^2}\left({}^{n+1}x - {}^{n}x\right) - \frac{1}{\beta\Delta t}{}^{n}\dot{x} + \left(1-\frac{1}{2\beta}\right){}^{n}\ddot{x} && (108.4)
\end{aligned}
$$

The predictors are then:

$$
\begin{aligned}
{}^{n+1}\dot{x}^{\diamond} &= -\frac{\gamma}{\beta\Delta t}{}^{n}x + \left(1-\frac{\gamma}{\beta}\right){}^{n}\dot{x} + \Delta t\left(1-\frac{\gamma}{2\beta}\right){}^{n}\ddot{x} && (108.5)\\
{}^{n+1}\ddot{x}^{\diamond} &= -\frac{1}{\beta\Delta t^2}{}^{n}x - \frac{1}{\beta\Delta t}{}^{n}\dot{x} + \left(1-\frac{1}{2\beta}\right){}^{n}\ddot{x} && (108.6)
\end{aligned}
$$

and the correctors:

$$
\begin{aligned}
{}^{n+1}\dot{x} &= {}^{n+1}\dot{x}^{\diamond} + \frac{\gamma}{\beta\Delta t}{}^{n+1}x && (108.7)\\
{}^{n+1}\ddot{x} &= {}^{n+1}\ddot{x}^{\diamond} + \frac{1}{\beta\Delta t^2}{}^{n+1}x && (108.8)
\end{aligned}
$$

The Newton integration method becomes

$$\left[\frac{M}{\beta\Delta t^2}+\frac{\gamma C}{\Delta t}+K\right]\Delta x=-{}^{n+1}R \tag{108.9}$$

Equation 108.5 to 108.9 constitute an iterative solving procedure (Argyris and Mlejnek, 1991).

If the parameters β and γ satisfy

$$\gamma\geq\frac{1}{2},\quad \beta\geq\frac{1}{4}(\gamma+\frac{1}{2})^2 \tag{108.10}$$

the procedure is unconditionally stable and second-order accurate. Any γ value greater than 0.5 will introduce numerical damping. Well-known members of the Newmark time integration method family include: trapezoidal rule or average acceleration method for $\beta = 1/4$ and $\gamma = 1/2$, linear acceleration method for $\beta = 1/6$ and $\gamma = 1/2$, and (explicit) central difference method for $\beta = 0$ and $\gamma = 1/2$. If and only if $\gamma = 1/2$, the accuracy is second-order Hughes (1987). For values of $\beta = 1$ and $\gamma = 2/3$, the strongest numerical damping is obtained, as spectral ratio $\rho_\infty = 0$ (Hughes (1987), page 502)

108.3.2 HHT Integrator

Numerical damping introduced in the Newmark time integration method will degrade the order of accuracy. The Hilber-Hughes-Tailor (HHT) time integration α-method (Hilber et al., 1977), (Hughes and Liu, 1978a) and (Hughes and Liu, 1978b) using an alternative residual form by introducing an addition parameter α to improve the performance:

$${}^{n+1}R=M\,{}^{n+1}\ddot{x}+(1+\alpha)F({}^{n+1}\dot{x},{}^{n+1}x)-\alpha F({}^{n}\dot{x},{}^{n}x)-\ {}^{n+1}f \tag{108.11}$$

but retaining the Newmark finite-difference formulas 108.1 and 108.2 or 108.3 and 108.4. If $\alpha = 0$, the HHT time integration method becomes exactly the same Newmark time integration method. Decreasing α value increase numerical dissipation (Hughes, 1987).

The iteration method for HHT time integration is similar to that of Newmark time integration. Due to the change of Equation 108.11, Equation 108.9 becomes

$$\left[M+(1+\alpha)\gamma\Delta tC+(1+\alpha)\beta\Delta t^2K\right]\Delta\ddot{x}=-{}^{n+1}R \tag{108.12}$$

for acceleration iteration and

$$\left[\frac{1}{\beta\Delta t^2}M+\frac{(1+\alpha)}{\gamma\Delta t}C+(1+\alpha)K\right]\Delta x=-{}^{n+1}R \tag{108.13}$$

for displacement iteration.

If the parameters α, β and γ satisfy

$$-1/3\leq\alpha\leq 0,\quad \gamma=\frac{1}{2}(1-2\alpha),\quad \beta=\frac{1}{4}(1-\alpha)^2 \tag{108.14}$$

it is unconditionally stable and second-order accurate (Hughes, 1987).

108.4 Synthetic Viscous Damping for Solids and Structures

Presented here are commonly used, viscous damping methods for time domain analysis of solids and structures. These methods, Rayleigh and Caughey damping, are mimicking viscous damping of of the solids and structures by generating the damping matrix $\mathbf{C}$ using mass and stiffness matrices.

These synthetic viscous damping approaches should be distinguished from a natural viscous damping that is created during interaction of fluid and soil. For example, a natural viscous damping occurs when pore fluid and porous solid have differential displacements, as described in section 102.12.1.4 on page 143 (see for example equation ?? on page ??).

108.4.1 Synthetic Viscous Damping Approaches

There are different numerical methods available to simulate the seismic wave propagation through the soil-structure systems such as boundary elements, finite elements, finite differences, meshfree methods, and spectral elements. There are advantages of using methods such as finite elements or spectral elements for complex geometries or modeling the nonlinearities but also disadvantage such as numerical dispersion for low-order finite elements or reflection of the motions from the boundaries of the model (Semblat et al. (2010)).

Boundary element method can deal better with the issue of reflecting the motions from boundaries comparing to other numerical methods. Research has been done on coupling this method with other numerical methods for better applications. Domain reduction method is also available for large models implemented in finite element in order to reduce the problem of reflection (Bielak et al. (2003a)).

There are methods so called non-reflecting boundary conditions which directly can attenuate the reflections at the mesh boundaries. One of the commonly used method is absorbing boundary conditions. Absorbing boundary conditions have special conditions at the model boundaries in order to approximate the radiation condition for seismic waves (Givoli (1991)).

Another method applicable in finite element methods is so called infinite element method. These elements can absorb the waves using decaying laws at model boundaries at infinity (Nenning and Schanz (2010); Kallivokas et al. (1997)). In this method it is assumed that the element and nodes of the boundary are in infinity. In this case the seismic waves have enough distance to dissipate at the boundaries and not to reflect back to the model.

There has been a recently developed method to prevent reflection of the waves from boundaries called Perfectly Matched Layers (PML). This absorbing layer is based on attenuation laws with specific properties and finite thickness located at the model boundaries. There are several PML formulations proposed for finite element methods which allows the treatment of surface waves as well as body waves

(Festa and Nielsen (2003); Basu (2009)).

Bilbao et al. (2006) proposed two energy-based methods to model damping in structures with added viscoelastic dampers. these methods approximate the effects of the added viscoelastic dampers with a damping matrix in the form of Caughey damping matrix.

The method to be used here is so called Caughey Absorbing Layer Method. The 2^{nd} order of this method is also known as a Rayleigh damping. Caughey damping is a classical method in which the damping matrix is built based on the mass and stiffness matrices. Since the stiffness and mass matrices of have to be created for solving the system of equations, they are used for creating the damping matrix as well.

Considering the relationship between internal friction and frequency for damping, it is possible to build a model involving the same attenuation/frequency dependence for Caughey damping (Semblat (1997)). The relation of the inverse of the quality factor Q^{-1} and the damping ratio ξ can be written as:

$$Q^{-1} \approx 2\xi \tag{108.15}$$

Caughey damping formulation in general can be expressed as

$$C = [M] \sum_{j=0}^{m-1} a_j ([M]^{-1}[K])^j \tag{108.16}$$

where the order to be used depends on number of modes to be considered for damping in the problem.

The way it is implemented in ESSI Simulator gives the opportunity to the user to use different types of damping for different elements. There might not be a need to use damping for all the elements of the model. In this case, damping could be used for particular elements and leave the rest of them with no physical Caughey damping. It can also be used for damping out the residual waves coming out of the domain reduction boundary layer.

108.4.2 Caughey Damping 2^{nd} Order, aka Rayleigh Damping

The second order Caughey damping, is also known as a Rayleigh damping, with $j = 1$ in Equation (108.16). From dynamic parameters and formulation of the system following equations can be observed:

$$\xi_n = \frac{C_n}{2M_n\omega_n} \tag{108.17}$$

$$K_n = \omega_n^2 M_n \tag{108.18}$$

Considering the first two terms in Caughey damping formulation, if the damping matrix formulation is written separately for each term:

$$C = a_0 M \tag{108.19}$$

Based on Equation (108.17), a_0 can be written as:

$$a_0 = 2\xi\omega \tag{108.20}$$

Writing the damping matrix based on the second coefficient:

$$C = a_1 K = a_1 \omega^2 M \tag{108.21}$$

Then a_1 can be obtained as:

$$a_1 = \frac{2\xi}{\omega} \tag{108.22}$$

So the damping ratio of the n^{th} mode of the system is:

$$\xi_n = \frac{a_0}{2}\frac{1}{\omega_n} + \frac{a_1}{2}\omega_n \tag{108.23}$$

Presenting Equation (108.23) for first two modes in matrix form leads to:

$$\frac{1}{2}\begin{bmatrix} \frac{1}{\omega_i} & \omega_i \\ \frac{1}{\omega_j} & \omega_j \end{bmatrix}\begin{bmatrix} a_0 \\ a_1 \end{bmatrix} = \begin{bmatrix} \xi_i \\ \xi_j \end{bmatrix} \tag{108.24}$$

The following procedure given by Hall (2006) is useful to conveniently determine Rayleigh damping coefficients a_0 and a_1. Select a desired amount of damping ξ and a frequency range from $\hat{\omega}$ to $R\hat{\omega}$, where $R > 1$. Compute Δ from:

$$\Delta = \xi\frac{1 + R - 2\sqrt{R}}{1 + R + 2\sqrt{R}} \tag{108.25}$$

where Δ determines bounds on the damping ratios that are imparted to those modes within the specified frequency range. Any such mode will have a damping ratio bounded by $\xi_{max} = \xi + \Delta$ and $\xi_{min} = \xi - \Delta$. If these bounds are satisfactorily narrow, the constants a_0 and a_1 are then calculated from:

$$a_0 = 2\xi\hat{\omega}\frac{2R}{1 + R + 2\sqrt{R}} \tag{108.26}$$

$$a_1 = 2\xi\frac{1}{\hat{\omega}}\frac{2}{1 + R + 2\sqrt{R}} \tag{108.27}$$

and can be used to compute an actual damping value ξ_n for mode n from Equation (108.23).

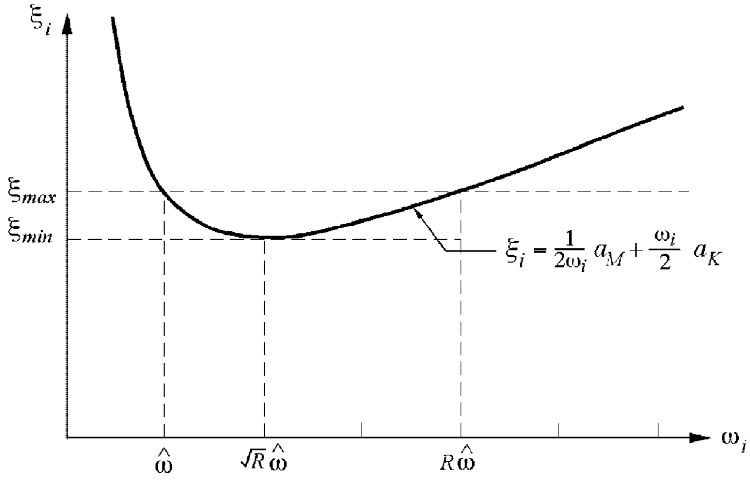

Figure 108.1: Actual damping ratio ξ_n of mode n as a function of frequency ω_n of mode n when using Rayleigh damping (Hall (2006)).

Figure (108.1) shows that $\xi_n = \xi_{max}$ if $\omega_n = \hat{\omega}$ or $\omega_n = R\hat{\omega}$, and that $\xi_n = \xi_{min}$ if $\omega_n = \sqrt{R}\hat{\omega}$. If ω_n is outside the range $\hat{\omega}$ to $R\hat{\omega}$, then $\xi_n > \xi_{max}$. Above $R\hat{\omega}$, ξ_n increases with ω_n, approaching a linear relation as the last term in Equation (108.23) dominates.

Note: It's worth pointing out that damping could be unrealistically high for motions outside the prescribed frequency range, if the frequency range is not well-chosen.

108.4.3 Caughey Damping 3^{rd} Order

Following the same logic as the 2^{nd} order, the last coefficient of the 3^{rd} order Caughey damping formulation can be written as following:

$$C = a_2 K M^{-1} K = a_2 \omega^4 M \tag{108.28}$$

So a_2 can be obtained as:

$$a_2 = \frac{2\xi}{\omega^3} \tag{108.29}$$

Considering the last coefficient in the formulation, the damping ratio of the system can now be shown as:

$$\xi_n = \frac{a_0}{2}\frac{1}{\omega_n} + \frac{a_1}{2}\omega_n + \frac{a_2}{2}\omega_n^3 \tag{108.30}$$

By solving the following set of equations, 3^{rd} order Caughey damping coefficients can be found:

$$\frac{1}{2}\begin{bmatrix} \frac{1}{\omega_i} & \omega_i & \omega_i^3 \\ \frac{1}{\omega_j} & \omega_j & \omega_j^3 \\ \frac{1}{\omega_k} & \omega_k & \omega_k^3 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \end{bmatrix} = \begin{bmatrix} \xi_i \\ \xi_j \\ \xi_k \end{bmatrix} \tag{108.31}$$

108.4.4 Caughey Damping 4^{th} Order

The 4^{th} coefficient of the Caughey damping formulation cab obtained as:

$$C = a_3 K M^{-1} K M^{-1} K = a_3 \omega^6 M \tag{108.32}$$

$$a_3 = \frac{2\xi}{\omega^5} \tag{108.33}$$

$$\xi_n = \frac{a_0}{2}\frac{1}{\omega_n} + \frac{a_1}{2}\omega_n + \frac{a_2}{2}\omega_n^3 + \frac{a_3}{2}\omega_n^5 \tag{108.34}$$

So the damping coefficients can be obtained by solving the following set of equations:

$$\frac{1}{2}\begin{bmatrix} \frac{1}{\omega_i} & \omega_i & \omega_i^3 & \omega_i^5 \\ \frac{1}{\omega_j} & \omega_j & \omega_j^3 & \omega_j^5 \\ \frac{1}{\omega_k} & \omega_k & \omega_k^3 & \omega_k^5 \\ \frac{1}{\omega_l} & \omega_l & \omega_l^3 & \omega_l^5 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \end{bmatrix} = \begin{bmatrix} \xi_i \\ \xi_j \\ \xi_k \\ \xi_l \end{bmatrix} \tag{108.35}$$

Chapter 109

Earthquake Soil Structure Interaction, Theoretical Aspects

(1989-2001-2006-2016-2018-2019-2020-2021-)

(In collaboration with Dr. Nima Tafazzoli, Prof. José Abell, Dr. Yuan Feng, Dr. Hexiang Wang)

109.1 Chapter Summary and Highlights

109.2 Seismic Energy Propagation and Dissipation

Jeremić (2010)

109.2.1 Seismic energy input into SSI system

Earthquakes release large amounts energy at the source[1] Part of released energy is radiated as mechanical waves ($\approx 1.6 \times 10^{-5}$) and part of that energy makes it to the surface where SSI system is located.

Mechanical seismic wave energy enters the SSI system through a closed surface Γ that encompasses (significant) soil volume as well as foundation system and the structure (see Figure 109.7). Kinetic energy flux through closed surface Γ includes both incoming and outgoing waves and can be calculated using Domain Reduction Method (Bielak et al., 2003a) as:

$$E_{flux} =$$
$$\left[0; -M^{\Omega+}_{be}\ddot{u}^0_e - K^{\Omega+}_{be}u^0_e; M^{\Omega+}_{eb}\ddot{u}^0_b + K^{\Omega+}_{eb}u^0_b\right]_i \times u_i$$

where $M^{\Omega+}_{be}$, $M^{\Omega+}_{eb}$, $K^{\Omega+}_{be}$, $K^{\Omega+}_{eb}$ are mass and stiffness matrices, respectively for a single layer of elements just outside of the boundary Γ, while $\ddot{u}^0_e$ and u^0_e are accelerations and displacements from a free field model for nodes belonging to that layer of elements. Alternatively, energy flux can be calculated using ((Aki and Richards, 2002), page 122):

$$E_{flux} = \rho A c \int_0^t \dot{u}_i^2 dt$$

Outgoing kinetic energy can be obtained from outgoing wave field w_i, (from DRM, Bielak et al. (2003a)), while the difference then represents the incoming kinetic energy that needs to be dissipated with SSI region.

109.2.2 Seismic Energy Dissipation in SSI System

Seismic energy that enters the SSI system will be dissipated in a number of ways. Part of the energy that enters SSI system is reflected and radiated back into domain outside Γ by

- wave reflection from impedance boundaries (free surface, soil/rock layers, foundations, etc.).
- SSI system oscillates and emits, radiates waves back into the domain

---

[1] for example, some of the recent large earthquake energy releases are listed: Northridge, 1994, $M_{Richter} = 6.7$, $E_r = 6.8 \times 10^{16} J$; Loma Prieta, 1989, $M_{Richter} = 6.9$, $E_r = 1.1 \times 10^{17} J$; Sumatra-Andaman, 2004, $M_{Richter} = 9.3$, $E_r = 4.8 \times 10^{20} J$; Valdivia, Chile, 1960, $M_{Richter} = 9.5$, $E_r = 7.5 \times 10^{20} J$;

The rest of seismic energy is dissipated through one of the following mechanisms within SSI system:

- Inelastic, elasto-plastic behavior of soil and rock
- Inelastic, elasto-plastic, damage behavior of the foundation system
- Inelastic, elasto-plastic, damage behavior of the structure
- Viscous coupling of porous solid with pore fluid (air, water)
- Viscous coupling of structure with surrounding, internal and external fluids (air, water)

It is also important to note that in numerical simulations, part of the energy can be dissipated or produced by purely numerical means. That is, numerical energy dissipation (damping) or production (negative damping) has to be carefully controlled (Argyris and Mlejnek, 1991), (Hughes, 1987).

109.2.2.1 Energy Dissipation by Plasticity

Elastic-plastic deformation of soil, foundation and structure is probably responsible for major part of the energy dissipation for large earthquakes. This, displacement proportional dissipation is a result of plastic dissipation and is present in all three components of the system (soil, foundation and the structure).

A note about plastic dissipation is important at this point. There is a misconception about plastic energy dissipation that is being widely used. Here are some details:

- Origins of the Misconception: The paper by Uang and Bertero (1990) has been considered the definitive work in using energy as a measure of structural demand by many researchers (Léger and Dussault, 1992; Cosenza et al., 1993; Kalkan and Kunnath, 2007, 2008; Symans et al., 2008; Chopra, 2000; Gajan and Saravanathiiban, 2011; Moustafa, 2011; Moustafa and Mahmoud, 2014; Mezgebo and Lui, 2017; Deniz et al., 2017). An energy analysis methodology based on absolute input energy (or energy demand) was presented and discussed. Numerical analysis results were compared with experiments on a multi-story building. In this paper, hysteretic energy is calculated indirectly by taking the difference of absorbed energy and elastic strain energy. The term *absorbed energy* of each time step was simply defined as force times incremental displacement. It was stated that *hysteretic energy* is irrecoverable, which indicates that this parameter was considered the same as *hysteretic dissipation* or *plastic dissipation*. An equation for energy balance is given:

$$E_i = E_k + E_\xi + E_a = E_k + E_\xi + E_s + E_h \tag{109.1}$$

where E_i is the (absolute) input energy, E_k is the (absolute) kinetic energy, E_ξ is the viscous damping energy, E_a is the absorbed energy, which is composed of elastic strain energy E_s and hysteretic energy E_h.

The problem of this theory is the absence of plastic free energy, which is necessary to correctly evaluate energy dissipation of elastic-plastic materials and to uphold the second law of thermodynamics. There was no direct plot of plastic dissipation (hysteretic energy) in this paper, since it was not defined directly. There were plots of other energy components and plastic dissipation can be easily calculated or deducted from these plots. After doing this, indications of negative incremental energy dissipation, which violates the basic principles of thermodynamics, were found in various sections of the paper.

This misconception could be clarified by renaming hysteretic energy to *plastic work*, which is the combination of plastic dissipation and plastic free energy. Both plastic work and plastic free energy can be incrementally negative, but plastic dissipation (defined as the difference of plastic work and plastic free energy) must be incrementally non-negative during any time period. Unfortunately, this misconception has been inherited (if not magnified) by almost all following studies on energy analysis of earthquake soils and structures.

Besides, another issue regarding energy dissipation is found in in this paper. *Viscous damping energy* (or viscous damping energy) was calculated directly using damping coefficient and velocity. The author stated that this term should always be non-negative. But it was ignored that the incremental viscous energy dissipation should also be non-negative. In fact, the equation used to compute viscous energy dissipation should be able to ensure that it remains non-negative incrementally. However, it appeared in one of the plots that (accumulated) viscous damping energy was clearly dropping during certain time periods, which was in contradiction with the equation derived in the same paper. Such result was also a violation of thermodynamics.

- Misconception in Other Studies: Although input energy was the key parameter used in Uang and Bertero (1990), the misconception of energy dissipation has been carried on in a vast number of studies on energy analysis of ESSI systems.

  Léger and Dussault (1992) used Equation 109.1 from Uang and Bertero (1990) to perform energy response analysis of multi-story buildings under earthquake loading. It was stated that the total input energy at the end of ground motion is approximately equal to the total dissipated energy. This statement is only valid if plastic free energy remains constant, which is generally not true in elastic-plastic materials.

  Kalkan and Kunnath (2007) calculated energy dissipation of a single-degree-of-freedom (SDOF) oscillator under earthquake loading. Inelastic material was used so plastic energy dissipation appeared in the results. Negative incremental hysteretic energy (plastic dissipation) was observed in the plots, which is a clear violation of thermodynamics. The change of plastic free energy was not considered in this study. Several papers by the same authors performed energy analysis on various structures using the same theory, and similar misconceptions can be noticed in these publications.

Symans et al. (2008) summarized current practice and recent developments in the application of passive energy dissipation systems for seismic protection of structures. There was no consideration of plastic free energy in the energy balance equation, which was very close to the ones present by Uang and Bertero (1990) and Léger and Dussault (1992). It was stated that the cumulative hysteretic energy is equal to the energy demand (absolute input energy) at the end of earthquake. Although no direct violation of thermodynamics was observed, such statement clearly indicated the same misconception of plastic work and plastic dissipation appeared in other publications.

Gajan and Saravanathiiban (2011) performed both numerical simulations and centrifuge experiments on a rocking foundation system. Energy dissipation in foundation soil and structural elements were calculated. It can be observed that hysteretic energy dissipation in both the soil and the structure was decreasing during certain time periods, which is a direct violation of thermodynamics. Again, this was a misconception of plastic work and plastic energy dissipation. The change in plastic free energy of the system was significant in this case, since large drops of plastic work were noticed in the plots.

Chopra (2000) used similar set of equations in section 7.9, and equation 7.9.6 is clearly wrong!

A number of recent studies Moustafa (2011); Moustafa and Mahmoud (2014); Mezgebo and Lui (2017); Deniz et al. (2017) performed energy analysis on ESSI systems without considering plastic free energy. Misleading results were obtained using the wrong energy balance equation. This means that the misconception of plastic work and plastic energy dissipation is still not realized by many researchers. Note that the influence of this mistake could be negligible or significant, depending on the case analyzed. Nevertheless, plastic free energy should not be ignored without plausible reasoning or experimental evidences.

- Early Studies on Plastic Free Energy (Cold Work): This issue has been pointed out and studied extensively by researchers from mechanical engineering and material science. In the early 20th century, Taylor and his colleagues Farren and Taylor (1925), Taylor and Quinney (1934) performed experiments on metals and proved that a large part, but not all, of the input mechanical energy is converted into heat. The remaining part of the non-recoverable plastic work is known as the stored energy of cold work. The ratio of plastic work converted into heating (Quinney–Taylor coefficient), usually denoted as β, has been used in almost all later papers on this topic. Based on large amount of experimental data, this ratio was assumed to be a constant between 0.6 to 1.0 in many studies (e.g. Clifton et al. (1984), Belytschko et al. (1991), Zhou et al. (1996), Dolinski et al. (2010), Ren and Li (2010), Osovski et al. (2013)). It has been realized that this assumption is not valid in all cases, but it's simply too complicated to involve the evolution of Quinney–Taylor coefficient in thermomechanical constitutive models.

Decades later, Mason et al. (1994) showed that the fraction of plastic work converted into heat is both strain and strain rate dependent. Infrared imaging was used in this study (and almost all future studies) to obtain temperature distribution in the material, because it is the only effective approach to directly measure energy dissipation (heat). In the recent 20 years, there has been many developments on this issue. Rittel (Rittel, 2000; Rittel and Rabin, 2000; Rittel et al., 2003) published several insightful papers on the energy dissipation (heat generation) of polymers during cyclic loading, presenting both experimental and theoretical works. Rosakis et al. (2000) presented a constitutive model based on thermoplasticity to model the evolution of in metal. This model is capable of calculating the evolution of energy dissipation and material properties, and is validated by sets of experiments. There are some follow-up papers by Rosakis and his colleagues (Hodowany et al., 2000; Ravichandran et al., 2002) on the same issue with some assumptions to simply the problem. One widely used assumption is the adiabatic condition, since air conducts heat much slower than metal. This assumption is reasonable in rapid monotonic or cyclic loading (impact, vibration, earthquake). One application of this theory in geotechnical engineering is presented in papers of (Veveakis et al., 2007, 2012), in which thermoporomechanics is used to model the heating and pore pressure increase in large landslides, like the 1963 Vajont slide in Italy.

In the field of civil engineering, the basic principles of thermodynamics are frequently used to derive new constitutive models Dafalias and Popov (1975); Ziegler and Wehrli (1987); Collins and Houlsby (1997); Houlsby and Puzrin (2000); Collins (2002); Collins and Kelly (2002); Collins (2003); Feigenbaum and Dafalias (2007). to enforce the second law of thermodynamics for developed constitutive models. Note that plastic free energy is the same concept as cold work. The former term is more popular in solid physics and geotechnical engineering, while the latter is used in mechanical engineering. energy dissipation due to plasticity and plastic work, which is often a source of a confusion. through a conceptual example that is analyzed on particle scale. development of plastic free energy is caused by particle rearrangement in granular assembly under external loading.

Ideally, majority of the incoming energy would be dissipated in soil, before reaching foundation and structures. The possibility to direct energy dissipation to soil can be used in design by recognizing energy dissipation capacity for different soils. For example, simple elastic-plastic models of stiff and soft clay as well as dense and loose send predict different energy dissipation capacities, as shown in Figure 109.1, for single loading-unloading-reloading cycle. While Figure 109.1 shows that stiff clay and dense sand have much higher dissipation capacity, it is important to note that soft/loose soils can undergo much larger deformation/strain, thus offering increased energy dissipation capacity through flexibility.

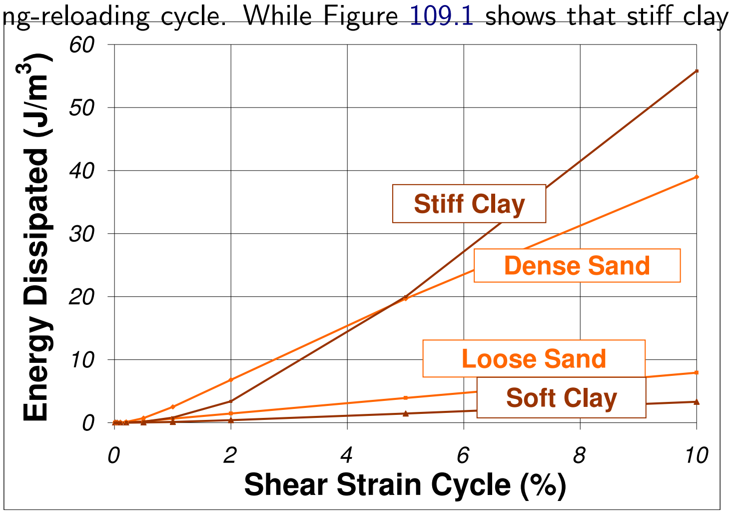

Figure 109.1: Energy dissipation capacity for one cycle at various strains for four generic soils.

109.2.2.2 Energy Dissipation by Viscous Coupling

Viscous coupling of pore fluid (air, water...) and soil particles and/or foundation or structural components is responsible for velocity proportional energy dissipation. In particular, viscous coupling of porous solid and fluid results in $E_{vc} = n^2 k^{-1} (\dot{U}_i - \dot{u}_i)^2$ energy loss per unit volume. It is noted that this type of dissipation is realistically modeled using $u-p-U$ formulation (Jeremić et al., 2008).

109.2.2.3 Numerical Energy Dissipation and Production

As noted above, numerical integration of nonlinear equations of motions affects calculated energy in various ways. Most common effect for nonlinear (elastic-plastic) systems is the positive (energy dissipation) and negative (energy production) damping. For example Newmark (N) (Newmark, 1959) and Hilber–Hughes–Taylor (HHT) (Hilber et al., 1977) are energy preserving for linear elastic system with proper choice of constants ($\alpha = 0.0; \beta = 0.25, \gamma = 0.5$). Both methods can also be used to dissipate higher frequency modes for linear elastic models by changing constants so that for N: $\gamma \geq 0.5, \quad \beta = 0.25(\gamma + 0.5)^2$, while for HHT: $-0.3\dot{3} \leq \alpha \leq 0, \quad \gamma = 0.5(1-2\alpha), \quad \beta = 0.25(1-\alpha)^2$. However, for nonlinear problems it is impossible to maintain energy of the system throughout computations (Argyris and Mlejnek, 1991).

109.2.2.5 Energy Dissipation by Nonlinearities in Soil/Rock – Foundation Interface Zone

Gap, Slip
  Dry
  Saturated

109.2.2.6 Energy Dissipation by Nonlinearities in Seismic Isolators

109.2.2.7 Energy Dissipation by Nonlinearities in Structures, Systems and Components

109.2.2.8 Numerical Energy Dissipation and Production

109.2.3 Seismic Motions: Empirical Models

109.2.4 1D/1C Wave Propagation Modeling

The theory of wave propagation is associated with vertical propagation of shear and/or comporessional waves through the linear viscoelastic system is described in this section. Developments shown here follow standard approach, as found by, for example, Kramer (1996a). Shown in Figure 109.2 is a 1C wave propagation setup. The model consists of N horizontal layers, that extend to infinity in the horizontal direction. At the bottom of layers is bedrock that represents a halfspace. Each layer is homogeneous and isotropic and is characterized by the thickness h, mass density ρ, shear wave velocity V_s[2], and compressional wave velocity V_p[3] and damping factor, β.

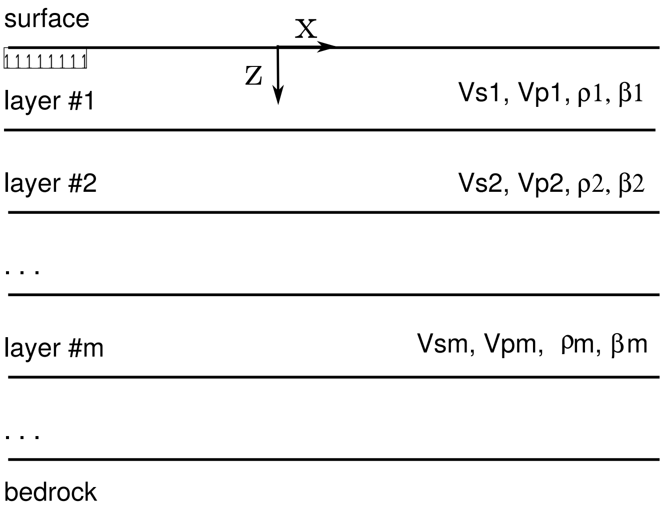

Figure 109.2: Problem Description: Wave Propagation

Vertical propagation of shear or compressional waves will cause only horizontal of vertical displacements respectively.

$$u = u(z, t) \tag{109.2}$$

Focusing on vertical propagation of shear waves, and with a presence of displacements in x direction only, a wave equation, that describes wave propagation in vertical, z directions can be written as

$$\rho \frac{\partial^2 u}{\partial t^2} = G \frac{\partial^2 u}{\partial z^2} + \eta \frac{\partial^3 u}{\partial z^2 \partial t} \tag{109.3}$$

---

[2] Shear Wave velocity is used to obtain shear shear modulus G, $V_s = \sqrt{G/\rho}$, $G = V_s^2 \rho$, $G = E/(2(1+\nu))$, $E = (9KG)/(3K+g)$, $E = (G(3M-4G))/(M-G))$.

[3] Compressional wave velocity is lused to obtain constrained modulus M $V_p = \sqrt{M/\rho}$, $M = V_p^2 \rho$, $M = K + 4G/3$, $M = E(1-\nu)/((1+\nu)(1-2\nu)))$.

Harmonic oscillation, displacements with frequency ω, can be written in the as:

$$u(z,t) = U(z) \cdot e^{i\omega t} \tag{109.4}$$

Substituting Eq (109.4) into Eq (109.3) one obtains

$$(G + i\omega\eta)\frac{\partial^2 u}{\partial z^2} = \rho\omega^2 U \tag{109.5}$$

which has the general solution:

$$U(z) = Ee^{ikz} + Fe^{-ikz} \tag{109.6}$$

in which

$$k^2 = \frac{\rho\omega^2}{G + i\omega\eta} = \frac{\rho\omega^2}{G^*} \tag{109.7}$$

where k is the complex wave number and G^* is the complex shear modulus. The critical damping ratio, β, is related to the viscosity η by

$$\omega\eta = 2G\beta \tag{109.8}$$

For convenience, one can use use soil damping ratio β to represent the complex shear modulus.

$$G^* = G + i\omega\eta = G(1 + 2i\beta) \tag{109.9}$$

By combine Eq. (109.4) and Eq. (109.6) one obtains the wave equation for a harmonic motion of frequency ω.

$$u(z,t) = Ee^{i(kz+\omega t)} + Fe^{-i(kz-\omega t)} \tag{109.10}$$

where the first term represents the incident wave traveling in the upward, in positive z direction and the second term represents the reflected wave traveling in the negative, downward z–direction.

This equation is valid for each of the soil and rock layers.

Introducing a local coordinate system Z for each layer, the displacements at the top and bottom of layer m are :

$$u_m(z = 0) = (E_m + F_m)e^{i\omega t} \tag{109.11}$$

$$u_m(z = h_m) = (E_m \cdot e^{ik_m h_m} + F_m e^{-ik_m h_m}) \cdot e^{i\omega t} \tag{109.12}$$

The shear stress on a horizontal plane is

$$\tau(z,t) = G \cdot \frac{\partial u}{\partial z} + \eta \frac{\partial u}{\partial z \partial t} = G^{*} \frac{\partial u}{\partial z} \tag{109.13}$$

In another form,

$$\tau(z,t) = ikG^{*}(Ee^{ikz} - Fe^{-ikz})e^{i\omega t} \tag{109.14}$$

and the shear stress at the top and bottom of layer m are respectively:

$$\tau_m(z=0) = ik_m G^{*}_m (E_m - F_m) e^{i\omega t} \tag{109.15}$$

$$\tau_m(z=h_m) = ik_m G^{*}_m (Ee^{ik_m h_m} - Fe^{-ik_m h_m}) e^{i\omega t} \tag{109.16}$$

Stresses and displacements must be continuous at all interfaces. Hence, by Eq (109.11), (109.12), (109.15) and (109.16), the coefficients are

$$E_{m+1} + F_{m+1} = E_m e^{ik_m h_m} + F_m e^{-ik_m h_m} \tag{109.17}$$

$$E_{m+1} - F_{m+1} = \frac{k_m G^{*}_m}{k_{m+1} G^{*}_{m+1}} (E_m e^{ik_m h_m} - F_m e^{-ik_m h_m}) \tag{109.18}$$

Subtraction and addition Eqs. 15 and 16 yield the following recursion formulas for the amplitudes, E_{m+1} and F_{m+1}, of the incident and reflected wave in layer m+1, expressed in terms of the amplitudes in layer m:

$$E_{m+1} = \frac{1}{2} E_m (1+\alpha_m) e^{ik_m h_m} + \frac{1}{2} F_m (1-\alpha_m) e^{-ik_m h_m} \tag{109.19}$$

$$F_{m+1} = \frac{1}{2} E_m (1-\alpha_m) e^{ik_m h_m} + \frac{1}{2} F_m (1+\alpha_m) e^{-ik_m h_m} \tag{109.20}$$

where α_m is the complex impedance ratio

$$\alpha_m = \frac{k_m G^{*}_m}{k_{m+1} G^{*}_{m+1}} = (\frac{\rho_m G^{*}_m}{\rho_{m+1} G^{*}_{m+1}})^{1/2} \tag{109.21}$$

At the free surface, the shear stresses must be zero. In addition, according to Eq. (109.15), it obtains $E_1 = F_1$. Namely, the amplitudes of the incident and reflected waves are always equal at the free surface. Beginning with the surface layer, repeated use of Eq (109.19) and Eq (109.20) to build the wave field:

$$E_m = e_m(\omega) E_1 \tag{109.22}$$

$$F_m = f_m(\omega)E_1 \tag{109.23}$$

The transfer function e_m and f_m are simply the amplitudes for the case $E_1 = F_1 = 1$, and can be determined by substituting this condition into the above recursion formulas. Other transfer functions are easily obtained from the e m and f m functions. The transfer function A n,m between the displacements at level n and m is defined by:

$$A_{n,m}(\omega) = \frac{u_m}{u_n} \tag{109.24}$$

and can be represented by

$$A_{n,m}(\omega) = \frac{e_m(\omega) + f_m(\omega)}{e_n(\omega) + f_n(\omega)} \tag{109.25}$$

Based on these equations, the transfer function $A(w)$ can be found between any two layers in the system. Hence, if the motion is known in any one layer in the system, the motion can be computed in any other layer.

In summary, after the E and F are computed for all layers in the system, the accelerations are expressed by the equaction:

$$\ddot{u}(z,t) = \frac{\partial^2 u}{\partial t^2} = -\omega^2 (Ee^{i(kz+\omega t) + Fe^{-i(kz-\omega t)}}) \tag{109.26}$$

109.2.5 Seismic Motions: 3D/3C Analytic Wave Propagation Modeling

Thomson (1950); Haskell (1953)

This is based in part on Wang et al. (2020a).

Considered is the inclined wave propagation in the layered ground as shown in Fig. 109.3. There are n layers with layer thickness d_m, density ρ_m, compressional velocity α_m and shear wave velocity β_m ($m = 1, 2, .., n$). Since the incidence of out-of-plane SH wave is simpler (no mode conversion), here we focus on the incidence of P and SV wave and account for the mode conversion between them. The wave potential formulations below are general and also applicable to incident SH wave (Haskell, 1953). Without loss of generality, incident waves is considered to be monochromatic with angular frequency w and horizontal phase velocity c. For incident waves with arbitrary time signal and multiple frequencies, free field motions can be Fourier synthesized from the monochromatic solutions.

According to Helmholtz decomposition theorem (Arfken and Weber, 1999), the displacement of wave propagation Eq. (109.27) in linear elastic media can be expressed with P wave scalar potential ϕ and S wave vector potential $\mathbf{\Psi}$ as shown in Eq. 109.28, where ϕ is the curl free part corresponding to volumetric deformation and Ψ is divergence free part corresponding to deviatoric deformation.

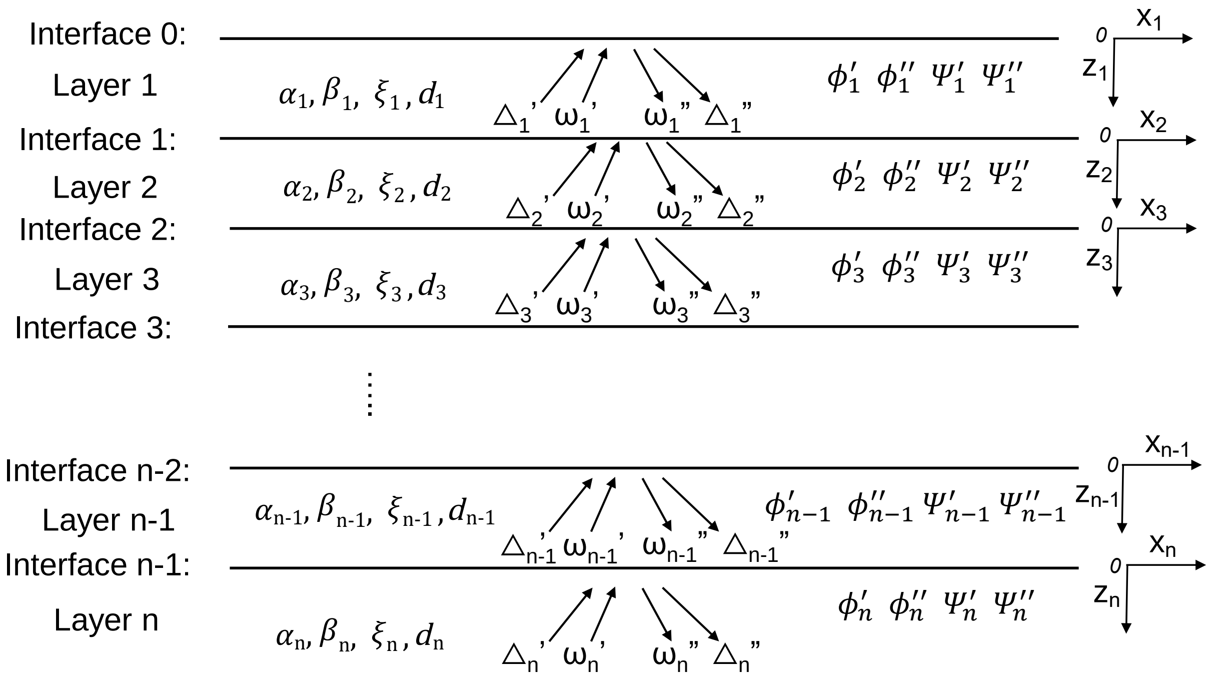

Figure 109.3: 2D layered ground and free field motion

$$\rho \ddot{\boldsymbol{u}} = (\lambda + 2\mu)\nabla\nabla \cdot \boldsymbol{u} - \mu\nabla \times \nabla \times \boldsymbol{u} \tag{109.27}$$

$$\boldsymbol{u} = \nabla\phi + \nabla \times \Psi \tag{109.28}$$

Therefore, the unknown variables for m^{th} layer are simplified into incident P wave potential magnitude $\phi_m^{'}$, reflected P wave potential magnitude $\phi_m^{''}$, incident SV wave potential magnitude $\Psi_m^{'}$ and reflected SV wave potential magnitude $\Psi_m^{''}$.

$$\begin{aligned} \phi_m &= [\phi_m^{'} e^{ik(x-\gamma_{\alpha m} z)} + \phi_m^{''} e^{ik(x+\gamma_{\alpha m} z)}] e^{-iwt} \\ \Psi_m &= [\Psi_m^{'} e^{ik(x-\gamma_{\beta m} z)} + \Psi_m^{''} e^{ik(x+\gamma_{\beta m} z)}] e^{-iwt} \end{aligned} \tag{109.29}$$

The P and SV wave potential can be expressed as Eq. (109.29), where k is the horizontal wave number, equals to w/c. And $cot^{-1}\gamma_{\alpha_m}$ and $cot^{-1}\gamma_{\beta_m}$ are incident and reflected angles for P and SV wave, respectively. The harmonic nature of the potential field is characterized by the time factor e^{-iwt}. It will be understood and omitted hereafter. γ_{α_m} and γ_{β_m} can be determined by Snell's law (equation ??). Note that when α_m or β_m is greater than c, the incidence from P or SV wave is beyond the critical angle. γ_{α_m} and γ_{β_m} become complex numbers. The plane wave magnitude exponentially decays along the depth. To be consistent with the original formulation by Haskell (1953), dilatational wave solutions Δ_m and rotational wave solutions ω_m are first introduced as Eq. (109.30).

$$
\begin{aligned}
\Delta &= \frac{\partial u_x}{\partial x} + \frac{\partial u_z}{\partial z} \\
\omega &= \frac{1}{2}(\frac{\partial u_x}{\partial z} - \frac{\partial u_z}{\partial x})
\end{aligned}
\tag{109.30}
$$

ϕ_m and Ψ_m are related to Δ_m and ω_m as follows:

$$
\begin{aligned}
\phi_m &= -(\frac{\alpha_m}{w})^2 \Delta_m \\
\Psi_m &= 2(\frac{\beta_m}{w})^2 \omega_m
\end{aligned}
\tag{109.31}
$$

The displacements (u_x, u_y) and interfacial stresses (σ_{zz}, τ_{zx}) can be expressed in wave potential magnitudes ϕ and Ψ.

From Eqs. (109.28)-(109.31), the displacement and stress field of m^{th} layer can be calculated from the dilatational wave and rotational wave solutions Δ_m and ω_m as follows:

$$
\begin{aligned}
u_x = \{&-ik(\frac{\alpha_m}{\omega})^2[(\Delta_m^{'} + \Delta_m^{''})cos(k\gamma_{\alpha_m}z) - i(\Delta_m^{'} - \Delta_m^{''})sin(k\gamma_{\alpha_m}z)] \\
&+2ik\gamma_{\beta_m}(\frac{\beta_m}{\omega})^2[(\omega_m^{'} - \omega_m^{''})cos(k\gamma_{\beta_m}z) + i(\omega_m^{''} + \omega_m^{'})sin(k\gamma_{\beta_m}z)]\}e^{ikx}
\end{aligned}
\tag{109.32}
$$

$$
\begin{aligned}
u_z = \{&ik\gamma_{\alpha_m}(\frac{\alpha_m}{\omega})^2[(\Delta_m^{'} - \Delta_m^{''})cos(k\gamma_{\alpha_m}z) - i(\Delta_m^{''} + \Delta_m^{'})sin(k\gamma_{\alpha_m}z)] \\
&+2ik(\frac{\beta_m}{\omega})^2[(\omega_m^{'} + \omega_m^{''})cos(k\gamma_{\beta_m}z) - i(\omega_m^{'} - \omega_m^{'})sin(k\gamma_{\beta_m}z)]\}e^{ikx}
\end{aligned}
\tag{109.33}
$$

$$
\begin{aligned}
\sigma_{zz} = \rho_m\{&\alpha_m^2(1 - 2\frac{\beta_m^2}{c^2})[(\Delta_m^{'} + \Delta_m^{''})cos(k\gamma_{\alpha_m}z) - i(\Delta_m^{'} - \Delta_m^{''})sin(k\gamma_{\alpha_m}z)] \\
&+4\frac{\beta_m^4}{c^2}\gamma_{\beta_m}[(\omega_m^{'} - \omega_m^{''})cos(k\gamma_{\beta_m}z) - i(\omega_m^{'} + \omega_m^{''})sin(k\gamma_{\beta_m}z)]\}e^{ikx}
\end{aligned}
\tag{109.34}
$$

$$
\begin{aligned}
\tau_{zx} = 2\rho_m\beta_m^2\{&-\gamma_{\alpha_m}(\frac{\alpha_m}{c})^2[(\Delta_m^{'} - \Delta_m^{''})cos(k\gamma_{\alpha_m}z) - i(\Delta_m^{''} + \Delta_m^{'})sin(k\gamma_{\alpha_m}z)] \\
&+[1 - 2(\frac{\beta_m}{c})^2][(\omega_m^{'} + \omega_m^{''})cos(k\gamma_{\beta_m}z) - i(\omega_m^{'} - \omega_m^{''})sin(k\gamma_{\beta_m}z)]\}e^{ikx}
\end{aligned}
\tag{109.35}
$$

Define the displacement and stress solution at m^{th} interface as $S^{(m)}$, which is equal to $[\dot{u}_x(z_m = d_m)/c, \dot{u}_z(z_m = d_m)/c, \sigma_{zz}(z_m = d_m), \tau_{zx}(z_m = d_m)]^T$. Eqs. (109.32) - (??) can be reduced to the following matrix notations (Haskell, 1953):

$$S^{(m-1)} = \boldsymbol{E_m}[\Delta_m^{''} + \Delta_m^{'}, \Delta_m^{''} - \Delta_m^{'}, \omega_m^{''} - \omega_m^{'}, \omega_m^{''} + \omega_m^{'}]^T \tag{109.36}$$

$$S^{(m)} = \boldsymbol{D_m}[\Delta_m^{''} + \Delta_m^{'}, \Delta_m^{''} - \Delta_m^{'}, \omega_m^{''} - \omega_m^{'}, \omega_m^{''} + \omega_m^{'}]^T \tag{109.37}$$

where transformation matrix $\boldsymbol{E_m}$ and $\boldsymbol{D_m}$ are given in Appendix (Eqs. ?? and ??). The recurrence relation between $S^{(m)}$ and $S^{(m-1)}$ then can be established as Eq. 109.38, where $\boldsymbol{G_m} = \boldsymbol{D_m}\boldsymbol{E_m^{-1}}$.

$$S^{(m)} = \boldsymbol{D_m}\boldsymbol{E_m^{-1}}S^{(m-1)} = \boldsymbol{G_m}S^{(m-1)} \tag{109.38}$$

Recursively applying Eq. 109.38 leads to Eq. 109.39. Using the relation between $S^{(m-1)}$ and Δ_m, ω_m, Eq. 109.40 bridges the gap between the upper boundary (i.e., response at ground surface $S^{(0)}$) and lower boundary (i.e., solutions of wave incident layer Δ_n and ω_n), upon which specific boundary conditions can be imposed.

$$S^{(n-1)} = \prod_{i=1}^{n-1} \boldsymbol{G_i} S^{(0)} \tag{109.39}$$

$$\begin{gathered} S^{(0)} = \boldsymbol{L}[\Delta_n^{''} + \Delta_n^{'}, \Delta_n^{''} - \Delta_n^{'}, \omega_n^{''} - \omega_n^{'}, \omega_n^{''} + \omega_n^{'}]^T \\ \boldsymbol{L} = (\prod_{i=1}^{n-1} \boldsymbol{G_i})^{-1}\boldsymbol{E_n} \end{gathered} \tag{109.40}$$

Following boundary conditions are incorporated: (1) At n^{th} layer, the incident in-plane P and SV wave potential magnitude $\phi_n^{'}$ and $\Psi_n^{'}$ are given as K_1 and K_2; (2) At the ground surface ($z = 0$), the traction is free (i.e., the third and fourth component of $S^{(0)}$ is 0). Therefore, the reflected dilatational wave magnitude and rotational wave magnitude can be solved by Eq. 109.41, where $\Delta_n^{'}$ is $-K_1\omega^2/\alpha_n^2$ and $\omega_n^{'}$ is $K_2 w^2/(2\beta_n^2)$.

$$\begin{bmatrix} \Delta_n^{''} \\ \omega_n^{''} \end{bmatrix} = \begin{bmatrix} L_{31} + L_{32} & L_{33} + L_{34} \\ L_{41} + L_{42} & L_{43} + L_{44} \end{bmatrix}^{-1} \begin{bmatrix} (L_{32} - L_{31})\Delta_n^{'} + (L_{33} - L_{34})\omega_n^{'} \\ (L_{42} - L_{41})\Delta_n^{'} + (L_{43} - L_{44})\omega_n^{'} \end{bmatrix} \tag{109.41}$$

Finally, recurrence relation Eq. 109.42 can be used to trace back dilatational wave magnitude Δ_m and rotational wave magnitudes ω_m for the rest $n-1$ layers. Based on these solved dilatational and rotational magnitudes of each layer, the whole displacement and stress field can be easily computed following Eqs. (109.32)-(??).

$$\begin{bmatrix} \Delta''_{m-1} + \Delta'_{m-1} \\ \Delta''_{m-1} - \Delta'_{m-1} \\ \omega''_{m-1} - \omega'_{m-1} \\ \omega''_{m-1} + \omega'_{m-1} \end{bmatrix} = \boldsymbol{D^{-1}_{m-1} E_m} \begin{bmatrix} \Delta''_{m} + \Delta'_{m} \\ \Delta''_{m} - \Delta'_{m} \\ \omega''_{m} - \omega'_{m} \\ \omega''_{m} + \omega'_{m} \end{bmatrix} \tag{109.42}$$

In addition, viscosity can also be included with slight modification. Considering Kelvin-Voigt viscoelastic material (Chiriță et al., 2008), viscosity can be handled with complex Lame modulus and wave velocities as shown in Eq. 109.43, where ξ is the damping ratio.

$$G^* = G(1+2\xi i) \quad \beta^*_m \simeq \beta_m(1+\xi i) \quad \alpha^*_m \simeq \alpha_m(1+\xi i) \tag{109.43}$$

109.2.6 Seismic Motions: Large Scale Geophysical Models

109.2.6.1 Regional Seismic Motion Modeling using Serpentine Wave Propagation, SW4

109.2.7 Site Response

Site response is ...

This is part of free field motions section and just uses free field motions for producing site response.

109.2.8 Seismic Motion Incoherence

Seismic motion incoherence (as it is called for frequency domain analysis, for time domain analysis it is called lack of correlation) is a phenomena that results in spatial variability of ground motions over small distances. Significant work has been done in researching seismic motion incoherence over the last few decades. The main sources of lack of spatial correlation, according to Zerva (2009) are due to:

- Attenuation effects,
- Wave passage effects,
- Scattering effects,
- Extended source effects

Figure 109.4 shows an illustration of main sources of lack of correlation.

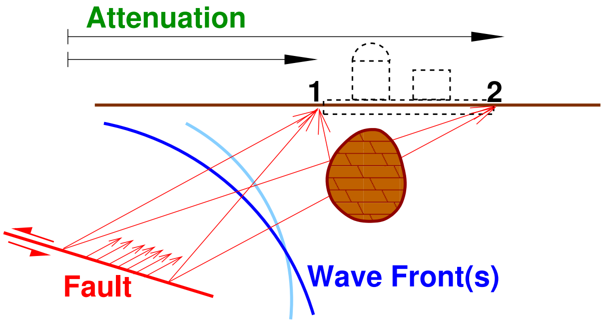

Figure 109.4: Four main sources contributing to the lack of correlation of seismic waves as measured at two observation points.

1. Attenuation effects are responsible for change in amplitude and phase of seismic motions due to the distance between observation points and losses (damping, energy dissipation) that seismic wave experiences along that distance. This is a significant source of lack of correlation for long structures (bridges), however for NPPSSS it is not of much significance.
2. Wave passage effects contribute to lack of correlation due to difference in recorded wave field at two location points as the (surface) wave travels, propagates from first to second point.

3. Scattering effects are responsible to lack of correlation by creating a scattered wave field. Scattering is due to (unknown or not known enough) subsurface geologic features that contribute to modification of wave field.

4. Extended source effects contribute to lack of correlation by creating a complex wave source field, as the fault ruptures, rupture propagates and generate seismic sources along the fault. Seismic energy is thus emitted from different points (along the rupturing fault) and will have different travel path and timing as it makes it observation points.

Early studies concluded that the correlation of motions increases as the separation distance between observation points decreases. In addition to that, correlation increased for decrease in frequency of observed motions. Moreover, there is a strong probabilistic nature of this phenomena, as significant uncertainty is present in relation to all four sources of lack of correlation, mentioned above. A number of excellent references are available on the subject of incoherent (or lacking correlation) seismic motions Abrahamson et al. (1991); Roblee et al. (1996); Abrahamson (1992a, 2005, 1992b); Zerva and Zervas (2002); Liao and Zerva (2006); Zerva (2009)

It is very important to note that all current models for modeling incoherent seismic motions make an ergodic assumption. That is all the models assume that a variability of seismic motions at a single site – source combination will be the same as variability in the ground motions from a data set that was collected over different site and source locations Walling (2009). Unfortunately, there does not exist a large enough data set for east North American seismic seismic events that can be used to develop incoherence models. Rather, there are models that are used to model possible incoherent behavior for east North American seismic wave propagations.

109.2.8.1 Lack of Correlation Modeling and Simulation

Incorporation of lack of correlation effects in seismic motions can be done using the following methods:

- along 1D, in one direction, usually one of the horizontal directions, where all the points that are the same distance (in 1D) from a control point, plane) share a single lack of correlation,

- along 2D, in two directions, usually in a vertical plane or in a horizontal plane, where all the points in a set of vertical planes or a set of horizontal planes, share same lack of correlation, and

- in full 3C, where every point of interest (in a 3D volume of soil/rock) has it own, specified, lack of correlation.

The method used here is using the so called seed motions, motions obtained through DRM in full 3C (inclined, body and surface waves), that are than enriched with appropriate uncorrelated (incoherent) components. It is important to note that only translational motions are used to model incoherence effects, while the rotational motions are not perturbed/made incoherent. This stems from the fact that currently vast majority of seismic recording stations only record translational motions and that only those translational motions are used to develop incoherent motions models. Code developed by Abrahamson (1992b) is used for this purpose.

109.2.9 Lack of Volume Change Data for Soil

Use of G/G_{max} and damping curves for describing and calibrating material behavior of soil is missing a very important (crucial) information about soil/rock volume change during shearing deformation. Volume change data is very important for soil behavior. It is important to emphasize that soil behavior is very much a function of volumetric response during shear. During shearing of soil there are two essential types of soil behavior:

- Dilative (dense) soils will increase volume due to shearing
- Compressive (loose) soils will decrease volume due to shearing

The soil volume response, that is not provided by G/G_{max} and damping curves data can significantly affect affect response due to volume constraints of soil. For example, for one dimensional site response (1C wave propagation, vertically propagating (SV) shear waves) the soil will try to change its volume (dilate if it is dense or compress if it is loose). However, such volume change can only happen vertically (since there is no constraint (foundation for example) on top, while horizontally the soil will be constraint by other soil. That means that any intended volume change in horizontal direction will be resisted by change in (increase for dense and decrease for loose soil) horizontal stress. For example for dilative (dense) soil, additional horizontal stress will contribute to the increase in mean pressure (confinement) of the soil, thus increasing the stiffness of that soil. It is the opposite for compressive soil where shearing will result in a reduction of confinement stress. Figure 109.5 shows three responses for no-volume change (left), compressive (middle) and dilative (right) soil with full volume constraint, resulting in changes in stiffness for compressive (reduction in stiffness), and dilative (increase in stiffness).

Changes in stiffness of soil during shearing deformation will influence wave propagation and amplification of different frequencies. Figure 109.6 shows response of no-volume change soil (as it is/should be assumed if only G/G_{max} and damping curves are available, with no volume change data) and a response of a dilative soil which stiffens up during shaking due to restricted intent to dilate. It is clear that dilative soil will show significant amplification of higher frequencies.

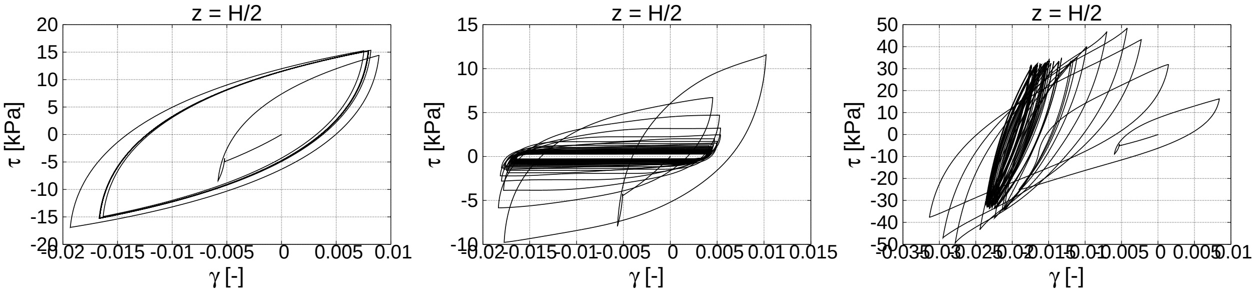

Figure 109.5: Constitutive Cyclic response of soils with constraint volumetric deformation: (left) no volume change (soil is at the critical state); (middle) compressive response with decrease in stiffness; (right) dilative response with increase in stiffness.

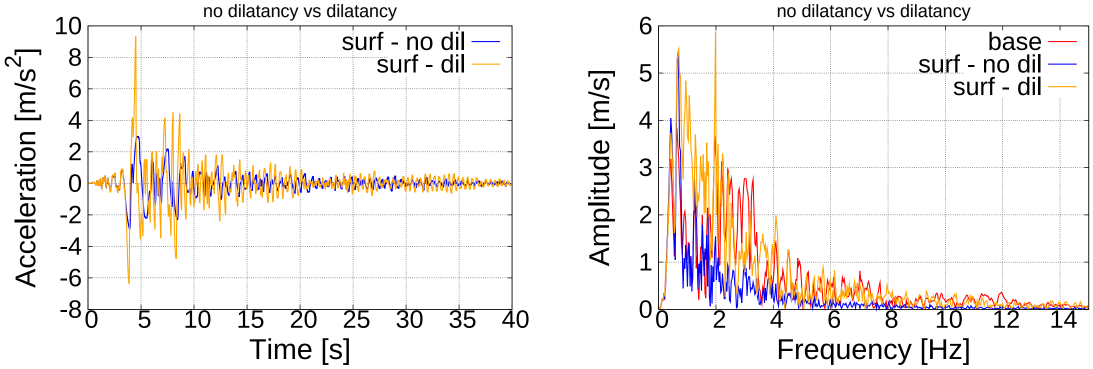

Figure 109.6: One dimensional seismic wave propagation through no-volume change and dilative soil. Please note the (significant) increase in frequency of motions for dilative soil. Left plot is a time history of motions, while the right plot shows amplitudes at different frequencies.

109.3 Earthquake Soil Structure Interaction

Current design practice for structures subject to earthquake loading regards dynamic SSII to be mainly beneficial to the behavior of structures (Jeremić and Preisig, 2005). Including the flexibility of the foundation reduces the overall stiffness of a system and therefore reduces peak loads caused by a given ground motion. Even if this is true in most cases there is the possibility of resonance occurring as a result of a shift of the natural frequencies of the SSI-system. This can lead to large inertial forces acting on a structure.

As a result of these large inertial forces caused by the structure oscillating in it's natural frequency the structure as well as the soil surrounding the foundation can undergo plastic deformations. This in turn further modifies the overall stiffness of the SSI-system and makes any prediction on the behavior very difficult.

Dynamic SSII also becomes important in the design of large infrastructure projects. As authorities and insurance companies try to introduce the concept of performance based design to the engineering community more sophisticated models are needed in order to obtain the engineering demand parameters (EDP's). A good numerical model of a soil-foundation-structure system can therefore not only prevent the collapse or damage of a structure but also help to save money by optimizing the design to withstand an earthquake with a certain return period.

A variety of methods of different levels of complexity are currently being used by engineers. In the following an overview over the most important ones is presented. A more thorough discussion on methods and specific aspects of dynamic SSII is available in Wolf (1985) and more recently in Wolf and Song (2002).

- No SSII

  The ground motion is applied directly to the base of the building. Alternatively, instead of applying the ground motion directly to the base of the structure, effective earthquake forces proportional to the base acceleration can be applied to the nodes.

  This procedure is reasonable only for flexible structures on very stiff soil or rock. In this case the displacement of the ground doesn't get modified by the presence of the structure. For stiffer structures on soil the ground motion has to be applied to the soil. The model has to incorporate propagation of the motion through the soil, its interaction with the structure and the radiation away from the structure.

- Direct methods

  Direct methods treat the SSI-system as a whole. The numerical model incorporates the spatial discretization of the structure and the soil. The analysis of the entire system is carried out in one step. This method provides most generality as it is capable of incorporating all nonlinear behavior of the structure, the soil and also the interface between those two (sliding, uplift).

- Substructure methods

  Substructure methods refer to the principle of superposition. The SSI-system is generally subdivided into a structure part and a soil part. Both substructures can be analyzed separately and the total displacement can be obtained by adding the contributions at the nodes on the interface.

  This method reduces the size of the problem considerably. As the time needed for an analysis doesn't increase linearly with an increasing number of equations the substructure method is much faster than the direct method. The biggest drawback of the method however is the fact that linearity is assumed. For nonlinear systems the substructure method cannot be used.

For the direct method different levels of sophistication are possible:

- Foundation stiffness approach

  The behavior of the soil is accounted for by simple mechanical elements such as springs, masses and dash pots. Different configurations of the subsoil can be taken into account by connecting several springs, masses and dash pots whose parameters have been determined by a curve fitting procedure Wolf (1994). This approach is very popular among structural engineers as it is relatively easy to be integrated in a commonly used finite element code.

  Other methods use frequency dependent springs and dash pots and therefore require an analysis in frequency domain. Relatively complex configurations of layered subsoil and embedded foundations can be modeled with good accuracy by replacing the (elastic) soil with a sequence of conical rods Wolf and Song (2002) and Wolf and Preisig (2003).

- p-y methods

  Attempts have been made to apply the static p-y approach for evaluating lateral loading on pile foundations to dynamic problems. Mostafa and El Naggar (2002) lists several references and provides a parametric study of single piles and pile groups in different soil types under simplified loading cases.

  Even if p-y curves are widely used for estimating lateral loading on piles they are rarely used in full dynamic soil-structure interaction analysis. Current work trying to implement these methods into finite element codes is likely to make them more popular with the engineering community.

- Full 3d

  Full nonlinear three-dimensional modeling of dynamic soil-foundation-structure interaction can be regarded as the 'brute force' approach. Displacements and forces can be obtained not only for the structure as in the above mentioned methods but also for the soil. In spite of the computational resources and modeling effort required for an analysis it is the only method that remains valid for all kinds of problems involving material nonlinearities, contact/interface problems, different loading cases and complex geometries.

109.4 Earthquake Soil Structure Interaction Modeling Details

109.4.1 Seismic Motions Input into Finite Element Model

A number of methods is used to input seismic motions into finite element model. Most of them are based on simple intuitive approaches, and as such are not based on rational mechanics. Most of those currently still widely used methods cannot properly model all three components of body waves as well as always present surface waves. There exist a method that is based on rational mechanics and can model both body and surface seismic waves input into finite element models with high accuracy. That method is called the Domain Reduction Method (DRM) (Bielak et al., 2003a; Yoshimura et al., 2003a)). The DRM aims to reduce the large computational domain, encompassing fault, rock, soil and the structure, to a much smaller domain, encompassing only local soil and the structure. The method was developed with earthquake ground motions in mind, with the main idea to replace the force couples at the fault with their counterpart acting on a continuous surface surrounding local feature of interest. The local feature can be any geologic or man made object that constitutes a difference from the simplified large domain, free field, for which displacements and accelerations are easier to obtain.

The DRM is applicable to a much wider range of problems. It is essentially a variant of global–local set of methods and as formulated can be used for any problems where the local feature can be bounded by a continuous surface (that can be closed or not). The local feature in general can represent a soil–foundation–structure system (bridge, building, dam, tunnel...), or it can be a crack in large domain, or some other type of inhomogeneity that is fairly small compared to the size of domain where it is found.

In what follow, the DRM is developed in a somewhat different way than it was done in original papers by Bielak et al. (2003a); Yoshimura et al. (2003a)). The main features of the DRM are then analyzed and appropriate practical modeling issues addressed.

109.4.1.1 The Domain Reduction Method (DRM) Development

A large physical domain is to be analyzed for dynamic behavior. The source of disturbance is a known time history of a force field $P_e(t)$. That source of loading is far away from a local feature which is dynamically excited by $P_e(t)$ $P_e(t)$ (see Figure 109.7).

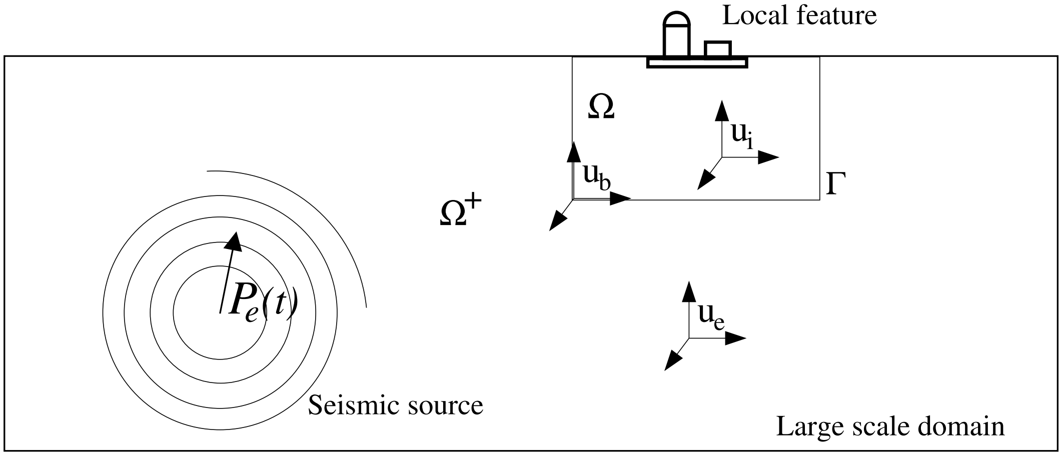

Figure 109.7: Large physical domain with the source of load $P_e(t)$ and the local feature (in this case a soil-structure system.

The system to be analyzed can be quite large, for example earthquake hypocenter can be many kilometers away from the local feature of interest. Similarly, the small local feature in a machine part can be many centimeters away from the source of dynamic loading which influences this local feature. In this sense the term large domain is relative to the size of the local feature and the distance to the dynamic forcing source.

It would be beneficial not to analyze the complete system, as we are only interested in the behavior of the local feature and its immediate surrounding, and can almost neglect the domain outside of some relatively close boundaries. In order to do this, we need to somehow transfer the loading from the source to the immediate vicinity of the local feature. For example we can try to reduce the size of the domain to a much smaller model bounded by surface Γ as shown in Figure 109.7. In doing so we must ensure that the dynamic forces $P_e(t)$ are appropriately propagated to the much smaller model boundaries Γ.

DRM Formulation In order to appropriately propagate dynamic forces $P_e(t)$ one actually has to solve the large scale problem which will include the effects of the local feature. Most of the time this is impossible as it involves all the complexities of large scale computations and relatively small local feature. Besides, the main goal of presented developments is to somehow reduce the large scale domain as to be able to analyze in details behavior of the local feature.

In order to propagate consistently the dynamic forces $P_e(t)$ we will make a simplification in that we will replace a local feature with a simpler domain that is much easer to be analyzed. That is, we replace the local feature (bridge, building. tunnel, crack) with a much simpler geometry and material. For example, Figure 109.8 shows a simplified model, without a foundation–building system.

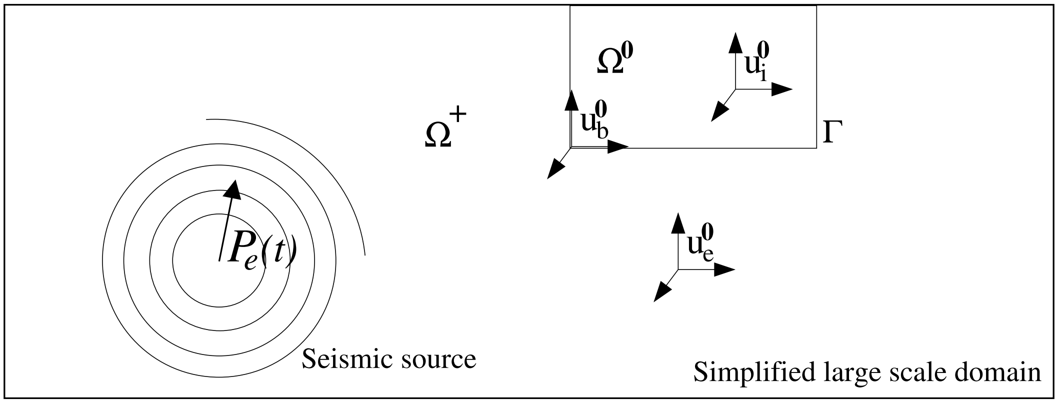

Figure 109.8: Simplified large physical domain with the source of load $P_e(t)$ and without the local feature (in this case a soil–foundation–building system. Instead of the local feature, the model is simplified so that it is possible to analyze it and simulate the dynamic response as to consistently propagate the dynamic forces $P_e(t)$

The idea is to simplify the model so that it is much easier to consistently propagate the dynamic forces to the boundary Γ. The notion that it is much easier to propagate those dynamic forces is of course relative. This is still a very complex problem, but at least the influence of local feature is temporarily taken out.

It is convenient to name different parts of domain. For example, the domain inside the boundary Γ is named Ω_0. The rest of the large scale domain, outside boundary Γ, is then named Ω^+. The outside domain Ω^+ is still the same as in the original model, while the change, simplification, is done on the domain inside boundary Γ. The displacement fields for exterior, boundary and interior of the boundary Γ are u_e, u_b and u_i, respectively, on the original domain.

The equations of motions for the complete system can be written as

$$\left[M \right] \left\{ \ddot{u} \right\} + \left[K \right] \left\{ u \right\} = \left\{ P_e \right\} \tag{109.44}$$

or, if written for each domain (interior, boundary and exterior of Γ) separately, the equations obtain the following form:

$$\begin{bmatrix} M_{ii}^{\Omega} & M_{ib}^{\Omega} & 0 \\ M_{bi}^{\Omega} & M_{bb}^{\Omega}+M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ 0 & M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_i \\ \ddot{u}_b \\ \ddot{u}_e \end{Bmatrix} + \begin{bmatrix} K_{ii}^{\Omega} & K_{ib}^{\Omega} & 0 \\ K_{bi}^{\Omega} & K_{bb}^{\Omega}+K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ 0 & K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_i \\ u_b \\ u_e \end{Bmatrix} = \begin{Bmatrix} 0 \\ 0 \\ P_e \end{Bmatrix} \tag{109.45}$$

In these equations, the matrices $\mathbf{M}$ and $\mathbf{K}$ are mass and stiffness matrices respectively; the subscripts i, e, and b are referencing nodes in either the interior (i) or exterior (e) domain or on their common boundary (b), while the superscripts Ω and Ω^+ reference domains to which matrices belong.

The previous equation can be separated provided that we maintain the compatibility of displacements and equilibrium. The resulting two equations of motion are

$$\begin{bmatrix} M_{ii}^{\Omega} & M_{ib}^{\Omega} \\ M_{bi}^{\Omega} & M_{bb}^{\Omega} \end{bmatrix} \begin{Bmatrix} \ddot{u}_i \\ \ddot{u}_b \end{Bmatrix} + \begin{bmatrix} K_{ii}^{\Omega} & K_{ib}^{\Omega} \\ K_{bi}^{\Omega} & K_{bb}^{\Omega} \end{bmatrix} \begin{Bmatrix} u_i \\ u_b \end{Bmatrix} = \begin{Bmatrix} 0 \\ P_b \end{Bmatrix}, \quad \text{in}\Omega \tag{109.46}$$

and

$$\begin{bmatrix} M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_b \\ \ddot{u}_e \end{Bmatrix} + \begin{bmatrix} K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_b \\ u_e \end{Bmatrix} = \begin{Bmatrix} -P_b \\ P_e \end{Bmatrix}, \quad \text{in}\Omega^+ \tag{109.47}$$

Compatibility of displacements is maintained automatically since both equations contain boundary displacements u_b (on boundary Γ), while the equilibrium is maintained through action–reaction forces P_b.

In order to simplify the problem, the local feature is removed from the interior domain. Thus, the interior domain is significantly simplified. In other words, the exterior region and the material therein are identical to those of the original problem as the dynamic force source. On the other hand, the interior domain (denoted as Ω_0), is simplified, the localized features is removed (as seen in figure 109.8).

For this simplified model, the displacement field (interior, boundary and exterior, respectively) and action–reaction forces are denoted by u_i^0, u_b^0, u_e^0 and P_b^0. The entire simplified domain Ω_0 and Ω^+ is now easier to analyze.

The equations of motion in Ω^+ for the auxiliary problem can now be written as:

$$\begin{bmatrix} M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_b^0 \\ \ddot{u}_e^0 \end{Bmatrix} + \begin{bmatrix} K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_b^0 \\ u_e^0 \end{Bmatrix} = \begin{Bmatrix} -P_b^0 \\ P_e \end{Bmatrix} \tag{109.48}$$

Since there was no change to the exterior domain Ω^+ (material, geometry and the dynamic source are still the same) the mass and stiffness matrices and the nodal force P_e are the same as in Equations (109.46) and (109.47).

Previous equation 109.48 can be used to obtain the dynamic force P_e:

$$P_e = M_{eb}^{\Omega+}\ddot{u}_b^0 + M_{ee}^{\Omega+}\ddot{u}_e^0 + K_{eb}^{\Omega+}u_b^0 + K_{ee}^{\Omega+}u_e^0 \tag{109.49}$$

The total displacement, u_e, can be expressed as the sum of the free field u_e^0 (from the background, simplified model) and the residual field w_e (coming from the local feature) as following:

$$u_e = u_e^0 + w_e \tag{109.50}$$

It is important to note that this is just a change of variables and not an application of the principle of superposition. The residual displacement field, w_e is measured relative to the reference free field u_e^0.

By substituting Equation 109.50 in Equation 109.45 one obtains:

$$\begin{bmatrix} M_{ii}^{\Omega} & M_{ib}^{\Omega} & 0 \\ M_{bi}^{\Omega} & M_{bb}^{\Omega} + M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ 0 & M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_i \\ \ddot{u}_b \\ \ddot{u}_e^0 + \ddot{w}_e \end{Bmatrix} + \begin{bmatrix} K_{ii}^{\Omega} & K_{ib}^{\Omega} & 0 \\ K_{bi}^{\Omega} & K_{bb}^{\Omega} + K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ 0 & K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_i \\ u_b \\ u_e^0 + w_e \end{Bmatrix} = \begin{Bmatrix} 0 \\ 0 \\ P_e \end{Bmatrix} \tag{109.51}$$

which, after moving the free field motions u_e^0 to the right hand side, becomes

$$\begin{bmatrix} M_{ii}^{\Omega} & M_{ib}^{\Omega} & 0 \\ M_{bi}^{\Omega} & M_{bb}^{\Omega} + M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ 0 & M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_i \\ \ddot{u}_b \\ \ddot{w}_e \end{Bmatrix} + \begin{bmatrix} K_{ii}^{\Omega} & K_{ib}^{\Omega} & 0 \\ K_{bi}^{\Omega} & K_{bb}^{\Omega} + K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ 0 & K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_i \\ u_b \\ w_e \end{Bmatrix} = \begin{Bmatrix} 0 \\ -M_{be}^{\Omega+}\ddot{u}_e^0 - K_{be}^{\Omega+}u_e^0 \\ -M_{ee}^{\Omega+}\ddot{u}_e^0 - K_{ee}^{\Omega+}u_e^0 + P_e \end{Bmatrix} \tag{109.52}$$

By substituting Equation 109.49 in previous Equation 109.52, the right hand side can now be written as

$$\begin{bmatrix} M_{ii}^{\Omega} & M_{ib}^{\Omega} & 0 \\ M_{bi}^{\Omega} & M_{bb}^{\Omega} + M_{bb}^{\Omega+} & M_{be}^{\Omega+} \\ 0 & M_{eb}^{\Omega+} & M_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} \ddot{u}_i \\ \ddot{u}_b \\ \ddot{w}_e \end{Bmatrix} + \begin{bmatrix} K_{ii}^{\Omega} & K_{ib}^{\Omega} & 0 \\ K_{bi}^{\Omega} & K_{bb}^{\Omega} + K_{bb}^{\Omega+} & K_{be}^{\Omega+} \\ 0 & K_{eb}^{\Omega+} & K_{ee}^{\Omega+} \end{bmatrix} \begin{Bmatrix} u_i \\ u_b \\ w_e \end{Bmatrix} = \begin{Bmatrix} 0 \\ -M_{be}^{\Omega+}\ddot{u}_e^0 - K_{be}^{\Omega+}u_e^0 \\ M_{eb}^{\Omega+}\ddot{u}_b^0 + K_{eb}^{\Omega+}u_b^0 \end{Bmatrix} \tag{109.53}$$

The right hand side of equation 109.53 is a dynamically consistent replacement force, the so called effective force, P^{eff} for the dynamic source forces P_e. In other words, the dynamic force P_e was consistently replaced by the effective force P^{eff}:

$$P^{eff} = \left\{ \begin{array}{c} P_i^{eff} \\ P_b^{eff} \\ P_e^{eff} \end{array} \right\} = \left\{ \begin{array}{c} 0 \\ -M_{be}^{\Omega+}\ddot{u}_e^0 - K_{be}^{\Omega+}u_e^0 \\ M_{eb}^{\Omega+}\ddot{u}_b^0 + K_{eb}^{\Omega+}u_b^0 \end{array} \right\} \tag{109.54}$$

DRM Discussion

Single Layer of Elements used for P^{eff}. The Equation (109.54) shows that the effective nodal forces P^{eff} involve only the sub-matrices M_{be}, K_{be}, M_{eb}, K_{eb}. These matrices vanish everywhere except the single layer of finite elements in domain Ω^+ adjacent to Γ. The significance of this is that the only wave-field (displacements and accelerations) needed to determine effective forces P^{eff} is that obtained from the simplified (auxiliary) problem at the nodes that lie on and between boundaries Γ and Γ_e, as shown in Figure 109.9.

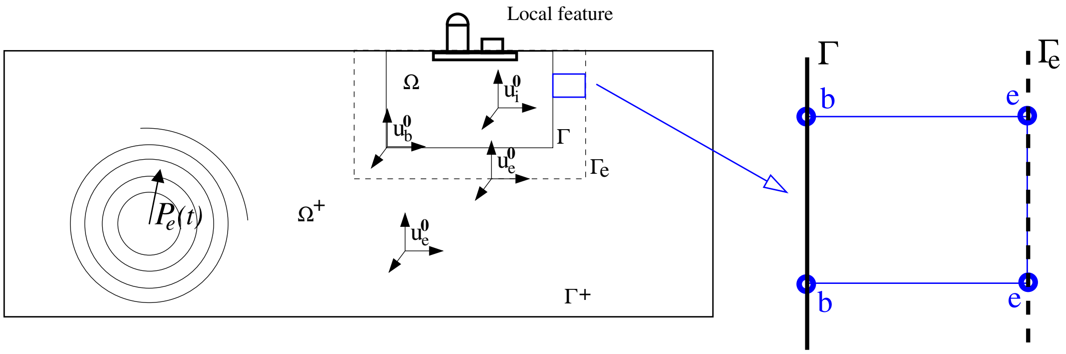

Figure 109.9: DRM: Single layer of elements between Γ and Γ_e is used to create P^{eff}, for a section of 8 node brick.

Figure 109.10 show boundary and external nodes for a section of a 27 node brick. Please note that for a 20, 20-17 and 27 node bricks, boundary nodes are nodes that belong to Γ surface, so for 27 node brick there are 9 nodes on that face, while the external nodes are all the nodes that are not boundary nodes, there will be 18 of those nodes.

Only residual waves outgoing. Another interesting observation is that the solution to problem described in Equation (109.53) comprises full unknowns (displacements and accelerations) inside and on the boundary Γ ($\mathbf{u}_i$ and $\mathbf{u}_b$ respectively). On the other hand, the solution for the domain outside single layer of finite elements (outside Γ_e) is obtained for the residual unknown (displacement and accelerations) field,

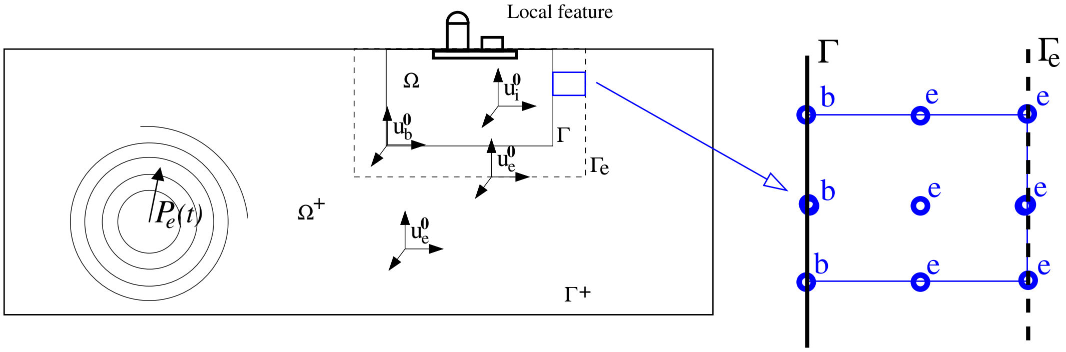

Figure 109.10: DRM: Single layer of elements between Γ and Γ_e is used to create P^{eff}, for 20, 20-17 and 27 node Brick.

w_e only. This residual unknown field is measured relative to the reference free field of unknowns (see comments on page 572). That effectively means that the solution to the equation Equation (109.53) outside the boundary Γ_e will only contain additional waves field resulting from the presence of a local feature. This in turn means that if the interest is in behavior of local feature and the surrounding media (all within boundary Γ) one can neglect the behavior of the full model (outside Γ_e in Ω^+) and provide appropriate supports (including fixity and damping) at some distance from the boundary Γ_e into region Ω^+. This is significant for a number of reasons:

- large models can be reduced in size to encompass just a few layers of elements outside boundary Γ_e (significant reduction for, say earthquake problems where the size of a local feature is orders of magnitudes smaller then the distance to the dynamic source force P_e (earthquake hypocenter).
- the residual unknown field can be monitored and analyzed for information about the dynamic characteristics of the local feature. Since the residual wave field is w_e is measured relative to the reference free field u_0^e, the solution for w_e has all the characteristics of the additional wave field stemming from the local feature.

Inside domain Ω can be inelastic. In all the derivations in section 109.4.1.1 no restriction was made on the type of material inside the plastic bowl (inside Γ_e). That is, the assumption that the material inside is linear elastic is not necessary as the DRM is not relying on principle of superposition. The Equation 109.50 was only describing the change of variables, and clearly there was no use of the principle of superposition, which is only valid for linear elastic solids and structures. It is therefore possible to assume that the derivations will still be valid with any type of material (linear or nonlinear, elastic or inelastic) inside Γ_e. With this in mind, the DRM becomes a very powerful method for analysis of soil–foundation–structure systems.

All types of realistic seismic waves are modeled. Since the effective forcing P^{eff} consistently replaces the effects of the seismic source, all appropriate (real) seismic waves are properly (analytically) modeled, including body (SV, SH, P) and surface (Rayleigh, Love, etc...) waves.

Properties of finite elements inside the DRM Layer. The DRM layers, a single layer of finite elements just outside Γ surfaces, where effective DRM forces P_{eff} are applied, needs to be carefully modeled. A number of conditions regarding the DRM layer need to be taken into account:

- The finite elements within the DRM layer need to be linear elastic.
- Material models for the finite elements within the DRM layer need to have same, or very similar material properties as the elastic part of material properties as the material inside the DRM layer. Although material inside the DRM layer can be elastic-plastic, it is beneficial if the linear elastic portion of material properties, for example for nonlinear elastic material at zero strain or for elastic-plastic material, elastic properties inside yield surface, for the DRM layer, is same, similar to the material used inside the DRM layer. All of the used elastic material properties need to be same as elastic material properties used for free field analysis in order to have consistent wave field.
- Dimensions of the DRM layer finite elements (thickness of the DRM layer) need to follow the same rule for element size (depending on chosen stiffness) so that there is no artificial (mesh dependent) filtering above certain frequencies. That means that 10 linear interpolation finite elements (8 node bricks) or 2 quadratic interpolation elements (27 node bricks) are needed per wave length (Bathe and Wilson, 1976; Hughes, 1987; Argyris and Mlejnek, 1991). For example if maximum modeling frequency is f_{max} = 20 Hz, and wave length is given as $\lambda_{min} = v/f_{max}$, where v is the wave velocity, maximum grid spacing (element size) for linear interpolation elements Δh^{LE} should not exceed

  $$\Delta h^{LE} \leq \frac{\lambda}{10} = \frac{v}{10 f_{max}} = \frac{v}{10 \times 20 \text{ Hz}} = \frac{v}{200 \text{ Hz}}$$

  while for quadratic interpolation elements such grid spacing (element size) Δh^{QE} is limited to

  $$\Delta h^{QE} \leq \frac{\lambda}{2} = \frac{v}{2 f_{max}} = \frac{v}{2 \times 20 \text{ Hz}} = \frac{v}{40 \text{ Hz}}$$

  The wave velocity v is the lowest wave velocity that is of interest in the simulation, usually the shear wave velocity.

Properties of the finite elements outside of the DRM Layer. Finite elements outside DRM layer need special considerations as well.

- Material outside the DRM layer needs to be linear elastic with addition of viscous damping, Caughey, Rayleigh, etc.
- At least one layer of finite elements outside DRM layer needs to be provided. If damping of outgoing waves, the so called radiation damping, is to be modeled, then more than one layer of finite elements outside DRM needs to be provided.
- If radiation damping is modeled, it is recommended to have more than just two layers, outside DRM layer. For example 4 or 5 additional layers work quite well.
- First layer outside DRM layer needs to be linear elastic, of similar/same properties as material inside DRM layer, and with NO viscous damping. The reason for this requirement, is explained by the fact that P^{eff} force, see equation 109.54 on page 573, is applied to finite elements within DRM layer. If finite elements that are outside/adjacent to the DRM layer have large viscous damping, then P^{eff} forces will be producing potentially significant reaction forces from large viscous damping that is placed on nodes of elements that are shared with DRM finite element nodes, and nodes of finite elements just outside DRM layer, and are connected to DRM finite elements. These reaction, viscous forces, will affects, change P^{eff} forces in a way that will not be consistent with seismic wave field that was used to develop P^{eff}.
- Viscous damping, Caughey, Rayleigh, should be placed on finite elements outside this first layer of elements, that is outside, adjacent to DRM layer, in order to damp out outgoing waves, the differential wave field, the "w_e" waves, see equation 109.50 on page 572. Additional viscous damping layers are added to damp out any additional waves, the so called radiation damping from structural oscilations. Damping in those additional layers is to be progressively larger, much larger than physical viscous damping. Values of equivalent damping of 20%, then 30%, then 50%, or higher have been used in order to damp outgoing waves, to model radiation damping.

A Note on Input Motions for DRM. Seismic motions (free field) that are used for input into a DRM model need to be consistent. In other words, a free field seismic wave that is used needs to fully satisfy equations of motion. For example, if free field motions are developed using a tool (SHAKE, or EDT or SW4, or fk, &c.) using time step $\Delta t = 0.01$s and then you decide that you want to run your analysis with a time step of $\Delta t = 0.001$s, simple interpolation (10 additional steps for each of the original steps) might create problems. Simple linear interpolation actually might (will) not satisfy wave propagation equations and if used will introduce additional, high frequency motions into the model. It is a very good idea to generate free field motions with the same time step as it will be used in ESSI simulation.

Similar problem might occur if spacial interpolation is done, that is if location of free field model nodes is not very close to the actual DRM nodes used in ESSI model. Spatial interpolation problems are actually a bit less acute, however one still has to pay attention and test the ESSI model for free conditions and only then add the structure(s) on top.

Input motions for the DRM are based on Free Field motions, that can be developed by a number of methods, as described in section 502.2.3 on page 2266.

DRM in Action, 1C vs 6C Free Field Motions

- One component of motions, 1C from 6C
- Excellent fit, however wrong physics

Figure 109.11: 6C real and 1C "horizontal motions fit" seismic motions. (Figure is a link to mp4 animation).

Chapter 110

Parallel Computing in Computational Mechanics

(1998-2000-2005-2015-2016-2017-2018-2019-2021-)

(In collaboration with Dr. Guanzhou Jie and Dr. Yuan Feng, and Prof. Han Yang)

110.1 Chapter Summary and Highlights

110.2 Introduction

110.2.1 High Performance Computing on DMPs, SMPs, GPGPUs, FPGA

110.2.1.1 Distributed Memory Parallel (SMP) Computations

110.2.1.2 Shared Memory Parallel (SMP) Computations

110.2.1.3 General Purpose Graphical Processiong Units (GPGPUs)

110.2.1.4 Fast Programmable Gate Arrays (FPGAs)

110.2.2 Parallel Computing for Elastic-Plastic Solids and Structures

110.2.3 Problem Requirements

Stages, Increments, Iterations

For many classes of scientific simulations, an initial (static) decomposition of a finite element mesh needs to be computed such that the number of mesh elements assigned to each processor is roughly equal and the number of mesh elements that are adjacent to elements assigned to other processors (i.e., the size of the subdomain boundary) is minimized. Ensuring that the number of mesh elements is balanced will result in a load-balanced computation, while minimizing the size of the subdomain boundary will minimize the inter-processor communications overhead. Such a decomposition is usually obtained by a graph partitioning algorithm. Recently, a number of multilevel graph partitioning algorithms (e.g. Hendrickson and Leland (1995), Karypis and Kumar (1998b,a), Monien et al. (1999), Walshaw and Cross (1999)) have been developed that are able to compute excellent static decompositions for a wide range of scientific simulations.

110.2.3.1 Finite Element Computations in Geomechanics

The distinct feature of elasto–plastic finite element computations is the presence of two iteration levels. In a standard displacement based finite element implementation, constitutive driver at each Gauss point iterates in stress and internal variable space, computes the updated stress state, constitutive stiffness tensor and delivers them to the finite element functions. Finite element functions then use the updated stresses and stiffness tensors to integrate new (internal) nodal forces and element stiffness matrix. Then, on global level, nonlinear equations are iterated on until equilibrium between internal and external forces is satisfied within some tolerance. In more details:

Elastic computations. In the case of elastic computations constitutive driver has a simple task of computing increment in stresses ($\Delta\sigma_{ij}$) for a given deformation increment ($\Delta\epsilon_{kl}$), through a closed form equation ($\Delta\sigma_{ij} = E_{ijkl}\Delta\epsilon_{kl}$) (Jeremić and Sture, 1997). It is important to note that in this case the amount of work per Gauss point is known in advance. The amount of computational work is the same for every integration point. If we assume the same number of integration points per element, it follows that the amount of computational work is the same for each element and it is known in advance.

Elasto–plastic computations. On the other hand, for elasto–plastic problems, for a given incremental deformation the constitutive driver is iterating in stress and internal variable space until consistency condition is satisfied ($F = 0$). The number of iterations is not known in advance. Initially, all Gauss points are in elastic range, but as we incrementally apply loads, the plastic zones develop. For Gauss points still in elastic range, there are no iterations, the constitutive driver just computes incremental stresses from closed form solution. Computational load will increase significantly for integration of constitutive equations in plastic range. In particular, constitutive level integration algorithms (Jeremić et al., 1998, 1999; Jeremić and Yang, 2002) for soils are very computationally demanding. From the experience of the PI, more than 70% of wall clock time during an elasto–plastic finite element analysis is spent in constitutive level iterations. This is in sharp contrast with elastic computations where the dominant part is solving the system of equations which consumes about 80% of run time. The extent of additional, constitutive level iterations is not known before the actual computations are over. In other words, the extent of elastic-plastic domain is not known ahead of time.

The traditional preprocessing type of DD method (also known as topological DD) splits domain based on the initial geometry and assigns roughly the same number of elements to every computational node and minimizes the size of subdomain boundaries. This approach might result in serious computational load imbalance for elasto–plastic problems. For example one domain might be assigned all of the elasto–plastic elements and spend large amount of time in constitutive level iterations. The other domains will have elements in elastic state and thus spend far less computational time in computing stress increments. This results in program having to wait for the slowest domain (the one with large number of elasto–plastic finite elements) to complete constitutive level iterations and only proceed with global system iterations after that.

This illustrates a two–fold challenge with computational load balancing for elastic–plastic simulations in geomechanics.

110.2.3.2 Adaptive Computation

First, these computations are dynamic in nature. That is, the structure of elastic and elastic–plastic domains changes dynamically and unpredictably during the course of the computation. For this reason, a static decomposition computed as a pre-processing step is not sufficient to ensure the computational load-balance of the entire computation. Instead, periodic computational load-balancing is required during the course of the computation. The problem of computing a dynamic decomposition shares the same requirements as that of computing the initial decomposition (i.e., balance the mesh elements and minimize the inter-processor communications), while also requiring that the cost associated with redistributing the data in order to balance the computational load is minimized. This last requirement prevents us from simply computing a whole new static partitioning from scratch each time computational load-balancing is required.

Often, the objective of minimizing the data redistribution cost is at odds with the objective of minimizing the inter-processor communications. For applications in which the computational requirements of different regions of the domain change rapidly, or the amount of state associated with each element is relatively high, minimizing the data redistribution cost is preferred over minimizing the communications incurred during parallel processing.

For applications in which computational load-balancing occurs very infrequently, the key objective of a load-balancing algorithm is in obtaining the minimal inter-processor communications. For many application domains, it is straightforward to select a primary objective to minimize (i.e., minimize whichever cost dominates). However, one of the key issues concerning the elastic-plastic computation is that the number of iterations between computational load-balancing phases is both unpredictable and dynamic. For example, in the case of static problems, zones in the 3D solid may become plastic and then unload to elastic (during increments of loading) so that the extent of plastic zone is changing. The change can be both slow and rapid. Slow change usually occurs during initial loading phases, while the later deformation tends to localize in narrow zones rapidly and the rest of the solid unloads rapidly (becomes elastic again). The narrow, localized zone has heavy computational load on the constitutive level (in each integration point within elements). Similar phenomena is observed in seismic soil–structure interaction computations where stiff structure interacts with soft soil and elastic and elastic–plastic zones change significantly during loading cycles. In this type of computation, it is extremely difficult to select the type of computational load-balancing algorithm to employ. Furthermore, the preferred computational load-balancing algorithm is liable to change during the course of the computation, and so the selection must be made dynamically.

110.2.3.3 Multi-phase Computation

The second challenge associated with computational load-balancing elastic-plastic computations in geomechanics is that these are two-phase computations. That is, plastic computations follow up the elastic computations. There is a synchronization phase between the computations, as only after the elastic computation is finished is it possible to check if the plastic computation is required for a given integration (Gauss) point within an element. For regions of the mesh in which this check indicates that the plastic computation is necessary, lengthy plastic computations are then performed. The existence of the synchronization step between the two phases of the computation requires that each phase be individually load balanced. That is, it is not sufficient to simply sum up the relative times required for each phase and to compute a decomposition based on this sum. Doing so may lead to some processors having too much work during the elastic computation (and so, these may still be working after other processors are idle), and not enough work during the plastic computation, (and so these may be idle while other processors are still working), and vice versa. Instead, it is critical that every processor have an equal amount of work from both of the phases of the computation.

110.2.4 Parallel Computing Hardware

110.2.4.1 DMPs and SMPs

Scalability issues for SMPs Cache coherence

Compute Nodes, CPUs, Cores,

GPUs (band-with and latency with the main memeory)

Networks (band-with and latency) 10, 100, 1,000, 10,000, Infiniband,

Large parallel supercomputers

small, user owned parallel machines (clusters of clusters)

ESSI Computer

- 208 (784) CPU cores,
- 288GB (1056GB) of distributed RAM,
- 24TB (48TB) of distributed disk space, and
- dual neetwork, InfiniBand for MPI, and GigaBit for file system

Small ESSI Computer

- 32 CPU cores (AMD), 24 CPU cores (Intel)

- 64GB RAM,
- 4TB
- on-board network

110.2.5 Parallel Computing Software

110.2.5.1 Amdahl's Law

n is a number of parallel processes

B is the fraction of algorithm that is serial

Total time to finish (wall clock time) with n parallel processes $T(n)$

$$T(n) = T(1)(B + \frac{1}{n}(1 - B)) \tag{110.1}$$

Theoretical speedup

$$S(n) = \frac{T(1)}{T(n)} = \frac{T(1)}{T(1)(B + \frac{1}{n}(1 - B))} = \frac{1}{(B + \frac{1}{n}(1 - B))} \tag{110.2}$$

110.2.5.2 Static and Dynamic Graph Partitioning

google search, data mining etc.

110.2.5.3 Real parallel and embarrassingly parallel

Finite Element matrices computations (elastic and elastic-plastic)

System of equation solvers (non-iterative and iterative)

Examples for

elastic (elements (Seq) + solver(P))

elastic (elements (P) + solver (Seq))

elastic (elements (P) + solver (P))

elastic-plastic (Seq) + solver (P)

elastic-plastic (P) + solver (Seq)

elastic-plastic (P) + solver (P)

110.2.5.4 Parallel Computing for Elastic-Plastic FEM

- Current Parallel FEM are
  - Well developed for elastic FEM
  - Undeveloped for elastic–plastic FEM
  - Well developed for homogeneous distributed memory parallel (DMP) computers,
  - Undeveloped for multiple performance (multi–generation) DMPs (example MOOSE, ESSI...)
- Need: dynamic computational load balancing for
  - multiple element types,
  - multiple material models
  - multiple compute node performances
  - multiple network performance performances

110.2.5.5 Plastic Domain Decomposition

- Multi-objective optimization problem (minimize both the inter-processor communications, the data redistribution costs and create balanced partitions)
- computational load balancing adds overhead $T_{overhead} := T_{comm} + T_{regen}$
  - T_{comm} data communication load depending on network conditions.
  - T_{regen} model regeneration for new partitioning, application (model) dependent
- Computional load among CPUs $T_j := \sum_{i=1}^{nel} ElemCompLoad[i], \;\; j = 1, ..., nCPU$
- Goal: minimize maximum compute time (slowest CPU) $T_{max} := max(T_j) \;\; j = 1, ..., nCPU$
- Total compute time (not wall clock time) $T_{sum} := sum(T_j)$
- Best execution time (perfect load balancing) $T_{best} := T_{sum}/nCPU, \;\Rightarrow\; T_j \equiv T_{best}$ for each $j = 1, ..., nCPU$
- Best performance gain $T_{gain} := T_{max} - T_{best}$
- Computational load balancing is beneficial iff $T_{gain} \geq T_{overhead} = T_{comm} + T_{regen}$
- Scalability (saturation, superlinear ...)

110.2.5.6 Template Meta-programs

Fine grained parallelism

110.3 Plastic Domain Decomposition Algorithm

110.3.1 Introduction

Domain Decomposition approach is the most popular and effective method to implement parallel finite element method. The underlying idea is to physically divide the problem domain into subdomains and finite element calculations will be performed on each individual domain in parallel. Domain Decomposition can be overlapping or non-overlapping. The overlapping domain decomposition method divides the problem domain into several slightly overlapping subdomains. Non-overlapping domain decomposition is extensively used in continuum finite element modeling due to the relative ease to program and organize computations and is the one that will be examined in this chapter.

In general, a good non-overlapping decomposition algorithm should be able to

- handle irregular mesh of arbitrarily shaped domain.
- minimize the interface problem size by delivering minimum boundary connectivity, which will help reducing the communication overheads.

The well-known idea of domain decomposition method can be found in a 1870 paper by the father of domain decomposition, H.A. Schwarz (Rixena and Magoulès, 2007). Domain decomposition method is also the underlying paradigm of substructuring methods developed in the sixties, which aim at reducing the dimension of models in structural analysis by applying static condensation-type techniques to subdomains.

Other than static condensation, Farhat and Roux (1991a); Farhat (1991); Farhat and Geradin (1992) proposed FETI (Finite Element Tearing and Interconnecting) method for domain decomposition analysis. In FETI method, Lagrange multipliers are introduced to enforce compatibility at the interface nodes. Rigid body modes are eliminated in parallel from each local problem and a direct scheme is applied concurrently to all subdomains in order to recover each partial local solution. The contributions of these modes are then related to the Lagrange multipliers through an orthogonality condition. This FETI method has been shown that it can deliver high efficiency for parallel implicit transient simulations in structural mechanics (Crivelli and Farhat, 1993).

Domain decomposition itself has become a active topic as parallel processing techniques receive much more attention in mathematics and engineering world during recent years. Domain decomposition was revived as a natural paradigm for parallel solvers (Rixena and Magoulès, 2007). Many papers have discussed two algorithms that are currently receiving much research effort, namely the FETI-DP (or Dual Primal Finite Element Tearing and Interconnecting) method and the even more recent BDDC (or Balancing Domain Decomposition by Constraints).

FETI-DP is the third generation FETI method (Bavestrello et al., 2007) developed for the fast, scalable, and domain-decomposition-based iterative solution of symmetric systems of equations arising from the finite element (FE) discretization of static, dynamic, structural and acoustic problems (Farhat et al., 2001, 2000).

BDDC, on the other hand, derives its formulation from substructuring method by enforcing constraints associated with disjoint sets of nodes on substructure boundaries using constrained energy minimization concepts (Dohrmann, 2003; Mandel and Dohrmann, 2003).

An early endeavor on dynamic computational load balancing was presented by McKenna (1997). Limited number of examples show that run time, dynamic computational load balancing can indeed improve parallel program performance in some cases, particularly when nonlinearities are involved.

Although many works have been presented on domain decomposition methods, the most popular methods such as FETI-type and BDDC all stem from the root of subdomain interface constraints handling. The merging of iterative solving with domain decomposition-type preconditioning is promising as shown by many researchers (Pavarino, 2007; Li and Widlund, 2007). Schwartz-type preconditioners for parallel domain decomposition system solving have also shared part of the spotlight (Hwang and Cai, 2007; Sarkis and Szyld, 2007).

In solid finite element methods, it has been assumed that the equation solving is the most computational expensive part so it is totally reasonable that all focus has been set on equation solver during the past decades.

Work presented in this chapter, however, has originated from the observation that for highly nonlinear materials, the constitutive level computation can be at least equally costly as equation solving, if not more expensive. The novelty of this chapter is to break out of the existing substructuring or FETI frameworks to further address the fundamental load balance issue of parallel computing. Namely, in order to achieve better parallel performance, we want to keep all processors equally busy. Load imbalance issue resulted from nonlinear constitutive level computations is too important to be neglected. This chapter proposes the Plastic Domain Decomposition algorithm which focuses on adaptive load balancing operation for nonlinear finite elements.

From the implementation point of view, for mesh-based scientific computations, domain decomposition corresponds to the problem of mapping a mesh onto a set of processors, which is well defined as a graph partitioning problem (Schloegel et al., 1999).

Formally, the graph partitioning problem is as follows. Given a weighted, undirected graph $G = (V; E)$ for which each vertex and edge has an associated weight, the k-way graph partitioning problem is to split the vertices of V into k disjoint subsets (or subdomains) such that each subdomain has roughly an equal amount of vertex weight (referred to as the balance constraint), while minimizing the sum of the weights of the edges whose incident vertices belong to different subdomains (i. e., the edge-cut).

In computational solid mechanics, the element graph is naturally used in parallel finite element method due to the fact that elemental operation forms the basis of finite element method. On the other hand, for material nonlinearity simulations, the element calculations represent the most computationally expensive part. In order to facilitate consistent interfaces for computational load measuring and data migration, element graph has been utilized as fundamental graph structure in this chapter, although it has been shown that the node-graph can be used as well for structure dynamics problem and the element-cut partitioning can make certain algorithms simpler (Krysl and Bittnar, 2001).

The graph partitioning problem is known to be NP-complete [1]. Therefore, generally it is not possible to compute optimal partitioning for graphs of interesting size in a reasonable amount of time. Various heuristic approaches have been developed, which can be classified as either geometric, combinatorial, spectral, combinatorial optimization techniques, or multilevel methods (Dongarra et al., 2003).

In finite element simulations involving nonlinear material response, static graph partitioning mentioned above does not guarantee even load distribution among processors. Plastification introduces work load that is much heavier than pure elastic computation. So for this kind of multiphase simulation, adaptive computational load balancing scheme has to be considered to keep all processing units equally busy as much as possible. Traditional static graph partitioning algorithm is not adequate to do multiphase partition/repartitioning. A parallel multilevel graph partitioner has been introduced in this research to achieve dynamic load balancing for inelastic finite element simulations.

In this chapter, the algorithm of Plastic Domain Decomposition (PDD) is proposed. The adaptive multi-level graph partitioning kernel of the PDD algorithm is implemented through the ParMETIS interface. Studies are performed to extract optimal algorithmic parameters for our specific applications.

110.3.2 Inelastic Parallel Finite Element

The distinct feature of inelastic (elastic-plastic) finite element computations is the presence of two iteration levels. In a standard displacement based finite element implementation, constitutive driver

---

[1] The complexity class NP is the set of decision problems that can be solved by a non-deterministic Turing machine in polynomial time. the NP-complete problems are the most difficult problems in NP ("non-deterministic polynomial time") in the sense that they are the smallest subclass of NP that could conceivably remain outside of P, the class of deterministic polynomial-time problems, http://en.wikipedia.org/wiki/NP-complete

at each Gauss point iterates in stress and internal variable space, computes the updated stress state, constitutive stiffness tensor and delivers them to the finite element functions. Finite element functions then use the updated stresses and stiffness tensors to integrate new (internal) nodal forces and element stiffness matrix. Then, on global level, nonlinear equations are iterated on until equilibrium between internal and external forces is satisfied within some tolerance.

- Elastic Computations

  In the case of elastic computations constitutive driver has a simple task of computing increment in stresses ($\Delta\sigma_{ij}$) for a given deformation increment ($\Delta\epsilon_{kl}$), through a closed form equation ($\Delta\sigma_{ij} = E_{ijkl}\Delta\epsilon_{kl}$) It is important to note that in this case the amount of work per Gauss point is known in advance. The amount of computational work is the same for every integration point. If we assume the same number of integration points per element, it follows that the amount of computational work is the same for each element and it is known in advance.

- Elastic-Plastic Computations

  On the other hand, for elastic-plastic problems, for a given incremental deformation the constitutive driver is iterating in stress and internal variable space until consistency condition is satisfied ($F = 0$). The number of iterations is not known in advance. Initially, all Gauss points are in elastic range, but as we incrementally apply loads, the plastic zones develop. For Gauss points still in elastic range, there are no iterations, the constitutive driver just computes incremental stresses from closed form solution. Computational load will increase significantly for integration of constitutive equations in plastic range. In particular, constitutive level integration algorithms for soils, concrete, rocks, foams and other granular materials are very computationally demanding. More than 70% of wall clock time during an elastic-plastic finite element analysis is spent in constitutive level iterations. This is in sharp contrast with elastic computations where the dominant part is solving the system of equations which consumes about 80% of run time. The extent of additional, constitutive level iterations is not known before the actual computations are over. In other words, the extent of elastic-plastic domain is not known ahead of time.

  The traditional preprocessing type of Domain Decomposition method (also known as topological DD) splits domain based on the initial geometry and assigns roughly the same number of elements to every computational node and minimizes the size of subdomain boundaries. This approach might result in serious computational load imbalance for elastic-plastic problems. For example one domain might be assigned all of the elastic-plastic elements and spend large amount of time in constitutive level iterations. The other domains will have elements in elastic state and thus spend far less computational time in computing stress increments. This results in program having to wait for the slowest domain (the one with large number of elastic-plastic finite elements) to complete constitutive level iterations and only proceed with global system iterations after that.

This illustrates a two-fold challenge with computational load balancing for inelastic simulations in mechanics. These two challenges is described below in some more detail.

110.3.2.1 Adaptive Computation

First, these computations are dynamic in nature. That is, the structure of elastic and elastic-plastic domains changes dynamically and unpredictably during the course of the computation. For this reason, a static decomposition computed as a pre-processing step is not sufficient to ensure the computational load-balance of the entire computation. Instead, periodic computational load-balancing is required during the course of the computation. The problem of computing a dynamic decomposition shares the same requirements as that of computing the initial decomposition (i.e., balance the mesh elements and minimize the inter-processor communications), while also requiring that the cost associated with redistributing the data in order to balance the computational load is minimized. This last requirement prevents us from simply computing a whole new static partitioning from scratch each time computational load-balancing is required.

Often, the objective of minimizing the data redistribution cost is at odds with the objective of minimizing the inter-processor communications. For applications in which the computational requirements of different regions of the domain change rapidly, or the amount of state associated with each element is relatively high, minimizing the data redistribution cost is preferred over minimizing the communications incurred during parallel processing.

For applications in which computational load-balancing occurs very infrequently, the key objective of a load-balancing algorithm is in obtaining the minimal inter-processor communications. For many application domains, it is straightforward to select a primary objective to minimize (i.e., minimize whichever cost dominates). However, one of the key issues concerning the elastic-plastic computation is that the number of iterations between computational load-balancing phases is both unpredictable and dynamic. For example, in the case of static problems, zones in the 3D solid may become plastic and then unload to elastic (during increments of loading) so that the extent of plastic zone is changing. The change can be both slow and rapid. Slow change usually occurs during initial loading phases, while the later deformation tends to localize in narrow zones rapidly and the rest of the solid unloads rapidly (becomes elastic again). The narrow, localized zone has heavy computational load on the constitutive level (in each integration point within elements). Similar phenomena is observed in seismic soil-structure interaction computations where stiff structure interacts with soft soil and elastic and elasto-plastic zones change significantly during loading cycles. In this type of computation, it is extremely difficult to select the type of computational load-balancing algorithm to employ. Furthermore, the preferred computational load-balancing algorithm is liable to change during the course of the computation, and so the selection must be made dynamically.

110.3.2.2 Multiphase Computation

The second challenge associated with computational load-balancing elastic-plastic computations in geomechanics is that these are two-phase computations. That is, elastic-plastic computations follow up the elastic computations. There is a synchronization phase between the computations, as only after the elastic computation is finished is it possible to check if the elastic-plastic computation is required for a given integration (Gauss) point within an element. For regions of the mesh in which this check indicates that the elastic-plastic computation is necessary, lengthy elastic-plastic computations are then performed. The existence of the synchronization step between the two phases of the computation requires that each phase be individually load balanced. That is, it is not sufficient to simply sum up the relative times required for each phase and to compute a decomposition based on this sum. Doing so may lead to some processors having too much work during the elastic computation (and so, these may still be working after other processors are idle), and not enough work during the elastic-plastic computation, (and so these may be idle while other processors are still working), and vice versa. Instead, it is critical that every processor have an equal amount of work from both of the phases of the computation.

110.3.2.3 Multiconstraint Graph Partitioning

Elastic-plastic FE computation can be understood as a two-phase calculation, which is also dynamic in nature. Traditional graph partitioning formulations are not adequate to ensure its efficient execution on high performance parallel computers. In this chapter very recent progresses from the graph partitioning algorithm research will be investigated. We need new adaptive graph partitioning formulations, which can compute adaptive partitioning-repartitionings that can satisfy an arbitrary number of balance constraints.

- Static Graph Partitioning
  Given a weighted, undirected graph $G = (V, E)$, for which each vertex and edge has an associated weight, the k-way graph partitioning problem is to split the vertices of V into k disjoint subsets (or subdomains) such that each subdomain has roughly an equal amount of vertex weight (referred to as the balance constraint), while minimizing the sum of the weights of the edges whose incident vertices belong to different subdomains (i.e., the edge-cut).

1. Geometric Techniques

   Compute partitioning based solely on the coordinate information of the mesh nodes, without considering edge-cut. Popular methods include, Coordinate Nested Dissection (CND or Recursive Coordinate Bisection), Recursive Inertial Bisection (RIB), Space-Filling Curve techniques and Sphere-Cutting approach.

2. Combinatorial Techniques

   Attempt to group together highly connected vertices whether or not these are near each other in space. That is combinatorial partitioning schemes compute a partitioning based only on the adjacency information of the graph; they do not consider the coordinates of the vertices. They tend to have lower edge-cuts but generally slower. Popular methods include, Levelized Nested Dissection (LND) and Kernighan-Lin/Fiduccia-Mattheyses (KL/FM) partitioning refinement algorithm, which needs an initial partition input to do swapping refinement.

3. Multilevel Schemes

   The multilevel paradigm consists of three phases: graph coarsening, initial partitioning, and multilevel refinement. Firstly, we form coarse graph by collapsing together selected vertices of the input graph. After rounds of coarsening, we get coarsest graph, on which an initial bisection will be performed. Then the KL/FM algorithm can be used to refine the partition back to the finest graph.

   The multilevel paradigm works well for two reasons. First, a good coarsening scheme can hide a large number of edges on the coarsest graph, which makes the task of computing high-quality partitioning easier. Second reason, incremental refinement schemes such as KL/FM become much more powerful in the multilevel context.

   Popular algorithms include Multilevel Recursive Bisection and Multilevel k-Way Partitioning.

- Adaptive Graph Partitioning

  For large scale elasto-plastic FE simulations, it is necessary to dynamically load-balance the computations as the analysis progresses due to unpredictable plastification inside the domain. This dynamic load balancing can be achieved by using a graph partitioning algorithm.

  Adaptive graph partitioning shares most of the requirements and characteristics of static graph partitioning but also adds an additional objective. That is, the amount of data that needs to be redistributed among the processors in order to balance the load should be minimized. If the vertex weight represents the computational cost of the work carried by the vertex, another metric, size of the vertex needs to be considered as well, which reflects distribution cost of the vertex. Thus, the repartitioner should attempt to balance the partitioning with respect to vertex weight while minimizing vertex migration with respect to vertex size.

Different approaches are available. One can simply compute a new graph from scratch, so called Scratch-Remap Repartitioner, which expectedly introduces more data redistribution than necessary. Diffusion-Based Repartitioner attempt to minimize the difference between the original partitioning and the final repartitioning by making incremental changes in the partitioning to restore balance. This method has been an very active topic during recent years, Dongarra et al. (2003) gives up-to-date review.

- Multiconstraint Graph Partitioning

  We can see traditional graph partitioning typically balances only a single constraint (i.e., the vertex weight) and minimizes only a single objective (i.e., the edge-cut). If we replace the vertex weight, which is a single number, with a weight vector of size m, then the problem becomes that of finding a partitioning that minimizes the edge-cuts subject to the constraints that each of the m weights is balanced across subdomains.

  Multilevel graph partitioning algorithms for solving multiconstraint/multiobjective problems have been very successful Schloegel et al. (1999). The software libraries METIS and ParMETIS are widely used in computational mechanics research.

110.3.2.4 Adaptive PDD Algorithm

In this chapter, the Plastic Domain Decomposition (PDD) has been developed using multi-level, multi-objective graph partitioning algorithm. This algorithm automatically monitors load balancing condition and updates element graph structure accordingly as the simulation progresses. Element redistribution will be triggered to achieve load balance when nonlinearity of materials brings down the parallel performance.

110.3.3 Adaptive Multilevel Graph Partitioning Algorithm

Kaypis and Kumar (1998) present a k-way multilevel partitioning algorithm whose run time is linear in the number of edges $|E|$ (i.e., O($|E|$)); whereas the run time of multilevel recursive bisection schemes is O($|E|$log$k$) for k-way partitioning. Kaypis and Kumar (1998) show that the proposed multilevel partitioning scheme produces partitioning that are of comparable or better quality than those produced by multilevel recursive bisection, while requiring substantially less time. This paradigm consists of three phases: graph coarsening, initial partitioning, and multilevel refinement. In the graph coarsening phase, a series of graphs is constructed by collapsing together selected vertices of the input graph in order to form a related coarser graph. This newly constructed graph then acts as the input graph for another round of graph coarsening, and so on, until a sufficiently small graph is obtained. Computation of the initial bisection is performed on the coarsest (and hence smallest) of these graphs, and so is very fast. Finally, partition refinement is performed on each level graph, from the coarsest to the nest (i.e., original graph) using a KL/FM-type algorithm Dongarra et al. (2003). Figure 110.1 illustrates the multilevel paradigm. This algorithm is available in METIS Karypis and Kumar (1998d) which is used in this research to provide initial static partitioning.

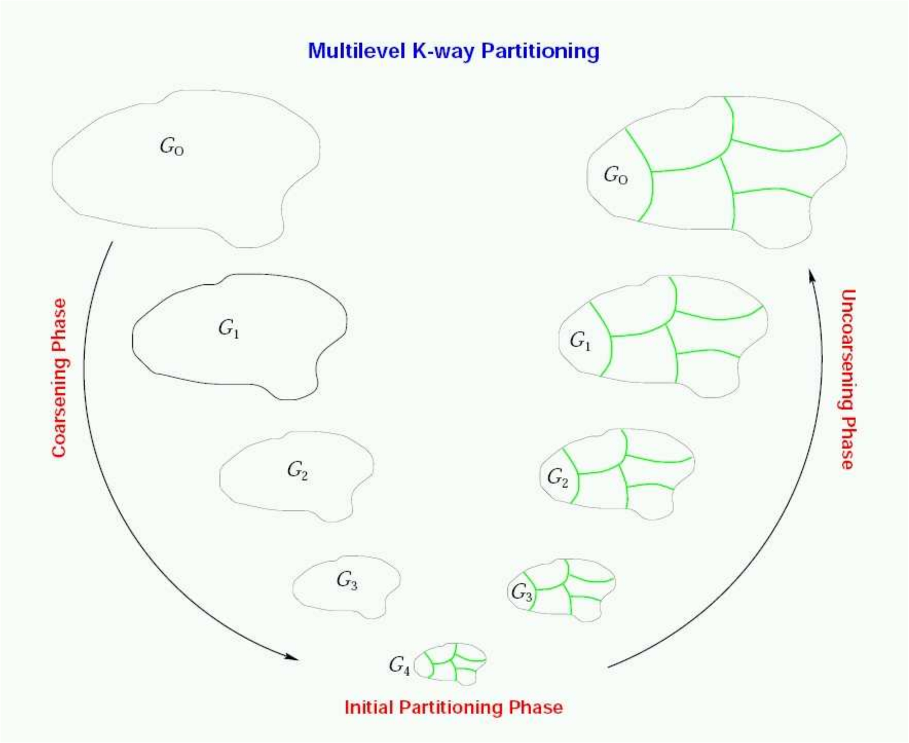

Figure 110.1: Multilevel Graph Partitioning Scheme Karypis et al. (2003)

Adaptive graph repartitioning algorithm can be used to achieve dynamic load balancing of multiphase elastic-plastic finite element simulations. Adaptive graph partitioning differs from static graph partitioning algorithm in the sense that one additional objective has to be targeted. That is, the amount of data the needs to be redistributed among the processors in order to balance the load should be minimized. In order to measure this redistribution cost, not only does the weight of a vertex, but also its size have to be considered. In our implementation for the purpose of this research, the vertex weight represents the computational load of each finite element, while the size reflects its redistribution cost. Thus, the application of adaptive graph partitioning algorithm aims at balancing the partitioning with respect to vertex weight while minimizing vertex migration with respect to vertex size.

A repartitioning of a graph can be obtained simply by partitioning a new graph from a scratch, which tends to bring much more unnecessary communications because the old distribution has not been taken into account. Diffusion-based Repartitioner is more popular in which one attempts to minimize the difference between the original partitioning and the final repartitioning by making incremental changes in the partitioning to restore balance. Dongarra et al. (2003) gives a comprehensive review on this subject. Adaptive repartitioning is available in ParMETIS Karypis et al. (2003) and Jostle Warshaw (1998). The former is chosen in this research considering the fact that ParMETIS provides seamless interface for METIS 4.0 which makes the comparison between static and adaptive partitioning schemes more consistent.

PARMETIS is an MPI-based parallel library that implements a variety of algorithms for partitioning and repartitioning unstructured graphs and for computing fill-reducing orderings of sparse matrices Karypis et al. (2003). PARMETIS is particularly suited for parallel numerical simulations involving large unstructured meshes. In this type of computation, PARMETIS dramatically reduces the time spent in communication by computing mesh decompositions such that the numbers of interface elements are minimized. The algorithms in PARMETIS are based on the multilevel partitioning and fill-reducing ordering algorithms that are implemented in the widely-used serial package METIS Karypis and Kumar (1998c). However, PARMETIS extends the functionality provided by METIS and includes routines that are especially suited for parallel computations and large-scale numerical simulations. In particular, PARMETIS provides the following functionality Karypis et al. (2003):

- Partition unstructured graphs and meshes.
- Repartition graphs that correspond to adaptively refined meshes.
- Partition graphs for multi-phase and multi-physics simulations.
- Improve the quality of existing partitioning.
- Compute fill-reducing orderings for sparse direct factorization.
- Construct the dual graphs of meshes.

Both METIS and PARMETIS are used in this research. METIS routines are called to construct static partitioning for commonly used one-step static domain decomposition, while adaptive load-balancing is achieved by calling PARMETIS routines regularly during the progress of nonlinear finite element simulations.

Adaptive load-balancing through domain repartitioning is a multi-objective optimization problem, in which repartitionings should minimize both the inter-processor communications incurred in the iterative mesh-based computation and the data redistribution costs required to balance the load. PARMETIS provides the routine ParMETIS_V3_AdaptiveRepart for repartitioning the previous unbalanced computational domain. This routine assumes that the existing decomposition is well distributed among the processors, but that (due to plastification of certain nonlinear elements) this distribution is poorly load balanced.

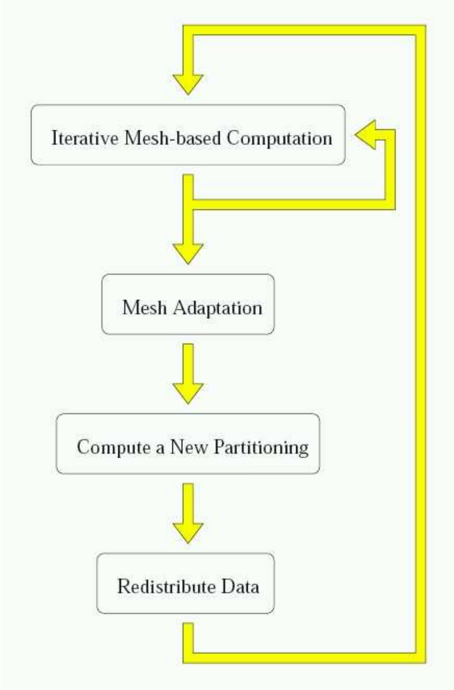

Figure 110.2: A diagram illustrating the execution of adaptive scientific simulations on high performance parallel computers Schloegel et al. (1999)

Figure 110.2 Schloegel et al. (2000) shows common steps involved in the execution of adaptive mesh-based simulations on parallel computers. Initially, the mesh is equally distributed on different processors. As all elements are elastic at the very beginning (carrying the same amount of elemental calculation work), computation load balance can be guaranteed with a even distribution. A number of iterations of the simulation are performed in parallel, after which plasticity occurs in certain nonlinear elements thus introducing some amount of load imbalance. A new partitioning based on the unbalanced domain is computed to re-balance the load, and then the mesh is redistributed among the processors, respectively. The simulation can then continue for another number of iterations until either more mesh adaptation is required or the simulation terminates.

If we consider each round of executing a number of iterations of the simulation, mesh adaptation, and load-balancing to be an epoch, then the run time of an epoch can be described by, Schloegel et al.

(2000)

$$(t_{comp} + f(|E_{cut}|))n + t_{repart} + g(|V_{move}|) \tag{110.3}$$

where n is the number of iterations executed, t_{comp} is the time to perform the computation for a single iteration of the simulation, $f(|E_{cut}|)$ is the time to perform the communications required for a single iteration of the simulation, and t_{repart} and $g(|V_{move}|)$ represent the times required to compute the new partitioning and to redistribute the data. Here, the inter-processor communication time is described as a function of the edge-cut of the partitioning and the data redistribution time is described as a function of the total amount of data that is required to be moved in order to realize the new partitioning. Adaptive repartitioning affects all of terms in Equation 110.3. How well the new partitioning is balanced influences t_{comp}. The inter-processor communications time is dependent on the edge-cut of the new partitioning. The data redistribution time is dependent on the total amount of data that is required to be moved in order to realize the new partitioning. It is critical for adaptive partitioning schemes to minimize both the edge-cut and the data redistribution when computing the new partitioning. Viewed in this way, adaptive graph partitioning is a multi-objective optimization problem.

There are various approaches how to handle this dual-objective problem. In general, two approaches have primarily been taken when designing adaptive partitioners. Schloegel et al. (2000) gives a comprehensive review on this topic. The first approach is to attempt to focus on minimizing the edge-cut and to minimize the data redistribution only as a secondary objective. This family of methods can be called scratch-remap repartitioner. These use some type of state-of-the-art graph partitioner to compute a new partitioning from scratch and then attempt to intelligently remap the subdomain labels to those of the original partitioning in order to minimize the data redistribution costs. Since a state-of-the-art graph partitioner is used to compute the partitioning, the resulting edge-cut tends to be extremely good. However, since there is no guarantee as to how similar the new partitioning will be to the original partitioning, data redistribution costs can be high, even after remapping. The second approach is to focus on minimizing the data redistribution cost and to minimize the edge-cut as a secondary objective, or so-called diffusion-based repartitioner. These schemes attempt to perturb the original partitioning just enough so as to balance it. This strategy usually leads to low data redistribution costs, especially when the partitioning is only slightly imbalanced. However, it can result in higher edge-cuts than scratch-remap methods because perturbing a partitioning in order to balance it also tends to adversely affect its quality.

These two types of repartitioner allow the user to compute partitioning that focus on minimizing either the edge-cut or the data redistribution costs, but give the user only a limited ability to control the tradeoffs among these objectives. This control of the tradeoffs is sufficient if the number of iterations that a simulation performs between load-balancing phases (i.e. the value of n in Equation 110.3) is either very high or very low. However, when n is neither very high nor very low, neither type of scheme precisely minimizes the combined costs of $f(E_{cut}|)n$ and $g(|V_{move}|)$. Another disadvantage exists for applications in which n is difficult to predict or those in which n can change dynamically throughout the course of the computation. As an example, one of the key issues concerning the elastic-plastic soil-structure interaction computations required for earthquake simulation is that the number of iterations between load-balancing phases is both unpredictable and dynamic. Here, zones in the 3D solid may become plastic and then unload (during increments of loading) so that the extent of the plastic zone is changing. The change can be both slow and rapid. Slow change usually occurs during initial loading phases, while the later deformation tends to localize in narrow zones rapidly and the rest of the solid unloads rapidly (becomes elastic again) Jeremić and Xenophontos (1999).

Schloegel et al. (2000) presents a parallel adaptive repartitioning scheme (called the Unified Repartitioning Algorithm) for the dynamic load-balancing of scientific simulations that attempts to solve the precise multi-objective optimization problem. By directly minimizing the combined costs of $f(E_{cut}|)n$ and $g(|V_{move}|)$, the proposed scheme is able to gracefully tradeoff one objective for the other as required by the specific application. The paper shows that when inter-processor communication costs are much greater in scale than data redistribution costs, the proposed scheme obtains results that are similar to those obtained by an optimized scratch-remap repartitioner and better than those obtained by an optimized diffusion-based repartitioner. When these two costs are of similar scale, the scheme obtains results that are similar to the diffusive repartitioner and better than the scratch-remap repartitioner. When the cost to perform data redistribution is much greater than the cost to perform inter-processor communication, the scheme obtains better results than the diffusive scheme and much better results than the scratch-remap scheme. They also show in the paper that the Unified Repartitioning Algorithm is fast and scalable to very large problems.

110.3.3.1 Unified Repartitioning Algorithm

A key parameter used in Unified Repartitioning Algorithm (URA) is the Relative Cost Factor (RCF). This parameter describes the relative times required for performing the inter-processor communications incurred during parallel processing and to perform the data redistribution associated with balancing the load. Using this parameter, it is possible to unify the two minimization objectives of the adaptive graph partitioning problem into the unified cost function

$$|E_{cut}| + \alpha|V_{move}| \tag{110.4}$$

where α is the Relative Cost Factor, $|E_{cut}|$ is the edge-cut of the partitioning, and $|V_{move}|$ is the total amount of data redistribution. The Unified Repartitioning Algorithm attempts to compute a repartitioning while directly minimizing this cost function.

The Unified Repartitioning Algorithm is based upon the multilevel paradigm that is illustrated in Figure 110.1, which can be described as three phases: graph coarsening, initial partitioning, and uncoarsening/refinement Schloegel et al. (2000). In the graph coarsening phase, coarsening is performed using a purely local variant of heavy-edge matching. That is, vertices may be matched together only if they are in the same subdomain on the original partitioning. This matching scheme has been shown to be very effective at helping to minimize both the edge-cut and data redistribution costs and is also inherently more scalable than global matching schemes.

110.3.3.2 Study of ITR in ParMETIS

The RCF in the URA implementation controls the tradeoff between two objectives, minimizing data redistribution cost or edge-cut. In our application, ParMETIS library has been linked to a MOSS (Modified OpenSees Services) analysis model to facilitate the partitioning/adaptive repartitioning scheme. The RCF is defined as a single parameter ITR in ParMETIS Karypis et al. (2003). This parameter describes the ratio between the time required for performing the inter-processor communications incurred during parallel processing compared to the time to perform the data redistribution associated with balancing the load. As such, it allows us to compute a single metric that describes the quality of the repartitioning, even though adaptive repartitioning is a multi-objective optimization problem. As recommended by Karypis et al. (2003), appropriate values to pass for the ITR Factor parameter can be determined depending on the times required to perform

1. all inter-processor communications that have occurred since the last repartitioning, and
2. the data redistribution associated with the last repartitioning/load balancing phase.

Simply divide the first time measurement by the second time measurement. The result is the correct ITR Factor. In case these times cannot be ascertained (e.g., for the first repartitioning/load balancing phase), Karypis et al. (2003) suggests that values between 100 and 1000 work well for a variety of situations. By default ITR is between 0.001 and 1000000. If ITR is set high, a repartitioning with a low edge-cut will be computed. If it is set low, a repartitioning that requires little data redistribution will be computed.

110.4 Performance Studies on PDD Algorithm

110.4.1 Introduction

In this chapter, parallel performance of the proposed PDD algorithm is thoroughly investigated. There are two major focuses for the timing analysis. Firstly we want to see how much performance gain we can have by introducing the PDD algorithm into inelastic finite element calculations. Secondly, we also want to show how scalable the proposed PDD algorithm is.

As our final objective is to apply PDD in large scale SFSI finite element simulations, finite element models of SFSI have been set up to study the parallel performance of the PDD based parallel program. Implicit constitutive integration scheme Jeremić and Sture (1997) has been used to expose the load imbalance by plasticity calculation. Only continuum element has been studied due to the fact they can be easily visualized to obtain partition and/or repartition figures.

Distributed memory Linux/Unix clusters are major platforms used in this chapter for speed up analysis.

110.4.2 Parallel Computers

Performance measurement has been carried out on two SMP-based clusters.

- IBM eServer p655

  The DataStar IBM eServer p655 cluster consists of 176 8-way P655+ nodes at San Diego Supercomputer Center. System configuration is shown in Fig 110.3. The network benchmark is shown in Table 110.1.

  Table 110.1: Latency and Bandwidth Comparison (as of August 2004)

	MPI Latencies (μsec)	Bandwidth (MBs)
Intra-node	3.9	3120.4
Inter-node	7.65	1379.1

- TeraGrid IA-64 Intel-Based Linux Cluster

  The TeraGrid project was launched by the the National Science Foundation with $53 million in funding to four sites: the National Center for Supercomputing Applications (NCSA) at the University of Illinois, Urbana-Champaign, the San Diego Supercomputer Center (SDSC) at the University of California, San Diego, Argonne National Laboratory in Argonne, IL, and Center for Advanced Computing Research (CACR) at the California Institute of Technology in Pasadena.

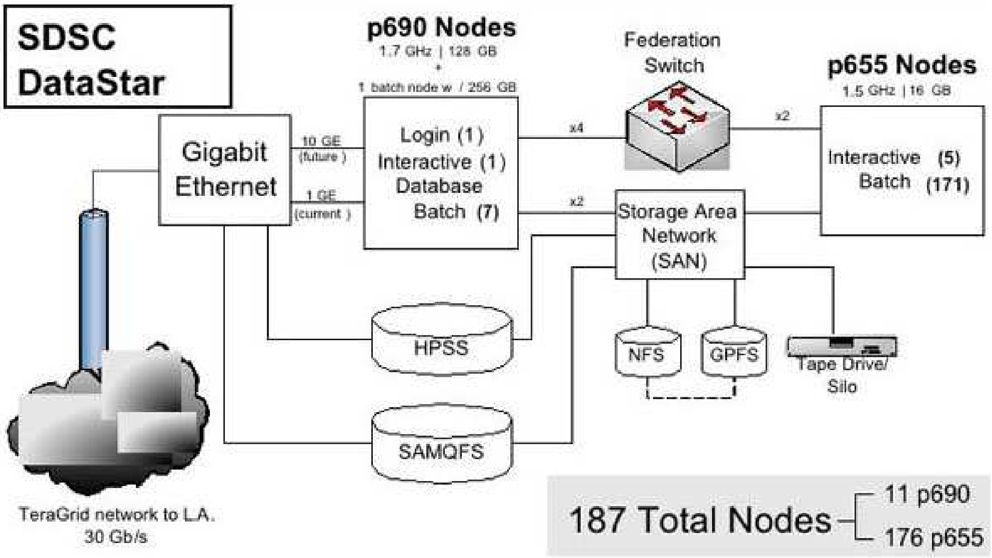

Figure 110.3: System Configuration of DataStar http://www.sdsc.edu/user_services/datastar/ (2020)

SDSC's TeraGrid cluster currently consists of 256 IBM cluster nodes, each with dual 1.5 GHz Intel Itanium 2 processors, for a peak performance of 3.1 teraflops. The nodes are equipped with four gigabytes (GBs) of physical memory per node. The cluster is running SuSE Linux and is using Myricom's Myrinet cluster interconnect network. Table 110.2 shows the technical configuration of the IA64 cluster, on which the second part of the performance study has been done.

110.4.3 Soil-Foundation Interaction Model

A soil-shallow-foundation interaction model as shown in Figure 110.4 has been set up to study the parallel performance. 3D brick element with 8 integration (Gaussian) points is used. The soil is modeled by Template3D elasto-plastic material model (Drucker-Prager model with Armstrong Frederick nonlinear kinematic hardening rule) and linear elasticity is assumed for the foundation. More advanced constitutive laws can be applied through Template3D model although the model used here suffices the purpose of this research to show repartitioning triggered by plastification. It is shown in this research that the speedup by adaptive load balancing is significant even for seemingly simple constitutive model. The material properties are shown in Table 110.3 and the vertical loading is applied at 5.0kN increments. The performance analysis has been carried out on DataStar supercomputer at San Diego Supercomputing Center (P655+ 8-way nodes).

Table 110.2: Technical Information of IA64 TeraGrid Cluster at SDSC

IA-64 Cluster (tg-login.sdsc.teragrid.org)	
COMPONENT	DESCRIPTION
Architecture	Linux Cluster
Access Nodes	⋆ quad-processor ⋆ ECC SDRAM memory: 8 GB ⋆ 2 nodes (8 processors)
Compute Nodes	⋆ dual-processor ⋆ ECC SDRAM memory: 4 GB ⋆ 262 nodes (524 processors)
Processor	⋆ Intel Itanium 2, 1.5 GHz ⋆ Integrated 6 MB L3 cache ⋆ Peak performance 3.1 Tflops
Network Interconnect	Myrinet 2000, Gigabit Ethernet, Fiber Channel
Disk	1.7 TB of NFS, 50 TB of GPFS (Parallel File System)
Operating System	Linux 2.4-SMP (SuSE SLES 8.0)
Compilers	⋆ Intel: Fortran77/90/95 C C++ ⋆ GNU: Fortran77 C C++
Batch System	Portable Batch System (PBS) with Catalina Scheduler

Table 110.3: Material Constants for Soil-Foundation Interaction Model

Soil

110.4.4 Numerical Study for ITR

As described in Section 110.3.3.2, the parameter ITR in ParMETIS describes the ratio between the time required for performing the inter-processor communications incurred during parallel processing compared to the time to perform the data redistribution associated with balancing the load. It acts like a switch on algorithmic approaches of ParMETIS repartitioning kernel. With ITR factor being very small, the ParMETIS tends to do that repartitioning which can minimize data redistribution cost. If the ITR factor is set to be very large, ParMETIS tends to minimize edge-cut of the final repartition.

In parallel design of PDD, if repartitioning is necessary to achieve load balance after each load increment, the whole AnalysisModel McKenna (1997) has to be wiped off thus a new analysis container can be defined to reload subsequent analysis steps. The data redistribution cost can be much higher than communication overhead only. In order to determine an adequate ITR value for our application, preliminary study needs to be performed to investigate the effectiveness of the URA. In this research, two extreme values of the ITR (0.001 and $1,000,000$) are prescribed and then parallel analysis is carried out on 2, 4 and 8 processors to see how the partition/repartition algorithm behaves. Two soil-structure interaction models as shown in Figure 110.6 have been used in this parametric study. Timing data and partition figures have been collected to investigate the performance of different approaches. The one that tends to bring better performance will be adopted in subsequent parallel analysis for prototype 3D soil structure interaction problems. Figure 110.7 to Figure 110.12 shows the initial partition and final repartition figures for two different types of algorithms. With ITR factor to be very small, the URA tends to present results that minimize data redistribution cost, in which diffusive repartitioning approach is used. On the other hand, if the ITR factor is set to be very large, then the URA algorithm tends to give repartitioning with lowest edge cut but with considerably higher data redistribution cost.

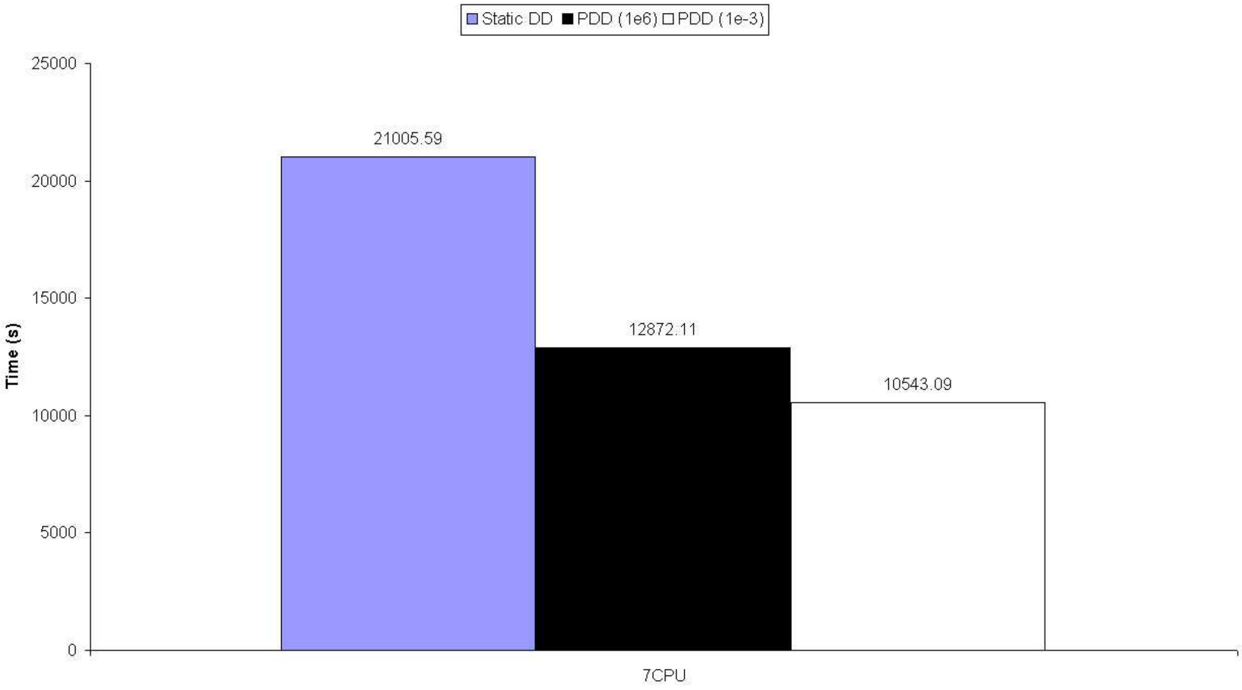

Figure 110.17: Timing Data of ITR Parametric Studies (4,938 Elements, 17,604 DOFs, Imbal. Tol. 5%)

Figures 110.15, 110.16 and 110.17 show the speedup data of parametric study on ITR factors. The purpose is to expose the the more efficient approach to do repartitioning for our specific parallel SFSI simulations, either scratch-remap approach ($ITR = 1e6$) or diffusive approach ($ITR = 1e-3$). Through the study of this chapter, some conclusions can be drawn.

1. Smaller value of ITR (1e-3) outperforms larger value (1e6). The performance gain is up to 22.1% for 7 processors. As the model gets larger, the speedup tends to get better.

2. With small ITR value, the URA algorithm tends to give results for diffusive partition/repartitioning scheme, which is good for performance for our application in overall due to the fact that the overhead associated with data redistribution in this research is very high. Diffusive approach minimizes possible data movement thus delivers better performance. The drawback is the diffusive approach typically gives very bad or even disconnected graphs with very high edge-cut as shown in Figures 110.7, 110.9 and 110.11. So careful attention must be paid to these graph structures when programing the finite element calculation. In this sense, the diffusive algorithm is not as robust as scratch/remapping. One very important observation was that repetitive repartitionings tend to yield totally ill-connected graph.

3. With large ITR value, the URA algorithm adopts the scratch/remapping scheme which inevitably introduce huge data redistribution cost. But this approach gives high quality graph and the integrity of original graph is well preserved as shown Figures 110.8, 110.10 and 110.12. This will be of great meaning for parallel finite element method based on substructure-type methods. Another important observation was, the scratch/remapping approach performed much more repartitionings than diffusive approach for same analysis. Repetitive repartitionings by scratch/remapping method tends to totally migrate all elements out of their initial partitioning and repartitioning never stops even though the computation is stabilized (in the sense of formation of plastic zones). This also explains in part why the diffusive approach can substantially outperform scratch/remapping.

4. Based on the timing analysis performed in this chapter, ITR=1e-3 is the best choice that brings substantially better performance over large ITR values. With the increase of number of processing units or the model size, the performance gain is more significant as shown in Figures 110.15, 110.16 and 110.17. Robustness of the diffusive approach has not caused much trouble in our application.

110.4.5 Parallel Performance Analysis

Timing routines have been implemented in PDD (MOSS and other used libraries, such as Template3DEP/NewTemplate3D to study the parallel performance. The preprocessing unit, like reading model data from file, has not been timed so the speed up here reflects only algorithmic gain by graph partitioning. In the current phase of this research, the equation solving problem has not been addressed yet. More meaningful perspective would be to consider performance gains by simply switching from plain graph partitioning to adaptive graph partitioning, which is also the basic aim of this research. As we can see from the results below, adaptive graph partitioning improves the overall performance of elasto-plastic finite element computations. The partitioning/repartitioning overhead has been minimized by using parallel partitioner.

As stated in previous sections of this chapter, there are a couple of key parameters that control performance of the adaptive load balancing algorithm. One is the ITR factor, and the other is the computational load imbalance tolerance.

1. ITR is the key parameter which determines the algorithmic approach of the adaptive load balancing scheme. Depending on different applications and network interconnections, this value can be set to very small (0.001) or very large (up to 1,000,000) and algorithm focus will be set to minimizing data redistribution or edge-cut respectively as explained in previous sections.
2. Computational Imbalance Load Tolerance is the other key factor affecting greatly the overall performance of the whole application codes. Basically speaking, with larger finite element model, the tolerance should be set higher due to the fact that data redistribution and subsequent analysis-restarting overhead can be substantially higher as the finite element model size increases.

The performance tunings on ITR factor tend to yield consistent results as stated previously that smaller ITR (0.001) brings better performance over large ITR values. Diffusive repartitioning algorithm outperforms scratch/remapping in our application.

While on the other hand, tuning on load imbalance studies has been more illusive. The first conclusion is that load imbalance tolerance larger than 5% was not able to work robustly as the size of finite element model increases in the application study of this chapter.

Detailed parametric studies have been performed on DataStar IBM Power4 and IA64 Intel clusters to indicate the effectiveness of the proposed adaptive PDD algorithm. Models with different sizes have been tested on various number of processors to show the scalability of computational performance. All results will be compared with static one-step Domain Decomposition approach to investigate the advantage of proposed PDD algorithm in nonlinear elastic-plastic finite element calculations.

In the following sections, timing data and partition/repartition figures will be presented and results will be discussed at the end of this chapter.

110.4.5.1 Soil-Foundation Model with 4,035 DOFs

The partition/repartition figures by PDD have been shown in Figure 110.18, 110.19, 110.20.

110.4.6 Algorithm Fine-Tuning

From performance analysis results in previous sections, it has been shown that adaptive graph partitioning algorithm based on element graph can improve overall load balance for nonlinear elastic-plastic finite element calculations. Speed up has been observed on example problems. While on the other hand, we can also see as the model size increases, the efficiency of proposed PDD algorithm dropped sharply as shown in Figures 110.33 and 110.34.

So the naive implementation of PDD does not work as expected. With load balancing, one expects that the performance of PDD should not be worse than the DD case. It otherwise implies that the PDD does not bring performance gain that can completely offset its own extra load balancing operations-related overheads.

In this chapter, more detailed algorithm fine-tuning has been performed to address the problems we had in previous sections of the naive PDD implementation.

In order to improve the overall efficiency of proposed PDD algorithm. we have to consider two levels of costs when one wishes to balance the computational load among processing units. One is the data communication cost, and the other one is finite element model regeneration overhead associated with specific application problems.

Currently the adaptive graph partitioning algorithm does not consider the fact that the network communication patterns might differ much among processing nodes. The single ITR value indicates the algorithmic approach of the graph partitioning algorithm, but the real communication performance has not been addressed in the implementation.

On the other hand, certain applications impose extra problem-dependent overhead to repartitioning operations. For example, whenever data communications happen, the finite element model has to be wiped off and regenerated. This is not inherent with the graph partitioning algorithm but still needs to be addressed in order to get the best performance. As observed in this chapter, model regeneration overhead increases when the finite element model becomes bigger.

In order to improve the overall performance of our application, we hope to consider both data communication and model regeneration cost and create a new strategy through which we can adaptively monitor the extra overheads to assure that load balancing operation can offset both costs.

This chapter will first investigate the effect of load balance tolerance on performance and then a new globally adaptive strategy will be proposed to handle both communication and model regeneration overhead. Speedup analysis have been done to show performance gains.

110.4.7 Fine Tuning on Load Imbalance Tolerance

If one finds out that the application-associated overhead (say, model regeneration cost) overwhelms when repartitioning happens, the most natural way to improve performance is to increase the load imbalance tolerance of the adaptive repartition routine. In this way, one hopes to increase the critical load imbalance that can trigger the balancing routine and so that the repartition counts can be reduced. As a result, model regeneration cost can do less harm to the overall performance.

This should rather viewed as a work-around and has not been effective in our application.

The tuning approach aims at improving efficiency of previous runs that failed showing speedup over static domain decomposition method. Shallow foundation model with 9,297 Elements, 32,091 DOFs has been chosen to study the effect of imbalance tolerance on parallel performance. Model setup has been the same as in previous sections.

Speedup analysis results have been shown in Figures 110.40, 110.41 and 110.42.

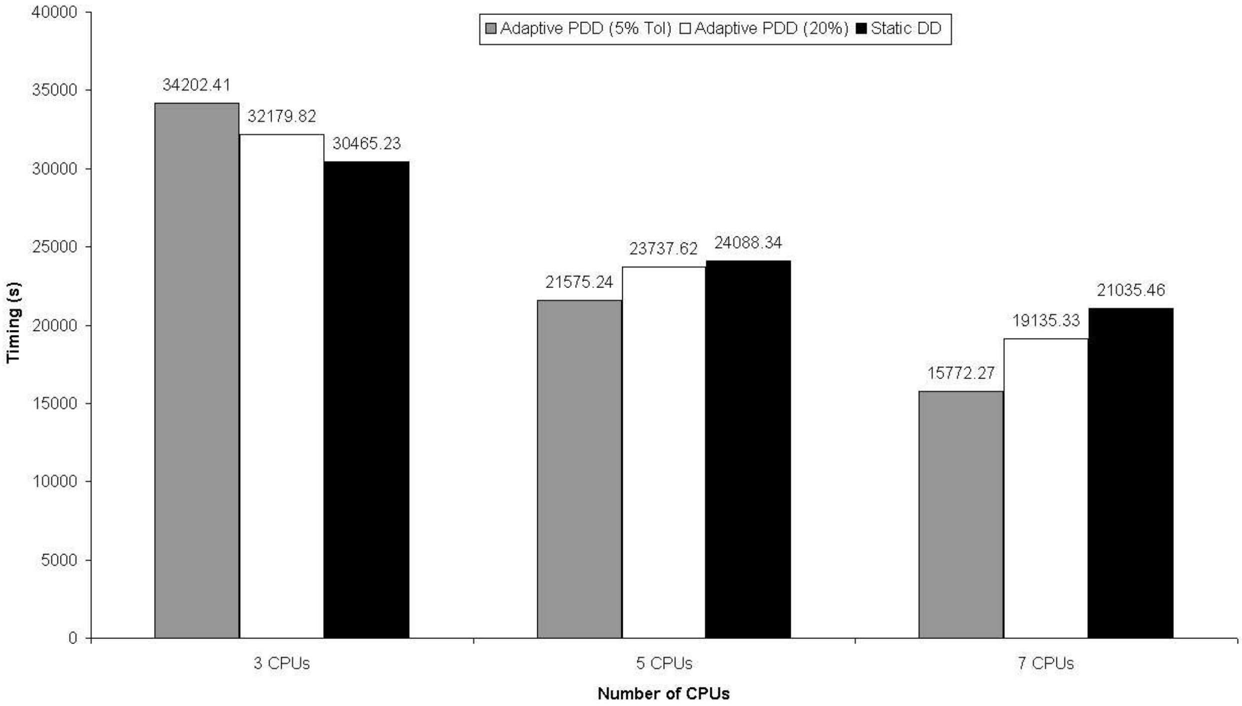

Figure 110.40: Timing Data of Parallel Runs on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 20%

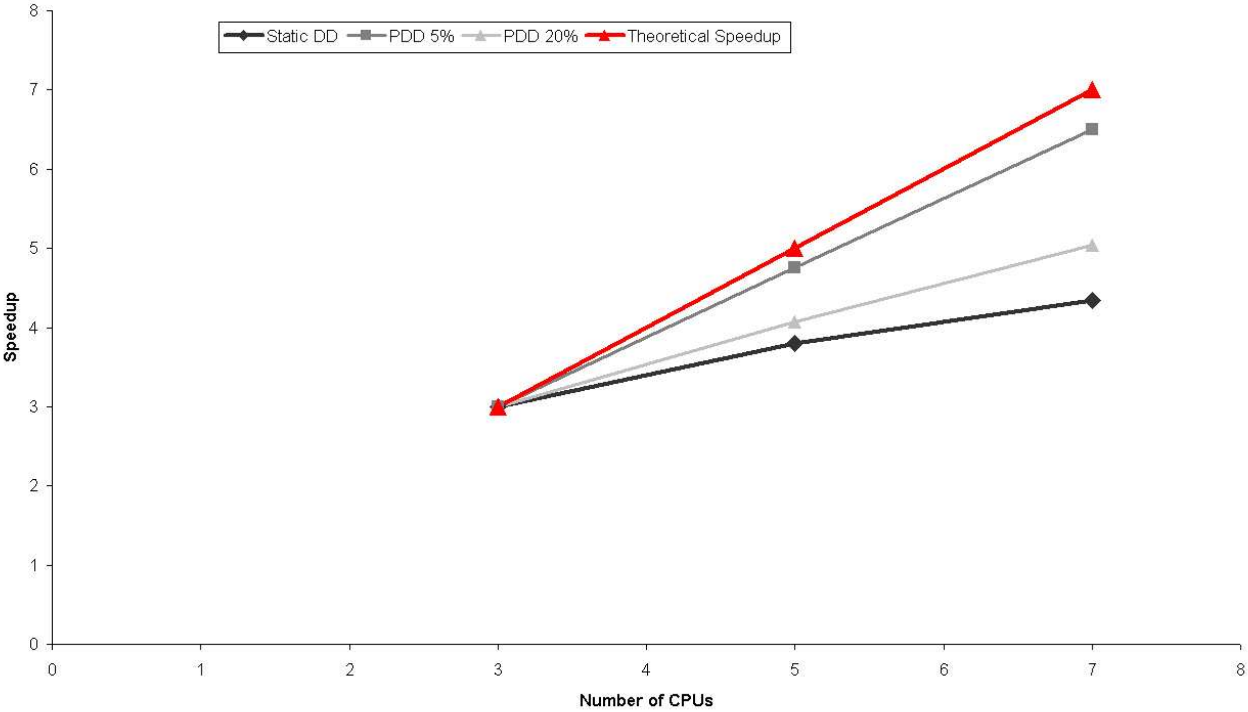

Figure 110.41: Absolute Speedup Data of Parallel Runs on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 20%

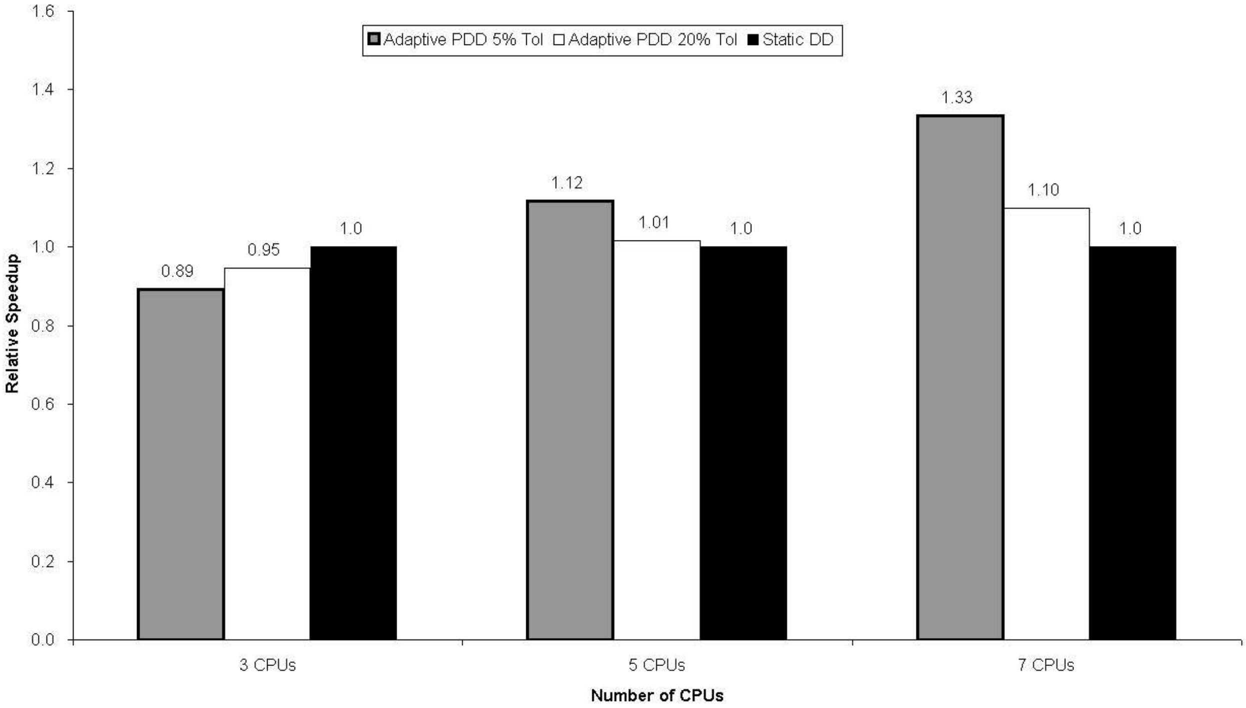

Figure 110.42: Relative Speedup of PDD over Static DD on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 20%

From the performance results, we can see that increasing load imbalance tolerance does not lead to efficiency for our application. As the number of processing units increases, the whole performance of application codes deteriorates. It is also important to note that the adaptive graph partitioning/repartitioning kernel in ParMETIS has not been capable of producing adequate partitions for finite element calculations when the load imbalance tolerance is larger than the recommended 5% Karypis et al. (2003). The application crushed with 20% imbalance tolerance for same models tested in previous sections.

The conclusion reached for the application in this chapter is that load imbalance tolerance larger than 5% has not been proved more efficient. This can also be explained in more details.

In the implementation of ParMETIS, load imbalance tolerance is one of the most important parameters in the sense that this value determines whether repartition will be switched on. The other equally significant implication of this value comes from the fact that it also establishes target load imbalance residual to be achieved after adaptive load balancing. That means for each repartition, the ParMETIS will only reduce the load imbalance to the provided tolerance.

In current implementation, the load imbalance tolerance is set to be the same for both switch-on and target values, which is not capable of bringing the best performance into our application due to the fact that aside from data redistribution cost, analysis model reconstruction is equally expensive. The dilemma is described by numerical example as shown in Table 110.5.

Table 110.5: Observation on Load Imbalance Tolerance %5

Model	20,476 Elements, 68,451 DOFs
CPUs	32
Imbalance Before	7.018%
Imbalance After	4.9%
Model Regeneration	57.2934 seconds
Total Step Time	140.961 seconds

We can easily see that tiny portion of data movement to balance out $7.018 - 4.9 = 2.228\%$ loads still invoked analysis model regeneration, which accounts for extra overhead that is about 40.6% of total step time.

Because the load balance tolerance is also the target value that the repartitioning operation hopes to achieve. The implication is that after repartitioning, the load distribution among processing units is barely under this acceptable tolerance. The performance study conducted so far showed that continuous plastification can easily creates load imbalance over this tolerance so another round of repartitioning would be launched again. It greatly brings down the performance of the whole application when the huge data redistribution overhead is taken just to overcome a tiny imbalance. This explains why changing the tolerance was not able to bring better performance in our application.

In order to improve performance while still minimizing load imbalance, we hope to maximize the efficiency of model regeneration routine in our application. This is a two-fold statement, firstly, we don't want to blindly increase the load imbalance because it basically claims we fail our adaptive PDD algorithm by not switching on repartitioning (5% is suggested by the author of ParMETIS Karypis et al. (2003) and has been proved to be the most stable value in this chapter), secondly, with each repartitioning, we hope to achieve "perfect balance" as much as possible and in this way, the huge model regeneration cost can be offset by performance gain. What was proposed as future extension of this chapter is the idea of dual load imbalance tolerances. Load balancing triggering tolerance and the target tolerance can be defined separately. We can set higher triggering tolerance to reduce the number of repartition counts, while on the other hand a strict target tolerance can be set close to 1.0 to get better load distribution out of the balancing routine. With proposed approach, our application in this chapter will be able to fully take advantage of the repartition routines without sacrificing too much on model regenerations.

110.4.8 Globally Adaptive PDD Algorithm

One significant drawback of current implementation is that neither network communication nor model regeneration cost has been considered in element-graph-based type domain decomposition algorithm. Element graph only records computational load carried by each element. Only one ITR factor characterizes algorithmic approach of the load balancing operation and this is apparently too crude for complicated network/hardware configurations. The ignorance of the repartitioning-associated overheads inherent with application codes can lead to serious performance drop of the proposed PDD algorithm as shown in Figure 110.43.

This drawback can harm the overall performance of the whole application code more seriously when the simulation is to be run on heterogeneous networks, which means we can have different network connections and nodes with varied computational power. The dilemma is, without exact monitoring of network communication and local model regeneration costs, we can easily sacrifice the performance gain by load balancing operations.

A second approach proposed in this chapter was the idea of modified Globally Adaptive PDD algorithm. The novelty comes from the fact that both data redistribution and analysis model regeneration costs will be monitored during execution. Load balancing will be triggered only when the performance gain necessarily offset the extra cost associated with the whole program. Domain graph structures will be kept intact till successful repartitioning happens. Meanwhile all elemental calculations will be timed to provide graph vertex weights. Data will be accumulated till algorithm restart happens, when all analysis

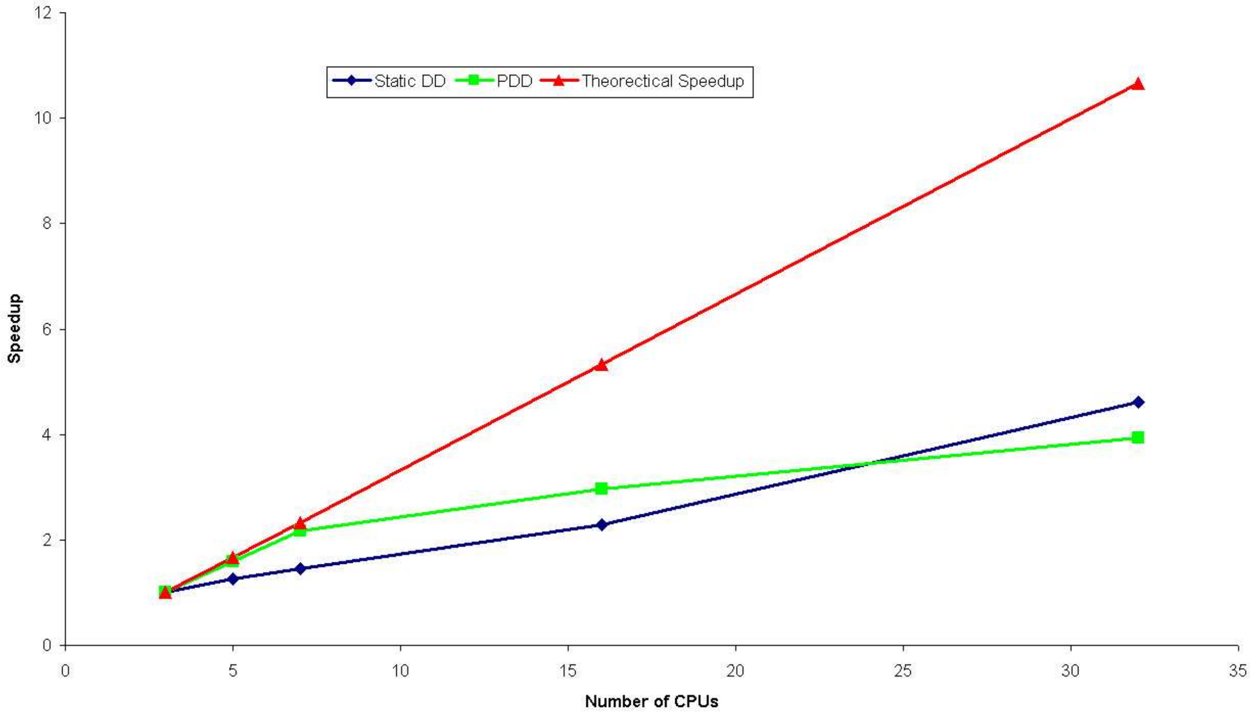

Figure 110.43: Absolute Speedup Data of Parallel Runs on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 5%

model and vertex weights will be nullified.

This improvement aims at handling network communication and any specific application-associated overheads automatically at the global level in order to remedy the drawback that the element graph repartitioning kernel currently supported by ParMETIS is not capable of directly reflecting this application level overheads. The new strategy is to automatically monitor network communication and local model regeneration timings which will be integrated to the entry of load balancing routines to act as additional triggers of the operation along with the load imbalance tolerance.

Performance study shows that PDD algorithm with the new additions significantly improve performance even when the number of processing units is large. This modification fixes the drawback shown in previous sections that the performance of PDD was beaten by static domain decomposition when the number of processors increases.

This strategy is called to be globally adaptive because both data communication and model regeneration costs are monitored at the application level, which tells best how the real application performs on all kinds of networks. Whatever the network/hardware configurations might be, real application runs always deliver the most accurate performance counters. This information can be applied on top of graph partitioning algorithm as a supplement to account for the drawback that the algorithm kernel is not capable of integrating global data communication costs.

110.4.8.1 Implementations

We can define the global overhead associated with load balancing operation as two parts, data communication cost T_{comm} and finite element model regeneration cost T_{regen},

$$T_{overhead} := T_{comm} + T_{regen} \tag{110.5}$$

Performance counters have been setup to study both.

- T_{comm}

  Data communication patterns characterizing the network configuration can be readily measured as the program runs the initial partitioning. As described in previous sections, initial domain decomposition needs to be done to send elements over to processing nodes. This step is necessary for parallel finite element processing and it provides perfect initial estimate how the communication pattern of the application performs on specific networks. Timing routines have been added to automatically measure the communication cost. This cost is inherently changing as the network condition might vary as simulation progresses, so whenever data redistribution happens, this metric will be automatically updated to reflect the network conditions.

- T_{regen}

  Model regeneration cost basically comes from the fact that if data redistribution happens, the analysis model needs to be regenerated to reflect changes of nodes and elements inside the domain. Detailed operations include renumbering DOFs and rehandling constraints. This part of cost is application-dependent. In current implementation of PDD, efforts have been made to set up timing stop at the entry and exit of model regeneration routines to get the accurate data for the extra overhead. It is also important to note that model regeneration happens when the initial data distribution finishes, again the initial domain decomposition phase provides perfect initial estimate of the model regeneration cost on any specific hardware configurations.

Naturally, for the load balancing operations to pay off, the $T_{overhead}$ has to be offset by the performance gain T_{gain}. This chapter also creates a strategy to estimate the performance gain T_{gain} even before the load balancing operation happens and this metric provides global control on top of the existing graph repartitioning algorithm.

As implemented in previous sections, the computational load on each element is represented by the associated vertex weight $vwgt[i]$. If the SUM operation is applied on every single processing node, the exact computational distribution among processors can be obtained as total wall clock time for each CPU as shown in Equation 110.6,

$$T_j := \sum_{i=1}^{n} vwgt[i],\ j = 1, 2, \ldots, np \tag{110.6}$$

in which n is the number of elements on each processing domain and np is the number of CPUs.

If we define,

$$T_{sum} := sum(T_j),\ T_{max} := max(T_j), \text{ and } T_{min} := min(T_j),\ j = 1, 2, \ldots, np \tag{110.7}$$

one always hope to minimize T_{max} because in parallel processing, T_{max} controls the total wall clock time. By load balancing operations, we mean to deliver evenly distributed computational loads among processors. So theoretically, the best execution time is,

$$T_{best} := T_{sum}/np, \text{ and } T_j \equiv T_{best},\ j = 1, 2, \ldots, np \tag{110.8}$$

if the perfect load balance is to be achieved.

Based on definitions above, the best performance gain T_{gain} one can obtain from load balancing operations can be calculated as,

$$T_{gain} := T_{max} - T_{best} \tag{110.9}$$

Finally, the load balancing operation will be beneficial IF AND ONLY IF

$$T_{gain} \geq T_{overhead} = T_{comm} + T_{regen} \tag{110.10}$$

110.4.8.2 Performance Results

The newly improved design has been compared to the old design to see the effectiveness of the globally adaptive switch of PDD algorithm.

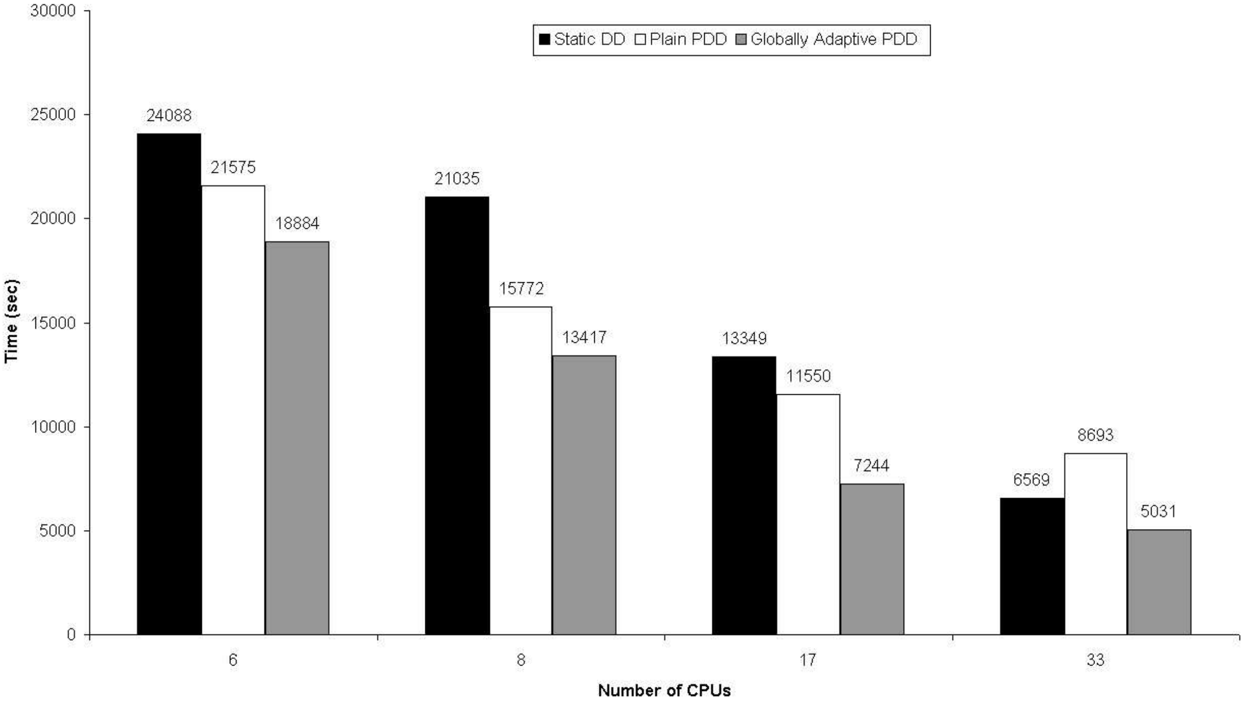

Figure 110.44: Performance of Globally Adaptive PDD on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 5%

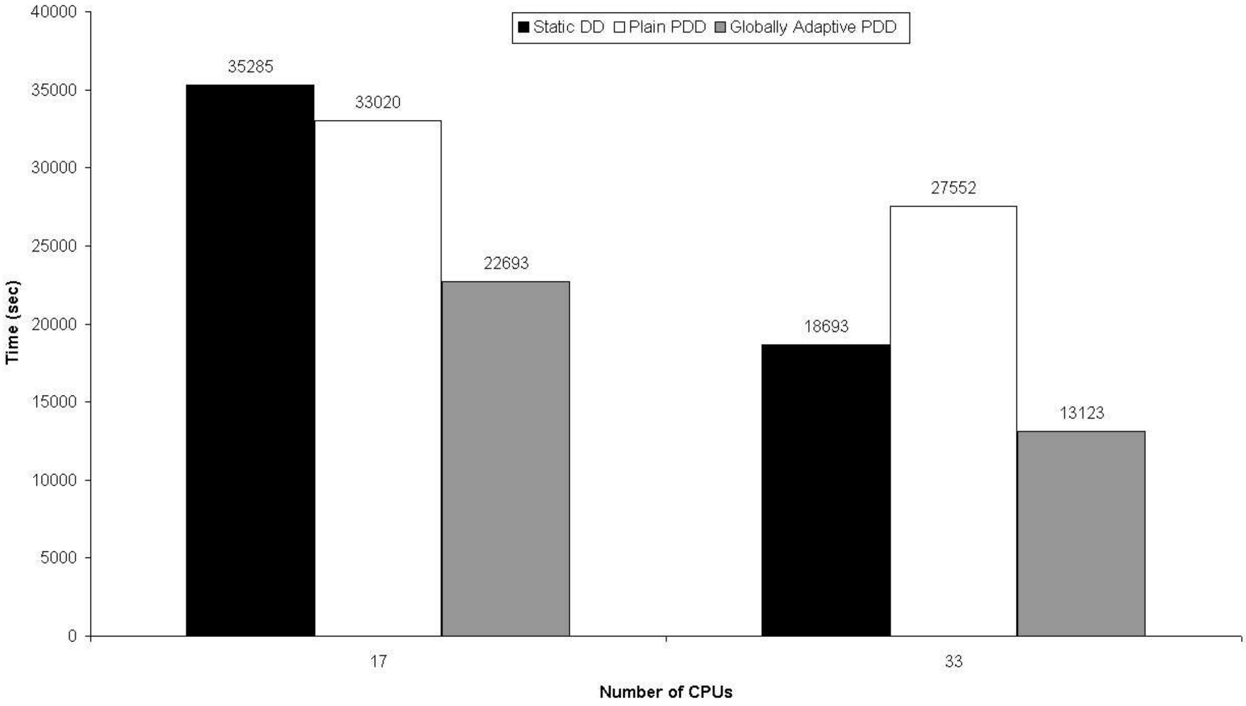

Figure 110.45: Performance of Globally Adaptive PDD on 20,476 Elements, 68,451 DOFs Model, ITR=1e-3, Imbal Tol 5%

From Figures 110.44 and 110.45, advantage of the improved globally adaptive PDD algorithm have clearly been shown. After considering the effect of both data communication and model regeneration costs, the adaptive PPD algorithm necessarily outperforms the static Domain Decomposition approach as expected. This new design also significantly improves the overall scalability of the proposed PDD algorithm as shown in Figure 110.46 and 110.47.

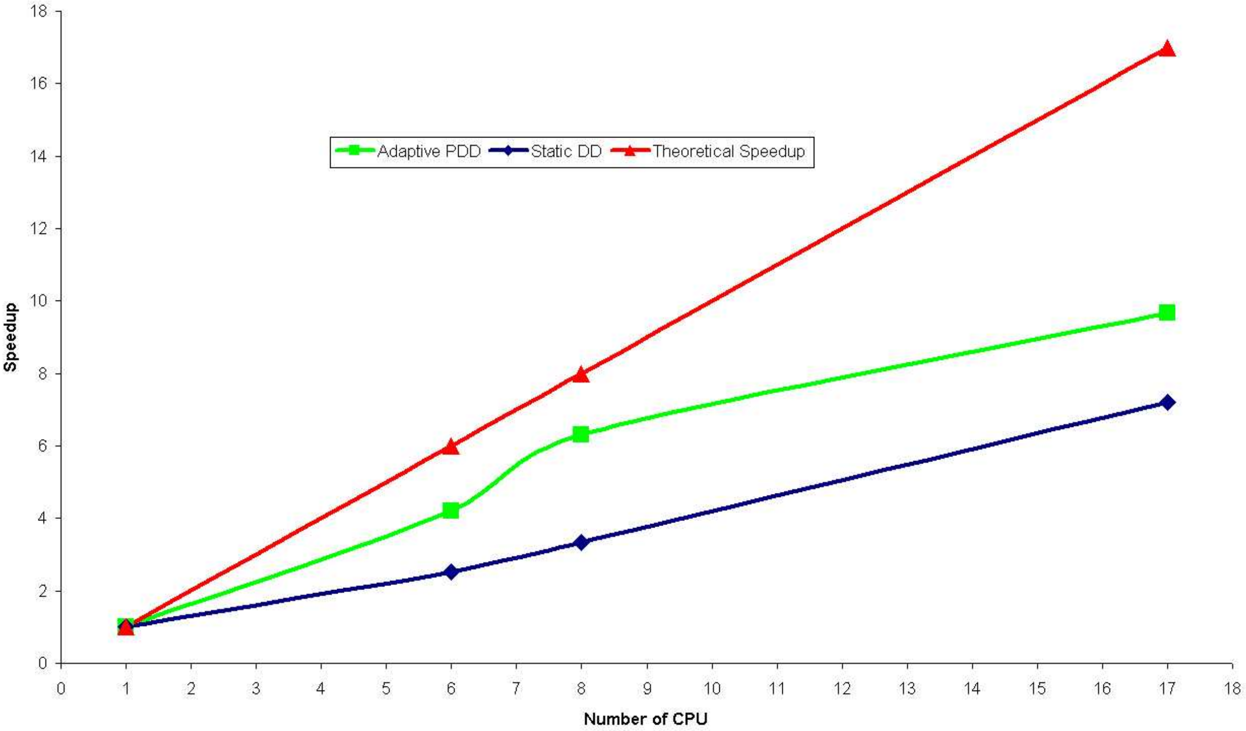

Figure 110.46: Scalability Study on 4,938 Elements, 17,604 DOFs Model, ITR=1e-3, Imbal Tol 5%

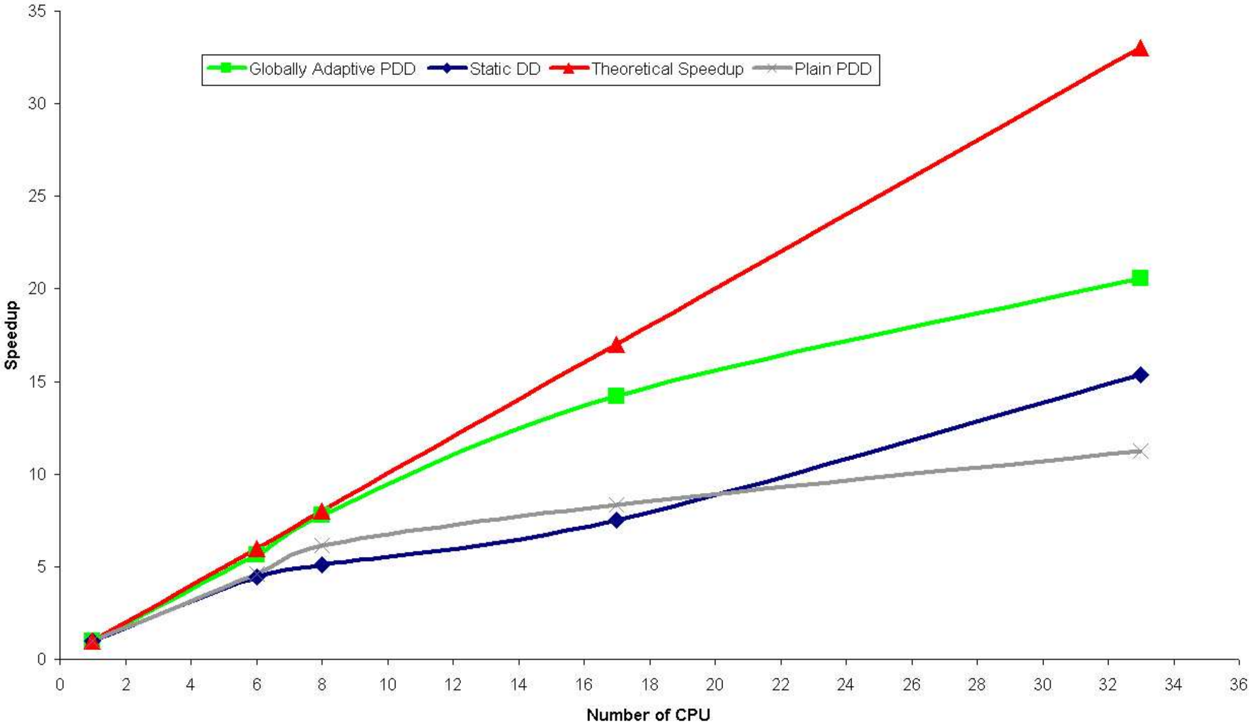

Figure 110.47: Scalability Study on 9,297 Elements, 32,091 DOFs Model, ITR=1e-3, Imbal Tol 5%

110.4.9 Scalability Study on Prototype Model

The ultimate purpose of this chapter is to develop an efficient parallel simulation tool for large scale earthquake analysis on prototype SFSI system. After in-depth development-refining process conducted in previous sections, real 3-bent production models have been set up to study the parallel performance of the proposed PDD algorithm using real world earthquake ground motions.

110.4.9.1 3 Bent SFSI Finite Element Models

As described in later sections, various sizes of a 3 bent bridge SFSI system has been developed to study dynamic behaviors of the whole system in different frequency domain. These models provide perfect test cases for parallel scalability study of our proposed PDD algorithm.

Detailed model description will be presented in later chapters of this chapter and only model size and mesh pictures are shown here to indicate the range of model sizes we have covered.

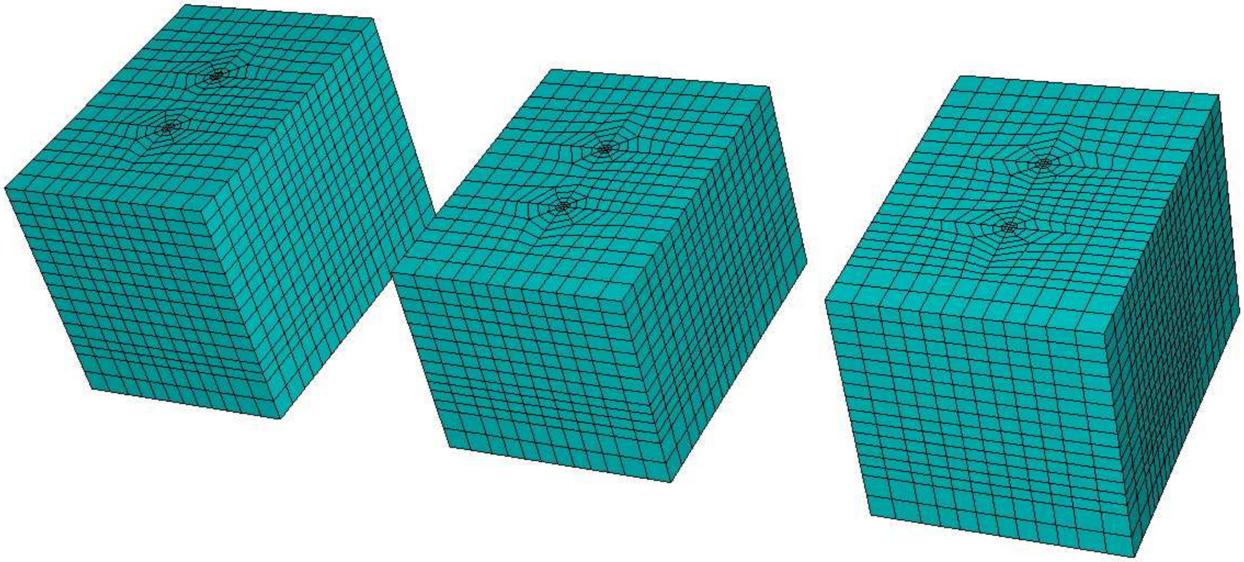

Figure 110.48: Finite Element Model - 3 Bent SFSI, 56,481 DOFs, 13,220 Elements, Frequency Cutoff > 3Hz, Element Size 0.9m, Minimum G/G_{max} 0.08, Maximum Shear Strain γ 1%

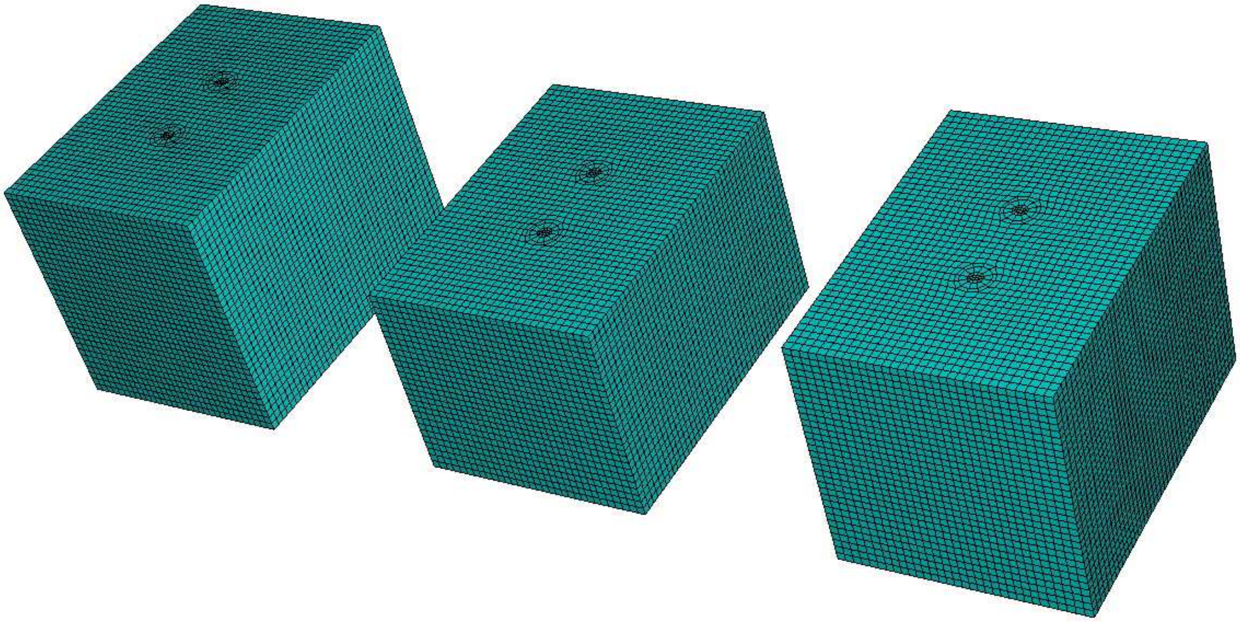

Figure 110.49: Finite Element Model - 3 Bent SFSI, 484,104 DOFs, 151,264 Elements, Frequency Cutoff 10Hz, Element Size 0.3m, Minimum G/G_{max} 0.08, Maximum Shear Strain γ 1%

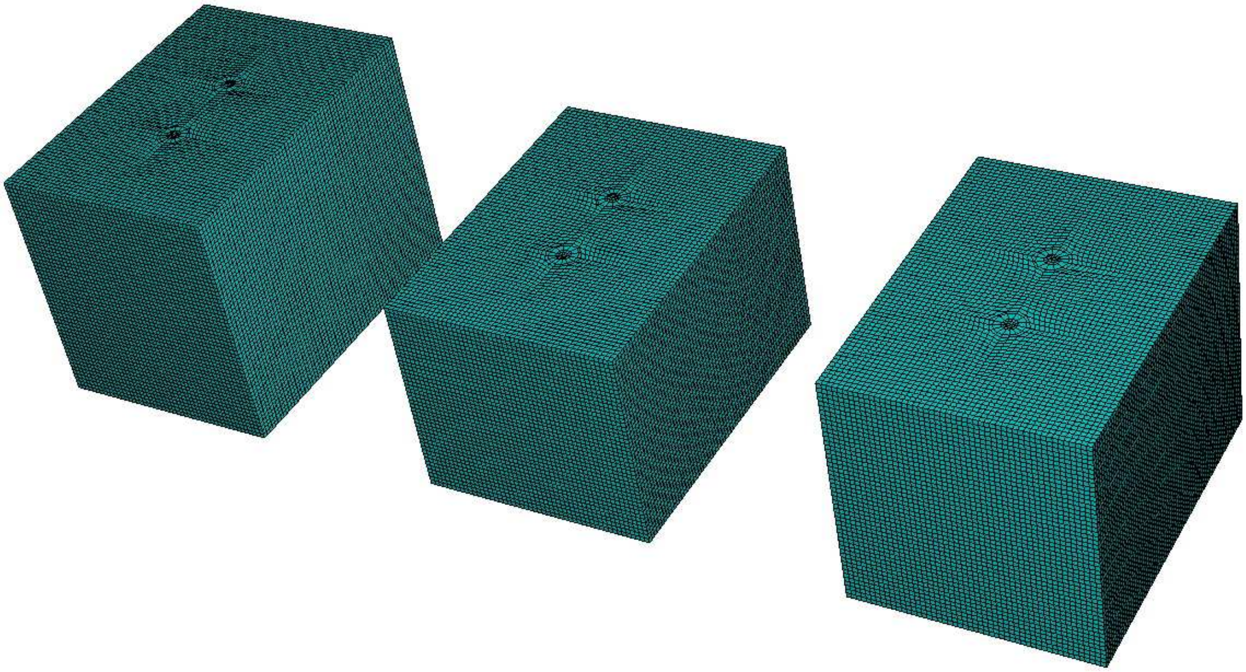

Figure 110.50: Finite Element Model - 3 Bent SFSI, 1,655,559 DOFs, 528,799 Elements, Frequency Cutoff 10Hz, Element Size 0.15m, Minimum G/G_{max} 0.02, Maximum Shear Strain γ 5%

110.4.9.2 Scalability Runs

The models with different detail levels have been subject to 1997 Northridge earthquake respectively for certain time steps and total wall clock time has been recorded to analyze the parallel scalability of our proposed PDD. The result is presented in Figure 110.51.

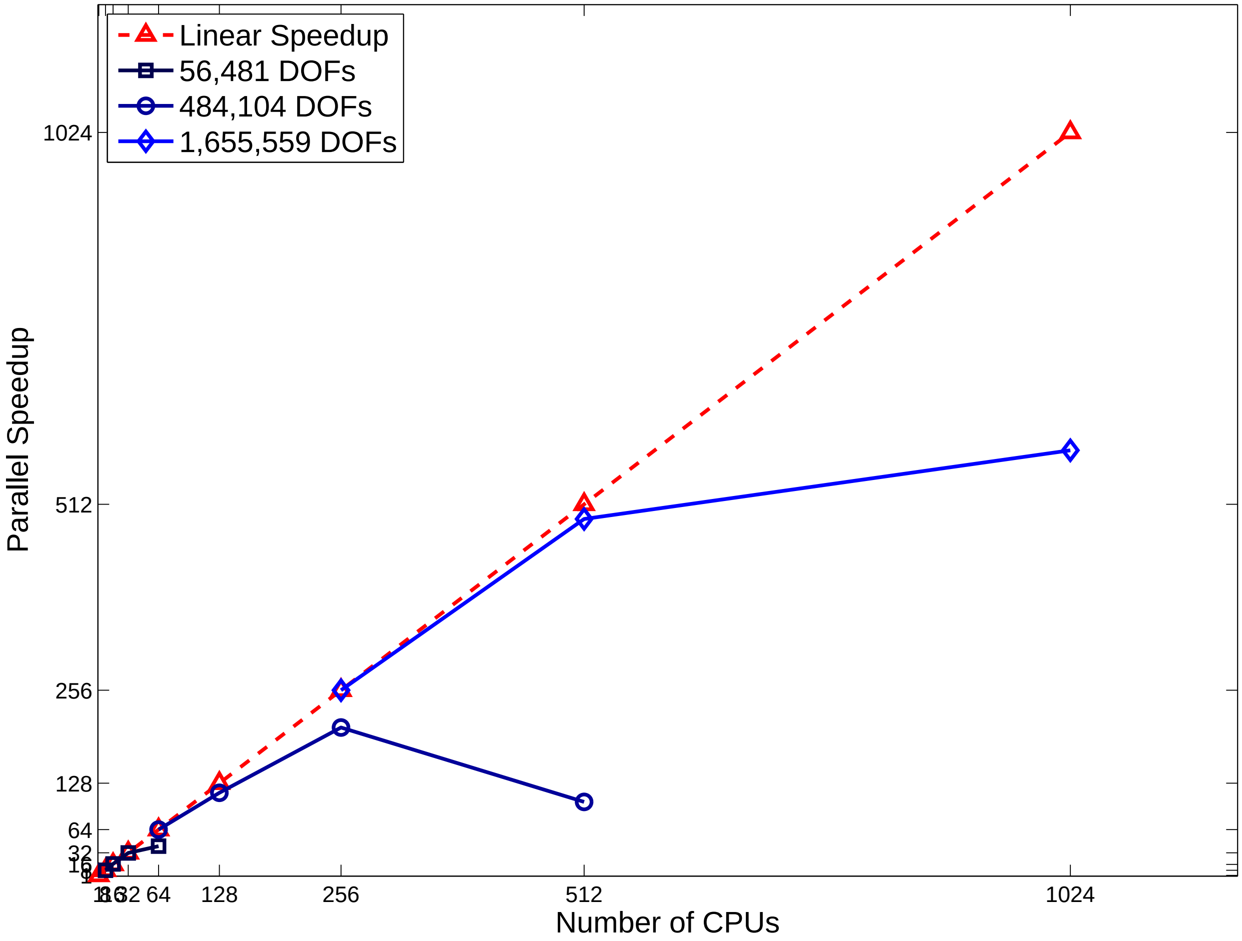

Figure 110.51: Scalability Study on 3 Bent SFSI Models, DRM Earthquake Loading, Transient Analysis, ITR=1e-3, Imbal Tol 5%, Performance Downgrade Due to Increasing Network Overhead

110.4.10 Conclusions

Through detailed performance studies as presented in previous sections, some conclusions can be drawn and future directions can be noted.

- Plastic Domain Decomposition (PDD) algorithm based on adaptive multilevel graph partitioning kernels has been shown to be effective for elastic-plastic parallel finite element calculations. PDD algorithm consistently outperforms classical Domain Decomposition method for models tested so far in this chapter as shown in Figures 110.52 and 110.54.

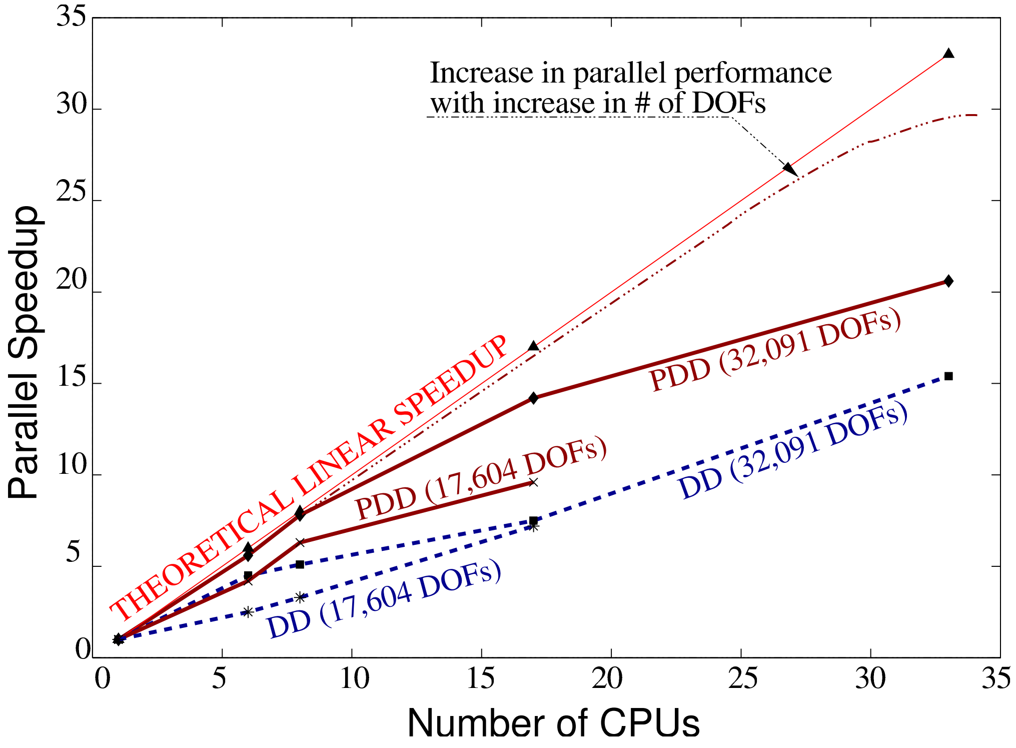

Figure 110.52: Relative Performance of PDD over DD, Shallow Foundation Model, Static Loading, ITR=1e-3, Imbal Tol 5%

- There are some parameters that can be calibrated in the current implementation. As indicated by results of thorough numerical tests, ITR=0.001 and load imbalance tolerance ubvec=1.05 (5%) should be adopted and studies on our application in this chapter have shown they are adequate and able to bring performance not worse than the commonly used domain decomposition method in parallel finite element analysis.

- For the parameters suggested in the chapter, we can see a general trend that the efficiency of PDD will drop as the number of processors increases. This can be explained. The implication of increasing processing units is that the subdomain problem size will decrease. It is naturally evident that the repartition load balancing won't be able to recover the overhead by balancing off small size local calculations. The improved design of globally adaptive PDD algorithm has been implemented in this chapter and both data communication and model regeneration costs associated with graph repartitioning have been integrated into the new globally adaptive strategy. With the new design, it has also been shown that the PDD algorithm consistently outperforms classic one step domain decomposition algorithm and better scalability can be obtained as shown in Figure 110.53. It has been shown that even for large number of processors, the current implementation can always guarantee that the performance of PDD is not worse than static DD method as shown in Figure 110.54. (the repartition routine has less than 5% overhead of the total wall clock time).

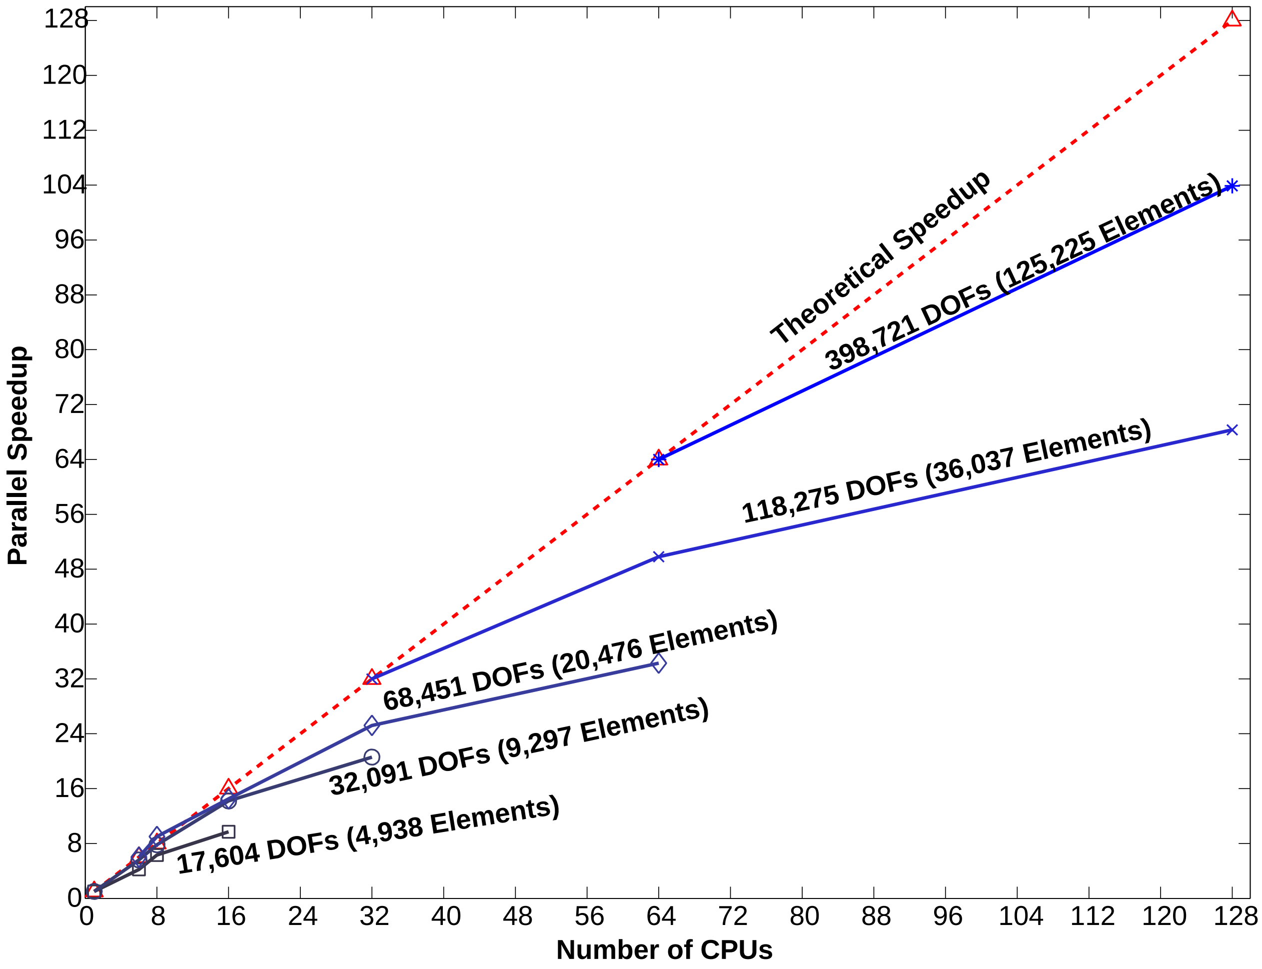

Figure 110.53: Scalability of PDD, Static Loading, Shallow Foundation Model, ITR=1e-3, Imbal Tol 5%

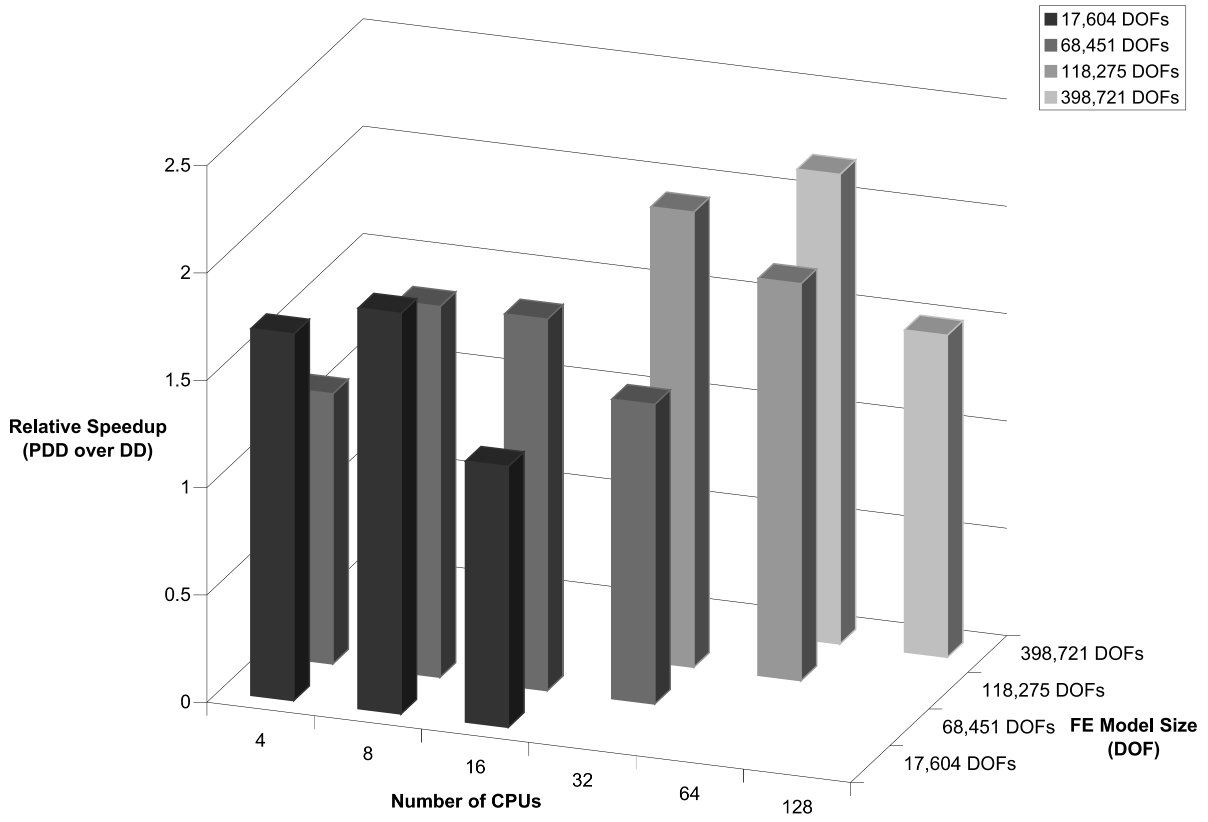

Figure 110.54: Relative Speedup of PDD over DD, Static Loading, Shallow Foundation Model, ITR=1e-3, Imbal Tol 5%

- If the problem size is fixed, there exists an optimum number of processors that can bring the best performance of the proposed load balancing algorithm. As the number of processing units increases after this number, the efficiency of proposed algorithm drops, which is understandable because the local load imbalance is so small overall that balancing gain won't offset the extra cost associated with repartitioning. But still the bottom line of proposed adaptive PDD algorithm is that it can run as fast as static one-step domain decomposition approach with less than 5% overhead of repartitioning routine calls. On the other hand, if the number of processing units is fixed, bigger finite element model will exhibit better performance. The conclusion is shown clearly in 3D in Figure 110.54.
- It is also worthwhile to point out that even without comparing with classical DD, PDD itself exhibits deteriorating performance as the number of processing units increases. Here the reproduction of Figure 110.53 is presented with some downside performance noted as shown in Figure 110.55.

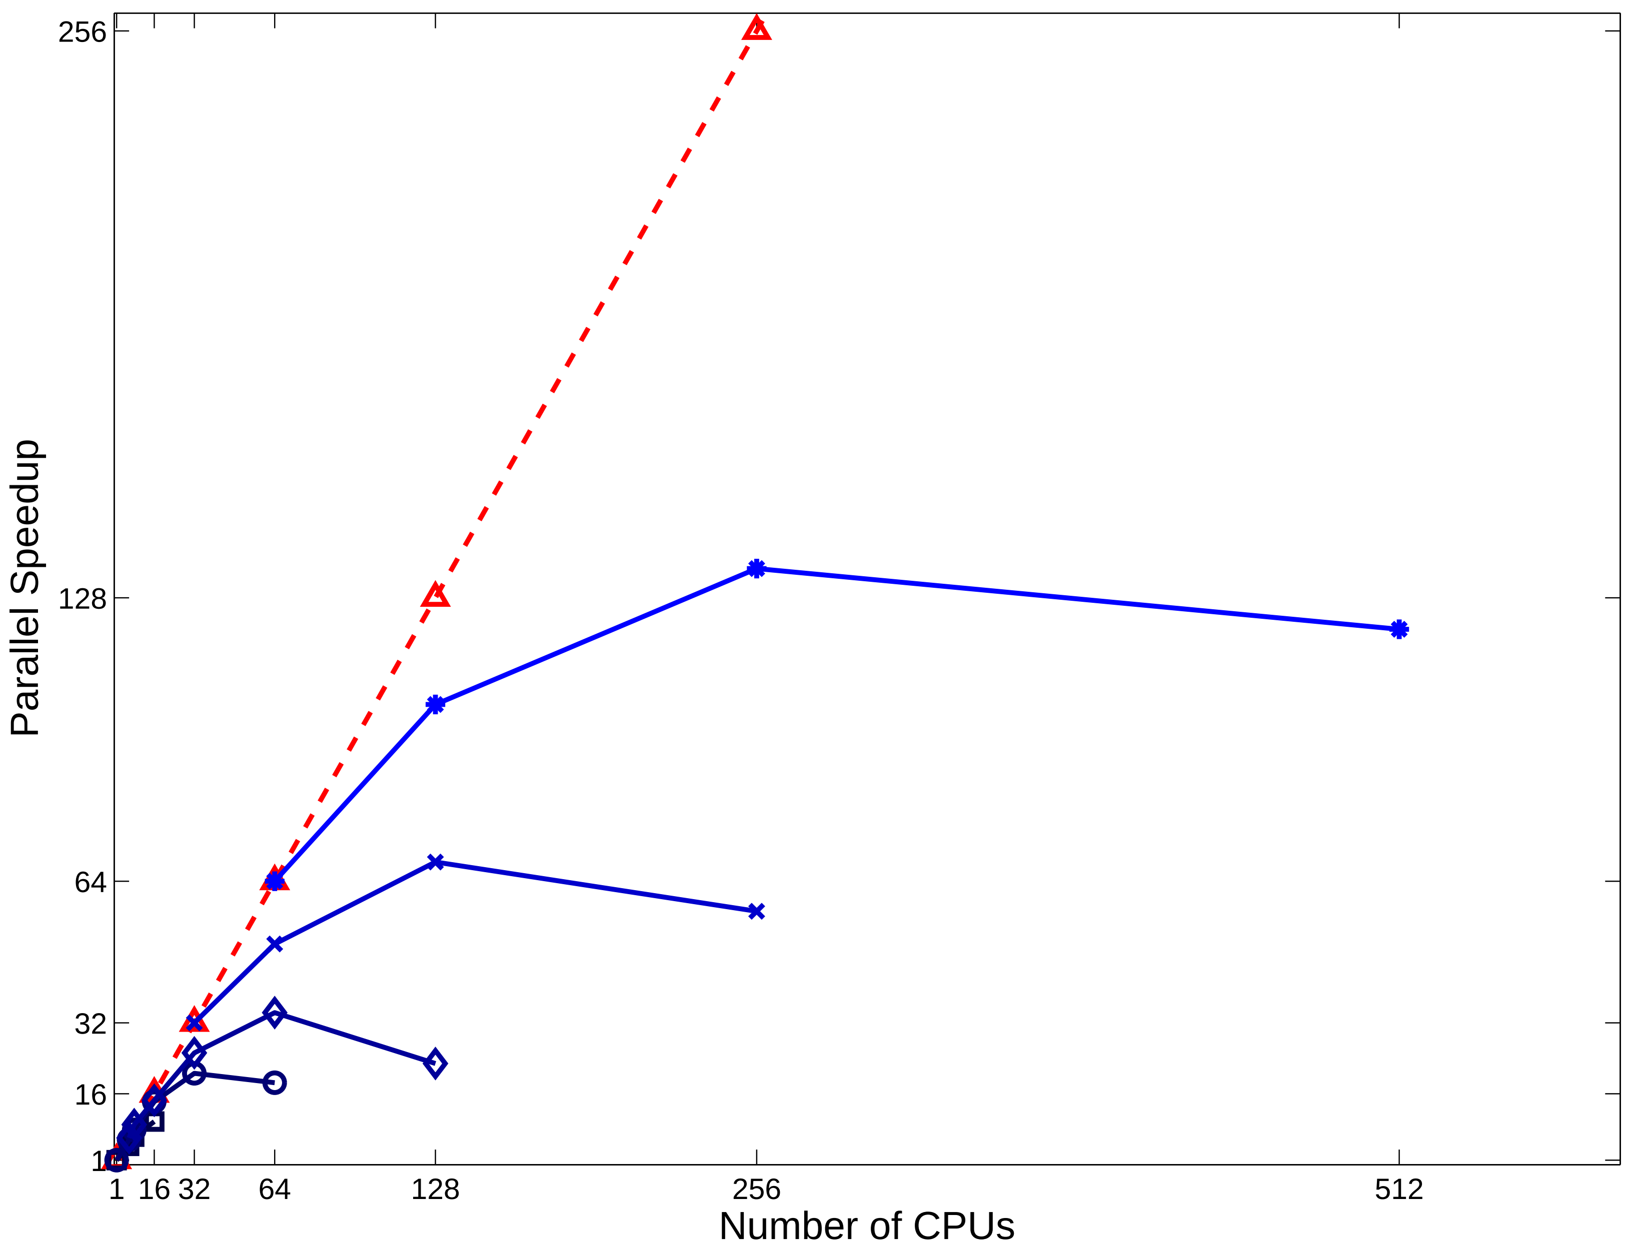

Figure 110.55: Full Range Scalability of PDD, Static Loading, Shallow Foundation Model, ITR=1e-3, Imbal Tol 5%, Performance Downgrade Due to Increasing Network Overhead

The implication is explained as follows:

- The performance drop partly is due to the communication overhead gets bigger and bigger so parallel processing will not be able to offset the communication loss.
- It is also noted that as the number of processing units increases, the elemental level calculation drops very scalably with the number of CPUs. This is inherently advantage of the proposed PDD algorithm. PDD through domain decomposition is very scalable for local level calculations because inherently local comp is element-based. when elements are distributed, loads are spread out evenly (during initial and redistribution). So as the number of CPU increases, the equation solving becomes more expensive.

  For the case of 56,481 DOFs prototype model with DRM earthquake loading, it has been observed that for sequential case (1 CPU), elemental computation takes 70% of time. As for parallel case (8 CPUs), we optimized parallel elemental computations through PDD, elemental computation only accounts for about 40%. As the number of CPU increases, parallel case (32 CPUs), the local level computation will only take less than 10% of total wall clock time.

  In other words, as the number of CPUs increases, PDD loses scalability because of the equation solving now dominates. As being discussed in Chapter 110.5, the parallel direct solver itself is not scalable up to large number of CPUs Demmel et al. (1999a). Parallel iterative solver is much more scalable but difficult to guarantee convergence. This is now also the most important topic in the whole scientific computing community.

For one set of fixed algorithm parameters, such as ITR and load imbalance tolerance, basic conclusion is there exists an optimal number of processors that can bring best performance and as finite element model size increases, this number increases as listed in Table 110.6.

Table 110.6: Best Performance Observed for ITR=0.001, Load Imbalance Tolerance %5

# of DOFs	Speedup	# of CPUs
4,035	1.553	4
17,604	1.992	7
32,091	1.334	7
68,451	1.068	16

The second point is related to the implementation of the multilevel graph partitioning algorithm. In current implementation of ParMETIS used in this chapter, vertex weight can only be specified as an int. That means in order to get timing data from local level calculation for each element, double data returned by MPI timing routine has to be converted to int. Significant digit loss can happen depending on what accuracy the system clock can carry. We can also adjust the vertex weight by amplifying the timing by scale factors in order to save effective digits. 10 millisecond has been used in this chapter to represent the effective timing digits when converting from double to int.

110.5 Application of Project-Based Iterative Methods in SFSI Problems

110.5.1 Introduction

Finite element method has been the most extensively used numerical method in computational mechanics. Equation solver is the numerical kernel of any finite element package. Gauss elimination type direct solver has dominated due to its robustness and predictability in performance.

As modern computer becomes more and more powerful, more advanced and detailed models need to be analyzed by numerical simulation. Direct solver is not the favorite choice for large scale finite element calculations because of high memory requirements and the inherent lack of parallelism of the method itself.

The motivation for presented work on iterative solvers stems from the need to expand the toolset of parallel iterative solvers for large scale simulation problems related to Earthquake-Soil-Structure interaction problems

In this section, the effectiveness of Krylov iterative methods has been tested in solving soil-structure interaction problems. Preconditioning techniques have been introduced. Robustness of iterative solvers has been investigated on equation systems from real soil-structure interaction problems. Several popular parallel algorithms and tools have been collected and implemented on PETSc platform to solve the SFSI problems. Performance study has been carried out using IA64 super computers at San Diego Supercomputing Center. A complete implementation has been developed within our computational system, within MOSS libraries, with extensive use of ParMETIS, and other material and numerical libraries.

110.5.2 Projection-Based Iterative Methods

Projection techniques are defined as methods to find approximate solutions $\hat{x}$ for $Ax = b$ ($A \in \mathcal{R}^{n \times n}$) in a subspace $\mathcal{W}$ of dimension m. Then in order to determine $\hat{x}$, we need m independent conditions. One way to obtain these is by requiring the residual $b - A\hat{x}$ is orthogonal to a subspace $\mathcal{V}$ of dimension m, i.e.,

$$\hat{x} \in \mathcal{W}, b - A\hat{x} \perp \mathcal{V} \tag{110.11}$$

The conditions shown in Equation 110.11 are known as Petrov-Galerkin conditions (Bai, 2007).

There are two key questions to answer if one wants to use projection techniques in solving large scale linear systems. Different answers lead to many variants of the projection method.

- Choice of Subspaces

  Krylov subspaces have been the favorite of most researchers and a large family of methods have been developed based on Krylov subspaces. Typically people choose either $\mathcal{V} = \mathcal{W}$ or $\mathcal{V} = A\mathcal{W}$ with $\mathcal{V}$ and $\mathcal{W}$ both Krylov subspaces.

- Enforcement of Petrov-Galerkin Conditions

  Arnoldi's procedure and Lanczos algorithm are two choices for building orthogonal or biorthogonal sequence to enforce the projection conditions.

The iterative methods discussed in this section are generally split into two categories, one based on Arnoldi's procedure and the other on Lanczos biorthoganalization. The most popular for the first family are Conjugate Gradient and General Minimum Residual methods, while Bi-Conjugate Gradient and Quasi-Minimum Residual methods represent the Lanczos family.

110.5.2.1 Conjugate Gradient Algorithm

The conjugate gradient (CG) algorithm is one of the best known iterative techniques for solving sparse symmetric positive definite (SPD) linear systems. This method is a realization of an orthogonal projection technique onto the Krylov subspace $\mathcal{K}_m(A, r_0)$, where r_0 is the initial residual. Because A is symmetry, some simplifications resulting from the three-term Lanczos recurrence will lead to more elegant algorithms (Demmel, 1997).

ALGORITHM CG (Saad, 2003)

```
1. Compute $r_0 := b - Ax_0$, $p_0 := r_0$
2. For $j = 0, 1, \cdots$, until convergence, Do
3.     $\alpha_j := (r_j, r_j)/(Ap_j, p_j)$
4.     $x_{j+1} := x_j + \alpha_j p_j$
5.     $r_{j+1} := r_j - \alpha_j Ap_j$
6.     $\beta_j := (r_{j+1}, r_{j+1})/(r_j, r_j)$
7.     $p_{j+1} := r_{j+1} + \beta_j p_j$
8. EndDo
```

- Applicability

  Matrix A is SPD.

- Subspaces

  Choose $\mathcal{W} = \mathcal{V} = \mathcal{K}_m(A, r_0)$, in which initial residual $r_0 = b - Ax_0$.

- Symmetric Lanczos Procedure

  This procedure can be viewed as a simplification of the Arnoldi's procedure when A is symmetric. Great three-term Lanczos recurrence is discovered when the symmetry of A is considered (Demmel, 1997).

- Optimality

  If A is SPD and one chooses $\mathcal{W} = \mathcal{V}$, enforcing Petrov-Galerkin conditions minimizes the A-norm of the error over all vectors $x \in \mathcal{W}$, i.e., $\hat{x}$ solves the problem,

  $$\min_{x \in \mathcal{W}} \|x - x^*\|_A, x^* = A^{-1}b \tag{110.12}$$

  From the lemma above, one can derive global minimization property of the Conjugate Gradient method. The vector x_k in the Conjugate Gradient method solves the minimization problem

  $$\min_x \phi(x) = \frac{1}{2}\|x - x^*\|_A^2, x - x_0 \in \mathcal{K}_k(A, r_0) \tag{110.13}$$

- Convergence

  In exact arithmetic, the Conjugate Gradient method will produce the exact solution to the linear system $Ax = b$ in at most n steps and it owns the superlinear convergence rate. The behavior of Conjugate Gradient algorithm in finite precision is much more complex. Due to rounding errors, orthogonality is lost quickly and finite termination does not hold anymore. What is more meaningful in application problems would be to use CG method for solving large, sparse, well-conditioned linear systems in far fewer than n iterations.

110.5.2.2 GMRES

The Generalized Minimum Residual method is able to deal with more general type of matrices.

ALGORITHM GMRES (Saad, 2003)

```
1. Compute $r_0 := b - Ax_0$, $\beta := \|r_0\|_2$, and $v_1 := r_0/\beta$
2. For $j = 1, 2, \cdots, m$, Do
3.         Compute $\omega_j := Av_j$
4.         For $i = 1, \cdots, j$, Do
5.             $h_{ij} := (\omega_j, v_i)$
6.             $\omega_j := \omega_j - h_{ij} v_i$
7.         EndDo
8.         $h_{j+1,j} = \|\omega_j\|_2$. If $h_{j+1,j} = 0$ set $m := j$ and go to 11
9.         $v_{j+1} = \omega_j / h_{j+1,j}$
10. EndDo
11. Define the $(m+1) \times m$ Hessenberg matrix $\bar{H}_m = \{h_{ij}\}_{1 \le i \le m+1, 1 \le j \le m}$
12. Compute $y_m$, the minimizer of $\|\beta_i e_1 - \bar{H}_m y\|_2$, and $x_m = x_0 + V_m y_m$
```

- Applicability

  Matrix A is nonsingular.

- Subspaces

  Choose $\mathcal{W} = \mathcal{K}_m(A, r_0)$ and $\mathcal{V} = A\mathcal{W} = A\mathcal{K}_m(A, r_0)$, in which initial residual $r_0 = b - Ax_0$.

- Arnoldi's Procedure

  Classic Arnoldi's procedure (modified Gram-Schmidt) is followed in GMRES (Bai, 2007).

- Optimality

  If one chooses $\mathcal{V} = A\mathcal{W}$, enforcing Petrov-Galerkin conditions solves the least square problem

$$\|b - A\tilde{x}\|_2 = \min_{x \in \mathcal{W}} \|b - Ax\|_2 \tag{110.14}$$

- Convergence

  It has been shown that in exact arithmetic, GMRES can not breakdown and will give exact solutions in at most n steps. In practice, the maximum steps GMRES can run depends on the memory due to the fact it needs to store all Arnoldi vectors. Restarting schemes have been proposed for a fixed m, which is denoted by GMRES(m). Typical value for m can be $m \in [5, 20]$. GMRES(m) can not breakdown in exact arithmetic before the exact solution has been reached. But it may never converge for $m < n$ (Bai, 2007).

110.5.2.3 BiCGStab and QMR

These two methods are based on nonsymmetric Lanczos procedure, which is quite different from Arnoldi's in the sense that it formulates biorthogonal instead of orthogonal sequence. They are counterparts of CG and GMRES method, which follows similar derivation procedure except the Lanczos biorthogonalization is used instead of Arnoldi's procedure (Bai, 2007).

110.5.3 Preconditioning Techniques

Lack of robustness is a widely recognized weakness of iterative solvers relative to direct solvers. Using preconditioning techniques can greatly improve the efficiency and robustness of iterative methods. Preconditioning is simply a means of transforming the original linear system into one with the same solution but easier to solve with an iterative solver. Generally speaking, the reliability of iterative techniques, when dealing with various applications, depends much more on the quality of the preconditioner than on the particular Krylov subspace accelerator used.

The first step in preconditioning is to find a preconditioning matrix M. The matrix M can be defined in many different ways but there are a few minimal requirements the M is supposed to satisfy (Benzi, 2002).

1. From practical point of view, the most important requirement of M is that it should be inexpensive to solve linear system $Mx = b$. This is because the preconditioned algorithm will all require a linear system solution with the matrix M at each step.
2. The matrix M should be somehow close to A and it should not be singular. We can see that actually most powerful preconditioners are constructed directly from A.
3. The preconditioned $M^{-1}A$ should be well-conditioned or has very few extreme eigenvalues thus M can accelerate convergence dramatically.

Once a preconditioner M is available, there are three ways to apply it.

1. Left Preconditioning

$$M^{-1}Ax = M^{-1}b \tag{110.15}$$

2. Right Preconditioning

$$AM^{-1}u = b, x \equiv M^{-1}u \tag{110.16}$$

3. Split Preconditioning

   It is a very common situation that M is available in factored form $M = M_L M_R$, in which, typically, M_L and M_R are triangular matrices. Then the preconditioning can be split,

$$M_L^{-1} A M_R^{-1} u = b, x \equiv M_R^{-1} u \tag{110.17}$$

   It is imperative to preserve symmetry when the original matrix A is symmetric, so the split preconditioner seems mandatory in this case.

Consider that a matrix A that is symmetric and positive definite and assume that a preconditioner M is available. The preconditioner M is a matrix that approximates A in some yet-undefined sense. We normally require that the M is also symmetric positive definite.

In order to preserve the nice SPD property, in the case when M is available in the form of an incomplete Cholesky factorization, $M = LL^T$, people can simply just use the split preconditioning, which yields the SPD matrix

$$L^{-1} A L^{-T} u = L^{-1} b, x \equiv L^{-T} u \tag{110.18}$$

However, it is not necessary to split the preconditioner in this manner in order to preserve symmetry. Observe that $M^{-1}A$ is self-adjoint for the M inner product

$$(x, y)_M \equiv (Mx, y) = (x, My) \tag{110.19}$$

since

$$(M^{-1}Ax, y)_M = (Ax, y) = (x, Ay) = (x, M(M^{-1}A)y) = (x, M^{-1}Ay)_M \tag{110.20}$$

Therefore, an alternative is to replace the usual Euclidean inner product in the CG algorithm with the M inner product (Saad, 2003).

If the CG algorithm is rewritten for this new inner product, denoting by $r_j = b - Ax_j$ the original residual and by $z_j = M^{-1} r_j$ the residual for the preconditioned system, the following sequence of operations is obtained, ignoring the initial step:

1. $\alpha_j := (z_j, z_j)_M / (M^{-1}Ap_j, p_j)_M$,

2. $x_{j+1} := x_j + \alpha_j p_j$,

3. $r_{j+1} := r_j - \alpha_j A p_j$ and $z_{j+1} := M^{-1} r_{j+1}$,

4. $\beta_j := (z_{j+1}, z_{j+1})_M / (z_j, z_j)_M$,

5. $p_{j+1} := z_{j+1} + \beta_j p_j$.

Since $(z_j, z_j)_M = (r_j, z_j)$ and $(M^{-1}Ap_j, p_j)_M = (Ap_j, p_j)$, the M inner products do not have to be computed explicitly. With this observation, the following algorithm is obtained.

ALGORITHM Preconditioned CG (Saad, 2003)

```
1. Compute $r_0 := b - Ax_0$, $z_0 := M^{-1}r_0$, $p_0 := z_0$
2. For $j = 0, 1, \cdots$, until convergence, Do
3.     $\alpha_j := (r_j, z_j)/(Ap_j, p_j)$
4.     $x_{j+1} := x_j + \alpha_j p_j$
5.     $r_{j+1} := r_j - \alpha_j Ap_j$
6.     $z_{j+1} := M^{-1}r_{j+1}$
7.     $\beta_j := (r_{j+1}, z_{j+1})/(r_j, z_j)$
8.     $p_{j+1} := z_{j+1} + \beta_j p_j$
9. EndDo
```

110.5.4 Preconditioners

Finding a good preconditioner to solve a given sparse linear system is often viewed as a combination of art and science. Theoretical results are rare and some methods work surprisingly well, often despite expectations. As it is mentioned before, the preconditioner M is always close to A in some undefined-yet sense. Some popular preconditioners will be introduced in this section.

110.5.4.1 Jacobi Preconditioner

This might be the simplest preconditioner people can think of. If A has widely varying diagonal entries, we may just use diagonal preconditioner $M = \text{diag}(a_{11}, \cdots, a_{nn})$. One can show that among all possible diagonal preconditoners, this choice reduces the condition number of $M^{-1}A$ to within a factor of n of its minimum value.

110.5.4.2 Incomplete Cholesky Preconditioner

Another simple way of defining a preconditioner that is close to A is to perform an incomplete Cholesky factorization of A. Incomplete factorization formulates an approximation of $A \approx \hat{L}\hat{L}^T$, but with less or no fill-ins relative to the complete factorization $A = LL^T$ (Demmel, 1997).

ALGORITHM Incomplete Cholesky Factorization (Saad, 2003)

```
1. For $j = 1, 2, \cdots, n$, Do
3.         $l_{jj} := \sqrt{a_{jj} - \sum_{k=1}^{j-1} l_{jk}^2}$
4.         For $i = j + 1, \cdots, n$, Do
5.               $l_{ij} = (a_{ij} - \sum_{k=1}^{j-1} l_{ik} l_{jk}) / l_{jj}$
6.               Apply dropping rule to $l_{ij}$
7.         EndDo
8. EndDo
```

There are many ways to control the number of fill-ins in IC factorization. No fill-in version of incomplete Cholesky factorization IC(0) is rather easy and inexpensive to compute. On the other hand, it often leads to a very crude approximation of A, which may result in the Krylov subspace accelerator requiring too many iterations to converge. To remedy this, several alternative incomplete factorizations have been developed by researchers by allowing more fill-in in L, such as incomplete Cholesky factorization with dropping threshold IC(ϵ). In general, more accurate IC factorizations require fewer iterations to converge, but the preprocessing cost to compute the factors is higher.

110.5.4.3 Robust Incomplete Factorization

Incomplete factorization preconditioners are quite effective for many application problems but special care must be taken in order to avoid breakdowns due to the occurrence of non-positive pivots during the incomplete factorization process.

The existence of an incomplete factorization $A \approx \hat{L}\hat{L}^T$ has been established for certain classes of matrices. For the class of M-matrices, the existence of incomplete Cholesky factorization was proved for arbitrary choices of the sparsity pattern (Meijerink and van der Vorst, 1977). The existence result was extended shortly thereafter to a somewhat larger class (that of H-matrices with positive diagonal entries) (Manteuffel, 1980; Varga et al., 1980; Robert, 1982). Benzi and Tůma (2003) presents reviews on the topic of searching for robust incomplete factorization algorithms and an robust algorithm based on A-Orthogonalization has been proposed.

In order to construct triangular factorization of A, the well-known is not the only choice. Benzi and Tůma (2003) shows how the factorization $A = LDL^T$ (root-free factorization) can be obtained by means of an A-orthogonalization process applied to the unit basis vectors $e_1, e_2, \cdots, e_n$. This is simply the Gram-Schmidt process with respect to the inner product generated by the SPD matrix A. This idea is not new and as a matter of fact, it was originally proposed at as early as 1940's in Fox et al. (1948). It has been observed in Hestenes and Stiefel (1952) that A-orthogonalization of the unit basis vectors is closely related to Gaussian elimination but this algorithm costs twice as much as the Cholesky factorization in the dense case.

Factored Approximate Inverse Preconditioner In reference Benzi et al. (1996) A-orthogonalization has been exploited to construct factored sparse approximate inverse preconditioners noting the fact that A-orthogonalization also produces the inverse factorization $A^{-1} = ZD^{-1}Z^T$ (with Z unit upper triangular and D diagonal). Because the A-orthogonaliza-tion, even when performed incompletely, is not subject to pivot breakdowns, these preconditioners are reliable (Benzi et al., 2000). However, they are often less effective than incomplete Cholesky preconditioning at reducing the number of PCG iterations and their main interest stems from the fact that the preconditioning operation can be applied easily in parallel because triangular solve is not necessary in approximate inverse preconditioning.

Reference Benzi and Tůma (2003) investigates the use of A-orthogonalization as a way to compute an incomplete factorization of A rather than A^{-1} thus a reliable preconditioning algorithm can be developed. The basic A-orthogonalization procedure can be written as follows (Benzi et al., 2000).

ALGORITHM Incomplete Factored Approximate Inverse (Benzi et al., 1996)

```
1.  Let $z_i^{(0)} = e_i$, for $i = 1, 2, \cdots, n$
2.  For $i = 1, 2, \cdots, n$, Do
3.        For $j = i, i+1, \cdots, n$, Do
4.              $p_j^{(i-1)} := a_i^T z_j^{(i-1)}$
5.        EndDo
6.        For $j = i+1, \cdots, n$, Do
7.              $z_j^{(i)} := z_j^{(i-1)} - (\frac{p_j^{(i-1)}}{p_i^{(i-1)}})$
8.              Apply dropping to $z_j^{(i)}$
9.        EndDo
10. EndDo
11. Let $z_i := z_i^{(i-1)}$ and $p_i := p_i^{(i-1)}$, for $i = 1, 2, \cdots, n$.
12. Return $Z = [z_1, z_2, \cdots, z_n]$ and $D = diag(p_1, p_2, \cdots, p_n)$.
```

The basic algorithm described above can suffer a breakdown when a negative or zero value of a pivot p_i. When no dropping is applied, $p_i = z_i^T A z_i > 0$. The incomplete procedure is well defined, i.e., no breakdown can occur, if A is an H-matrix (in the absence of round-off). In the general case, breakdowns can occur. Breakdowns have a crippling effect on the quality of the preconditioner. A negative p_i would result in an approximate inverse which is not positive definite; a zero pivot would force termination of the procedure, since step (7) cannot be carried out.

The way proposed to avoid non-positive pivots is simply to recall that in the exact A-orthogonalization process, the p_i's are the diagonal entries of matrix D which satisfies the matrix equation

$$Z^T A Z = D \tag{110.21}$$

hence for $1 < i < n$

$$p_i = z_i^T A z_i > 0 \tag{110.22}$$

since A is SPD and $z_i \neq 0$. In the exact process, the following equality holds

$$p_i = z_i^T A z_i = a_i^T z_i \quad \text{and} \quad p_j = z_i^T A z_j = a_i^T z_j \tag{110.23}$$

Clearly it is more economical to compute the pivots using just inner product $a_i^T z_i$ rather than the middle expression involving matrix-vector multiply. However, because of dropping and the resulting loss of A-orthogonality in the approximate $\bar{z}$-vectors, such identities no longer hold in the inexact process and for some matrices one can have

$$a_i^T \bar{z}_i \ll \bar{z}_i^T A \bar{z}_i \tag{110.24}$$

The robust algorithm requires that the incomplete pivots $\bar{p}_i$'s be computed using the quadratic form $\bar{z}_i^T A \bar{z}_i$ throughout the AINV process, for $i = 1, 2, \cdots, n$.

ALGORITHM Stabilized Incomplete Approximate Inverse (Benzi et al., 2000)

```
Let $z_i^{(0)} = e_i$, for $i = 1, 2, \cdots, n$
For $i = 1, 2, \cdots, n$, Do
    $v_i := A z_i^{(i-1)}$
    For $j = i, i+1, \cdots, n$, Do
        $p_j^{(i-1)} := v_i^T z_j^{(i-1)}$
    EndDo
    For $j = i+1, \cdots, n$, Do
        $z_j^{(i)} := z_j^{(i-1)} - (\frac{p_j^{(i-1)}}{p_i^{(i-1)}})$
        Apply dropping to $z_j^{(i)}$
    EndDo
EndDo
Let $z_i := z_i^{(i-1)}$ and $p_i := p_i^{(i-1)}$, for $i = 1, 2, \cdots, n$.
Return $Z = [z_1, z_2, \cdots, z_n]$ and $D = diag(p_1, p_2, \cdots, p_n)$.
```

Obviously, the robust (referred to as SAINV) and plain algorithm are mathematically equivalent. However, the incomplete process obtained by dropping in the z-vectors in step (9) of the robust algorithm leads to a reliable approximate inverse. This algorithm, in exact arithmetic, is applicable to any SPD matrix without breakdowns. The computational cost of SAINV is higher than basic AINV and special care has to be taken to do sparse-sparse matrix-vector multiply.

Incomplete Factorization by SAINV Consider now the exact algorithm (with no dropping) and write $A = LDL^T$ with L unit lower triangular and D diagonal. Observe that L in the LDL^T factorization of A and the inverse factor satisfy

$$AZ = LD \quad \text{or} \quad L = AZD^{-1} \tag{110.25}$$

where D is the diagonal matrix containing the pivots. This easily follows from

$$Z^T AZ = D \quad \text{and} \quad Z^T = L^{-1} \tag{110.26}$$

If we recall that pivot $d_j = p_j = z_j^T Az_j = \langle Az_j, z_j\rangle$, then by equating corresponding entries of AZD^{-1} and $L = [l_{ij}]$ we find that (Benzi and Tůma, 2003; Bollhöfer and Saad, 2001)

$$l_{ij} = \frac{\langle Az_j, z_i\rangle}{\langle Az_j, z_j\rangle} \quad i \geq j \tag{110.27}$$

Hence, the L factor of A can be obtained as a by-product of the A-orthogonal-ization, at no extra cost. In the implementation of SAINV, the quantities l_{ij} in Equation 110.27 are the multipliers that are used in updating the columns of Z. Once the update is computed, they are no longer needed and are discarded. To obtain an incomplete factorization of A, we do just the opposite; we save the multipliers l_{ij} , and discard the column vectors z_j as soon as they have been computed and operated with. Hence, the incomplete L factor is computed by columns; these columns can be stored in place of the z_j vectors, with minimal modifications to the code. Here, we are assuming that the right-looking form of SAINV is being used. If the left-looking one is being used, then L would be computed by rows. Please refer to Benzi and Tůma (2003) for more implementation details.

110.5.5 Numerical Experiments

Matrices from soil-structure interaction finite element analysis have been extracted from simulation system to study the performance of different preconditioning techniques on PCG method. The prototype of soil structure model has been shown in Figures 110.56 and 110.57. In order to introduce both of the nonlinear theories for soil and structures, we use continuum elements to model the soil and beam elements for the structures. Matrices from static pushover analysis and dynamic ground motion analysis have been collected for this research.

110.5.6 Conclusion and Future Work

1. For the soil-structure interaction problems investigated in this section, Conjugate Gradient method works fine and the convergence is acceptable for most cases.

2. Incomplete Cholesky factorization preconditioner has been shown to be very powerful in static pushover problems.

3. Dynamic problems formulated by Newmark integration scheme have not been extensively tested. But according to the data available so far, neither IC nor RIF preconditioners performed well and further testing is necessary to reach a more persuasive conclusion. The difficulty in dynamic analysis results from the fact that consistent mass and damping matrices used in continuum finite element formulations significantly degrade the conditioning number of the final system. This situation deteriorates when penalty handler is used to apply multiple point constraints, which introduces huge off-diagonal numbers to stiffness, mass and damping matrices (Cook et al., 2002).

4. Robust incomplete factorization preconditioning based on A-orthogonalization has not been shown competitive with IC preconditioners in this research. It is also worth noting that all timings are

---

[4] Density is defined as the number of non-zeros of the incomplete factor divided by the number of non-zeros in the lower triangular part of A.

[5] Iteration with tolerance 1e-2 failed to converge.

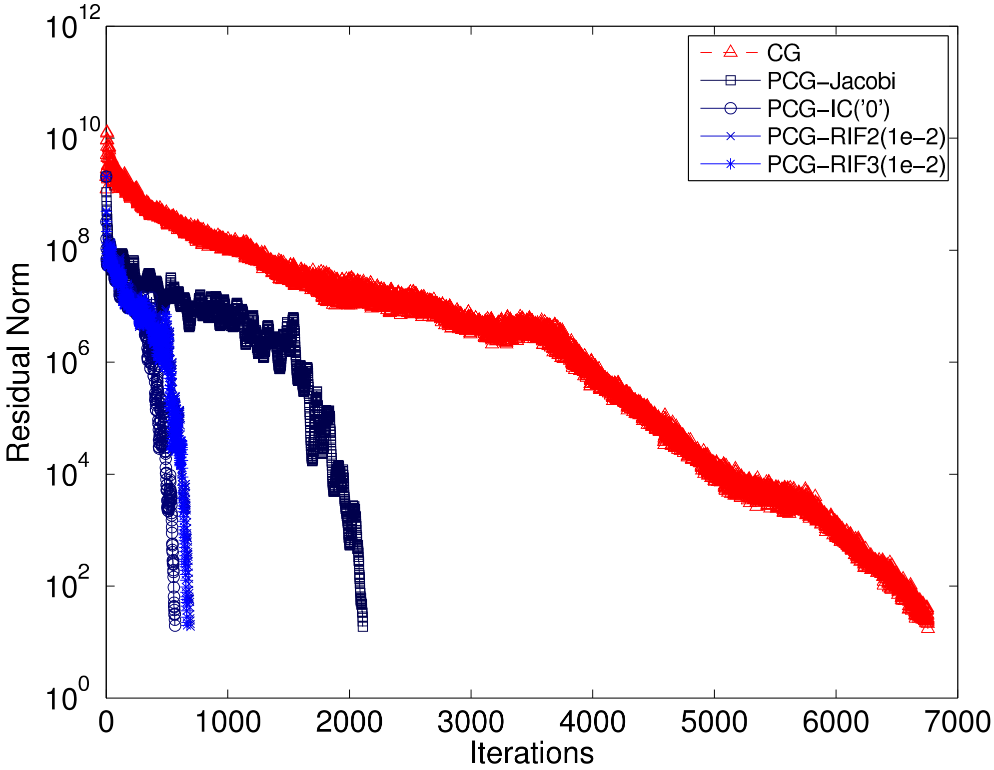

Figure 110.65: Convergence of CG and PCG Method (33081 DOFs Model)

taken in MATLAB. There are much more improvement can be achieved with a carefully coded FORTRAN program.

5. Static analysis has been extensively studied and it can be safely concluded that IC(0) and Jacobi preconditioners are good choices for the nonlinear soil-beam interaction simulations.

6. Dynamic analysis has also been studied but more work is needed to draw any detailed conclusion. Generally speaking, one should be alert if iterative solver is to be used for dynamic analysis. This partially comes from the fact that mass and damping matrices undoubtedly alter the structures of the coefficient matrix. This situation becomes more complicated if penalty handler is used to introduce off-diagonal numbers when handling multi-point constraints. So direct solver would be a more stable option for solving dynamic equations.

110.6 Performance Study on Parallel Direct/Iterative Solving in SFSI

The motivation of this section is to introduce a robust and efficient parallel equation solver into our parallel finite element analysis framework. Aside from sparsity, which has been well known as the

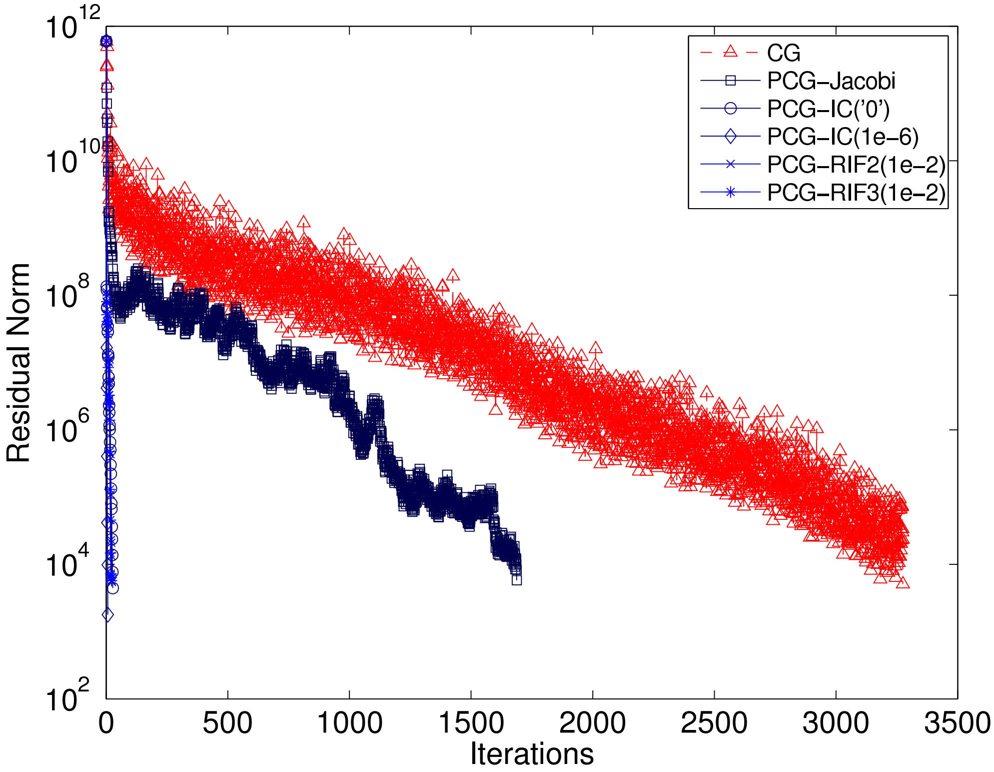

Figure 110.66: Convergence of CG and PCG Method (Soil-Beam Static Model)

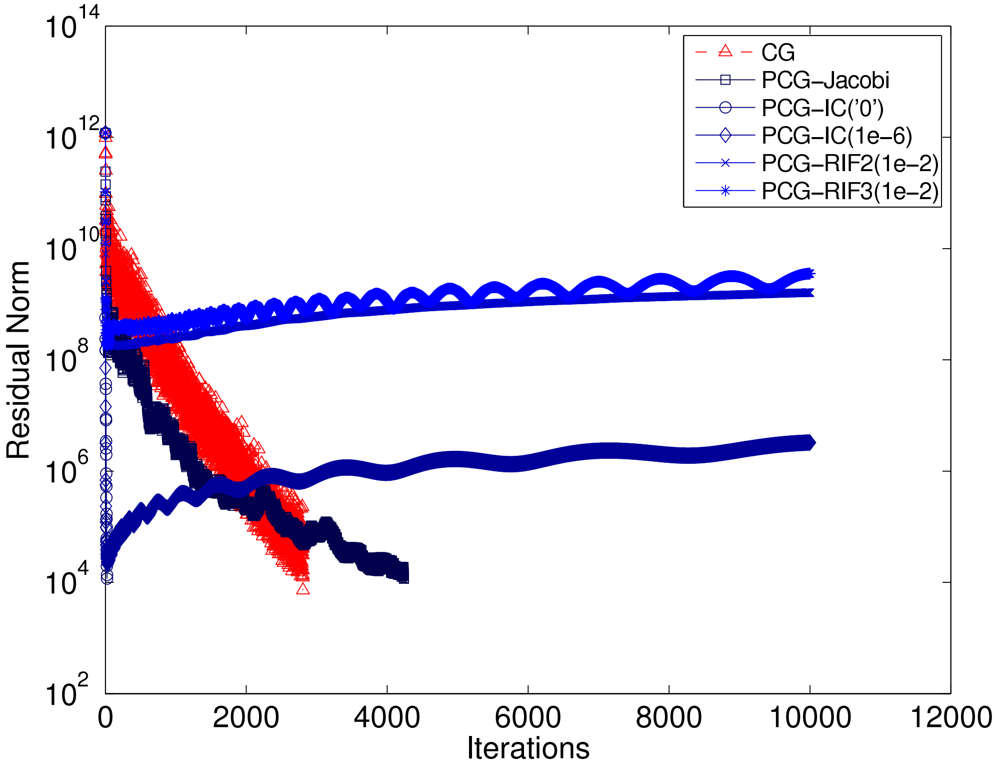

Figure 110.67: Convergence of CG and PCG Method (Soil-Beam Dynamic Model)

result of compact support that is inherent with finite element method, there exist some other special considerations that make the equation solving in finite element simulation a more involved problem.

In nonlinear finite element simulations, handling of constraints significantly affects the condition number of assembled equation systems. In SFSI simulations, multiple-point constraint is necessary to enforce the connection between soil and pile elements. In this research, penalty handler has been adopted to impose multiple point constraints on the assembled equation systems. Transformation and Lagrange multipliers are among those popular methods as well (Belytschko et al., 2000; Cook et al., 2002). The method of Lagrange multipliers adds extra constraints to the system and the resulted coefficient matrix will lose symmetric positive definiteness. Transformation is favorable especially in the sense that it reduces the order of the equation systems by condensing out slave/constrained DOFs. But the transformation is the most difficult to code and the situation of one single main/retained node with multiple follower/constrained nodes further complicates the problem.

Penalty method is chosen in this research due to the fact that it well preserves the symmetric positive definiteness of the system if the nice property is observed. Another consideration comes from the easiness with which the penalty methods can handle the single main/retained multiple follower/constrained situations. This is proven to be extremely valuable when data redistribution is required in adaptive parallel processing because the DOF_Graph object can be clearly tracked during partition and repartition phases.

The incapability of handling constraints accurately has been long known as the weakness of penalty method. The choice of the key penalty number seems arbitrary and largely depends on experience. The dilemma is with larger penalty number, the system can handle constraints more accurately while the coefficient matrix can become very ill-conditioned. This can lead to serious convergence problem for iterative solvers.

The majority of coefficient matrices resulted from finite element analysis are inherently symmetric positive definite, for which lots of numerical algorithms have been proposed and solving SPD, symmetric or closely symmetric systems has been relatively maturer than more common unsymmetric cases. Unfortunately, in geotechnical finite element simulations, unassociated constitutive models lead to unsymmetric stiffness matrices (Jeremić, 2004). More general parallel solvers must be coded to solve the problem.

In this section, both iterative and direct solvers are coded using the consistent PETSc interface (Balay et al., 2001, 2004, 1997). Popular direct solvers for general unsymmetric systems such as MUMPS, SPOOLES, SuperLU, PLAPACK have been introduced and performance study has been carried out to investigate the efficiency of different solvers on large scale SFSI simulations with penalty-handled unsymmetric equation systems. GMRES is always the first choice of iterative method when general unsymmetric systems are concerned. Preconditioning techniques have been thoroughly studied in this research to explore possible advantage of preconditioned iterative solver over direct solving. Jacobi, incomplete LU decomposition and approximate inverse preconditioners represent the most popular choices for Krylov methods and they are chosen in this performance survey.

All numerical algorithms have been implemented through interface of PETSc, which provides a consistent platform on which implementation issues can be avoided to expose individual algorithmic performance.

110.6.1 Parallel Sparse Direct Equation Solvers

The methods that we consider for the solution of sparse linear equations can be grouped into four main categories: general techniques, frontal methods, multifrontal approaches and supernodal algorithms (Dongarra et al., 1996).

110.6.1.1 General Techniques – SPOOLES

The so-called general approach can be viewed as parallel versions of sparse LU decomposition. Special cares must be taken to handle the sparse data structures. Sparsity ordering is crucial in parallel sparse equation solving in order to reduce fill-in and discover large-grain parallelism (Demmel et al., 1993).

Freely available package SPOOLES provides minimum degree (multiple external minimum degree (Liu, 1985)), generalized nested dissection and multisection ordering schemes for matrix sparsity ordering. Fundamental supernode tree built on top of vertex elimination tree is used to explore granularity in parallel (Ashcraft, 1999; Ashcraft et al., 1999).

110.6.1.2 Frontal and Multifrontal Methods – MUMPS

Frontal methods have their origins in the solution of finite element problems from structural analysis. The usual way to describe the frontal method is to view its application to finite element problems where the matrix A is expected as a sum of contributions from the elements of a finite element discretization (Dongarra et al., 1996). That is,

$$A = \sum_{l=1}^{m} A^{[l]}, \tag{110.28}$$

where $A^{[l]}$ is nonzero only in those rows and columns that correspond to variables in the lth element. If a_{ij} and $a_{ij}^{[l]}$ denote the (i,j)th entry of A and $A^{[l]}$, respectively, the basic assembly operation when forming A is of the form

$$a_{ij} \Leftarrow a_{ij} + a_{ij}^{[l]}. \tag{110.29}$$

It is evident that the basic operation in Gaussian elimination

$$a_{ij} \Leftarrow a_{ij} + a_{ip}[a_{pp}]^{-1}a_{pj}. \tag{110.30}$$

may be performed as soon as all the the terms in the triple product 110.30 are fully summed (that is, are involved in no more sums of the form 110.29). The assembly and Gaussian elimination processes can therefore be interleaved and the matrix A is never assembled explicitly. This allows all intermediate working to be performed in a dense matrix, termed frontal matrix, whose rows and columns correspond to variables that have not yet been eliminated but occur in at least one of the elements that have been assembled.

For general problems other than finite element, the rows of A (equations) are added into the frontal matrix one at a time. A variable is regarded as fully summed whenever the equation in which it last appears is assembled. The frontal matrix will, in this case, be rectangular.

The idea of multifrontal method is to couple a sparsity ordering with the efficiency of a frontal matrix kernel so allowing good exploitation of high performance computers. The basic approach is to develop separate fronts simultaneously which can be chosen using a sparsity preserving ordering such as minimum degree.

Elimination tree, again is the most important notion in the factorization process and also utilized to discover the potential of parallelism. An elimination tree defines the a precedence order within the factorization. The factorization commences at the leaves of of the tree and data is passed towards the root along the edges in the tree. To complete the work associated with a node, all the data must have been obtained from the children of the node, otherwise work at different nodes is independent.

Freely available package MUMPS (MUltifrontal Massively Parallel sparse direct Solver) has been used in this research to investigate the performance of multifrontal methods (http://graal.ens-lyon.fr/MUMPS/, 2006).

MUMPS is a package for solving systems of linear equations of the form $\mathbf{Ax} = \mathbf{b}$, where $\mathbf{A}$ is a square sparse matrix that can be either unsymmetric, symmetric positive definite, or general symmetric. MUMPS uses a multifrontal technique which is a direct method based on either the $\mathbf{LU}$ or the $\mathbf{LDL^T}$ factorization of the matrix. MUMPS exploits both parallelism arising from sparsity in the matrix $\mathbf{A}$ and from dense factorizations kernels.

The main features of the MUMPS package include the solution of the transposed system, input of the matrix in assembled format (distributed or centralized) or elemental format, error analysis, iterative refinement, scaling of the original matrix, and return of a Schur complement matrix. MUMPS offers several built-in ordering algorithms, a tight interface to some external ordering packages such as METIS and PORD, and the possibility for the user to input a given ordering. Finally, MUMPS is available in various arithmetics (real or complex, single or double precision).

The software is written in Fortran 90 although a C interface is available. The parallel version of MUMPS requires MPI for message passing and makes use of the BLAS, BLACS, and ScaLAPACK libraries. The sequential version only relies on BLAS.

MUMPS distributes the work tasks among the processors, but an identified processor (the host) is required to perform most of the analysis phase, to distribute the incoming matrix to the other processors (slaves) in the case where the matrix is centralized, and to collect the solution. The system $\mathbf{Ax} = \mathbf{b}$ is solved in three main steps:

1. Analysis. The host performs an ordering based on the symmetrized pattern $\mathbf{A} + \mathbf{A^T}$, and carries out symbolic factorization. A mapping of the multifrontal computational graph is then computed, and symbolic information is transferred from the host to the other processors. Using this information, the processors estimate the memory necessary for factorization and solution.

2. Factorization. The original matrix is first distributed to processors that will participate in the numerical factorization. The numerical factorization on each frontal matrix is conducted by a main compute processor (determined by the analysis phase) and one or more slave processors (determined dynamically). Each processor allocates an array for contribution blocks and factors; the factors must be kept for the solution phase.

3. Solution. The right-hand side $\mathbf{b}$ is broadcast from the host to the other processors. These processors compute the solution $\mathbf{x}$ using the (distributed) factors computed during Step 2, and the solution is either assembled on the host or kept distributed on the processors.

Each of these phases can be called separately and several instances of MUMPS can be handled simultaneously. MUMPS allows the host processor to participate in computations during the factorization and solve phases, just like any other processor.

For both the symmetric and the unsymmetric algorithms used in the code, a fully asynchronous approach with dynamic scheduling of the computational tasks has been chosen. Asynchronous communication is used to enable overlapping between communication and computation. Dynamic scheduling was initially chosen to accommodate numerical pivoting in the factorization. The other important reason for this choice was that, with dynamic scheduling, the algorithm can adapt itself at execution time to remap work and data to more appropriate processors. In fact, the main features of static and dynamic approaches have been combined and the estimation obtained during the analysis to map some of the main computational tasks has been used; the other tasks are dynamically scheduled at execution time. The main data structures (the original matrix and the factors) are similarly partially mapped according to the analysis phase.

110.6.1.3 Supernodal Algorithm – SuperLU

The left-looking or column Cholesky algorithm can be implemented for sparse system and can be blocked by using a supernodal formulation. The idea of a supernode is to group together columns with the same nonzero structure, so they can be treated as a dense matrix for storage and computation. Supernodes were originally used for (symmetric) sparse Cholesky factorization (Demmel et al., 1999a). In the factorization $\mathbf{A} = \mathbf{L}\mathbf{L}^{\mathbf{T}}$ (or $\mathbf{A} = \mathbf{L}\mathbf{D}\mathbf{L}^{\mathbf{T}}$), a supernode is a range $(r : s)$ of columns of $\mathbf{L}$ with the same nonzero structure below the diagonal; that is, $\mathbf{L}(r : s; r : s)$ is full lower triangular and every row of $\mathbf{L}(r : s; r : s)$ is either full or zero.

Then in left-looking Cholesky algorithm, all the updates from columns of a supernode are summed into a dense vector before the sparse update is performed. This reduces indirect addressing and allows the inner loops to be unrolled. In effect, a sequence of col-col updates is replaced by a supernode-column (sup-col) update. The sup-col update can be implemented using a call to a standard dense Level 2 BLAS matrix-vector multiplication kernel. This idea can be further extended to supernode-supernode (sup-sup) updates, which can be implemented using a Level 3 BLAS dense matrix-matrix kernel. This can reduce memory traffic by an order of magnitude, because a supernode in the cache can participate in multiple column updates (Demmel et al., 1999a). It has been reported in (Ng and Peyton, 1993) that a sparse Cholesky algorithm based on sup-sup updates typically runs 2.5 to 4.5 times as fast as a col-col algorithm. Indeed, supernodes have become a standard tool in sparse Cholesky factorization.

To sum up, supernodes as the source of updates help because of the following (Demmel et al., 1999a):

1. The inner loop (over rows) has no indirect addressing. (Sparse Level 1 BLAS is replaced by dense Level 1 BLAS.)
2. The outer loop (over columns in the supernode) can be unrolled to save memory references. (Level 1 BLAS is replaced by Level 2 BLAS.)
   Supernodes as the destination of updates help because of the following:
3. Elements of the source supernode can be reused in multiple columns of the destination supernode to reduce cache misses. (Level 2 BLAS is replaced by Level 3 BLAS.)

Supernodes in sparse Cholesky can be determined during symbolic factorization, before the numeric factorization begins. However, in sparse $\mathbf{LU}$, the nonzero structure cannot be predicted before numeric factorization, so supernodes must be defined dynamically. Furthermore, since the factors $\mathbf{L}$ and $\mathbf{U}$ are no longer transposes of each other, the definition of a supernode must be generalized.

Freely available package SuperLU proposed a couple of ways to generalize the symmetric definition of supernodes to unsymmetric factorization (Demmel et al., 1999a). It is now not possible to use Level 3 BLAS efficiently for unsymmetric systems. The implementation in SuperLU performs a dense matrix multiplication of a block of vectors and, although these can not be written as another dense matrix, it has been shown that this Level 2.5 BLAS has most of the performance characteristics of Level 3 BLAS since the repeated use of the same dense matrix allows good use of cache and memory hierarchy.

There are three versions of libraries collectively referred as SuperLU (Demmel et al., 2003),

- Sequential SuperLU is designed for sequential processors with one or more layers of memory hierarchy (caches).
- Multithreaded SuperLU (SuperLU_MT) is designed for shared memory multiprocessors (SMPs), and can effectively use up to 16 or 32 parallel processors on sufficiently large matrices in order to speed up the computation (Demmel et al., 1999b).
- Distributed SuperLU SuperLU_DIST is designed for distributed memory parallel processors, using MPI for interprocess communication. It can effectively use hundreds of parallel processors on sufficiently large matrices (Li and Demmel, 2003).

Parallelizing sparse direct solver for unsymmetric systems is more complicated than parallel sparse Cholesky case. The advantage of sparse Cholesky over the unsymmetric case is that pivots can be chosen in any order from the main diagonal while guaranteeing stability. This lets us perform pivot choice before numerical factorization begins, in order to minimize fill-in, maximize parallelism. precompute the nonzero structure of the Cholesky factor, and optimize the (2D) distributed data structures and communication pattern (Li and Demmel, 2003).

In contrast, for unsymmetric or indefinite systems, distributed memory codes can be much more complicated for at least two reasons. First and foremost, some kind of numerical pivoting is necessary for stability. Classical partial pivoting or the sparse variant of threshold pivoting typically cause the fill-ins and workload to be generated dynamically during factorization. Therefore, we must either design dynamic data structures and algorithms to accommodate these fill-ins, or else use static data structures which can grossly overestimate the true fill-in. The second complication is the need to handle two factored matrices $\mathbf{L}$ and $\mathbf{U}$, which are structurally different yet closely related to each other in the filled pattern. Unlike the Cholesky factor whose minimum graph representation is a tree (elimination tree), the minimum graph representations of the $\mathbf{L}$ and $\mathbf{U}$ factors are directed acyclic graphs (elimination DAGs).

In SuperLU_DIST, a static pivoting approach, called GESP (Gaussian Elimination with Static Pivoting) (Li and Demmel, 1998) is used. In order to parallelize the GESP algorithm, a 2D block-cyclic mapping of a sparse matrix to the processors is used. An efficient pipelined algorithm is also designed to perform parallel factorization. With GESP, the parallel algorithm and code are much simpler than dynamic pivoting.

The main algorithmic features of SuperLU_DIST solver are summarized as follows (Li and Demmel, 2003):

- supernodal fan-out (right-looking) based on elimination DAGs,
- static pivoting with possible half-precision perturbations on the diagonal,
- use of an iterative algorithm using the LU factors as a preconditioner, in order to guarantee stability,
- static 2D irregular block-cyclic mapping using supernodal structure, and
- loosely synchronous scheduling with pipelining.

In particular, static pivoting can be performed before numerical numerical factorization, allowing us to use all the techniques in good sparse Cholesky codes: choice of a (symmetric) permutation to minimize fill-in and maximize parallelism, precomputation of the fill pattern and optimization of 2D distributed data structures and communication patterns. Users are referred to Li and Demmel (2003) for algorithm details.

110.6.2 Performance Study on SFSI Systems

In this section, performance study on popular parallel direct and iterative solvers has been conducted. The purpose is to provide some guidelines on appropriate use of different solvers with the parallel finite simulation framework. Matrix systems from SFSI analysis are used as test cases. The performance investigation uses IA64 Intel-based cluster at SDSC.

110.6.3 Conclusion

This section presents the parallel solvers implemented in parallel finite element framework. Table 110.10, draws several conclusions about appropriate use of solvers:

- Direct solvers outperforms the iterative solver significantly for general cases. It is worthwhile to note that nonsymmetric solvers are used here due to their generality. For special cases such as SPD system, preconditioned CG will show much better performance.
- The Conjugate Gradient method applies only to Symmetric Positive Definite (SPD) system. This puts restriction on the material models we can use in our simulations. Generally speaking, elastic material will yield a SPD stiffness matrix. Plastic material with associative flow rule also satisfies

this category. Plastic material with non-associative flow rule has non-symmetric element stiffness matrix and so will be the global coefficient matrix of the equation system.

- Another category of matrix that deserves attention is the stiffness matrix from softening materials, which possesses at least one negative eigenvalue so the SPD property will be broken. For advanced geo-materials subject to complicated loadings, as the material develops nonlinearity, the condition of stiffness matrix might vary greatly from SPD (elastic phase), to singular (elastic-perfectly-plastic), and non-symmetric non-positive-definite (elastic-non-associative-plastic-softening) cases. This poses another challenge when one tries to use iterative solver for production runs. The unpredictability of stiffness matrix will disable the application of powerful solvers such as Conjugate Gradient for iterative case and Cholesky for direct case.
- The reason why iterative solver exhibits poor efficiency is partly due to the problem size. We can also see from the Table 110.10 that parallel direct solver is not scalable in general. Iterative solver, on the other hand, is more scalable and it is safe to project that when the size of matrix increases, iterative solver has the advantage from the memory requirement point of view.

Parallel equation solving itself is a complicated topic in numerical computing community. In this section, the main purpose is to introduce a robust and generally efficient parallel solver for finite element simulations. So in this sense, parallel direct solvers such as MUMPS and SPOOLES are recommended.

Chapter 111

Solid, Structure – Fluid Interaction

(2017-2019-2021-)

(In collaboration with Dr. Hexiang Wang)

111.1 Chapter Summary and Highlights

111.2 Introduction

The analysis of problems several civil engineering fields often requires a study of fluid-structure systems that are excited by dynamic loads. For example, the evaluation of the structural integrity of nuclear reactor components involves the analysis of structures of complex shape and their interaction with the fluid in which they are embedded Donea et al. (1982). In these cases, both the fluid and the structure might undergo non-linear response.

These needs for safety evaluations have motivated the development of computational methods capable to treat transient, non-linear fluid-structure interaction problems. Donea et al. (1982) presented an arbitrary Lagrangian-Eulerian (ALE) finite element method with automatic and continuous rezoning technique of the fluid mesh. With this method, dynamic response of nuclear reactor under solid fluid interaction has been simulated. Recently Park et al. (2014) examined the modal characteristics of Reactor vessel internals (RVIs) based on scale-similarity analysis with fluid-structure interaction (FSI). It was observed that the added-mass (A-M) model for submerged structures is considerably dependent on mode shapes and natural frequencies. Sigrist et al. (2006) conducted comparative dynamic analysis with FSI modeling for pressure vessel and internals in a nuclear reactor. They proved that the coupling effect is significant, whereas the effect of added-stiffness on global behavior is negligible. Je et al. (2017) stressed that improvement of numerical analysis methods has been required to solve complicated phenomena that occur in nuclear facilities. Particularly, fluid-structure interaction (FSI) behavior should be resolved for accurate design and evaluation of complex reactor vessel internals (RVIs) submerged in coolant. They investigated the FSI effect on dynamic characteristics of RVIs in a typical 1,000 MWe nuclear power plant. Modal analyses of an integrated assembly were conducted by employing the fluid-structure (F-S) model as well as the traditional added-mass model.

Though numerous efforts have been made on simulation of SFI problem in nuclear reactors, to the author's best knowledge, high fidelity modeling of this dynamic nonlinear phenomena with complex geometry is still unavailable. Full sets of Navier-stokes (N-S) equation is rarely solved for fully solid fluid coupling. Instead, many simplified analysis procedure is adopted: like added-mass (A-M) model (as shown in equation 111.1) Park et al. (2014); Sigrist et al. (2006) and simplified acoustic wave equation Je et al. (2017) (equation 111.2). These simplified methods introduce great modeling uncertainty to the simulation system.

$$
\begin{aligned}
&[M_s]\{\ddot{u}\} + [C_s]\{\dot{u}\} + [K_s]\{u\} = \{f_e\} + \{f_f\} \\
&\qquad f_f = \int_S \{N_p\}^T \{n\}\{P\} dS = -[M_a]\{\ddot{u}\}
\end{aligned}
\tag{111.1}
$$

$$
[M_f]\{\ddot{P}\} + [C_f]\{\dot{P}\} + [K_f]\{P\} + \rho [R_{int}]^T \{\ddot{u}\} = 0 \tag{111.2}
$$

On the other hand, ALE method, which was originally put forward as a powerful tool for fluid dynamics with deforming boundary Hirt et al. (1974), has been applied to fully solve the coupled N-S equation and solid mechanic equation Le Tallec and Mouro (2001); Murea and Sy (2017). The freedom in moving the fluid mesh offered by the ALE formulation is very attractive. However, it can be overshadowed by the burden of specifying grid velocities, well suited to a particular problem. As a consequence, the practical implementation of the ALE description requires that an automatic mesh displacement prescription algorithm to be supplied. Many methods have been put forward to overcome this difficulty. For example, pseudo-solid method was adopted by Van Loon et al. (2007) and Jasak and Tukovic (2006) came up with a simplified procedure by solving a Laplacian equation 111.3 of grid velocity with finite element discretization.

$$
\begin{aligned}
&\nabla \cdot (\gamma \nabla \boldsymbol{u}) = \boldsymbol{0} \\
&\boldsymbol{x}_{new} = \boldsymbol{x}_{old} + \boldsymbol{u}\Delta t
\end{aligned}
\tag{111.3}
$$

Seemingly, introducing these additional equations to specify the movement of fluid mesh can well resolve the inherent problem of ALE method. Based on specified grid velocity, solutions to ALE-formed N-S equations 111.4 can give precise response of fluid flow.

$$
\begin{aligned}
\frac{\partial}{\partial t}(\rho J) &= J \nabla \cdot (\boldsymbol{w} - \boldsymbol{v}) \\
\frac{\partial}{\partial t}(\rho \boldsymbol{v} J) &= J \nabla \cdot \boldsymbol{v}(\boldsymbol{w} - \boldsymbol{v}) + J(\rho \boldsymbol{b} - \nabla p)
\end{aligned}
\tag{111.4}
$$

However, mathematically the system equations (seen in section 111.3.1) to represent physical phenomena of SFI itself is sufficient and complete. Theoretically, no additional equations need to be added to the coupled system. The authors think that the ease gained here by introducing extra mesh movement equations to ALE method is sacrificed with the accuracy of the result of pressure field. Because in equation 111.4, the pressure is dependent on both absolute velocity $\boldsymbol{v}$ and relative velocity $(\boldsymbol{v} - \boldsymbol{w})$. Different configuration of mesh velocity can result in different relative velocity under the same absolute velocity, which in turn causes different pressure field.

This could be fine for pure fluid dynamics problem, where engineers care more about the fluid flow (i.e. velocity field). However, this may not be good enough for SFI, where hydrodynamic pressure at solid fluid interface is of great of importance for accurate Neumann boundary condition of solid domain. Therefore, precise pressure field is desired and indispensable in high-fidelity simulation of SFI.

The research presented here aims at realistic SFI modeling in nuclear reactors with solutions to fully coupled FSI system (i.e. N-S equations, solid mechanics equations and interface constraint equations). Geometric conformity is also achieved in this work. The great emphasis was put on accurate pressure field at solid fluid interface. A full sets of verification and validation tests are provided to guarantee the reliability of our modeling.

The limitation of current work is that relatively large displacement of solid fluid interface and accompanying Eulerian mesh distortion problem are not well resolved. Further development are needed for these topics.

111.3 Theoretical Formulation

111.3.1 Solid Fluid Interaction

The mathematical description of physical phenomenon of solid fluid interaction includes three parts Van Loon et al. (2007): The response of solid domain Ω_s is controlled by the theory of general continuum solid mechanics (equation 111.5). The governing equation in fluid domain is Navier-Stokes equation (N-S equations), which basically consists of mass conservation and momentum conservation equation (shown in equation 111.6). In the equations below, symbols $\boldsymbol{u}$, $\boldsymbol{\sigma}$, $\boldsymbol{f}$, p, G, ρ and η denote velocity, Cauchy stress tensor, body force, pressure, solid shear modulus, density and fluid viscosity. $\boldsymbol{F}$ is deformation gradient tensor defined as $\boldsymbol{F} = \nabla\chi(X,t)$.

$$\rho^s \frac{d\boldsymbol{u^s}}{dt} = \boldsymbol{\nabla} \cdot \boldsymbol{\sigma^s} + \rho^s \boldsymbol{f^s} \quad in\ \Omega_s \tag{111.5a}$$

$$det(\mathsf{F}) = 1 \quad in\ \Omega_s \tag{111.5b}$$

$$\boldsymbol{\sigma^s} = G(\boldsymbol{F} \cdot \boldsymbol{F^T} - \boldsymbol{I}) - p^s \boldsymbol{I} \quad in\ \Omega_s \tag{111.5c}$$

$$\rho^f \frac{\partial \boldsymbol{u^f}}{\partial t} + = \boldsymbol{\nabla} \cdot \boldsymbol{\sigma^f} + \rho^f \boldsymbol{f^f} \quad in\ \Omega_f \tag{111.6a}$$

$$\boldsymbol{\nabla} \cdot \boldsymbol{u^f} = 0 \quad in\ \Omega_f \tag{111.6b}$$

$$\boldsymbol{\sigma^f} = 2\eta \boldsymbol{D}(\boldsymbol{u^f}) - p^f \boldsymbol{I} \quad in\ \Omega_f \tag{111.6c}$$

At the solid fluid interface $D = \partial\Omega_s \cap \partial\Omega_f$, kinematic and dynamic constraints should be met, as shown in equation 111.7.

$$\boldsymbol{u}^s - \boldsymbol{u}^f = \boldsymbol{0} \quad in\ D \tag{111.7a}$$

$$\boldsymbol{\sigma}^s \cdot \boldsymbol{n} + \boldsymbol{\sigma}^f \cdot \boldsymbol{n} = \boldsymbol{0} \quad in\ D \tag{111.7b}$$

111.3.2 Finite Volume Discretization

For general purpose, the standard form pf the transport equation for a scalar property ϕ is considered here in 111.8. It is a second order equation as the diffusion term includes the second derivative of ϕ in space. Finite volume discretization will be applied to the integral form regarding to control volume V_p (equation 111.9) in both spatial and temporal sense Moukalled et al. (2016).

$$\underbrace{\frac{\partial\rho\phi}{\partial t}}_{\text{temporal derivative}} + \underbrace{\boldsymbol{\nabla}\cdot(\rho\boldsymbol{U}\phi)}_{\text{convection term}} - \underbrace{\boldsymbol{\nabla}\cdot(\rho\Gamma_\phi\boldsymbol{\nabla}\phi)}_{\text{diffusion term}} = \underbrace{S_\phi(\phi)}_{\text{source term}} \tag{111.8}$$

$$\underbrace{\int_{V_p}\frac{\partial\rho\phi}{\partial t}dV}_{\text{temporal derivative}} + \underbrace{\int_{V_p}\boldsymbol{\nabla}\cdot(\rho\boldsymbol{U}\phi)dV}_{\text{convection term}} - \underbrace{\int_{V_p}\boldsymbol{\nabla}\cdot(\rho\Gamma_\phi\boldsymbol{\nabla}\phi)dV}_{\text{diffusion term}} = \underbrace{\int_{V_p}S_\phi(\phi)dV}_{\text{source term}} \tag{111.9}$$

- Spatial discretization

  The spatial discretization of equation 111.9 includes three parts: discretization of convection term, diffusion term and source term, respectively. Using divergence theorem, the semi-discrete form of convection term at arbitrary control volume V_p can be given in equation 111.10, where F denotes the mass flux through the face defined in equation 111.11. In this semi-discrete form, we still need to calculate the face value ϕ_f and face mass flux F in order to evaluate the whole volume integral of convection term.

$$\int_{V_p} \boldsymbol{\nabla} \cdot (\rho \boldsymbol{U} \phi) dV = \sum_f \boldsymbol{S} \cdot (\rho \boldsymbol{U} \phi)_f \tag{111.10a}$$

$$= \sum_f \boldsymbol{S} \cdot (\rho \boldsymbol{U})_f \phi_f \tag{111.10b}$$

$$= \sum_f F \phi_f \tag{111.10c}$$

$$F = \boldsymbol{S} \cdot (\rho \boldsymbol{U})_f \tag{111.11}$$

The face value ϕ_f at face center f can be obtained from face interpolation scheme using ϕ value at control volume center ϕ_p and value at neighboring volume center ϕ_N (equation 111.12).

$$\phi_f = f_x \phi_p + (1 - f_x) \phi_N \tag{111.12}$$

Here f_x is the interpolation factor defined as the ratio of distances $\overline{fN}$ and $\overline{PN}$:

$$f_x = \frac{\overline{fN}}{\overline{PN}} \tag{111.13}$$

Similarly, for diffusion term the semi-discrete form is presented in equation 111.14. With the semi-discrete form, $(\boldsymbol{\nabla}\phi)_f$ still needs to be evaluated to achieve full discretization. For orthogonal mesh, following equation 111.15 can be used to simplify our analysis, where $|d|$ is the magnitude of vector $\overline{PN}$.

$$\int_{V_p} \boldsymbol{\nabla} \cdot (\rho \Gamma_\phi \boldsymbol{\nabla} \phi) dV = \sum_f \boldsymbol{S} \cdot (\rho \Gamma_\phi \boldsymbol{\nabla} \phi)_f \tag{111.14a}$$

$$= \sum_f (\rho \Gamma_\phi)_f \boldsymbol{S} \cdot (\boldsymbol{\nabla} \boldsymbol{\phi})_f \tag{111.14b}$$

$$\boldsymbol{S} \cdot (\nabla \phi)_f = |\boldsymbol{S}| \frac{\phi_N - \phi_P}{|\boldsymbol{d}|} \tag{111.15}$$

The source term $S_\phi(\phi)$ can be a general function of ϕ. Before the actual discretization, the source term is first linearized, where S_u and S_p also depend on ϕ. Then the volume integral of source term can be evaluated with equation 111.17.

$$S_\phi(\phi) = Su + Sp\phi \tag{111.16}$$

$$\int_{V_p} S_\phi(\phi)dV = S_u V_p + S_p V_p \phi_p \tag{111.17}$$

- Temporal discretization

Conducting time integration from t to $t + \Delta t$ with both sides of equation 111.9 yields equation 111.18.

$$\int_t^{t+\Delta t} [\frac{\partial}{\partial t}\int_{V_p} \rho\phi dV + \int_{V_p} \boldsymbol{\nabla}\cdot(\rho \boldsymbol{U}\phi)dV - \int_{V_p} \boldsymbol{\nabla}\cdot(\rho\Gamma_\phi \boldsymbol{\nabla}\phi)]dt = \int_t^{t+\Delta t} (\int_{V_p} S_\phi(\phi)dV)dt \tag{111.18}$$

Substituting the spatial semi-discretization shown above (equations 111.10, 111.14 and 111.17) into equation 111.18 and assuming that the control volumes do not change in time, equation 111.18 can be written as ;

$$\int_t^{t+\Delta t} [(\frac{\partial \rho\phi}{\partial t})_p V_p + \sum_f F\phi_f - \sum_f (\rho\Gamma_\phi)_f \boldsymbol{S}\cdot(\boldsymbol{\nabla}\phi)_f]dt = \int_t^{t+\Delta t} (S_u V_p + S_p V_p \phi_p)dt \tag{111.19}$$

Here further temporal discretization are needed to evaluate equation 111.19:

$$(\frac{\partial \rho\phi}{\partial t})_p = \frac{\rho_P^n \phi_P^n - \rho_P^0 \phi_P^0}{\Delta t} \tag{111.20a}$$

$$\int_t^{t+\Delta t} \phi(t)dt = \frac{1}{2}(\phi^0 + \phi^n)\Delta t \tag{111.20b}$$

where

$$\phi^n = \phi(t + \Delta t)$$

$$\phi^0 = \phi(t)$$

Assuming that the density and diffusivity do not change in time, the final semi-discrete form including both spatial and temporal discretization can be given in equation 111.21. Since in equation 111.21, ϕ_f^n, $(\nabla\phi)_f^n$ can be expressed with ϕ values at control cell ϕ_P and neighboring cells ϕ_N with equation 111.12 and 111.15. Therefore, equation 111.21 can be finalized into algebraic equation form (equation 111.22).

$$\begin{aligned} &\frac{\rho_P\phi_P^n - \rho_p\phi_P^0}{\Delta t}V_p + \frac{1}{2}\sum_f F\phi_f^n + \frac{1}{2}\sum_f F\phi_f^0 \\ -&\frac{1}{2}\sum_f(\rho\Gamma_\phi)_f\boldsymbol{S}\cdot(\nabla\phi)_f^n - \frac{1}{2}\sum_f(\rho\Gamma_\phi)_f\boldsymbol{S}\cdot(\nabla\phi)_f^0 \\ &= SuV_p + \frac{1}{2}S_pV_P\phi_P^n + \frac{1}{2}S_pV_P\phi_P^0 \end{aligned} \tag{111.21}$$

$$a_P\phi_P^n + \sum_N a_N\phi_N^n = R_P \tag{111.22}$$

For every control volume, one equation of this form is assembled. The value of ϕ_P^n depends on the values in the neighboring cells, thus creating a system of algebraic equations 111.23, where [A] is a sparse matrix, with coefficients a_P on the diagonal and a_N off the diagonal, $[\phi]$ is the vector of ϕ-s for all control volumes and $[R]$ is the source term vector.

$$[A][\phi] = [R] \tag{111.23}$$

111.3.3 Volume of Fluid Method

The physical phenomena of earthquake soil structure interaction in fluid domain is essentially free surface flow. There are three types of problems in the numerical treatment of free boundaries: (1) their discrete representation, (2) their evolution in time, and (3) the manner in which boundary conditions are imposed on them.

Volume of Fluid method is originally put forward by Hirt and Nichols (1981) to solve free surface flow problems (free boundary problems). Different from traditional one-phase method, VOF method considers more general two-phase flow problem. In special case where we take one phase as air and another phase as any liquid that needs to be simulated, then VOF becomes also applicable for free surface flow.

The idea of Volume of Fluid method is to introduce a new field variable - volume fraction value (α) for each control volume, which is defined in equation ?? where V_i is the total volume of cell i and V_i^w is the volume of water contained in the cell. From the definition, it can be seen that α values range between 0 and 1. If the cell is completely filled with fluid then $\alpha = 1$ and if it is filled with void phase then its value should be 0. In VOF method, momentum equation and continuity equation are solved for one composite fluid phase characterized by volume fraction α. The physical properties of this one fluid are calculated as weighted averages based on the volume fractions of two phases in one cell. E.g., the density of any point in the domain is calculated with equation 111.24.

$$\rho = \alpha\rho_w + (1-\alpha)\rho_a \tag{111.24}$$

The evolution of volume fraction α is controlled by an additional convection transport equation 111.26. By solving this equation, the distribution of volume fraction α can be obtained. Then the free fluid interface can be automatically identified as the zone where the volume fraction α ranges between 0 to 1. In this way, the fluid flow can be represented as the redistribution of α along with the time.

$$\alpha_i = \frac{V_i^w}{V_i} \tag{111.25}$$

$$\frac{\partial\alpha}{\partial t} + \boldsymbol{\nabla}\cdot(\alpha\boldsymbol{U}) = 0 \tag{111.26}$$

The free surface flow solver used here is interFoam implemented based on OpenFOAM. In interFoam, the necessary compression of the phase interface is achieved by introducing an extra artificial compression term into the transport convection equation of α, as shown in equation 111.27. U_r is the velocity field suitable to compress the interface. This artificial term is active only in the interface region due to the term $\alpha(1-\alpha)$.

$$\frac{\partial\alpha}{\partial t} + \boldsymbol{\nabla}\cdot(\alpha\boldsymbol{U}) + \boldsymbol{\nabla}\cdot(\alpha(1-\alpha)U_r) = 0 \tag{111.27}$$

111.3.4 Pressure-velocity coupling: PISO algorithm

For incompressible form of the fluid system (equation 111.28), two issues require special attention: non-linearity of the momentum equation and the pressure-velocity coupling Jasak (1996). The non-linear term in equation 111.29 is $\boldsymbol{\nabla}\cdot(\boldsymbol{U}\boldsymbol{U})$, *i.e.* velocity is "being transported by itself". The discretized form of this expression would be quadratic in velocity and the resulting system of algebraic equations would therefore be non-linear. There are two possible solutions for this problem - either use a solver for non-linear systems, or linearize the convection term.

$$\nabla \cdot \boldsymbol{U} = 0 \tag{111.28}$$

$$\frac{\partial \boldsymbol{U}}{\partial t} + \nabla \cdot (\boldsymbol{U}\boldsymbol{U}) - \nabla \cdot (\nu \nabla \boldsymbol{U}) = -\nabla p \tag{111.29}$$

According to section 111.3.2, convection term can be discretized with equation 111.30, where F, a_P and a_N are a function of $\boldsymbol{U}$. The important issue is that the fluxes F should satisfy the continuity equation 111.28. Linearization of the convection term implies than an existing velocity (flux) field that satisfies equation 111.28 will be used to calculate a_P and a_N.

$$\begin{aligned}\nabla \cdot (\boldsymbol{U}\boldsymbol{U}) &= \sum_f \boldsymbol{S} \cdot (\boldsymbol{U})_f (\boldsymbol{U})_f \\ &= \sum_f F(\boldsymbol{U})_f \\ &= a_P \boldsymbol{U}_P + \sum_N a_N \boldsymbol{U}_N\end{aligned} \tag{111.30}$$

PISO (Pressure-Implicit Splitting of Operators) procedure proposed by Venier et al. (2017) is used here for pressure-velocity coupling in transient calculations. In order to derive the pressure equation, a semi-discrete form (equation 111.31) of momentum equation is adopted, where pressure gradient term is not discretized at this stage. The $\boldsymbol{H}(\boldsymbol{U})$ term consists of two parts: the "transport part", including the matrix coefficients for all neighbors multiplied by corresponding velocities and the "source part" including the source part of the transient term.

$$\begin{aligned} a_P \boldsymbol{U}_P &= \boldsymbol{H}(\boldsymbol{U}) - \nabla p \\ \boldsymbol{H}(\boldsymbol{U}) &= -\sum_N a_N \boldsymbol{U}_N + \frac{\boldsymbol{U}^0}{\Delta t}\end{aligned} \tag{111.31}$$

In addition, the discrete form of continuity equation is:

$$\nabla \cdot \boldsymbol{U} = \sum_f \boldsymbol{S} \cdot \boldsymbol{U}_f = 0 \tag{111.32}$$

From equation 111.31, $\boldsymbol{U}$ can be explicitly expressed with equation 111.33. Then from the explicit solution $\boldsymbol{U}_P$ velocities at cell face $\boldsymbol{U}_f$ can be calculated through face interpolation (equation 111.34). Substituting equation 111.34 into equation 111.32 yields the equivalent form of continuity condition (equation 111.35).

$$\boldsymbol{U}_P = \frac{\boldsymbol{H}(\boldsymbol{U})}{a_P} - \frac{1}{a_P}\boldsymbol{\nabla} p \tag{111.33}$$

$$\boldsymbol{U}_f = (\frac{\boldsymbol{H}(\boldsymbol{U})}{a_P})_f - (\frac{1}{a_P})_f(\boldsymbol{\nabla} p)_f \tag{111.34}$$

$$\sum_f \boldsymbol{S} \cdot [(\frac{1}{a_P})_f(\boldsymbol{\nabla} p)_f] = \sum_f \boldsymbol{S} \cdot (\frac{\boldsymbol{H}(\boldsymbol{U})}{a_P})_f \tag{111.35}$$

The fully discrete form of momentum equation is given in equation 111.36. Equation 111.35 and equation 111.36 constitute the discrete form of incompressible Navier-Stokes system. The face flux F can be calculated using equation 111.37. When equation 111.35 is satisfied, the face fluxes are guaranteed to be conservative.

$$a_P \boldsymbol{U}_P = \boldsymbol{H}(\boldsymbol{U}) - \sum_f \boldsymbol{S}(p)_f \tag{111.36}$$

$$F = \boldsymbol{S} \cdot \boldsymbol{U}_f = \boldsymbol{S} \cdot [(\frac{\boldsymbol{H}(\boldsymbol{U})}{a_P})_f - (\frac{1}{a_P})_f(\boldsymbol{\nabla} p)_f] \tag{111.37}$$

With all the discrete form of system equations prepared, the PISO algorithm can be described as follows:

- The momentum equation is solved first. The exact pressure gradient source term is not known at this stage – the pressure field from the previous time-step is used instead. This stage is called the momentum predictor. The solution of the momentum equation, Eqn. 111.36, gives an approximation of the new velocity field.

- Using the predicted velocities, the $\boldsymbol{H}(\boldsymbol{U})$ operator can be assembled and the pressure equation can be formulated. The solution of the pressure equation 111.35 gives the first estimate of the new pressure field. This step is called the pressure correction.

- Eqn. 111.37 provides a set of conservative fluxes consistent with the new pressure field. The velocity field should also be corrected as a consequence of the new pressure distribution. Velocity correction is done in an explicit manner, using Eqn. 111.36. This is the explicit velocity correction stage.

- Eqn. 111.36 reveals that velocity correction consists of two parts: a correction due to the change in the pressure gradient and the transported influence of corrections of neighboring velocities. Explicit velocity correction means that the latter part is neglected. The whole velocity error is assumed to come from the error in pressure term. This is not true. It is therefore necessary to correct the $\boldsymbol{H}(\boldsymbol{U})$ term and repeat pressure correction and explicit velocity correction stage. In other words, the PISO loop consists of an implicit momentum predictor followed by a series of pressure solutions and explicit velocity corrections. The loop is repeated until a pre-determined tolerance is reached.

111.3.5 Explicit transient algorithm

The algorithm for solid fluid coupling is an explicit segregated approach. The solving of system equation 111.5 in solid domain and system equation 111.6 in fluid domain are performed by RealESSI and InterFoam respectively. A new container called SSFI is implemented in RealESSI to control all the boundary information of solid fluid interface. The algorithm is illustrated in figure 111.1.

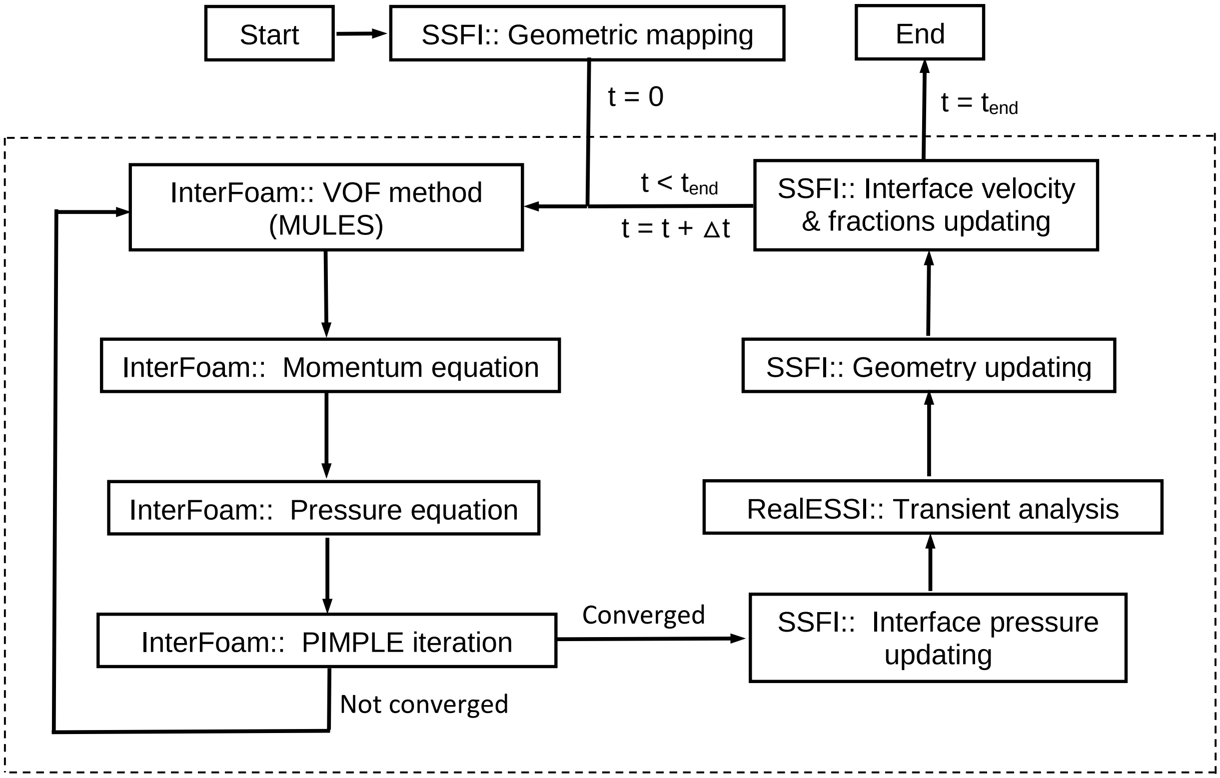

Figure 111.1: Flowchart of explicit transient algorithm

Initially all the geometric mapping information of solid fluid interaction is built by SSFI. There are 4 types of geometric mapping in SSFI: Foam node (interface node in fluid domain) maps to foam surface (interface surfaces in fluid domain), ESSI node (interface node in solid domain) maps to foam nodes, foam surface maps to ESSI nodes and foam node maps to ESSI nodes. The specific definitions of these geometric mappings and implementation details can be found in section 111.4.4. These geometric mapping information is indispensable part while conducting the interpolation for interface pressure, velocity and nodal displacement.

Then the equilibrium state of fluid domain is solved first by Interfoam based on the boundary conditions from the response of solid domain at last time step. Here the PIMPLE algorithm Chen et al. (2014) is implemented in InterFoam to couple pressure and velocity, which is a hybrid of the PISO and SIMPLE (Semi-Implicit Method for Pressure-Link Equations) algorithms. In the PIMPLE loop, the transport equation of volume fraction (equation 111.26) is firstly calculated based on existing velocities and surface fluxes. Following that, there is an implicit momentum predictor and several pressure-velocity correctors. After the fluid domain achieves equilibrium for the new time step, the pressures at fluid interface are transformed to equivalent nodal force and applied at the solid interface. This operation is called interface pressure updating.

With updated nodal force at solid interface and some other transient boundary conditions, the response of solid domain for the new step is obtained through transient analysis of RealESSI (Jeremić et al. (1988-2025)). Based on the latest location of solid interface, the geometry of fluid interface is updated correspondingly to make sure the geometric conformity of both domains.

No slip boundary condition is adopted here for the velocity at fluid interface. Therefore, the new boundary velocities are also calculated from the response of solid domain. In addition, it is crucially important to update volume fractions so that mass conservation is guaranteed. The detailed information about interpolation and updating of these physical fields (i.e. pressure, velocity and volume fractions) is presented in section 111.4.6 and 111.4.5.

For the above explicit transient algorithm, both solid domain and fluid domain can individually reach equilibrium states through iterations at both sides with updated interface boundary conditions. However, this two equilibrium states are not achieved at the same time. Current equilibrium state of solid domain matches with the equilibrium sate of fluid domain at the last time step. Therefore, the algorithm is only valid and accurate when time step is small enough. Different time step lengths in solid domain and fluid domain can also be handled through Shepherd method. SSFI can go through transient analysis in solid domain and fluid domain alternatively according to different time step length.

111.4 Implementation Details

111.4.1 Installation of OpenFoam

The official website of Openfoam: www.openfoam.com/down load/install-source.php gives detailed instruction about how to build Openfoam from source on different operating systems. Installation of customized version of OpenFOAM, that can interact, connect to Real-ESSI is described in some detail in chapter 209.6 on page 1335.

Note that after installation of Openfoam, you need to source the OpenFOAM environment by executing, e.g. for bash shells and OpenFoam version v1706:

```
source  /OpenFOAM/OpenFOAM-v1706/etc/bashrc
```

111.4.2 Integrated Preprocessor-gmFoam

gmFoam is designed as an integrated preprocessor developed for analysis of solid fluid interaction. It enables user to build an integrated geometric model (including both solid part and fluid part) in Gmsh and generate input files for both RealESSI and interFoam in a very easy way. Some simple examples can be seen in figure 111.2. Its main functions are listed below:

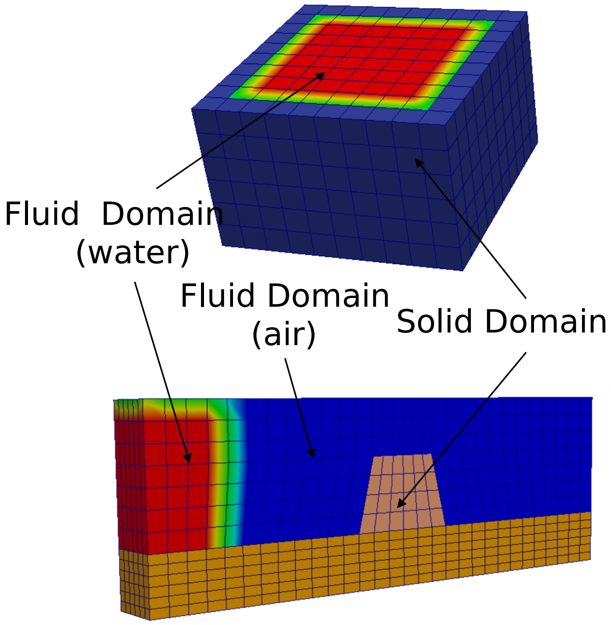

Figure 111.2: Numerical models built with gmFoam

- Mesh separation

Note that FVM mesh supported by Openfoam is very flexible. It can be any types of convex polyhedron as shown in figure 111.3). And the geometric description of FVM mesh required by Openfoam is totally different from that of FEM mesh. The description of FVM mesh is face-based. Faces (including both boundary surfaces and exterior surfaces) of control volumes are defined by a list a point IDs that consist of the face. Also the owner cell ID and neighbor cell ID of each face have to be specified. In contrast, the description of FEM mesh is element-based. After defining all the nodes in the model, the element is described by a list of node IDs. gmFoam supports both types of mesh description. User can build an integrated geometric model in Gmsh and define solid part and fluid part as different physical volume groups. After meshing it, gmFoam can separate the mesh information about solid domain and fluid domain and transfer them to FEM mesh and FVM mesh, respectively.

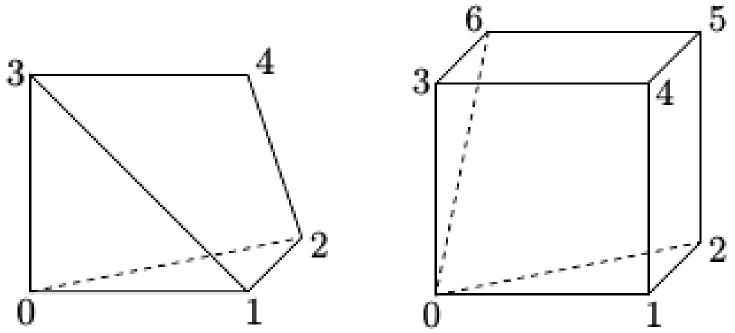

Figure 111.3: Mesh for FVM

- GmESSI incorporation

gmFoam perfectly incorporates current RealESSI preprocessor GmESSI so that it can quickly generate ESSI input files for the simulation of solid part. Also it has the capability to quickly generate input files for Openfoam. Currently the input file organization of Openfoam is very complicated. Several folders and files are needed to prepare in order to complete a very simple simulation. But with gmFoam all these basic information can be written in one single file with suffix as .gmfoam and gmFoam will automatically parse the content inside and produce all the input folders and files. In addition, with the help of physical group, gmFoam enables user to set different boundary conditions in a very convenient way. This is extremely helpful when we conduct solid fluid interaction analysis for big models with complicated boundary conditions.

- Interface geometry extraction

  gmFoam can extract the geometric information of solid-fluid interface and write down corresponding information as input files. The information is used to initialize SSFI object and build important geometric interface mapping.

- Support discontinuous mesh

  Discontinuous mesh is supported. This is very important, especially for large-scale simulation for solid fluid interaction. Usually refined mesh is needed for fluid part to get accurate enough result using VOF. Discontinuous mesh enables us to arbitrarily refine fluid mesh without changing solid mesh. Therefore, increase of computational efforts in solid part can be avoided. Figure 111.4 shows a model with discontinuous mesh (fluid mesh size : solid mesh size=1:3).

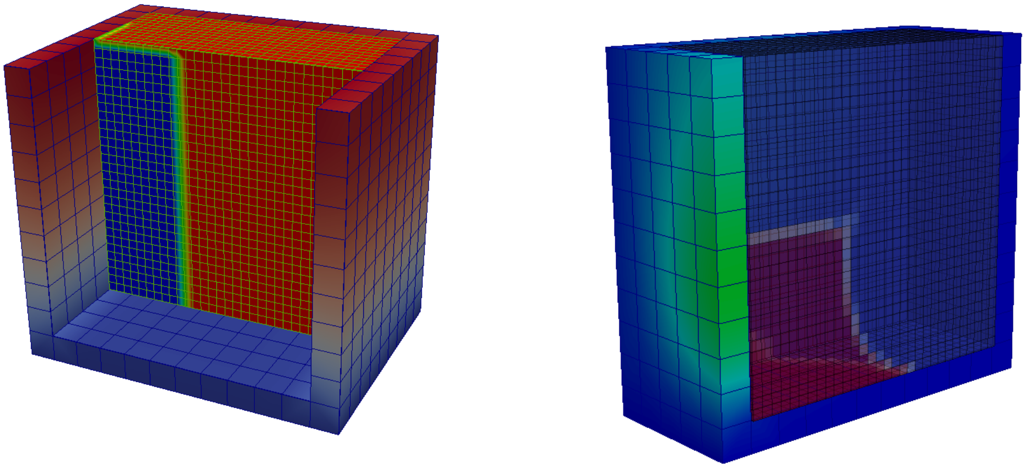

Figure 111.4: Numerical model with discontinuous mesh

111.4.3 Interface Domain-SSFI

An interface class SSFI was implemented in RealESSI to couple computations between solid domain and fluid domain. SSFI behaves like a container (called interface domain) to control geometric mapping, sequence of computation and boundary data interpolation and transmission. SSFI class contains and operates the objects of four base classes: ESSINode, ESSISurface, FoamNode, FoamSurface. Two core member functions: SSFI::FoamToESSIUpdate(double t) and SSFI::ESSIToFoamUpdate(Domain* theDomain, double t) are designed to perform all necessary updates on solid domain and fluid domain, respectively.

111.4.4 Geometric Mapping

Following geometrical mappings are built and maintained in SSFI.

- Foam node mapping to Foam surfaces

  For each foam node in solid fluid interface, this mapping returns all the IDs of its surrounding foam surfaces. For example, as shown in figure 111.5(a), foam node 5 is mapped to foam surface 1,2,3 and 4.

Foam node →	Foam Surfaces
5	(1,2,3,4)

- ESSI node mapping to Foam nodes

  For each ESSI node in solid fluid interface, this mapping returns all the IDs of its surrounding foam nodes within certain search radius (by default the radius is set as 0.1 meters). If the mesh size is very refined, reducing the searching radius helps to improve accuracy.

- Foam face mapping to ESSI nodes

  For each foam face in solid fluid interface, this mapping returns 4 vertex node IDs of an ESSI surface that contains the center of this foam face. Like in figure 111.5(b), foam face 1 (consists of foam node 1,2,3 and 4) is mapped to ESSI nodes 1,2,3 and 4.

Foam face →	ESSI nodes
1	(1,2,3,4)

- Foam node mapping to ESSI nodes

  For each foam node in solid fluid interface, this mapping returns 4 vertex node IDs of an ESSI surface that contains the Foam node. In figure 111.5(b), foam node 1 is mapped to ESSI nodes 1,3,8 and 7.

Foam node →	ESSI nodes
1	(1,3,8,7)

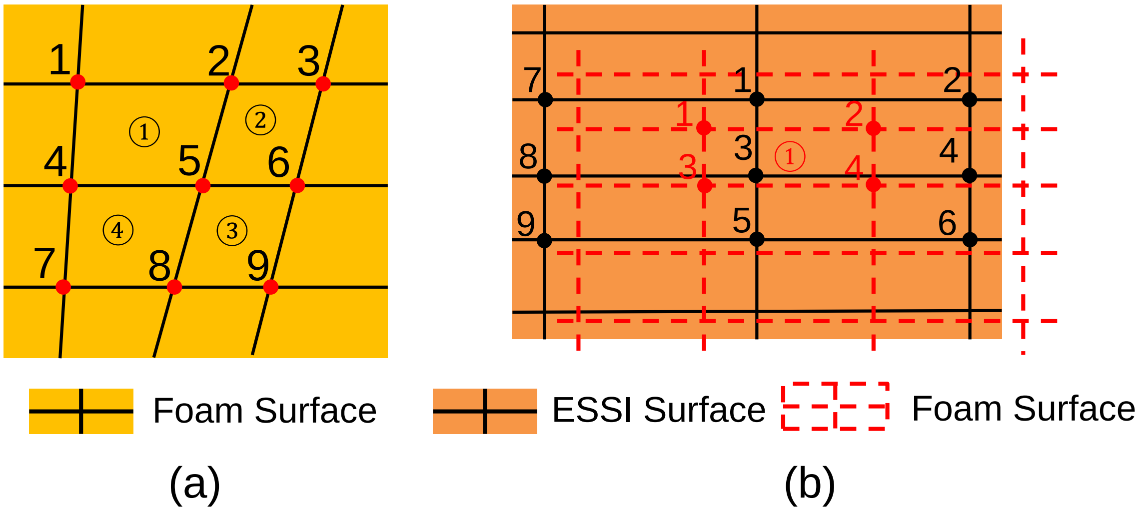

Figure 111.5: Geometric mapping in SSFI

111.4.5 SFI Interpolation

After building all of these geometric mapping, interpolation scheme is also needed to fully determine the values of interface variables (pressure, velocity and displacement) and update these values during the interaction process. There are three types of interpolation and updating involved here:

- Pressure interpolation

  The interpolation and updating of interface pressure happen during the process of FOAM to ESSI updating. After the fluid domain achieves its equilibrium, the new pressure values at interface foam faces need to be interpolated and transfered to corresponding ESSI nodes. The pressure interpolation scheme is following:

  Firstly, using the mapping from foam node to foam surfaces, pressure at each interface foam node is calculated by taking the average pressure values of its surrounding foam surfaces. Like in figure 111.5(a), the pressure at interface foam node 5 is the average value of pressure at interface foam surface 1,2,3 and 4. Then according to the mapping from ESSI node to foam nodes, the updated pressure at interface ESSI node is calculated as the average pressure value of corresponding foam nodes.

- Velocity interpolation

  Velocity interpolation takes place during the process of ESSI to FOAM updating. After RealESSI conducts transient analysis for solid domain, the velocities at interface ESSI nodes need to be fed back to corresponding interface foam surface. The velocity interpolation scheme is following:

The mapping from Foam face to ESSI nodes can give four vertex interface ESSI node ID. For example, in figure 111.5(b), foam face 1 is mapped to four ESSI nodes (1,2,3,4). With coordinates of foam face center and four ESSI nodes already known, inverse isoparametric mapping Hua (1990) is used here to determine the local coordinates (ζ, η) of foam face center. The formula of inverse isoparametric mapping is shown below:

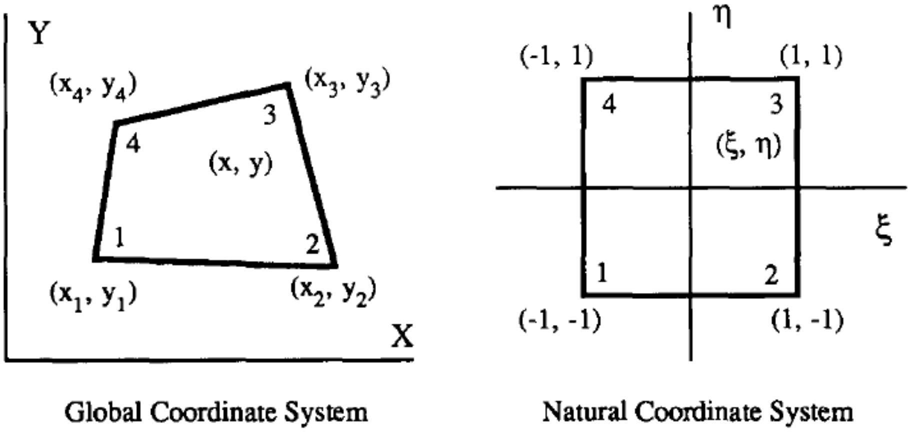

Figure 111.6: Illustration of isoparametric mapping Hua (1990)

$$\begin{bmatrix} a_1 & a_2 \\ b_1 & b_2 \\ c_1 & c_2 \end{bmatrix} = \begin{bmatrix} 1 & -1 & 1 & -1 \\ -1 & 1 & 1 & -1 \\ -1 & -1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 & y_1 \\ x_2 & y_2 \\ x_3 & y_3 \\ x_4 & y_4 \end{bmatrix} \tag{111.38}$$

$$\begin{aligned} d_1 &= 4x - (x_1 + x_2 + x_3 + x_4) \\ d_2 &= 4y - (y_1 + y_2 + y_3 + y_4) \end{aligned} \tag{111.39}$$

A compact notation to represent the determinant of a 2 matrix is introduced as

$$r_s = \begin{vmatrix} r_1 & s_1 \\ r_2 & s_2 \end{vmatrix} = r_1 s_2 - r_2 s_1 \tag{111.40}$$

where $r,s = a,b,c,d$. Notice that $r_s = -s_r$.

With all the notations well defined, the solutions to local coordinate given by Hua (1990) are shown below:

- $a_1 a_2 a_b a_c \neq 0$

$$\begin{cases} a_b\zeta^2 + (c_b + d_a)\zeta + d_c = 0 \\ \eta = (a_d + b_a\zeta)/a_c \end{cases} \quad \text{where } \zeta \in [-1,1]$$

- $a_1 = 0$ *and* $a_2 c_1 \neq 0$

$$\begin{cases} a_b\zeta^2 + (c_b + d_a)\zeta + d_c = 0 \\ \eta = (a_d + b_a\zeta)/a_c \end{cases} \quad \text{where } \zeta \in [-1,1]$$

- $a_2 = 0$ *and* $a_1 b_2 \neq 0$

$$\begin{cases} a_b\zeta^2 + (c_b + d_a)\zeta + d_c = 0 \\ \eta = (a_d + b_a\zeta)/a_c \end{cases} \quad \text{where } \zeta \in [-1,1]$$

- $a_1 a_2 \neq 0$ *and* $a_b = 0$

$$\begin{cases} \zeta = (a_1 d_c)/(b_1 a_c + a_1 a_d) \\ \eta = a_d/a_c \end{cases}$$

- $a_1 a_2 \neq 0$ *and* $a_c = 0$

$$\begin{cases} \zeta = a_d/a_b \\ \eta = (a_1 d_b)/(c_1 a_b + a_1 a_d) \end{cases}$$

- *All other conditions*

$$\begin{cases} \zeta = d_c/(a_1 d_2 + b_c) \\ \eta = b_d/(a_2 d_1 + b_c) \end{cases}$$

After obtaining local coordinates (ζ,η) corresponding to foam surface center, isoparametric mapping can be conducted through the shape function of 4-node quadrilateral element. The interpolated velocity can be calculated with equation 111.41.

$$
\begin{aligned}
N_1 &= \frac{1}{4}(1-\zeta)(1-\eta) \\
N_2 &= \frac{1}{4}(1+\zeta)(1-\eta) \\
N_3 &= \frac{1}{4}(1+\zeta)(1+\eta) \\
N_4 &= \frac{1}{4}(1-\zeta)(1+\eta) \\
\boldsymbol{v} &= N_1\boldsymbol{v_1} + N_2\boldsymbol{v_2} + N_3\boldsymbol{v_3} + N_4\boldsymbol{v_4}
\end{aligned}
\tag{111.41}
$$

- Displacement interpolation

  Displacement interpolation also takes place during ESSI to FOAM updating. In order to meet the geometric conformity, the Eulerian mesh of fluid domain should dynamically move along with the real-time response of solid domain. Therefore, it is necessary to interpolate the displacement of interface ESSI nodes to interface foam nodes. The displacement interpolation scheme is similar to velocity interpolation scheme and shown below:

  The mapping from Foam node to ESSI nodes can give four vertex interface ESSI node ID. Inverse isoparametric mapping is first performed to compute local coordinate of Foam node. Then displacement of foam node is interpolated from displacement of four vertex ESSI nodes through isoparametric mapping.

111.4.6 Mass Conservation

There are two levels of mass conservation conditions needed to be satisfied during the SFI.

One is local level: Regarding each control volume, the amount of fluid flows in should equal to the amount of fluid that flows out for incompressible fluid. This local mass conservation condition is mathematically represented by continuity equation in equation 111.6 and can be approximately met through finite volume discretization. Another level of mass conservation is global level: For a closed fluid domain (no fluid transfer with other external fluid system), the total amount of fluid should keep constant during SFI. The global level of mass conservation is trivial for pure fluid flow system with static Eulerian boundary mesh. Since for this kind of flow system, global level of mass conservation is free and automatically holds based on local level of mass conservation.

However, for flow system with deforming boundary, especially when Lagrangian movement of Eulerian mesh is involved (like Arbitrary Lagrangian method Souli and Zolesio (2001)), the local level of mass conservation does not guarantee the mass conservation of global level. Demirdžić and Perić (1988) pointed out that for moving mesh, one more conservation equation so called space conservation needed to be solved simultaneously with the mass, momentum and energy conservation equations. Otherwise artificial mass addition or reduction is generated which may cause the solution to be greatly in error.

The space conservation law is expressed by equation 111.42, where J is the determinant of the metric tensor and $\boldsymbol{v_g}$ is the grid velocity of the mesh. Correspondingly, the finite volume discrete evaluation of volume integral of equation 111.42 can be given in equation 111.43, where $\delta V = V^n - V^0$ is the change of cell volume during Δt, $\boldsymbol{v_{g(f)}}$ is the mesh velocity of cell face and $\boldsymbol{S}$ is cell face vector.

$$\frac{\partial J}{\partial t} - J\boldsymbol{\nabla} \cdot \boldsymbol{v_g} = 0 \tag{111.42}$$

$$\frac{V^n - V^0}{\Delta t} = \sum_f \boldsymbol{v_{g(f)}} \cdot \boldsymbol{S} \tag{111.43}$$

In our implementation, consider the coupling with VOF method and our SFI simulation is generally for small deformation of fluid boundary, a simplified procedure is adopted here to guarantee the global level of mass conservation: Only the location of foam nodes at solid fluid interface is updated with Lagrangian motion of corresponding ESSI nodes while interior foam nodes remain static. After geometry updating of the mesh, the volume of foam cells at interface is re-evaluated and volume fraction values are also updated according to equation 111.44 to ensure the mass conservation. Then the transport equation 111.27 is solved based on new α values.

$$\alpha = \frac{\int \alpha^0 dV^0}{\int dV} = \frac{\alpha^0 V^0}{V} \tag{111.44}$$

Chapter 201

The Real ESSI Simulator System

(1986-1989-1993-1994-1996-1999-2003-2007-2019-2020-2021-)

201.1 Chapter Summary and Highlights

201.2 Introduction to the Real-ESSI Simulator System

The Real-ESSI Simulator (Realistic Modeling and Simulation of Earthquakes, and/or Soils, and/or Structures and their Interaction) is a software, hardware and documentation system for high performance, sequential or parallel, time domain, linear or nonlinear, elastic and inelastic, deterministic or probabilistic, finite element modeling and simulation of

- statics and dynamics of soil,
- statics and dynamics of rock,
- statics and dynamics of structures,
- statics of and dynamics of soil-structure systems,
- dynamics of earthquakes, and
- dynamic earthquake-soil-structure interaction.

The Real-ESSI Simulator systems is used for design and for assessment of static and dynamic behavior of infrastructure objects, including buildings, bridges, dams, nuclear installations, tunnels, etc.

Design: Multiple linear elastic load cases can be combined and design quantities, sectional forces exported for design.

Assessment: Practical, realistic, inelastic, nonlinear load staged analysis, with accurate modeling of elastic and inelastic, nonlinear components, and with all the simulation, algorithmic features available, as listed below, is performed to assess design, current safety margins and economy of objects.

The Real-ESSI Simulator is developed at the University of California, Davis, in collaboration and with partial financial support from the USDOE, USNRC, USNSF, USBR, USFEMA, CalTrans, CNSC-CCSN, UN-IAEA, Shimizu, Private Donors, etc. The Real-ESSI Simulator develops methods and models that inform and predict rather than (force) fit.

The Real-ESSI Simulator systems consists of the Real-ESSI Program, Real-ESSI Pre-Processing and Post-Processing tools, Real-ESSI Computer and Real-ESSI Notes.

201.2.1 Real-ESSI Program

The Real-ESSI program is a general purposes finite element program that features models and methods for analyzing static and dynamic behavior of Civil Engineering objects, such as buildings, bridges, dams, nuclear installations, tunnels, etc.

201.2.2 Real-ESSI Pre-Processing tools

The Real-ESSI Pre-Processing tools are a set of programs, scripts and modules that are used to develop Real-ESSI models. Mesh generation relies on Gmsh (Geuzaine and Remacle, 2009) and our own plugins Gm-ESSI, while there are also mesh translators from other input formats to Real-ESSI input format/language.

201.2.3 Real-ESSI Post-Processing tools

The Real-ESSI Post-Processing tools rely on Paraview (Ayachit, 2015) visualization platform, with our own plugins, as well as on a number of programs and scripts to visualize output using matlab, python, etc.

201.2.4 Real-ESSI Computer

The Real-ESSI Computer can be any single CPU, multiple CPU, and/or cluster of single/multiple CPUs computers using Linux operating system. The reason for using Linux is that state of the art development tools are available, and that Linux is used on virtually all large supercompters, so that the very same sources can be compiled and executables developed for small desktop computers, large server computers, local clusters of computers and large supercomputers. There is a possibility to build Real-ESSI and create executables on Macintosh and Windows platforms, as long as standard software tools and compiles, C++ and Fortran, are available. However, such work is not currently pursued.

201.2.5 Real-ESSI Notes

The Real-ESSI notes, documentation for the Real-ESSI Simulator System, is available through Lecture Notes by Jeremić et al. (1989-2025).

201.2.6 Real-ESSI Name

The Real-ESSI Simulator System name is based on an acronym: Realistic Modeling and Simulation of Earthquakes, and/or Soils, and/or Structures and their Interaction. Pronunciation of Real-ESSI is similar to ”real easy”, as in ”as easy as pie”. Translation of name Real ESSI to languages of developers and users is:

- Врло просто,
- Стварно просто,
- Стварно лако,
- Просто к’о пасуљ,
- Vrlo prosto,
- Stvarno prosto,
- 真简单 ,
- Muy fácil,
- অতি সহজ,
- **آسان واقعی**,
- Molto facile,
- 本当に簡単 ,
- Πραγματικά εύκολο,
- बहुत ही आसान,
- Très facile,
- Вистински лесно,
- Wirklich einfach,
- سهلٌ جداً
- Zelo enostavno
- Zares enostavno
- Muito Fácil
- Res lahko
- Dziecinna igraszka
- Çocuk oyuncaği

202.3 Object-Oriented Design of the Plastic Domain Decomposition (PDD)

202.3.1 Introduction

This section describes the object oriented design of the proposed PDD algorithm and its implementation into MOSS library framework. At the beginning of this section, the Object-Oriented approach to programming the Finite Element Method is reviewed based on the existing (as of 2005) implementation of OpenSees. Object-Oriented parallel design is then extended from the existing framework. Parallel algorithm adopts Main-Follower paradigm and the new design of data structures have strictly followed the Object-Oriented principle using C++ language. External utility libraries such as ParMETIS and PETSc have been incorporated to provide seamless parallel numerical manipulations including partitioning/repartitioning and equation solving.

In this chapter, the algorithm overview will be presented first. Then the implementation details in C++ will follow. The challenges of achieving load balancing in parallel Finite Element simulation have been divided into two parts, global level equation solving and constitutive level iterations. This research presents the PDD algorithm to demonstrate how to balance each stage systematically in applications.

202.3.2 Object-Oriented Parallel Finite Element Algorithm

Parts of OpenSees software framework (McKenna, 1997) have been used in this chapter. Object-Oriented design of OpenSees enables software reuse that greatly shortens the development life cycle of application codes.

OpenSees is comprised of a set of classes and objects that represent models perform computations for solving the governing equations, and provide access to processing results. There are four types of class objects in OpenSees McKenna (1997).

- Modeling Classes are used to create the Finite Element Model Classes for a given problem.
- Finite Element Model Classes are used to describe the finite element model and to store the results of the analysis performed on the model. Main class abstractions used in OpenSees are Node, Element, Constraint, Load and Domain. The relationship amongst these classes can be shown using the class diagram Figure 202.2 using the Rumbaugh notation as shown in Figure 202.1 Rumbaugh et al. (1991).
- Analysis Classes are used to perform the finite element analysis, i.e., to form and solve the global system of equations
- Numerical Classes are used to handle numerical operations in the solution procedure. Also included in this category are data structure classes such as Vector, Matrix and Tensor.

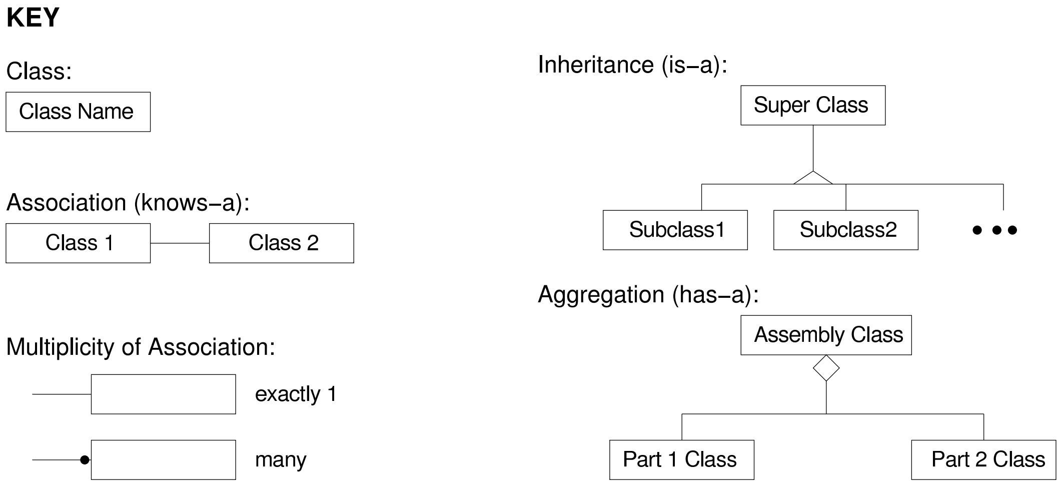

Figure 202.1: Rumbaugh Notation of-Object Oriented Design

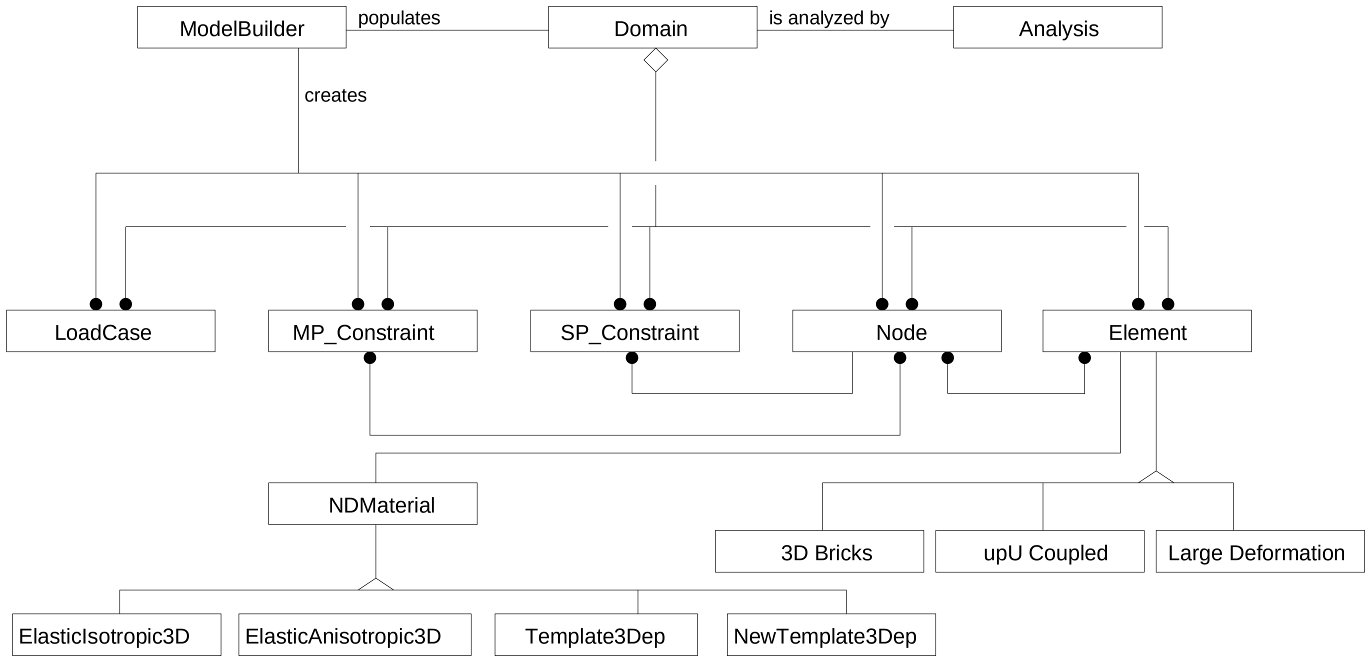

Figure 202.2: Class Diagram of Finite Element Model Classes

202.3.2.1 Modeling Classes

The modeling classes are responsible of creating the necessary components of the finite element model, such as nodes, elements, loads and constraints. There are a number of approaches proposed by various researchers. In some works, the user has the responsibility to create the finite element model in a single driver-type file Ross et al. (1992); Zeglinski et al. (1994); Cardona et al. (1994). In other works, an input file containing the model data is used to be read by the main program to create the model Forde et al. (1990); Dubois-Pelerin et al. (1992); Dubois-Pelerin and Zimmermann (1993); Menéntrey and Zimmermann (1993). Graphical interface for building models visually has also been proposed Ostermann et al. (1995); Mackie (1995).

In this research, the existing ModelBuilder interface class is reused to facilitate the finite element model construction. As shown in Figure 202.2, the ModelBuilder is associated with a single finite element Domain object. The interface (pure virtual function) buildFE_Model() must be redefined depending on the specific type of finite element model users want to build.

In parallel processing, PartitionedModelBuilder is used instead, in which the building process includes higher level control of building Subdomains from the PartitionedDomain. For each Subdomain, the PlaneFrameModelBuilder-type is invoked to build the finite element model on each Subdomain.

The Object-Oriented interface design of ModelBuilder through pure virtual function provides a consistent framework from which all kinds of engineering model can be readily extended.

202.3.2.2 Finite Element Model Class

In most of the works presented, main class abstractions used to describe a finite element model are: Node, Element, Constraint, Load and Domain Forde et al. (1990); Zimmermann et al. (1992a); Dubois-Pelerin et al. (1992); Dubois-Pelerin and Zimmermann (1993); Menéntrey and Zimmermann (1993); Pidaparti and Hudli (1993); Cardona et al. (1994); Chudoba and Bittnar (1995); Zahlten et al. (1995); Rucki and Miller (1996).

Node The most important feature of the Node class is the associativity with DOF class which contains the degree of freedoms of any specific instance of the Node class. The response quantities such as displacements of each DOF object will be stored in the Node class. Routines are available to set/get those solution quantities.

Element The functionality of an Element object is to provide the tangent stiffness, mass and the residual force corresponding to current loadings. Element class contains reference to its associated Node objects.

Element class is one of the most fundamental abstractions in Object-Oriented finite element software design. In this research, Element also acts as a container for material models, which is critical for simulations with nonlinear materials. Chudoba and Bittnar (1995) proposed a MaterialPoint object which is associated with GaussPoint object. In Zahlten et al. (1995), class abstractions such as cross section, material point, material law, yield surface, hardening rule and flow rule are introduced to model complicated materials within the Element class in an Object-Oriented flavor.

Jeremić and Yang (2002) present the complete formulation of Template3Dep material class, which is wrapped inside the Element class to enable a consistent interface for complex elastic-plastic material modeling.

Constraint There are two types of constraints in finite element simulations,

1. Single-Point constraints, which are applied to a specific DOF object;
2. Multi-Point constraints, which describe the relationship between more than one DOF objects.

In current implementation of OpenSees (version from 2005), the two classes SP_Constraint and MP_Contraint are designed but they do not handle the constraints. These two classes are responsible of setting up relations between Nodes and the constrained DOF_Groups. This will be covered shortly in Analysis class design.

Load There are also two types of loads that are commonly seen in finite element analysis:

1. node loads that act on specific Nodes;
2. element loads that act on specific Elements, which can be due to body forces, surface tractions, initial stresses and temperature gradients.

In the current (version version 2005) implementation of OpenSees, three extra classes are introduced to handle loading conditions, LoadPattern, NodalLoad and ElementLoad. The LoadPattern is a container class that provides methods in its interface to allow NodalLoad and ElementalLoad objects to be created, traversed and removed. As shown in Figure 202.2, each NodalLoad or ElementalLoad object is associated with a Node or Element object and is responsible of applying nodal or elemental loads to that object.

Domain The Domain class is the most important container class that is responsible of holding all components of the finite element model, i.e. all the Nodes, Elements, Constraints and Loads. Domain class acts as the interface between Analysis class and all the individual components of the finite element model. The interface of Domain enables component creation, information access and component removal.

202.3.2.3 Analysis

The Analysis class (McKenna, 1997) is responsible for forming and solving the governing equations for the finite element model. As for nonlinear problems, incremental solution techniques are required and iterative schemes such as Newton-Raphson needed to solver the nonlinear system of equations.

For incremental solution algorithm, the computational tasks are more involved for the finite element analysis.

- Assign equation numbers and map these to the nodal DOFs. This step can be of significant influence on the bandwidth of the coefficient matrix, which is inherently sparse due to the compact support of finite element formulation.
- Form the matrix equations using contributions from elements and nodes.
- Apply the constraints, which may involve transforming the element and nodal contributions or adding additional terms and unknowns to the matrix equations depending the method employed to handle constraints.
- Solve the matrix equations for the incremental nodal displacements.
- Determine the internal state and stresses in the elements.

The Object-Oriented design of the Analysis class is done by firstly breaking down the main tasks performed in a finite element analysis, abstracting them into separate classes, and then specifying the interface for these classes. The Analysis class is an aggregation of all the sub-functionality classes of following types:

1. SolutionAlgorithm class describes the complete computation procedure (steps) in the analysis.
2. AnalysisModel is a container class that stores and provides access to the following types of classes:
   (a) DOF_Group class represents the DOF at the Nodes or new DOF introduced into the analysis to enforce the constraints;
   (b) FE_Element class represents the real Elements in the Domain or they are introduced to add stiffness and/or load to the system of equations in order to enforce the constraints.
   It is worthwhile to mention that the FE_Elements and DOF_Groups have very important design implications although they might seem redundant at the first sight. The significance comes from the facts that
      i. they record the mapping between DOFs and equation numbers in the global system which greatly simplifies the interfaces of Node and Element class;

   ii. they also provide the interfaces for forming tangent and residual vectors which are used to form the global system of equations;
   iii. they are major utility classes of handling constraints.

3. Integrator defines how the FE_Elements and DOF_Groups contribute to the system of equations and how the response quantities should be updated given the solution to the global system of equations.
4. ConstraintHandler handles the constraint by creating adequate FE_Elements and DOF_Groups.
5. DOF_Numberer maps the equation number to the DOFs in the DOF_Groups.
6. SystemOfEqn encapsulates the global system of equations.

The aggregation of the Analysis object is shown in Figure 202.3.

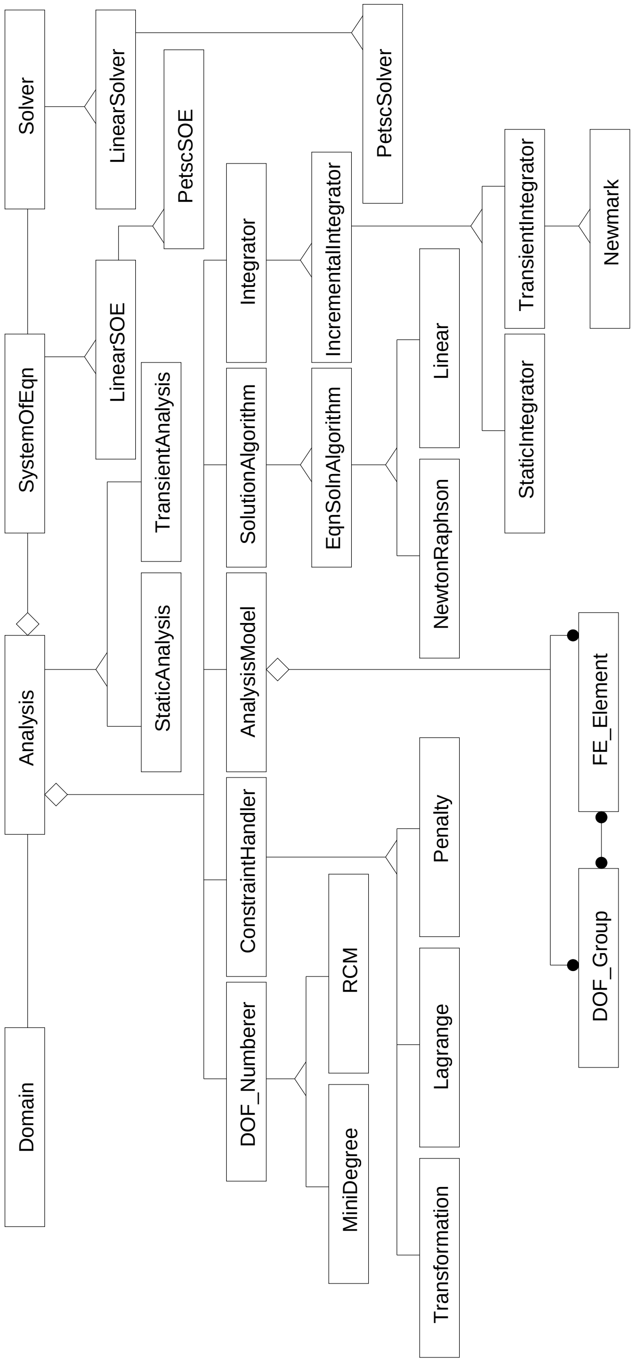

Figure 202.3: Class Diagram of Analysis Aggregation

Traditional program flow diagrams are used to describe how is the nonlinear finite element algorithm control flow implemented in OpenSees. These flow charts are organized as following:

Figure 202.4 shows the overall analysis algorithm flow for nonlinear finite elements.
Then this overall analysis flow is broken down into detailed subroutines, such as theIntegrator::newStep() and theAlgorithm::solveCurrentStep().

- Figure 202.5 explains in detail the function flow of theIntegrator::newStep(), which illustrates the (fairly standard) incremental finite element solution techniques implemented in OpenSees.
- Figure 202.6 shows the function flow of forming the tangent stiffness matrix, which is a loop assembling the global equation system involved in function theIntegrator::newStep().
- Figure 202.7 further describes the Newton-Raphson type iterative solution schemes involved in function theAlgorithm::solveCurrentStep().

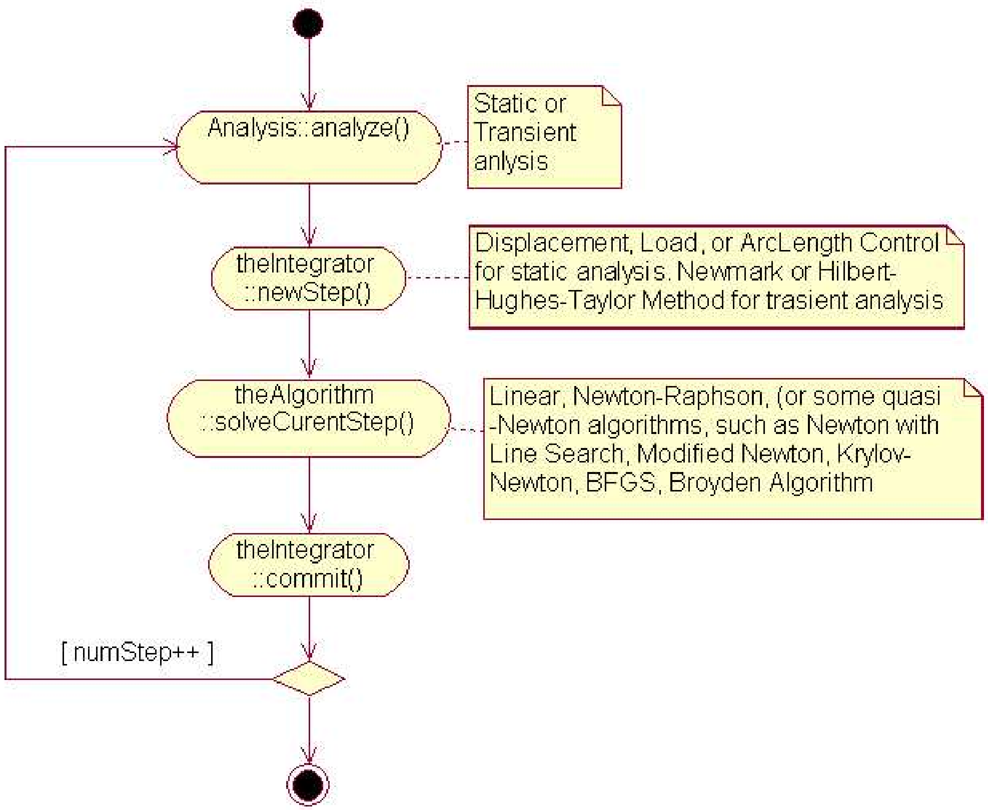

Figure 202.4: Overall Algorithm Flow Chart for Nonlinear Finite Element Analysis

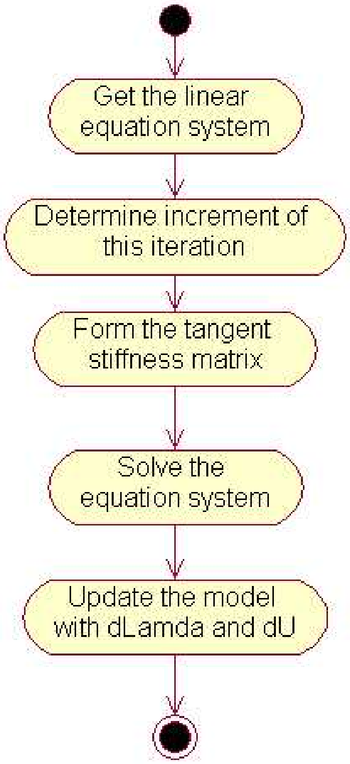

Figure 202.5: Detailed View: theIntegrator::newStep() - Incremental Solution Techniques for Nonlinear Finite Element Analysis

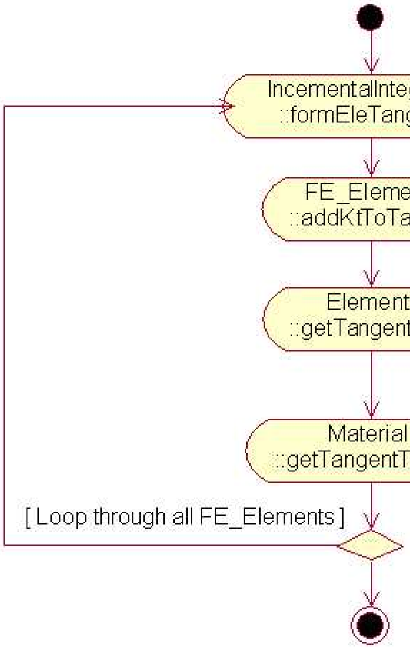

Figure 202.6: Detailed View: Assembly of Global Equation System in theIntegrator::newStep()

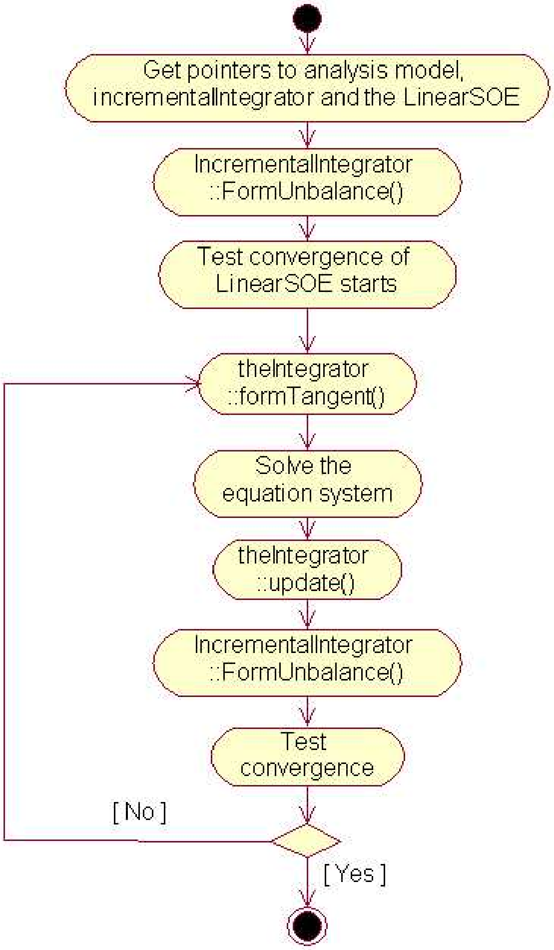

Figure 202.7: Detailed View: theAlgorithm::solveCurrentStep() - Newton-Raphson Iterative Schemes for Nonlinear Finite Element Analysis

Finite element simulations inherently are element-based operations, so little modification is needed to parallelize the algorithms described above, although special attention has to be paid to synchronize the computation among different processors. Figure 202.8 shows the activity flow for parallel nonlinear finite element simulations.

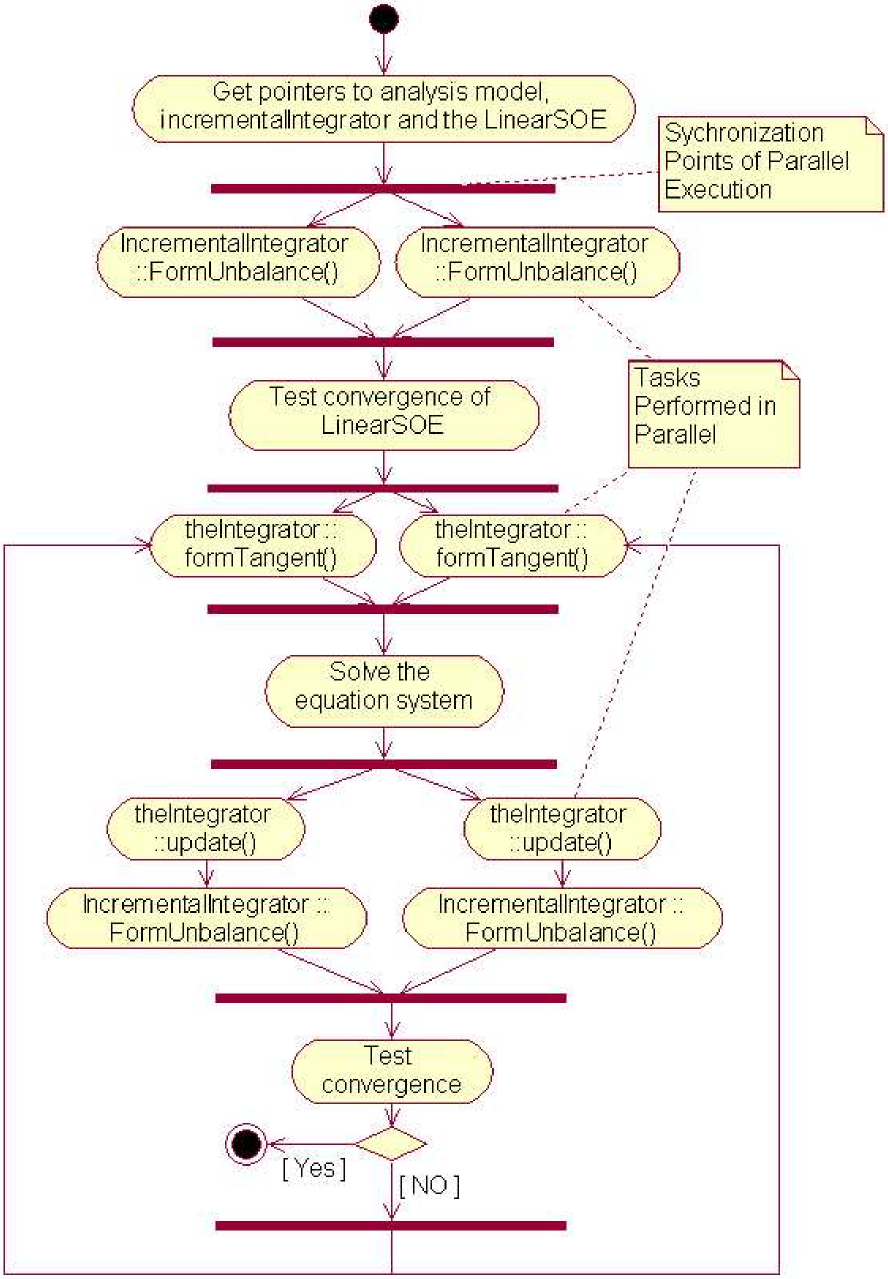

Figure 202.8: Parallel Activity Flow Diagram of Nonlinear Finite Element Analysis

202.3.2.4 Object-Oriented Domain Decomposition

There are three most notable designs of Domain Decomposition method in literature McKenna (1997).

1. Sause and Song (1994) presents an Object-Oriented design for linear static analysis using substructuring. The interface is restricted to substructuring or FETI Farhat and Roux (1991b) only, and repeated geometry limits the applicability of this design to large problems.
2. Archer (1996) proposes a SuperElement class that is a subclass of Element and has a Domain class aggregated. This design is conceptually inappropriate and it results excessive method calls as methods that are for the SuperElement must be called by the SuperElement on the associated Domain McKenna (1997).
3. Miller and Rucki (1993) introduces the Partition class which is associated with an Algorithm class. The Algorithm class is responsible for updating the state of a Partition so that it will be in equilibrium. Again, this design is good for substructuring type Domain Decomposition analysis. If we want to solve a problem before the interface solution can be determined, the design fails.

The current design of OpenSees McKenna (1997) proposes many new classes to facilitate flexible Object-Oriented Domain Decomposition. The main abstractions include PartitionedDomain, DomainDecompAnalysis, DomainDecompSolver Subdomain, DomainPartitioner and GraphPartitioner. The class diagram is shown in Figure 202.9.

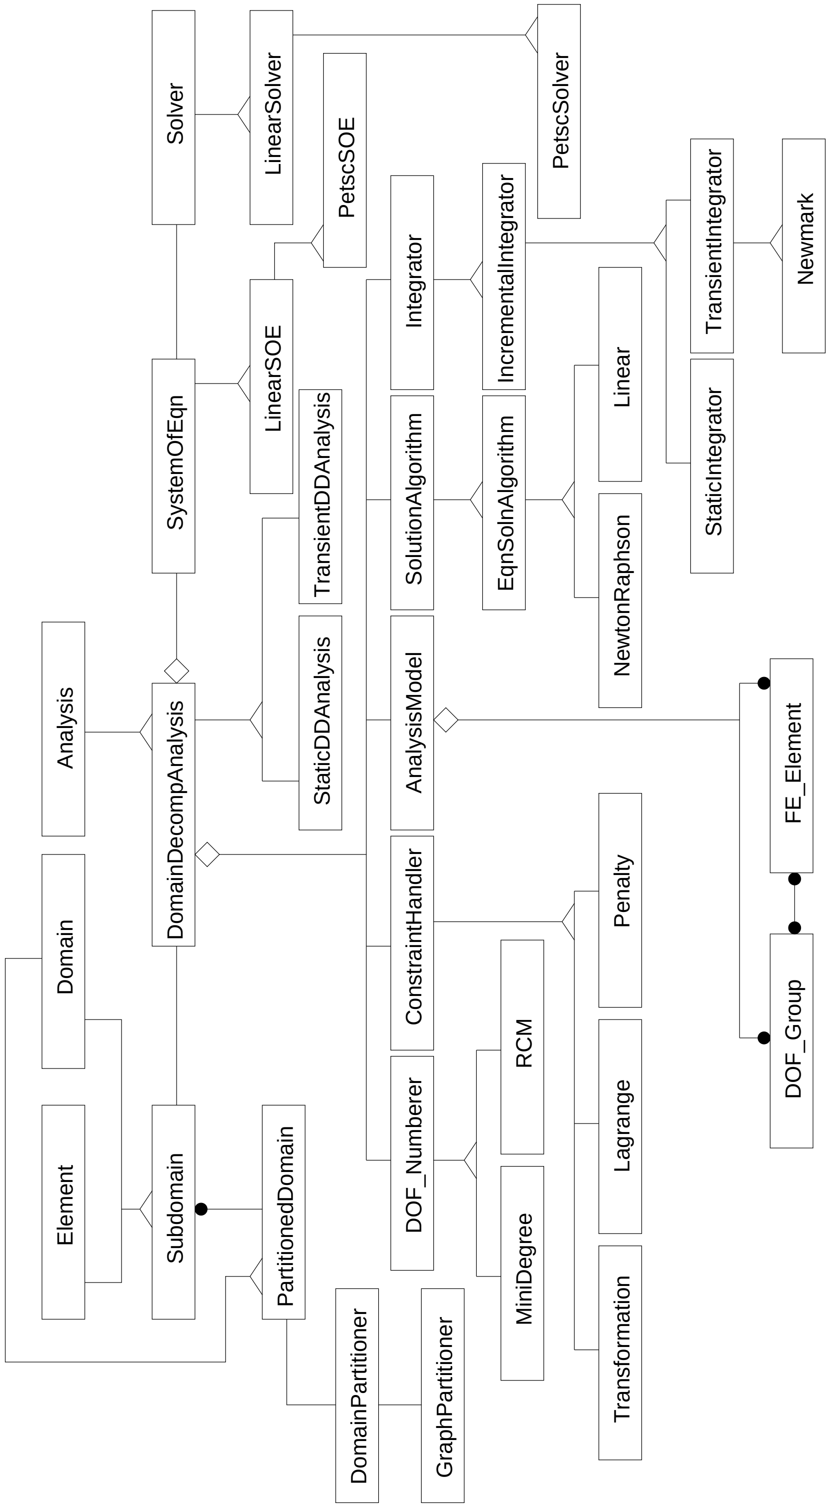

Figure 202.9: Class Diagram of Domain Decomposition Analysis

PartitionedDomain The PartitionedDomain class is a subclass of Domain whose objects can be partitioned into Subdomain objects. Aside from common functionality inherited from Domain, PartitionedDomain class provides methods for partitioning the Domain and retrieving information from Subdomains. PartitionedDomain the aggregation of Subdomains and is the major containing class in main compute process.

DomainPartitioner The DomainPartitioner class is responsible for performing the actual operation to split the PartitionedDomain. The DomainPartitioner will call its associated GraphPartitioner to partition the PartitionedDomain. It also provides the methods to migrate Elements, Nodes, Constraints, Loads amongst Subdomains.

DomainPartitioner is one of the most important utility class in OpenSees in the sense that all partitioning routine and data migration operations will be rooted from this class.

GraphPartitioner This class utilizes external graph partitioner to color the finite element connectivity graph, which will be constructed from the PartitionedDomain. The result will be fed back to DomainPartitioner to facilitate subsequent data distribution.

GraphPartitioner introduces graph partitioning into OpenSees and the main functionality of this class is to call API and provide necessary data structures from the specific application.

Subdomain The Subdomain class inherits from both Element and Domain. This has a dual-level design implication:

1. for the top PartitionedDomain, superclass Element is a proxy class of subclass Subdomain, in the sense that all the relevant operations on Elements invoked by PartitionedDomain will be redirected to the specific Subdomain;
2. for any specific Subdomain, it inherits all the interfaces of Domain to do all the computations required by PartitionedDomain.

202.3.2.5 Parallel Object-Oriented Finite Element Design

There has been much effort by researchers on parallel implementation of finite element computations, which can be categorized into either domain decomposition methods or parallel equation solving.

Domain decomposition is favored by many researchers due to its nice "divide and conquer" approach. The subdomains in the domain decomposition method are each assigned to a processing node, which will perform all the computations on that subdomain.

Of the domain decomposition methods, the substructuring method has been the most popular choice although other methods such as iterative substructuring Carter et al. (1989) and FETI (Finite Element Tearing and Interconnecting) Farhat and Roux (1991b); Farhat and Crivelli (1994) have also been used. In the substructuring method presented, static condensation is typically performed on the assembled system of equations.

Earlier works on parallel processing for inelastic mechanics focused on structural problems. We mention work by Noor et al. (1978); Utku et al. (1982); Storaasli and Bergan (1987) in which they used substructuring to achieve partitions. Fulton and Su (1992) developed techniques to account for different types of elements but used substructures of same element types (non–balanced computations). Hajjar and Abel (1988) developed techniques for dynamic analysis of framed structures with the objective of minimizing communications. Klaas et al. (1994) developed parallel computational techniques for elastic–plastic problems but tied the algorithm to the specific multiprocessor computers used (and specific network connectivity architecture). Farhat (1987) developed the so–called Greedy domain partitioning algorithm but stayed short of using redistribution of domains as a function of developed nonlinearities.

The major parallel programming model in OpenSees (McKenna, 1997) is the so-called Actor model, which is a mathematical model of concurrent computation that has its origins in Hewitt et al. (1973) . Actors Agha (1984) are autonomous and concurrently executing objects which execute asynchronously. Actors can create new actors and can send messages to other actors. The Actor model is an Object-Oriented version of message passing in which the Actors represent processes and the methods sent between Actors represent communications.

The Actor model adopts the philosophy that everything is an Actor. This is similar to the everything is an Object philosophy used by object-oriented programming languages, but differs in that object-oriented software is typically executed sequentially, while the Actor model is inherently concurrent, `http://en.wikipedia.org/wiki/Actor_model`.

An Actor is a computational entity with a behavior such that in response to each message received it can concurrently:

- send a finite number of messages to (other) Actors;
- create a finite number of new Actors;
- designate the behavior to be used for the next message received.

Note that there is no assumed sequence to above actions and that they could in fact be carried out in parallel.

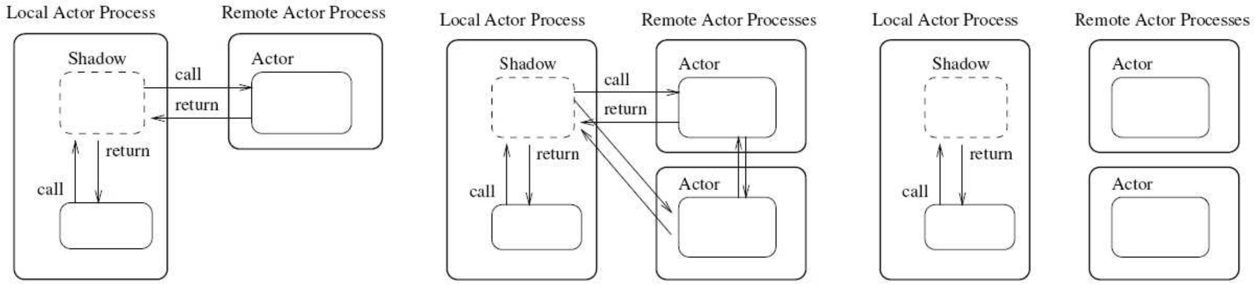
Communications with other Actors occur asynchronously (i.e. the sending Actor does not wait until the message has been received before proceeding with computation), which is the unblocking behavior.

Messages are sent to specific Actors, identified by address (sometimes referred to as the Actor's "mailing address"). As a result, an Actor can only communicate with Actors for which it has an address which it might obtain in the following ways:

- The address is in the message received;
- The address is one that the Actor already had, i.e. it was already an "acquaintance";
- The address is for a just created Actor.

The Actor model is characterized by inherent concurrency of computation within and among Actors, dynamic creation of Actors, inclusion of Actor addresses in messages, and interaction only through direct asynchronous message passing with no restriction on message arrival order.

In order to minimize the changes to the sequential Domain Decomposition design presented in previous sections, McKenna (1997) introduces the Shadow class. A Shadow object is an object in an Actor's local address space. Each Shadow is associated with one Actor or multiple Actors in the case of an aggregation. The Shadow object represents the remote object to the objects in the local Actor's space. The Shadow object is responsible for sending an appropriate message to the remote Actor or Actors if broadcasting. The remote Actor(s) will then, if required, return the result to the local Shadow object, which in turn replies to the local object. The communication process is shown in Figure 202.10.



(a) Actor - Communication Required

(b) Aggregate - Communication Required

(c) No Communication Required

Figure 202.10: Communication Pattern of Actor-Shadow Models McKenna (1997)

Some other new classes of parallel finite element programming are:

- Channel is the bridge through which the Actors and Shadows can communicate.
- Address represents the location of a Channel object in the machine space. Channel objects send/receive information to/from other Channel objects, whose locations are given by the Address objects.

- MovableObject is an object which can send its state from one actor process to another.
- ObjectBroker is an object in a local actor process for creating new objects.
- MachineBroker is an object in a local actor process that is responsible for creating remote actor processes at the request of Shadow objects in the same local process.

The relation between these classes is shown in Figure 202.11.

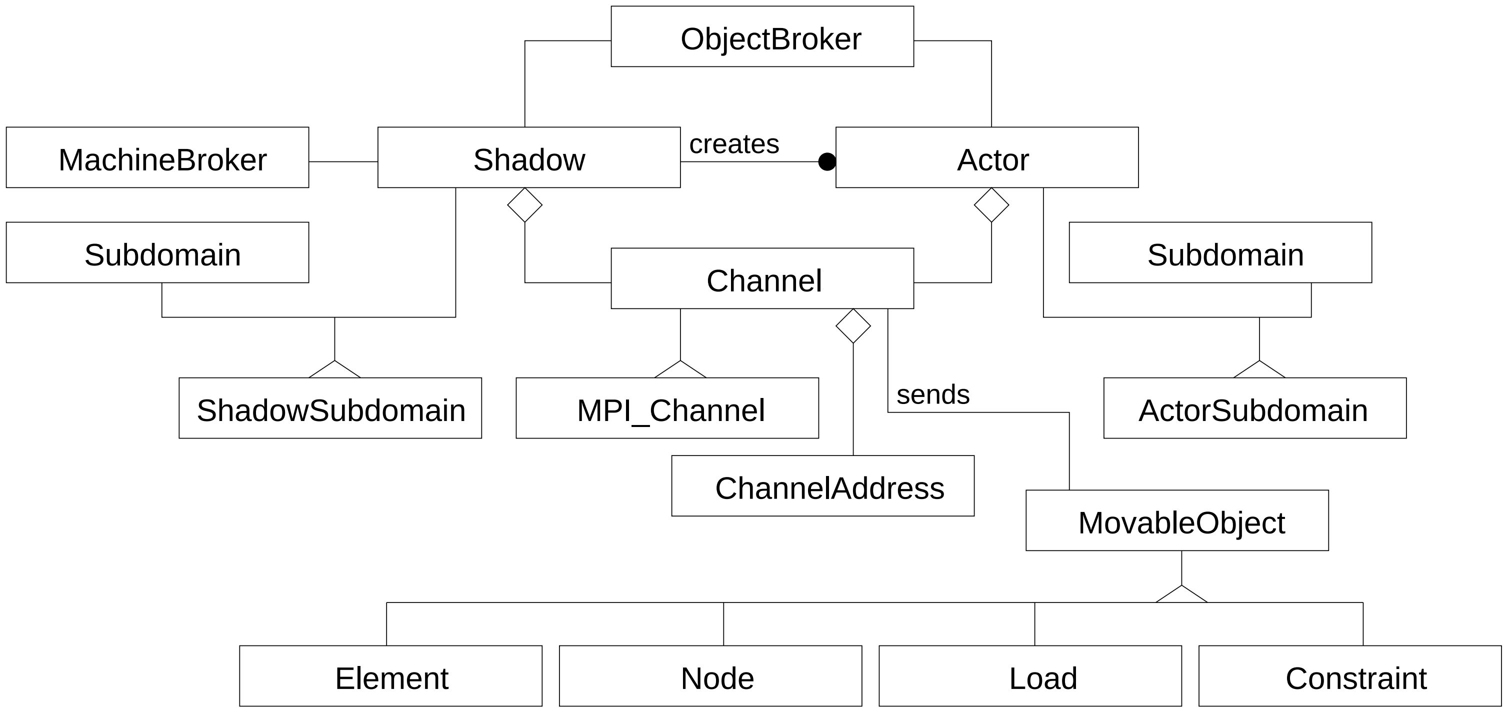


Figure 202.11: Class Diagram for Parallel Finite Element Analysis

202.3.3 Dual-Phase Adaptive Load Balancing

From the Figure 202.7, one can easily identify two computational phases that are fundamental to nonlinear elastic-plastic finite element simulations. One is well known as global level equation solving and the other is local level elemental calculations during which the elemental update happens for each element. In nonlinear elastic-plastic finite element simulations, the local computational phase can be much more expensive than the global equation solving phase due to the presence of complex material models and nonlinearity.

In this chapter, the implementation of proposed PDD algorithm has considered load balancing issues on both elemental level elastic-plastic computations and global level equation solving.

202.3.3.1 Elemental Level Load Balancing

The load balancing operation on constitutive level is built on the foundation of adaptive multilevel graph partitioning algorithm available through ParMETIS.

In this chapter, element-based graph is constructed from the Finite Element mesh on which the graph partitioning algorithm acts on to obtain partitions and/or repartitions. Each element will be assigned a vertex tag for identification.

When two elements at least share a single node, we assign an edge to both vertices because the element graph is deemed to be undirected, which means the edge is equally identified by two vertices without ordering required.

We creatively specify vertex weight to represent elemental level computational load for each vertex (element). In the implementation of this chapter, the vertex weight will be automatically updated as simulation progresses to reflect element computation cost. Performance timing has been added for constitutive update routines and the graph data structure will be refreshed every single iteration.

The last metric used is the vertex size of each vertex which basically contains the information that how much memory each vertex (element) requires in order to reproduce itself to other processes during data distribution. Adaptive load balancing is a multi-objective operation in the sense that both edge cut and data migration cost must be minimized simultaneously. The vertex size exactly describes the size of data that need to be shipped via communication. This metric must be correctly obtained for all available element types in order for the multi-objective load balancing algorithm to ensure the best performance.

202.3.3.2 Equation Solving Load Balancing

Parallel equation solving algorithm falls into two major different categories, direct solver and iterative solver.

Direct solver stems from Gaussian-type elimination and effective elimination tree is determined by the sparsity pattern of the stiffness matrix. Load balancing issue is addressed inherently when forming the elimination tree. Various packages such as SPOOLES and SuperLU provide scalable direct solutions to parallel equation systems. Chapter 110.5 discusses in further details about parallel direct solvers that are available as part of the release of this chapter.

Iterative solver has been the focus of this chapter in the sense that special care has been paid to achieve dynamic load balancing for each partition/repartition. The kernel of project-based iterative solvers is matrix-vector multiply. The issues of how to evenly distribute the stiffness matrix in parallel among different processors and how to reorder the sparse matrix to reduce data communications have been the focus of this chapter.

In order to achieve load balancing for parallel iterative solvers, parallel matrix/vector storage scheme and sparse matrix ordering are key factors. In the implementation of this chapter, even row-distribution of stiffness matrix among processing units is assumed. As shown in Figure 202.12, each processing unit has equal number of rows stored locally. The right hand side of the system is the force vector, which will be replicated for each processing unit. In this way, one can expect fastest matrix-vector multiply with the least amount of data needed to be communicated through network. As matrix-vector multiply is performed in parallel, load balancing issue is related to the number of nonzero numbers of the sparse stiffness matrix, which directly determines how many floating point multiplications are needed. In finite element computations, this nonzero pattern is determined by DOF numbering. Bandwidth reducing numbering scheme, or matrix ordering scheme, such as RCM Dongarra et al. (2003), can effectively lead to a sparse pattern that has similar number of nonzero elements on majority of rows as shown in Figure 202.12.

Finite element method inherently possesses compact support. Off-diagonal data of the stiffness matrix need to be synchronized among different processors. In order to reduce the extra overhead involved, in this chapter, several implementation solutions have been considered.

- Graph Partitioning Phase. As stated in previous chapters, minimizing edge-cut is one of the main objectives of the partitioning operation on the element graph. One extra benefit is that the bandwidth of the stiffness matrix will be greatly reduced. The number of nodes that need to be synchronized will be greatly reduced.

- DOF Numbering Phase. This phase is to renumber the DOFs of the finite element model after data redistribution in order to make sure contributions from local elements will sit on rows that are stored locally. This is done every time when the data migration is triggered. The idea is to start numbering the DOFs from local elements in Processor 1 to local elements in Processor N.

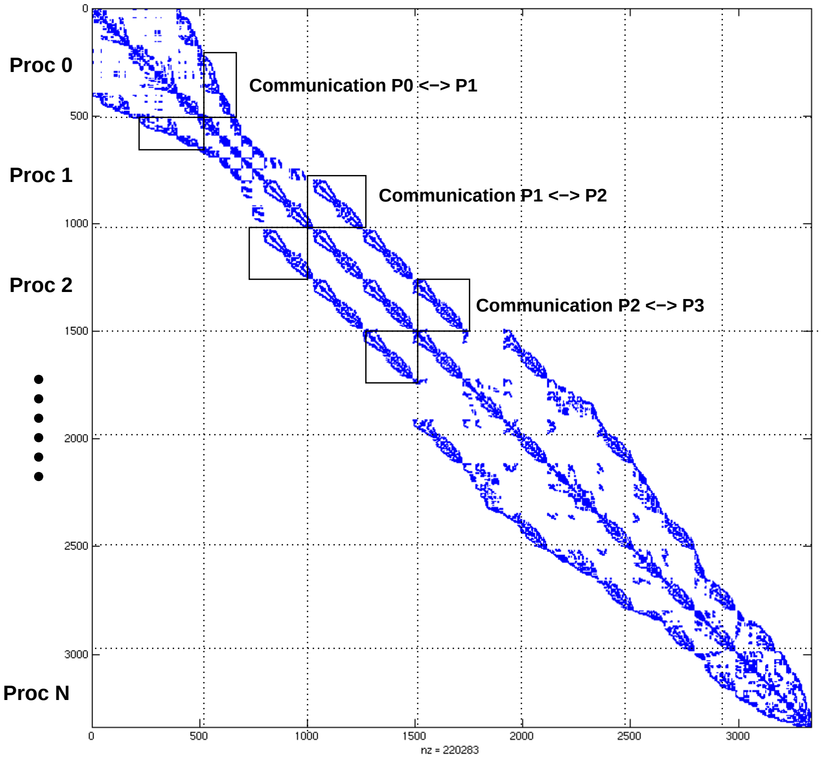

Figure 202.12: Parallel Data Organization of SFSI Equation System

In this way, when the global matrix is formed, local element stiffness matrix will always become clustered along the diagonal.

202.3.4 Object-Oriented Design of PDD

The parallel design of PDD basically follows Main-Follower algorithm structure as shown in Figure 202.13 and MPI has been adopted to facilitate inter-processor communications. The Actor/Shadow model described in previous sections is the used in PDD implementation and does nicely interact with parts of OpenSees framework, which uses Actor and Shadow classes to facilitate the inter-process communication between the main compute process and tied/follower compute processes.

- Main Compute Process

  Main compute process assumes the role to orchestrate the whole computation process. OpenSees uses tcl as an interpreter (or any other interpreted language that can be embedded into c or C++) to read input scripts from user. In parallel implementation of described here, main compute process

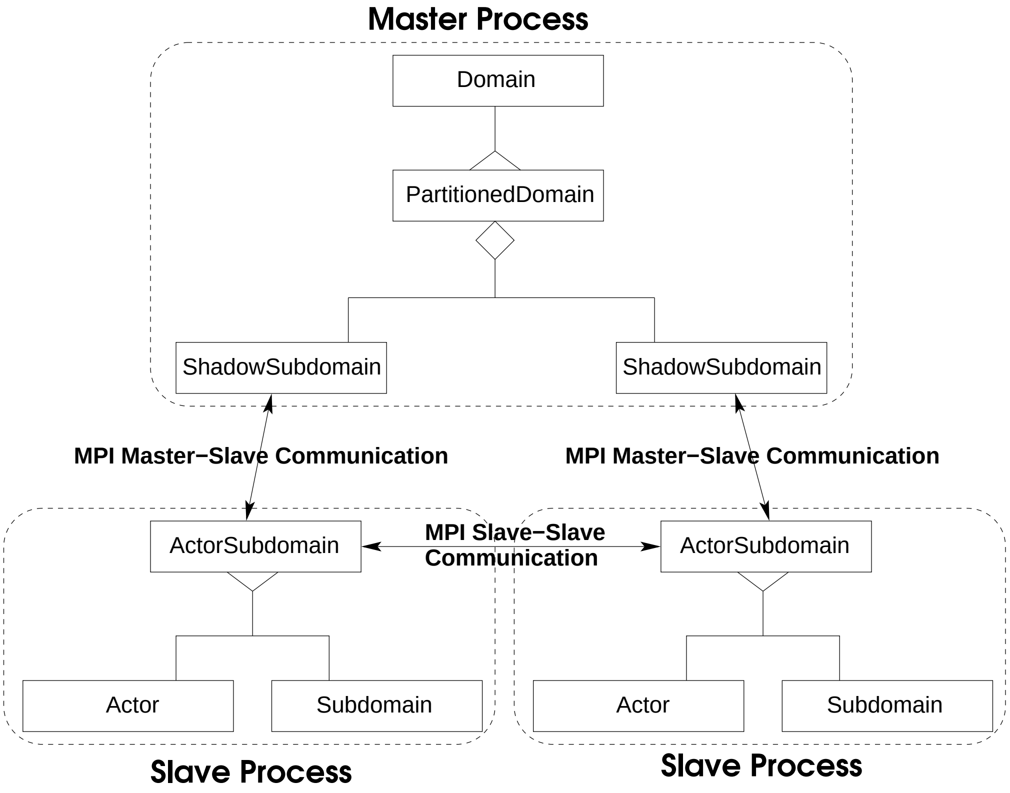

Figure 202.13: Main-Follower design used for PDD development.

is responsible for establishing the whole model for analysis and then distributing data among subprocessors. An important improvement in this chapter is that the main compute process does not actually create all finite element objects, whose memory space will only be allocated after they are sent to subdomains. This design helps avoid the high memory requirement on the main compute process side. Initial partitioning is done solely by main compute process process or in parallel by all working processes. Data movement is coordinated by the main compute process process, in which a complete element graph is kept intact.

As for repartitioning, the main compute process is still responsible for issuing commands to migrate data from this subprocessor to another even though the data is not in main compute process.

- Follower Compute Process

  The actor model has been used and modifications have been added to avoid unnecessary data communications. Basically speaking, actors in follower compute processes will be waiting for orders untill main compute process issues one and then do corresponding work on their own copy of data. The original design in OpenSees framework has disabled follower compute process to initiate communication, which means in order for a sub-processor to communicate with another sub-processor, it has to send all the data back to the main compute process first. This is highly inefficient and needed to be redeveloped, improved. In this research actor model has been implemented to enable direct communications between sub-processes and this improvement greatly reduced unnecessary communications.

All of the class designs for sequential version of OpenSees can be reused in parallel version following the Object-Oriented paradigm. There are some very important additions however in order to facilitate main–follower parallel processing. In this section, these classes will be revisited and updated/changes/improvements originally developed during this research will be explained thereafter.

- PartitionedDomain
  The PartitionedDomain class basically inherits all functionality from the Domain class in sequential version. This class acts as a container class in the main compute process. It differs from Domain class in the respect that all actions performed on the domain will be propagated to all subdomains when doing parallel processing.

- Subdomain
  The Subdomain is a child class of Domain. This class will be instanced by each follower compute process and it covers all functionality of the Domain class in sequential version. It can be called as an instance of Domain taking care of components only for the local follower compute process.

- ActorSubdomain & ShadowSubdomain
  The Actor/Shadow Subdomain classes are the most important classes for parallel version OpenSees. They are assuming the roles to initiate and facilitate all communications between main and follower compute processes. Both Actor/Shadow Subdomain will be instanced automatically when user creates follower compute process.
  ShadowSubdomain sits on main compute process. The function of this class is to represent a specific follower compute process in main compute process. Main compute process does not directly interact with follower compute process. Whatever action that needs to be performed by the follower compute process will be issued to ShadowSubdomain. This extra layer smooths the communication between main and follower nodes.
  On the other hand, ActorSubdomain sits on follower compute process and it hides main compute process from follower compute processes/nodes. All commands from main compute node will be received by ActorSubdomain and ActorSubdomain will match the command with some actions performed by Subdomain.
  Actor/Shadow Subdomain are extremely important classes in the parallel implementation of this

chapter. They carry all communication functionality required to finish the partition and adaptive repartition.

- Channel

  Channel is the class that really does the job of sending/receiving data between processors. Only MPI channel has been used in this chapter. Specific data structure, such as ID (integer array), vector (double array) or matrix needs to provide its own implementation for send/receive functionality.

- FEMObjectBroker

  This class is instanced only at follower compute processors, which is in charge of creating new model data for subdomains. This design isolates model creation from communication classes.

- Address

  Address class identifies parallel processes. With MPI channel used, the address corresponds to global process ID.

- DomainPartitioner

  DomainPartitioner assumes the responsibilities of invoking the GraphPartitioner and feeding necessary data to finish the partition/repartition. This class will also be in charge of data migration after partition/repartition is done.

- SendSelf & RecvSelf

  These two should be called functions rather than classes. SendSelf & RecvSelf are functions implemented to provide copy of model data to finish sending/receiving operations.

The old parallel design of OpenSees is not capable of performing elastic–plastic computations since it was designed and implemented for a single stage loading only. This single stage loading works fine for elastic analysis, but since elastic–plastic materials do have memory, staged loading is essential for any realistic computations with elastic–plastic material. This is particularly true for geotechnical and structural models, where simulations support for staged loading (self weight of soil medium for initial stress, construction process and subsequent static or dynamic loading) is essential if any modeling accuracy is to be achieved. One of new developments in this chapter was the addition of multi-stage elastic-plastic analysis. This improvement included modification of 3D solid and beam elements, Template3Dep/NewTemplate3Dep material models and DRM loading pattern for seismic analysis. Some of the old utility commands, such as "wipeAnalysis", were improved/redeveloped to enable parallel multi-stage analysis.

The most significant significant improvement developed during research over the old parallel design of OpenSees is the introduction of load balancing technique by adaptive graph partitioning algorithm through ParMETIS. Major improvements/updates have been introduced in PartitionedDomain, Actor/ShadowSubdomain, DomainPartitioner, FEM_ObjectBroker and Subdomain. Modifications done in this chapter also focus very much on performance issue. In order to reduce unnecessary data communication during partitioning/repartitioning, some functions have been rewritten. The functionality of Actor and ShadowSubdomain have been expanded so that any ActorSubdomain can initiate communication to another ActorSubdomain. The old design of OpenSees had to use main compute process as intermediate layer if subdomains want to exchange information.

For example, if Subdomain No. 1 needs to migrate an Element to Subdomain No. 2, the old design would issue a "remove Element" command from main compute process PartitionedDomain to Subdomain No. 1, then Subdomain No. 1 would remove the Element and send the Element back to main compute process, finally the Element would be migrated to Subdomain No. 2. We can clearly recognize the communication to main compute process is not necessary here. In order to develop adaptive load balancing while minimizing data redistribution cost, the improvement in this chapter is to allow ActorSubdomain at source Subdomain initiates communication with ActorSubdomain at target Subdomains and they can exchange information without recourse to main compute process. So the new communication pattern will be, again for the "migrate element" case, the main compute process will issue an "export element" command to Subdomain No. 1 and a "receive element from Subdomain No. 1" command to Subdomain No. 2, and then the element information will be directly sent from Subdomain No. 1 to No. 2.

Details of implementation are given in following sections.

202.3.4.1 MPI_Channel

- Functions sendnDarray and recvnDarray have been added to facilitate the data communication of Template3D material classes, which are based on nDarray tensor data structures.

  `int MPI_Channel::sendnDarray(int,int, const nDarray&, ChannelAddress*)`

  `int MPI_Channel::recvnDarray(int,int, const nDarray&, ChannelAddress*)`

202.3.4.2 MPI_ChannelAddress

- Function getOtherTag has been added to get MPI global ID for the specific MPI_Channel. This function is mainly used for data migration. It provides the MPI global communicator ID of the target process which the next communication will be directed to.

`int MPI_ChannelAddress::getOtherTag(void)`

202.3.4.3 FEM_ObjectBroker

- New functionality to instance 3D continuum brick elements has been added to getNewElement function.

  `Element* FEM_ObjectBroker::getNewElement(EightNodeBrickTag)`

- New functionality to instance Template3D/NewTemplate3D material models for continuum brick elements has been added to getNewNDMaterial function.

  `NDMaterial* FEM_ObjectBroker::getNewNDMaterial(int)`

- Template3D material is a stand-alone material library designed for general elastic-plastic materials. User can define separately YieldSurface, PotentialSurface, Scalar Evolution Law and Tensorial Evolution Law. Various material models have been implemented in OpenSees Jeremić and Yang (2002), such as Cam Clay, Drucker Prager and von Mises yield/potential surfaces, Armstrong Frederick nonlinear kinematic hardening law and bounding surface plasticity. All the material models have to be instanced by FEM_ObjectBroker during parallel processing.

  `YieldSurface* FEM_ObjectBroker::getYieldSurfacePtr(int)`

  `PotentialSurface* FEM_ObjectBroker::getPotentialSurfacePtr(int)`

  `EvolutionLaw_S* FEM_ObjectBroker::getEL_S(int)`

  `EvolutionLaw_T* FEM_ObjectBroker::getEL_T(int)`

- NewTemplate3D material is a newly designed material library which includes more advanced elastic-plastic constitutive models for geomaterials, such as Dafalias and Manzari 2004 model. The design of NewTemplate3D extends the principle of Template3D, in which key parameters describing plasticity model are abstracted as different class objects, such as YieldFunction, PlasticFlow, etc. In order to reduce unnecessary data allocation, new MaterialParameter class has been developed to carry all material parameters. New ElasticState has been used to store all intermediate and/or committed stress/strain data. All these material classes have to be instanced by FEM_ObjectBroker during parallel processing and new functions have been implemented in this chapter.

  `MaterialParameter* FEM_ObjectBroker::getNewMaterialParameterPtr(void)`

  `ElasticState* FEM_ObjectBroker::getNewElasticStatePtr(int)`

  `YieldFunction* FEM_ObjectBroker::getNewYieldFunctionPtr(int)`

  `PlasticFlow* FEM_ObjectBroker::getNewPlasticFlowPtr(int)`

  `ScalarEvolution* FEM_ObjectBroker::getNewScalarEvolutionPtr(int)`

  `TensorEvolution* FEM_ObjectBroker::getNewTensorEvolutionPtr(int)`

202.3.4.4 Domain

- Timing routines have been added to update function to measure computation time of constitutive level iterations for each element during every single loading increment. This metric will be assigned to the corresponding vertex of the element graph as the vertex weight. This metric represents element-level computational load against which subsequent load balancing techniques will be applied.

202.3.4.5 PartitionedDomain

- addElementalLoad function has been added to add ElementalLoad into LoadPattern, which was not supported in the old design.

  `bool PartitionedDomain::addElementalLoad(ElementalLoad*, int)`

- repartition function has been implemented to initiate adaptive repartitioning on the element graph of the Domain after every loading increment.

  `int PartitionedDomain::repartition(int)`

202.3.4.6 Node & DOF_Group

- sendSelf and recvSelf functions for Node class have been changed mainly to deal with the DOF_Group object associated with the Node. In the old design of parallel version of OpenSees, only one-step static domain partitioning would be invoked so that there is no need to pass the DOF_Group. But in this chapter, adaptive load balancing is developed to achieve better performance. The Node class should keep the information of its own DOF_Group, which guarantees the consistency of the DOF_Graph of the whole Domain. This point is extremely important when user tries to invoke Transformation constraint handler on the DOF_Graph. The addition of this feature in Node improved the robustness of the whole program.

- DOF_Group is a class carries information about the DOF_Graph of the analysis model, which will be used to finish assembling the stiff/mass/damping matrices. Each Node has its own DOF_Group to record the IDs of degree of freedoms in the global analysis model. Function unSetMyNode has been introduced to avoid segmentation fault. The reason is that after each round of repartitioning, if data movement is required, the AnalysisModel will be wiped off but Nodes are still in existence. Introduction of unSetMyNode function separates Node from its DOF_Group so the DOF_Group can be wiped and regenerated for the new model. `void DOF_Group::unSetMyNode(void)`

202.3.4.7 DomainPartitioner

DomainPartitioner is one of the most extensively changed classes in this chapter. This class acts as the entry point for PartitionedDomain to do domain decomposition and it basically has been rewritten to introduce new partition/repartition functionality and new data structures.

- Function repartition is implemented to do repartitioning after each loading increment. Partition and repartition are both implemented in parallel through ParMETIS library in this chapter. This function will collect ElementGraph from each Subdomain and pass them to GraphPartitioner. The global ElementGraph will be kept intact from which connectivity/adjacency information will be gathered to assemble child ElementGraphs and provide initial graph distribution data for repartition routines. After repartitioning by ParMETIS finishes, the function will verify the new partition against the original one to see if data redistribution is required to achieve load balancing. This repartition function also acts as a commander to control the data migration for adaptive load balancing. It issues commands to ShadowSubdomain to export/import Nodes, Elements, Constraintss, Loads, etc.

- The old design of OpenSees used multiplication of prime numbers as index number to record which partitions a specific node belongs to. This is a very good idea because with this approach, we only need one integer for each node to keep track of node partitions, which can be called as an index number for the node. The idea was to name each Subdomain with one specific prime number, if a node belongs to this Subdomain, we would multiply the index number of the node with the prime number of this Subdomain. In order to determine if a node belongs to on specific Subdomain, all we need is to divide the index number of the node with the prime number the Subdomain represents to see if we can get zero residual.

- The drawback of the old data structure based on prime numbers is that it only works when the number of processing units is small, say less than 16. In 3D continuum models, a single node might belong to up to 8 partitions simultaneously, which happens when a corner node sits on intersections of different Subdomains. As we know, prime numbers grow up very fast, multiplication with 8 prime numbers can easily overflow the index number of the node. A new data structure inspired by the Compressed Sparse Row (CSR) storage format popular in sparse matrix calculations has been introduced into in this chapter to solve the problem. One integer array has been used to store the partition data of all nodes, i.e. which partitions this node belongs to. Another integer array has been employed to record the count of partitions for each node. With these two arrays, we can load as many partitions as we want in our parallel processing.

202.3.4.8 Shadow/ActorSubdomain

As mentioned in previous sections of this chapter, Shadow/ActorSubdomain are the most important classes in parallel design of OpenSees McKenna (1997). ShadowSubdomains represent Subdomains in the main compute process PartitionedDomain. If PartitionedDomain requires one specific Subdomain to carry out some operations, it will send out orders to the ShadowSubdomain associated with the target Subdomain. Then the ShadowSubdomain sets up communication channel to communicate with the Subdomain through ActorSubdomain. ActorSubdomain, on the other hand, sits on each child process as an agent receiving and processing incoming operation requests. The major improvements in this chapter include new functionality for adaptive repartitioning and data migration, and several other minor changes to reduce unnecessary data communications, such as when the Subdomain is required to removeElement, the new design won't send the element information out, etc. New features will be introduced in this section.

- ShadowActorSubdomain_Partition
  New design used ParMETIS to do parallel graph partitioning instead of sequential partitioning by METIS in old design. This improvement helps to reduce partition/repartition overhead and enable the parallel adaptive repartitioning for PDD algorithms proposed in this chapter.

- ShadowActorSubdomain_BuildElementGraph
  In order to provide input graphs for adaptive load balancing, all Subdomains have to construct their own subElementGraph, which will be fed into ParMETIS routines for repartitioning.

- ShadowActorSubdomain_Repartition
  The repartitioning is implemented in parallel in this chapter so this entry point is set in the ActorSubdomain for each Subdomain.

- ShadowActorSubdomain_reDistributeData
  If data migration is needed to achieve load balancing, the main compute process will orchestrate the data redistribution process and the functionality here helps to facilitate the data communications between processes. This is one of the major additions to the existing design. Starting from this point, the ActorSubdomain is able to handle all required data movement on its own and ActorSubdomains representing other Subdomains will connect to the current working ActorSubdomain to receive/send data. Logically only one ActorSubdomain will be doing ShadowActorSubdomain_reDistributeData while others including the main compute process will be listening to separate MPI port for data migration requests.

- ShadowActorSubdomain_recvChangedNodeList

  This function is used to simplify the data migration routine. With this function, only Nodes/Elements and their associated Constraints, Loads etc. need to be moved between processors.

- ShadowActorSubdomain_ChangeMPIChannel

  This function prepares the current ActorSubdomain for messages from some specific processes. It changes the destination/source for subsequent outgoing/incoming communications, which helps redistributing data after load balancing.

- ShadowActorSubdomain_restoreChannel

  The default communication pattern in the old design of OpenSees was one to one, main to follower computer processes. This function helps restoring communication patterns of the whole model after data redistribution finishes.

- ShadowActorSubdomain_swapNodeFromInternalToExternal

  Nodes that only belongs to one single Subdomain is called internal nodes whose information will be stored only in that specific Subdomain. While for those nodes that belong to more than one Subdomains, their information should be accessible from all Subdomains with which the nodes are associated. Those nodes are called external nodes instead. It is possible that former internal nodes to one Subdomain become external after the adaptive repartitioning. What the old design would do is to remove the internal nodes from that Subdomain, gather the information back to the main compute process and then distribute it externally among those Subdomains as indicated by the newly obtained partitions. The improvement in this chapter avoids unnecessary data communication between current working Subdomain and the main compute process Domain. We can just swap the node in working Subdomain from internal status to external status and then export them to other specified Subdomains. This new design can improve performance if the data migration is extensive by avoiding unnecessary communications.

- ShadowActorSubdomain_swapNodeFromExternalToInternal

  This function is introduced due to the same reason as described previously although now the swapping direction is in reverse. It is noted that along with the swapping, removing operations must be invoked for those Subdomains that does not contain the node anymore.

- ShadowActorSubdomain_exportInternalNode

  This function handles the situation when a Node does not belong to the current Subdomain after adaptive repartitioning. The node will be removed from current Subdomain and exported to other Subdomains specified by the graph repartitioning. This again avoids the unnecessary data communication to/from main compute process by directly sending data to other Subdomains.

- ShadowActorSubdomain_resetRecorders
  The Recorders have to be reset after data migration to reflect component changes in each Subdomain.

202.3.4.9 Send/RecvSelf

As stated in previous sections, Send/RecvSelf must be provided by all domain components to finish data communication operations, such as Nodes, Elements, Loads, Constraints, Materials etc. In this chapter, new communication functions have been developed for EightNodeBrick element, ElasticIsotropic3D material, Template3Dep/NewTemplate3Dep material. The basic requirement to implement Send/RecvSelf is to replicate the source object instance in target process. For the old design, only one-step initial partitioning is performed and thus greatly simplifies the Send/RecvSelf routines because all the analysis-related information is null or void and only geometry-related data need to be transferred. But in this chapter, data migration is needed periodically to achieve load balance so the Send/RecvSelf has to be redesigned to carry analysis-related information besides the geometry model data. This is extremely important for Element and Material classes because they contain intermediate iteration/solution data of nonlinear finite element simulations. Figure 202.15 shows the class diagrams of brick Element and the associated Template3Dep material model. Send/RecvSelf operations have been implemented also for all classes associated with Template3Dep which are necessary to define a complete material model, such as Cam Clay, Drucker Prager and von Mises PotentialSurfaces, Cam Clay, Drucker Prager and von Mises YieldSurfaces, linear and nonlinear isotropic and kinematic hardening rules, etc.

202.3.5 Graph Partitioning

Graph partitioning approach has been extensively used in implementing domain decomposition type parallel finite element method. The element-based graph naturally becomes the favorite due to the fact that elemental operation forms the fundamental calculation unit in finite element analysis.

In this chapter, element graph has been constructed upon which graph partitioning algorithm acts to get domain decomposition for parallel finite element analysis. In the current implementation of this chapter, vertices of the element graph represent elements of the analysis model. Vertex weight is then specified as the computational load of each element. In elastic-plastic finite element simulations, the most expensive part has shown to be the elemental level calculations, which include constitutive-level stress update (strain-driven constitutive driver assumed) and formulation of elastic-plastic modulus (or so-called tangent stiffness tensor/matrix). In this research, the wall clock time used by elemental calculations has been dynamically collected and specified as the corresponding vertex weight for each element. The elemental calculation time clearly tells whether the element is elastic or plastified. With this timing metric, the graph can effectively reflect load distribution among elements thus load balancing repartition can be triggered on the graph to redistribute element between processors to achieve more balanced elastic-plastic calculation.

On the other hand, vertex size has to be defined for repartitioning problem as mentioned in previous sections. In this research, vertex size has been specified to be redistribution cost associated with each element. This information depends on the parallel implementation of the software and is discussed in the section immediately following.

202.3.5.1 Construction of Element Graph

Each element is considered as one vertex in the element graph. An edge is formed when two elements share a common node. In this chapter, the graph structure is assumed to be undirected, which means the same edge will be added to both vertex ends. The edge is weightless in our application considering the fact that the purpose of minimizing edge-cut is to reduce the data migration when assembling global stiffness matrix. In that sense, the edge of element graph should carry the same weight or, more directly no weight at all.

202.3.5.2 Interface to ParMETIS/METIS

Interfaces to both ParMETIS and METIS have been implemented in this chapter. ParMETIS is the parallel implementation of METIS and new adaptive repartitioning functionality is only available through ParMETIS.

All of the graph routines in ParMETIS/METIS take as input the adjacency structure of the graph, the weights of the vertices and edges (if any), and an array describing how the graph is distributed among the processors Karypis et al. (2003). The structure of the graph is represented by the compressed storage format (CSR), extended for the context of parallel distributed-memory computing. We will first describe the CSR format for serial graphs and then describe how it has been extended for storing graphs that are distributed among processors.

- Serial CSR Format The CSR format is a widely-used scheme for storing sparse graphs. Here, the adjacency structure of a graph is represented by two arrays, $xadj$ and $adjncy$. Weights on the vertices and edges (if any) are represented by using two additional arrays, $vwgt$ and $adjwgt$. For example, consider a graph with n vertices and m edges. In the CSR format, this graph can be described using arrays of the following sizes:

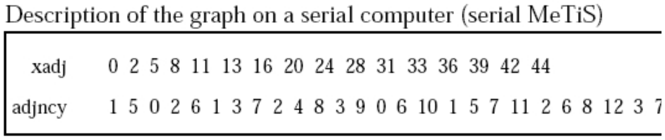
$$xadj[n+1], \quad vwgt[n], \quad adjncy[2m], \quad \text{and} \quad adjwgt[2m] \qquad (202.1)$$

Note that the reason both $adjncy$ and $adjwgt$ are of size $2m$ is because every edge is listed twice (i.e., as (v, u) and (u, v)). Also note that in the case in which the graph is unweighted (i.e., all vertices and/or edges have the same weight), then either or both of the arrays $vwgt$ and $adjwgt$ can be set to $NULL$. ParMETIS_V3_AdaptiveRepart additionally requires a $vsize$ array. This array is similar to the $vwgt$ array, except that instead of describing the amount of work that is associated with each vertex, it describes the amount of memory that is associated with each vertex.

The adjacency structure of the graph is stored as follows. Assuming that vertex numbering starts from 0 (C style), the adjacency list of vertex i is stored in array $adjncy$ starting at index $xadj[i]$ and ending at (but not including) index $xadj[i+1]$ (in other words, $adjncy[xadj[i]]$ up through and including $adjncy[xadj[i+1]-1]$). Hence, the adjacency lists for each vertex are stored consecutively in the array $adjncy$. The array $xadj$ is used to point to where the list for each specific vertex begins and ends. Figure 202.14(a) illustrates the CSR format for the 15-vertex graph shown in Figure 202.14(b). If the graph has weights on the vertices, then $vwgt[i]$ is used to store the weight of vertex i . Similarly, if the graph has weights on the edges, then the weight of edge $adjncy[j]$ is stored in $adjwgt[j]$. This is the format that is used by (serial) METIS library routines.

- Distributed CSR Format ParMETIS uses an extension of the CSR format that allows the vertices of the graph and their adjacency lists to be distributed among the processors. In particular, PARMETIS assumes that each processor P_i stores n_i consecutive vertices of the graph and the corresponding m_i edges, so that $n = \sum_i n_i$, and $2m = \sum_i m_i$. Here, each processor stores its local part of the graph in the four arrays $xadj[n_i + 1]$, $vwgt[n_i]$, $adjncy[m_i]$, and $adjwgt[m_i]$, using the CSR storage scheme. Again, if the graph is unweighted, the arrays $vwgt$ and $adjwgt$ can be set to $NULL$. The straightforward way to distribute the graph for PARMETIS is to take n/p consecutive adjacency lists from $adjncy$ and store them on consecutive processors (where p is the number of processors). In addition, each processor needs its local $xadj$ array to point to where each of its local vertices' adjacency lists begin and end. Thus, if we take all the local $adjncy$ arrays and concatenate them, we will get exactly the same $adjncy$ array that is used in the serial CSR. However, concatenating the local $xadj$ arrays will not give us the serial $xadj$ array. This is because the entries in each local $xadj$ must point to their local $adjncy$ array, and so, $xadj[0]$ is zero for all processors. In addition to these four arrays, each processor also requires the array $vtxdist[p + 1]$ that indicates the range of vertices that are local to each processor. In particular, processor P_i stores the vertices from $vtxdist[i]$ up to (but not including) vertex $vtxdist[i + 1]$.

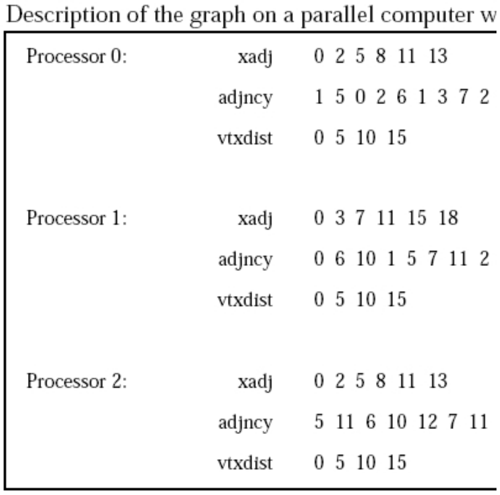
(a) A sample graph



Description of the graph on a serial computer (serial MeTiS)

xadj	0 2 5 8 11 13 16 20 24 28 31 33 36 39 42 44
adjncy	1 5 0 2 6 1 3 7 2 4 8 3 9 0 6 10 1 5 7 11 2 6 8 12 3

(b) Serial CSR format



Description of the graph on a parallel computer w

Processor 0:	xadj	0 2 5 8 11 13
	adjncy	1 5 0 2 6 1 3 7 2
	vtxdist	0 5 10 15
Processor 1:	xadj	0 3 7 11 15 18

(c) Distributed CSR forn

Figure 202.14: An example of the parameters passed to PARMETIS in a three processor case Karypis et al. (2003).

Figure 202.14(c) illustrates the distributed CSR format by an example on a three-processor system. The 15-vertex graph in Figure 202.14(a) is distributed among the processors so that each processor gets 5 vertices and their corresponding adjacency lists. That is, Processor Zero gets vertices 0 through 4, Processor One gets vertices 5 through 9, and Processor Two gets vertices 10 through 14. This figure shows the *xadj*, *adjncy*, and *vtxdist* arrays for each processor. Note that the *vtxdist* array will always be identical for every processor. All five arrays that describe the distributed CSR format are defined in PARMETIS to be of type *idxtype*. By default *idxtype* is set to be equivalent to type *int* (i.e., integers). However, *idxtype* can be made to be equivalent to a *short int* for certain architectures that use 64-bit integers by default. (Note that doing so will cut the memory usage and communication time required approximately in half.) The conversion of *idxtype* from *int* to *short* can be done by modifying the file parmetis.h. (Instructions are included there.) The same *idxtype* is used for the arrays that store the computed partitioning and permutation vectors.

When multiple vertex weights are used for multi-constraint partitioning, the c vertex weights for each vertex are stored contiguously in the *vwgt* array. In this case, the *vwgt* array is of size nc, where n is the number of locally stored vertices and c is the number of vertex weights (and also the number of balance constraints).

New GraphPartitioner class ParMETIS has been developed in this chapter to provide seamless interface to adaptive partitioning/repartitioning routines.

202.3.6 Data Redistribution

Data redistribution after repartitioning has been a challenging problem which needs careful study to guarantee correctness of subsequent analysis. In this research, Object-Oriented philosophy has been followed to abstract container classes to facilitate analysis and model data redistribution after repartition. As for the initial partitioning, only model data, such as geometry parameters, has to be exported to sub-processors, while in adaptive repartitioning finite element simulation, analysis data has to be moved as well. It is extremely important to have well-designed container classes to carry data around. Basic units of finite element analysis, such as nodes and elements naturally become our first choices. Not to give up generality, the design in OpenSees adopts basic iterative approach for nonlinear finite element analysis Crisfield (1997b), important intermediate analysis data include trial data, commit data, incremental data, element residual, element tangent stiffness, etc. Vertex size of each element has been defined as the total number of bytes that have to be transferred between sub-processors.

1. Node

   Other than geometric data such as node coordinates and number of degree of freedoms, the Node class contains nodal displacement data which should be sent together with the node to preserve continuity of the analysis model.

2. Element

   Element class is the basic construction unit in finite element model. In the design of this research, Element class keeps internal links to Template3D material class Jeremić and Yang (2002). In order to facilitate elastic-plastic simulation, EPState class is constructed to hold all the intermediate response data. This object-oriented abstraction greatly systematize the communication pattern. The information on class design is shown in the class diagram Figure 202.15 by Rational Rose Boggs and Boggs (2002).

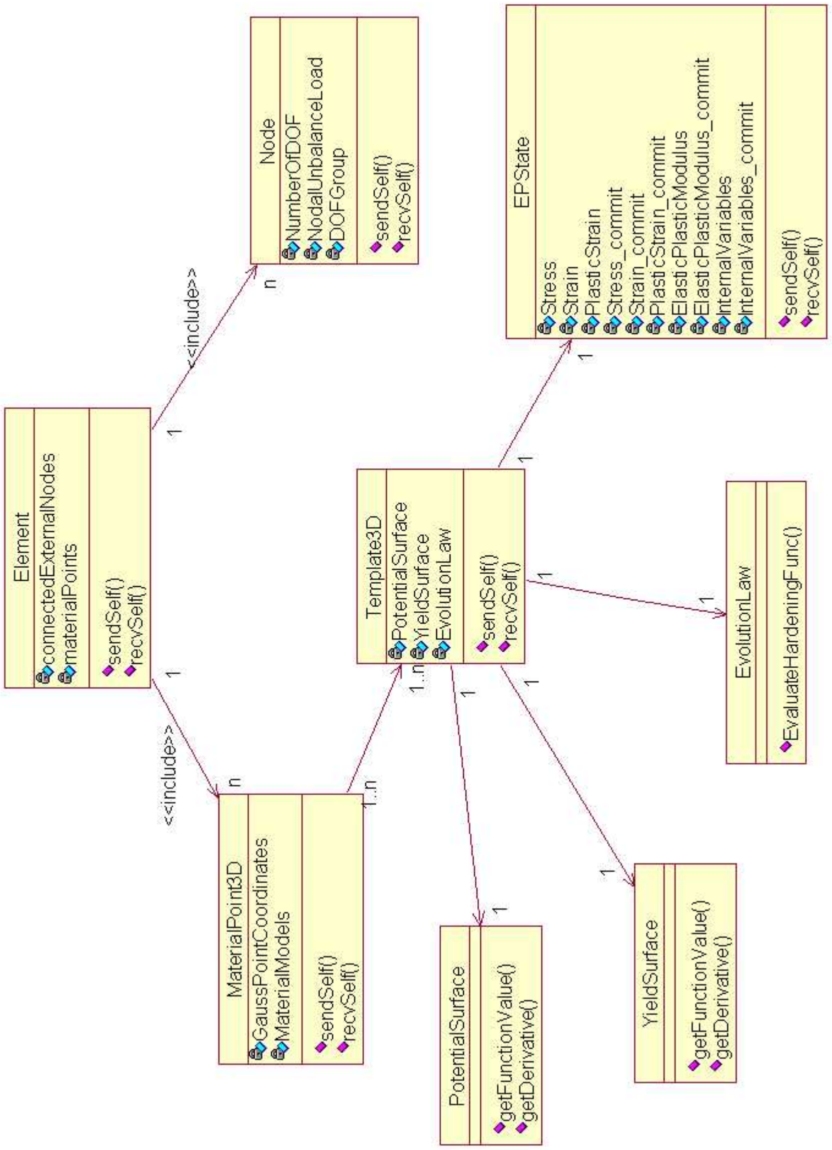

Figure 202.15: Class Diagram: Major Container Classes for Data Redistribution

All data communication operations have been implemented through the standard Send/RecvSelf interface, which forms a complete set of consistent point-to-point communication patterns and is convenient for future additions of new element/materials.

                int a3,
                int a4)
```

`MaterialNumber`: unique material Number ; `fy`: yield strength ; `Ep`: initial elastic tangent ; `Hd`: strain-hardening ratio (ratio between post-yield tangent and initial elastic tangent) ; `a1, a2, a3, a4`: isotropic hardening parameters ; `a1`: isotropic hardening parameter, increase of compression yield envelope as proportion of yield strength after a plastic strain of a2*(fy/Ep). ; `a2`: isotropic hardening parameter (see explanation under a1) ; `a3`: isotropic hardening parameter, increase of tension yield envelope as proportion of yield strength after a plastic strain of a4*(fy/Ep) ; `a4`: isotropic hardening parameter (see explanation under a3) ;

```
int add_constitutive_model_uniaxial_steel02(int MaterialNumber,
  double fy, double E0, double b,
  double R0, double cR1, double cR2,
  double a1, double a2, double a3, double a4)
```

`MaterialNumber`: unique material object Number ; `fy`: yield strength ; `E0`: initial elastic tangent ; `b`: strain-hardening ratio (ratio between post-yield tangent and initial elastic tangent) ; `R0, cR1, cR2`: control the transition from elastic to plastic branches. Recommended values: R0=between 10 and 20, cR1=0.925, cR2=0.15 ; `a1, a2, a3, a4`: isotropic hardening parameters ; `a1`: isotropic hardening parameter, increase of compression yield envelope as proportion of yield strength after a plastic strain of a2*(Fy/E). ; `a2`: isotropic hardening parameter (see explanation under a1) ; `a3`: isotropic hardening parameter, increase of tension yield envelope as proportion of yield strength after a plastic strain of a4*(Fy/E) ; `a4`: isotropic hardening parameter (see explanation under a3) ;

204.3.1.2 Modeling: Nodes

```
int add_node(int NodeNumber,
             int number_of_DOFs,
             double coordinate_x,
             double coordinate_y,
             double coordinate_z)
```

`NodeNumber`: integer Number identifying node ; `number_of_DOFs`: number of degrees of freedom for node ; `coordinate_x`: x coordinate of the node ; `coordinate_y`: y coordinate of the node ; `coordinate_z`: z coordinate of the node ;

```
int remove_node(int NodeNumber)
```

`NodeNumber`: integer Number identifying the node to be removed ;

```
int add_mass_to_node(int NodeNumber,
                     double massvalue1,
                     double massvalue2,
                     double massvalue3)

int add_mass_to_node(int NodeNumber,
                  double massvalue1,
                  double massvalue2,
                  double massvalue3,
                  double massvalue4,
                  double massvalue5,
                  double massvalue6)

int add_mass_to_node(int NodeNumber,
                  double massvalue1,
                  double massvalue2,
                  double massvalue3,
                  double massvalue4,
                  double massvalue5,
                  double massvalue6,
                  double massvalue7)
```

`NodeNumber`: integer Number of the node that mass would be applied to ; `massvalue(#)`: the amount of mass assigned to each degree of freedom ;

204.3.1.3 Modeling: Finite Elements

```
add_element_truss(int ElementNumber,
                int iNode,
                int jNode,
                int MaterialNumber,
                double sectionarea,
```

```
                double rho)
```

`ElementNumber`: unique element object Number ; `dimension`: number of dimensions of the beam ; `iNode` , `jNode`: end nodes ; `MaterialNumber`: Number of the uniaxial material to be used ; `sectionarea`: section area of the truss element ; `rho`: density ;

```
add_element_beam_elastic(int ElementNumber,
                double A,

                 double rigJntOffset2_x, double rigJntOffset2_y, double rigJntOffset2_z)
```

```
int remove_element(int ElementNumber)
```

`ElementNumber`: number identifying the element to be removed ;

204.3.1.4 Modeling: Damping

```
int add_damping_rayleigh(int dampingNumber,
                         double a0,
                         double a1,
                         string which_stiffness_to_use)
```

`dampingNumber`: damping Number number to be used in element definition ; `a0, a1`: Rayleigh order damping coefficients ; `which_stiffness_to_use`: `Initial_Stiffness/Current_Stiffness/Last_Commited_Stif`

```
add_damping_caughey3rd(int dampingNumber, double a0, double a1, double a2, string which_stiffne
```

```
add_damping_caughey4th(int dampingNumber, double a0, double a1, double a2, double a3, string wh
```

```
int add_damping_to_element(int elementNumber,
                           int dampingNumber)
```

`dampingNumber`: damping number to be assigned to element ; `elementNumber`: element number which damping is going to be assigned to ;

```
int add_damping_to_node(int nodeNumber,
               int dampingNumber)
```

`dampingNumber`: damping number to be assigned to node (note that only the mass proportional coefficient will be used for node) ; `nodeNumber`: node number which damping is going to be assigned to ;

204.3.1.5 Modeling: Constraints, Supports, Tied Nodes Connections, etc.

```
int add_support_to_all_dofs_of_node(int NodeNumber)
```

`NodeNumber`: integer Number of the node to be fixed ;

```
  int add_support_to_node(int NodeNumber,
                          int dof_number)
```

`NodeNumber`: integer Number identifying the node to be constrained ; `dof_number`: dof to be fixed ;

```
int add_equaldof_to_two_nodes(int nodeRetain,
                    int nodeConstr,
                    int dofID1,
                    int dofID2,
                    ...,
                    int dofID7)
```

`nodeRetain`: integer Number identifying the retained, or master node (rNode) ; `nodeConstr`: integer Number identifying the constrained, or slave node (cNode) ; `dofID`: nodal degrees-of-freedom that are constrained at the nodeConstr to be the same as those at the nodeRetain Valid range is from 1 to 7. ;

```
int remove_support_from_node_by_fixity_number(int FixityNumber)
```

`FixityNumber`: integer Number identifying the fixity to be removed ;

```
remove_support_from_node(int NodeNumber, int dofNumber)
```

`NodeNumber`: integer Number identifying the node number ; `dofNumber`: integer Number identifying the dof number ;

```
  int remove_equaldof_from_node(int NodeNumber)
```

`FixityNumber`: integer Number identifying the fixity to be removed ;

204.3.1.6 Modeling: Static Loads

```

                                                      double xpositive,
                                                      double xminus,
                                                      double ypositive,
                                                      double yminus,
                                                      double zpositive,
                                                      double zminus,
                                                      string ElementNumbersFilename,
                                                      string NodeNumbersFilename,
                                                      string ForceTimeHistoryFilename)
```

204.3.1.8 Modeling: Prescribed Displacements

```
add_imposed_motion(int GroundMotionNumber,
               int NodeNumber,
               int degree_of_freedom,
               double timestep,
               double displacement_scale,
               string displacementfilename,
               double velocity_scale,
               string velocityfilename,
               double acceleration_scale,
               string accelerationfilename)
```

204.3.1.9 Solid-Fluid Interface

Two new APIs and corresponding DSL commands have been added to RealESSI.

- define solid fluid interface “interface_name”
  This API is used to define solid fluid interface. Passing parameters into RealESSI to initialize our interface class SSFI.

- simulate No. steps using solid fluid interaction transient algorithm time_step = < time >
  This API aims to launch solid fluid transient interaction analysis. The time step defined here refers to the time step for the transient analysis in solid domain. The time step for fluid domain can be different and defined in the input files for OpenFOAM.

204.3.1.10 Outputs to mySQL database

```
restore_response_of_model_mysql_format(int Node_Number, int DOF_Number, int Step_Number,
                                       string databaseName, string host,
                                       string username, string password, unsigned int port,
                                       string socket)
```

```
restore_state_of_model_mysql_format(string databaseName, string host,
                                    string username, string password, unsigned int port,
                                    string socket)
```

```
save_response_of_model_mysql_format(string databaseName, string host,
                                    string username, string password, unsigned int port,
                                    string socket)
```

```
save_state_of_model_mysql_format(string databaseName, string host,
                                 string username, string password, unsigned int port,
                                 string socket)
```

204.3.2 Simulation

204.3.2.1 Simulation: Solvers

Definition of system of equation (linear) solvers to be used.

```
 int define_solver_profilespd_for_analysis()
```

```
int define_solver_umfpack_for_analysis()
```

```
int define_solver_petsc_for_analysis()
```

204.3.2.2 Simulation: Static Solution Advancement

Definition of static solution advancement algorithms (see more in section 107.6 on page 526).

```
int define_static_solution_advancement_integrator_displacement_control(int node_number,
         int doftomove,
         double dispincrement)
```

`dispincrement`: increment of displacement in each step of analysis ; `node_number`: node whose response controls the solution ; `doftomove`: degree-of-freedom whose response controls the solution. Valid range is from 1 through the number of nodal degrees-of-freedom. ;

```
int define_static_solution_advancement_integrator_load_control(double loadstep)
```

`loadstep`: load step size ;

204.3.2.3 Simulation: Dynamic Solution Advancement

Definition of dynamic, time integration/advancement algorithms (see more in section 108.3 on page 538).

```
int define_dynamic_solution_advancement_integrator_hilber_hughes_taylor(double HHT_Alpha)
```

`HHT_Alpha`: HHT α parameter ;

```
int define_dynamic_solution_advancement_integrator_newmark(double gamma, double beta)
```

`newmark_gamma, newmark_beta`: Newmark γ and β parameters ;

204.3.2.4 Simulation: Solution Algorithms

Definition of solution algorithms to be used:

```
int define_algorithm_with_no_convergence_check_for_analysis()
```

```
int define_algorithm_newton_for_analysis()
```

```
int define_algorithm_modifiednewton_for_analysis()
```

204.3.2.5 Simulation: Convergence Criteria

```
int define_convergence_test_energyincrement_for_analysis(double theTol,
                      int maxIter,
                      int PrintFlag)
```

`theTol`: convergence tolerance ; `maxIter`: maximum number of iterations that will be performed before "failure to converge" is returned ; `PrintFlag`: flag used to print information on convergence (optional) : 0: no print output ; 1: print information on each step ; 2: print information when convergence has been achieved ; 4: print norm, dU and dR vectors ; 5: at convergence failure, carry on, print error message, but do not stop analysis ;

```
int define_convergence_test_normdisplacementincrement_for_analysis(double theTol,
              int maxIter,
              int PrintFlag)
```

`theTol`: convergence tolerance ; `maxIter`: maximum number of iterations that will be performed before "failure to converge" is returned ; `PrintFlag`: flag used to print information on convergence (optional) ; 0: no print output ; 1: print information on each step ; 2: print information when convergence has been achieved ; 4: print norm, dU and dR vectors ; 5: at convergence failure, carry on, print error message, but do not stop analysis ;

```
int define_convergence_test_normunbalance_for_analysis(double theTol,
             int maxIter,
             int PrintFlag)
```

`theTol`: convergence tolerance ; `maxIter`: maximum number of iterations that will be performed before "failure to converge" is returned ; `PrintFlag`: flag used to print information on convergence (optional) ; 0: no print output ; 1: print information on each step ; 2: print information when convergence has been achieved ; 4: print norm, dU and dR vectors ; 5: at convergence failure, carry on, print error message, but do not stop analysis ;

204.3.2.6 Simulating Response

```
int simulate_using_static_multistep(int numSteps)
```

`numSteps`: number of static analysis steps which will advance the solution, ;

```
 int simulate_using_static_onestep()
```

```
int simulate_using_transient_multistep(double dT,
                        int numSteps)
```

dT: time-step increment ; `numSteps`: number of time steps ;

```
 int simulate_using_transient_onestep()
```

```
int simulate_using_transient_variable_multistep(double dT,
                                 int numSteps,
                                 double dtMin,
                                 double dtMax,
                                 int Jd)
```

`dT`: time-step increment ; `numSteps`: number of time steps ; `dtMin, dtMax`: minimum and maximum time steps ; `Jd`: ideal number of iterations performed at each step ;

```
int simulate_using_transient_variable_onestep()
```

```
int simulate_using_eigen_analysis(int number_of_eigen_values)
```

204.4 Application Programming Interface for Constitutive Simulations

204.5 Application Programming Interface for Finite Elements

204.6 Adding a New Command into Real-ESSI Simulator

This section describes how to add a new command, needed for the generation of random fields, into Real-ESSI Simulator by modifying an existing command.

204.6.1 Introduction

So far, random fields have been generated using the discrete form of auto-covariance. The size of the auto-covariance matrix is $n \times n$ with n equal to the number of Gauss points (GPs). In the case of a fine FE mesh, i.e., many GPs, this may result in a large computation time. Here, "shear beam" element is used. It has only one GP, in the middle of an element. Hence the number of GPs is here equal to the number of FE elements. It is easier for a user to input the number of FE elements than to input the number of GPs.

Generation of a random field in Real-ESSI is here extended with the possibility of the use of much less discrete points in the solution of the eigenproblem of auto-covariance (now, with the continuous form of auto-covariance using the PCE of auto-covariance function with Legendre polynomials, i.e., the eigenvalues and eigenfunctions are obtained instead of the eigenvalues and eigenvectors) than the GPs in the FEM.

204.6.2 Parser

Parser reads the DSL from input file `∗.fei` and interpretes it. `flex` and `bison` are used.

`HERMITE POLYNOMIAL CHAOS DIMENSION` is the chosen number of the first eigenvalues and eigenfunctions (or eigenvectors) of the auto-covariance function (or matrix) that will be calculated.

Copy existing commands that take

```
HERMITE POLYNOMIAL CHAOS DIMENSION
```

and modify them by adding `number_of_fe_elements`.

For example, copy:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with
Hermite polynomial chaos dimension <.> order <.> ↩
    correlation_kernel_inverse_order = <.>;
```

and modify it into:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with
Hermite polynomial chaos dimension <.> order <.> ↩
    correlation_kernel_inverse_order = <.> number_of_fe_elements = <.>;
```

In `.../GLOBAL_RELEASE/Real-ESSI/DSL/`, modify 2 files:

- `feiparser.yy` = grammar part handled by `bison`
- `feiparser.l` = lexical part handled by `flex`.

204.6.3 `feiparser.yy`

Change:

```
%token KARHUNEN LOEVE DIMENSION correlation_kernel_inverse_order AS GLOBAL dimension_file TRIPLE PRODUCT shape_parameter scale_parameter WEIBULL TRIANGULAR
```

into:

```
%token KARHUNEN LOEVE DIMENSION correlation_kernel_inverse_order AS GLOBAL dimension_file TRIPLE PRODUCT shape_parameter scale_parameter WEIBULL TRIANGULAR number_of_fe_elements
```

Then, copy the existing commands, like:

```
| HERMITE POLYNOMIAL CHAOS KARHUNEN LOEVE EXPANSION TO RANDOM FIELD TEXTNUMBER exp WITH HERMITE POLYNOMIAL CHAOS DIMENSION exp ORDER exp correlation_kernel_inverse_order '=' exp
    {
        args.clear(); signature.clear();
        args.push_back($11); signature.push_back(this_signature("RandomField_tag", &isAdimensional));
        args.push_back($17); signature.push_back(this_signature("Dimension_num", &isAdimensional));
        args.push_back($19); signature.push_back(this_signature("Order_num", &isAdimensional));
        args.push_back($22); signature.push_back(this_signature("correlation_kernel_inverse_order", &isAdimensional));
        $$ = new FeiDslCaller4<int, int, int, int>(&Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order, args, signature,
        "Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order");
        for(int i = 1; i <= 4; i++) nodes.pop();
        nodes.push($$);
    }
```

and modify it into:

```
| HERMITE POLYNOMIAL CHAOS KARHUNEN LOEVE EXPANSION TO RANDOM FIELD TEXTNUMBER exp WITH HERMITE POLYNOMIAL CHAOS DIMENSION exp ORDER exp correlation_kernel_inverse_order '=' number_of_fe_elements '=' exp
```

```
    {
        args.clear(); signature.clear();
        args.push_back($11); ↩
            signature.push_back(this_signature("RandomField_tag", ↩
            &isAdimensional));
        args.push_back($17); ↩
            signature.push_back(this_signature("Dimension_num", &isAdimensional));
        args.push_back($19); signature.push_back(this_signature("Order_num", ↩
            &isAdimensional));
        args.push_back($22); ↩
            signature.push_back(this_signature("correlation_kernel_inverse_order", ↩
            &isAdimensional));
        args.push_back($25); ↩
            signature.push_back(this_signature("number_of_fe_elements", ↩
            &isAdimensional));
        $$ = new FeiDslCaller5<int, int, int, int, ↩
            int>(&Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_FE_elements,
            args, signature,
        "Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_FE_elements");
        for(int i = 1; i <= 5; i++) nodes.pop();
        nodes.push($$);
    }
```

204.6.4 `feiparser.l`

Just add:

```
"number_of_fe_elements" {return token::number_of_fe_elements;}
```

204.6.5 `create_parallel.sh`

`create_parallel.sh` takes `feiparser.l` and `feiparser.yy`, and creates files needed for compilation of `essi.parallel`. For example, it creates `feiparser.lex.cpp`. In `feiparser.lex.cpp`: ∗`yytext` and `yyleng` will be defined twice and the compiler will complain during linking for `essi.parallel`. The second definitions of ∗`yytext` and `yyleng` need to be found in `feiparser.lex.cpp` and deleted manually. For this purpose, in `create_parallel.sh`, there are 2 lines:

```
sed -i '319d' feiparser.lex.cpp
```

```
sed -i '5642d' feiparser.lex.cpp
```

and lines, here 319 and 5643 (mind the preceding removal of 319), in `feiparser.lex.cpp` will be deleted.

204.6.6 `create_sequential.sh` and `create_parallel.sh`

In `.../GLOBAL_RELEASE/Real-ESSI/DSL/`, one can find `create_sequential.sh` and `create_parallel.sh`. Run both.

204.6.7 Application Programming Interface (API)

In `.../GLOBAL_RELEASE/Real-ESSI/API/MODELING/`, copy the following files:

`Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order.h`

`Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_hdf5_input.h`

and change their names to:

`Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_FE_elements.h`

`Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_hdf5_input_FE_elements.h`

and modify them to account for the number of GPs (= the number of FE elements here).

In `.../GLOBAL_RELEASE/Real-ESSI/API/`, there is file `api.h`. In `api.h`, add the following lines:

```
#include "MODELING/Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_FE_elements.h"
#include "MODELING/Hermite_polynomial_chaos_Karhunen_Loeve_expansion_inverse_order_hdf5_input_FE_elements.h
```

In this case, existing files `RandomField.cpp` and `RandomField.h` will be modified and no new files `*.cpp` and `*.h` have to be created. If new files, for example, `RandomFieldGaussianCorrelation.cpp` and `RandomFieldGaussianCorrelation.h`, are created, then additionally in `ESSI_API.h`, one needs to add:

```
#include <../CompGeoMechUCD_StochasticFEM/PolynomialChaos/RandomFieldGaussianCorrelation.h>
```

204.7 Adding New Finite Element into Real-ESSI Simulator

This section illustrates how to add a new element in Real-ESSI simulator. A detailed description of each steps involved is given. The developer is expected to understand these steps and replicate it for their new element. Also, it is quite useful to look at some previous elements already implemented in Real-ESSI.

204.7.1 Introduction

This documents provides detailed description of steps for adding a new element into the Real-ESSI Simulator. New Element Template source (.ccp) and header (.h) files can be located inside source code in *CompGeoMechUCD_FiniteElements* directory, and are also shown below in subsection 204.7.3 and subsection 204.7.4.

The list of all the steps to be followed are listed below

1. SubSec 204.7.2:: Creating New Element Directory and Linking to Real-ESSI
2. SubSec 204.7.3:: Writing the New Element Header File
3. SubSec 204.7.4:: Writing the New Element Source File
4. SubSec 204.7.5:: Setting the *ELE_TAG_NewElement* class tag and its description
5. SubSec 204.7.6:: Integrating new element with parser.
6. SubSec 204.7.7:: Compiling Real-ESSI
7. SubSec 204.7.8:: Verification of Implementation

These steps are shown in each sub-section. The first step starts creating a directory for the new element. After step [3], the new element would be linked with Real-ESSI source code. So, its good to start compiling (step [6]) and fixing bugs rather than going to step [4] or further ahead.

204.7.2 Getting Started:: Creating New Element Directory

The new element can be added in *CompGeoMechUCD_FiniteElements* directory of Real-ESSI source. A directory for new element lets say NewElement must be created. The next step is to add CMakeLists.txt and place into that directory. The contents of the cmake file is

```
# Builds all the CompGeoMechUCD_FiniteElements/NewElement module
# message("scanning newelements module...")

BUILD_LIB("newelements" ESSI_LIBS)
```

Also, in that directory new element header (NewElement.h) and source files (NewElement.cpp) must be placed. The contents of the cpp files are shown in subsection 204.7.3 and subsection 204.7.4.

The new element then must be included to the header file of Real-ESSI Elements i.e. *CompGeoMechUCD_FiniteElements.h* . The element header file is loaded in *CompGeoMechUCD_FiniteElements* directory. So, just add the new element header as

```
// /////////////////////////////////////////////////
// New Elements [XYZ, Month, Year]
// /////////////////////////////////////////////////

#include "./NewElement/NewElement.h"
```

This would link the new element source code to Real-ESSI. Next is to write the source code and header files of the new element.

204.7.3 Element Header File

The header file is self documented (read fully and carefully).

```
// Rename the header guard
#ifndef NewElementTemplate_h
#define NewElementTemplate_h

#include <Element.h>
#include <Matrix.h>
#include <Vector.h>

class Node;
class Channel;

class NewElementTemplate: public Element
{

public:
  // Constructor
  NewElementTemplate(int tag, int node1, .....); //You must implement this
  // Empty constructor
  NewElementTemplate();
  //Destructor
  ~NewElementTemplate();

  /*********************************************************************/
  /********* Functions to obtain information about dof & connectivity *****/

};
#endif
```

204.7.4 Element Source File

The source file is self documented (read fully and carefully).

```
#include <NewElement.h>
// Must define the class tag for
// the new element in this file.
#include <classTags.h>

// NOTE!! Follow the Element_Class_Desc Encoding
// See classTags.h for more details about encoding
// Declare if there is element output except at gauss points
vector<float> ←↩
    NewElementTemplate::Element_Output_Vector(number_of_Element_outputs) ;
// Declare only if there is any gauss point and there is
// 18 outputs per gauss points i.e stress, strain and plastic strain
vector<float> NewElementTemplate::Gauss_Output_Vector(number_of_gauss_points*18);
// Contains information about Number of Dof for each node of the element
ID NewElementTemplate::DofList(number_of_element_nodes);

//*************************************************************
// Constructor. Receive all input parameters. Should not allocate resources!
// * Input: Defined by user. At least should receive an integer tag, so that base
// class can be initialized.
// * Output: void
NewElementTemplate::NewElementTemplate(int tag, int node1, .....):
    Element(tag, ELE_TAG_NewElement),
    // add more initializers
{
    //ATTENTION!
    // ELE_TAG_NewElement !! Define the class tag in classTags.h
    // with provided encoding formula
    // for setting the material id to the element
    this->setMaterialTag(material->getTag());
    // fill DofList container with number of dofs for each node
    you must implement
}

//*************************************************************
// Empty constructor. Create an empty element (with possibly a bad state)
// * Input: Defined by user. At least should receive an integer tag,
// so that base class can be initialized.
// * Output: void
NewElementTemplate::NewElementTemplate():
    Element(0, ELE_TAG_NewElement),
    // add more initializers setting internal variables to null values
{
    //ATTENTION!
    // ELE_TAG_NewElement !! Define the class tag in classTags.h
    // with provided encoding formula
    // fill DofList container with number of dofs for each node
    you must implement
```

```
}

//*****************************************************************

// Add you own member functions at the end!
```

204.7.5 Element Class Tag Description

This subsection describes how to set up the *ELE_TAG_NewElement* for the new element. All the tags for element, material, load etc, must be included in *ClassTags.h* located in *ModifiedOpenSeesServices* directory. Each element has unique identifiers:

- Element Tag :: It is a unique tag given to each new element type. The element tags are in sequential order. So the new tag must be the next available tag in sequence.
- Element Tag Description :: It is an encoding containing information about the elements such as, type of element, number of nodes, number of gauss points , number of outputs etc. The element tag has 9 digits and follows a strict encoding a shown below

```
// All elements class tags would be in serial
// numbers from 1-N for optimization
/*********************************************************************
* Desc is [Dimension][N. Nodes][Dof per nodes][N. Gauss][No.of Outputs]
* <1-digit> <2-digit> <1-digit> <3-digit> <2-digit>
* - - - - - - - - - - - - - -- - - - - - - - -- - - - -
*
* [ElementCategory] = <num_of_digits = 1> Category of the element
* 1-> Structural Elements
* 2-> Contact Elements
* 3-> Brick Elements
* 4-> Special elements
*
* [N. Nodes] = <num_of_digits = 2> Number of nodes in elements
* xx-> number of nodes
*
* [Dof per nodes] = <num_of_digits = 1> Degree of freedom per node
* x-> DOFS per node
*
* [N. Gauss] = <num_of_digits = 3> Number of gauss points in elements
* xxx-> number of gauss points
*
* [No.of Outputs] = <num_of_digits = 2> no. of outputs other than at gauss points.
* xx-> no. of outputs other than at gauss points.
*
* Default Features
* - - - - - -- - -
* 1) Per gauss point there are in total 18 outputs
* of stress, plastic strain and total strain
* 2) No.of Outputs -> here means the extra outputs by an element
* except gauss points. For example:
* for eight node brick there is 000 No. of Outputs.
****************************************************************************/

//###----------------------------------------
```

```
//### NOTE!! :- Every Element have a responsibility to set
//### their tag_description Array. Based on the above encoding
//### NOTE!! :- Also increase the ELE_TAG_DESC_ARRAY_SIZE to the
//### number of element tags
//### ----------------------------------------
```

For example: Eight node brick element has element tag description as 308300800. Simple truss element has 102300002 as element tag description.

In order to set up the element tag, look for the next available element tag. Usually, the next available element tag would be equal to the *ELE_TAG_DESC_ARRAY_SIZE* which can be found inside *ClassTag.h* file below the initial element tags. The available number should be added as new element tag and the *ELE_TAG_DESC_ARRAY_SIZE* should be increased by 1.

This should be followed by appending the element class tag description in *ELE_TAG_DESC_ARRAY*. All the steps are shown below,

`ClassTags.h` Before:

```
........
#define ELE_TAG_DispBeamColumn3d 94 // 102600012
#define ELE_TAG_Cosserat_8node_brick 95 // 408600800

#define ELE_TAG_DESC_ARRAY_SIZE 96

.........................
..........................

#define ELE_TAG_DESC_ARRAY int ele_tag_desc_array[] = \
{ELE_TAG_DESC_ENCODING, \
100000000, \
308300800, \
308400800, \
308700800, \
308300100, \
308400100, \
........
........
202300009, \
102300002, \
102600024, \
103600006, \
104600000, \
302300100, \
102600012, \
102600012, \
408600800, \
}
```

`ClassTags.h` After:

```
........
#define ELE_TAG_DispBeamColumn3d 94 // 102600012
#define ELE_TAG_Cosserat_8node_brick 95 // 408600800
#define ELE_TAG_NewElement 96 // XXXXXXXXX

#define ELE_TAG_DESC_ARRAY_SIZE 97

........................
.........................

#define ELE_TAG_DESC_ARRAY int ele_tag_desc_array[] = \
{ELE_TAG_DESC_ENCODING, \
100000000, \
308300800, \
308400800, \
308700800, \
308300100, \
308400100, \
........
........
202300009, \
102300002, \
102600024, \
103600006, \
104600000, \
302300100, \
102600012, \
102600012, \
408600800, \
XXXXXXXXX, \
}
```

204.7.6 Integrating New Finite Element into Parser

Next is to integrate the new element with the parser using *feiparser.yy,feiparser.l* files located in *DSL* directory located in Real-ESSI source. This step requires some knowledge of yacc and lex. The NewElement DSL should added along with other defined element DSL's in *feiparser.yy* file. A typical parser for an element looks like as shown below

```
| TEXTNUMBER exp TYPE NewElement WITH NODES
 '(' exp ',' exp ',' exp ',' exp ')'
  USE MATERIAL TEXTNUMBER exp
  parameter1 '=' exp
  parameter2 '=' exp
{
 args.clear(); signature.clear();
 args.push_back($2); signature.push_back(this_signature("number", &isAdimensional));
 args.push_back($8); signature.push_back(this_signature("node1", &isAdimensional));
 args.push_back($10); signature.push_back(this_signature("node2", &isAdimensional));
 args.push_back($12); signature.push_back(this_signature("node3", &isAdimensional));
 args.push_back($14); signature.push_back(this_signature("node4", &isAdimensional));
 args.push_back($19); signature.push_back(this_signature("material", &isAdimensional));

 args.push_back($22); signature.push_back(this_signature("parameter1", &isThisUnit<-1,3,1>));
 //L^3*T/M
 args.push_back($25); signature.push_back(this_signature("parameter2", &isThisUnit<-1,3,1>));

 $$ = new FeiDslCaller8<int,int,int,int,int,int,
       double,double>(&add_element_new_element, args, signature, "add_element_new_element");

 for(int ii = 1;ii <=8; ii++) nodes.pop();
 nodes.push($$);
}
```

where, the code for DSL of the element corresponds as

```
TEXTNUMBER exp TYPE NewElement WITH NODES
 '(' exp ',' exp ',' exp ',' exp ')'
  USE MATERIAL TEXTNUMBER exp
  parameter1 '=' exp
  parameter2 '=' exp
```

which would look like the following in DSL language

```
add element # <.> type NewElement with nodes
 (<.>, <.>, <.>, <.>) use material # 1
 parameter1 = <.>
 parameter2 = <.>;
```

In the above DSL each word represents a token which must be included in *feiparser.yy* and defined in *feiparser.l*. There are some already defined tokens, which needs not to be defined. One can find if the token exits by searching it in *feiparser.l* or *feiparser.yy*.

In the above DSL, the tokens are TEXTNUMBER, TYPE, NewElement, WITH, NODES, USE, MATERIAL, TEXTNUMBER, parameter1 and parameter2. Among them, some of them like TEXTNUMBER, TYPE, NODES, .. etc are already defined and could be searched. But the tokens NewElement, parameter1 and parameter2 needs to be defined. First, these all undefined tokens needs to be included in *feiparser.yy* and then defined in *feiparser.l*.

204.7.6.1 feiparser.yy

The new tokens must be added in the beginning of the feiparser, where other tokens are defined.

The new tokens can be included as described below.

```
// Tokens for elements
%token EightNodeBrick TwentyNodeBrick TwentySevenNodeBrick
%token NewElement

// Element options tokens
%token porosity alpha rho_s rho_f k_x k_y k_z K_s K_f pressure cross_section ↩
   shear_modulus
%token friction_ratio maximum_gap
%token parameter1 parameter2
```

204.7.6.2 feiparser.l

The tokens needs to be defined as the following.

```
"HardContact" {return token::HardContact;}
"SoftContact" {return token::SoftContact;}
"NewElement" {return token::NewElement;}
```

204.7.6.3 Argument Stack, Signature and Units

Returning back to the code in parser:

```
| TEXTNUMBER exp TYPE NewElement WITH NODES
 '(' exp ',' exp ',' exp ',' exp ')'
  USE MATERIAL TEXTNUMBER exp
  parameter1 '=' exp
  parameter2 '=' exp
{
 args.clear(); signature.clear();
 args.push_back($2); signature.push_back(this_signature("number", ↩
     &isAdimensional));
 args.push_back($8); signature.push_back(this_signature("node1", ↩
     &isAdimensional));
 args.push_back($10); signature.push_back(this_signature("node2", ↩
     &isAdimensional));
 args.push_back($12); signature.push_back(this_signature("node3", ↩
     &isAdimensional));
 args.push_back($14); signature.push_back(this_signature("node4", ↩
     &isAdimensional));
 args.push_back($19); signature.push_back(this_signature("material", ↩
     &isAdimensional));

 args.push_back($22); signature.push_back(this_signature("parameter1", ↩
     &isThisUnit<-1,3,1>));
 //L^3*T/M
 args.push_back($25); signature.push_back(this_signature("parameter2", ↩
     &isThisUnit<-1,3,1>));

 $$ = new FeiDslCaller8<int,int,int,int,int,int,
        double,double>(&add_element_new_element, args, signature, ↩
            "add_element_new_element");

 for(int ii = 1;ii <=8; ii++) nodes.pop();
 nodes.push($$);
}
```

Each variable or parameter in Real-ESSI has units. So, for each of the variables UNIT must be specified. In the above code. *args* is a stack that should be filled with the tokens that are the parameters of element. The first step is to clear the *args* and the *signature* stacks. Pushing the element parameter tokens is done as described below

```
args.push_back($2); signature.push_back(this_signature("number", ↩
    &isAdimensional));
args.push_back($22); signature.push_back(this_signature("parameter1", ↩
    &isThisUnit<-1,3,1>));
 //L^3*T/M
```

Here, \$2 responds to the the second token i.e exp after *TEXTNUMBER*. Similarly, 5^{th} token in TYPE. In signature, the string can be anything, but should usually be the parameter name. The last is enforcing the units for each of the parameters by defining the required units. There are many units, such as *isAdimensional, isAdimensional, isMass, isLength, isTime, isFrequency, isArea, isVolume, isForce, isEnergy, isTorque, isPressure, isBodyForce, isDensity, isVelocity, isAcceleration, isAreaMomentOfInertia, isMassMomentOfInertia*. If the parameter has some other units then the other units can be defined as

$$\text{isThisUnit}< m, l, t >$$

which refers to the unit $M^m L^l T^t$ in standard units. Here, M, L, T are mass, length and time respectively.

204.7.6.4 FeiDslCaller

The next step is to send all the parameters to DSL Header File. The header file contains the code to create a new element inside simulation domain. The code that does this is

```
$$ = new FeiDslCaller8<int,int,int,int,int,int,
      double,double>
      (&add_element_new_element, args,
      signature, "add_element_new_element");

for(int ii = 1;ii <=8; ii++) nodes.pop();
nodes.push($$);
```

FeiDslCaller takes all the arguments and passes to the *add_element_new_element.h* header file. In the above code, the number 8 in function *FeiDslCaller* corresponds to the total number of arguments to the element and following that, the type of the arguments is defined. Here, the type of 8 arguments are *int, int, int,int, int, int, double, double*. The last step is the remove everything from the node stack by popping it equal to the number of times of argument and then finally pushing the *FeiDslCaller* to the nodes stack.

204.7.6.5 New DSL Header File

The header file of the new DSL must be created in */API/MODELING* directory. The header file must also be included in */API/api.h* header file. Here, the header file *add_element_new_element.h* has been created, which is called by *FeiDslCaller*.

```
int add_element_new_element(int ElementNumber, int Node1, int Node2, int Node3,
        int Node4, int MaterialId, double Parameter1, double Parameter2)
{
    Element* theElement = 0;
    theElement = new NewElement(ElementNumber, Node1, Node2, Node3, Node4,
    MaterialId, Parameter1, Parameter2);

    if (theElement == NULL){
```

```
        cerr << "Error: (add_element_new_element)
        memory allocation problem for theElement!" << endl;
        return -1;
    }

    if (theDomain.addElement(theElement) == false){
        cerr << "WARNING (add_element_new_element)
        could not add element to the domain\n";
        cerr << "Element Number: " << ElementNumber << endln;
        return -1;
    }

    return 0;
};
```

Header file in */API/api.h* file needs to be included:

```
// ##########################
// New Element [ABCD Month, Year]
// ##########################

#include "MODELING/add_element_new_element.h"
```

204.7.7 Compiling Real-ESSI

It is assumed that the person reading this document is developer and thus should already have the Real-ESSI dependencies. To compile Real-ESSI with the new element, it should be build from the beginning. Assuming that the build directory in *build* inside Real-ESSI source code, the steps to recompile are

```
cd build
rm -r *
cmake ..
make -j 20
```

204.7.8 Verification of Implementation

Once, the element is fully integrated with Real-ESSI Simulator, the developer should fully verify the implementation by carrying out verification runs. In addition, the developer should be able to run their examples in sequential and parallel and verify the implementation.

Chapter 205

Input, Domain Specific Language

(1991-2005-2010-2011-2012-2015-2016-2017-2018-2019-2020-2021-)

(In collaboration with Prof. José Abell, Dr. Yuan Feng, and Dr. Hexiang Wang)

205.1 Chapter Summary and Highlights

205.2 Introduction

This chapter presents the domain specific language developed for the Real-ESSI. The language was designed with a primary goal of developing FEA models and interfacing them with various Real-ESSI functionalities. In addition to that, syntax is used to self-document models, provide physical-unit safety, provide common flow control structures, provide modularity to scripting via user functions and "include" files, and provide an interactive environment within which models can be created, validated and verified.

The development of Real-ESSI Domain specific language (DSL) (the Finite Element Interpreter, FEI) is based on LEX (Lesk and Schmidt, 1975) and YACC (Johnson, 1975).

Self-documenting ensures that the resulting model script is readable and understandable with little or no reference to the users manual. This is accomplished by providing a command grammar structure and wording similar to what would be used in a natural language description of the problem.

FEA analysis is unitless, that is, all calculations are carried out without referencing a particular unit system. This leaves the task of unit correctness up to the user of FEA analysis. This represents a recurring source of error in FEA analysis. Physical unit safety is enforced in Real-ESSI by implementing all base variables as physical quantities, that is, all variables have a unit associated with it. The adimensional unit is the base unit for those variables which have no relevant unit (like node numbers). Command calls are sensitive to units. For example, the node creation command call expects the node coordinates to be input with the corresponding units (length in this case). Additionally, the programming/command language naturally supports operation with units like arithmetic operations (quantities with different unit types will not add or subtract but may be multiplied). This approach to FEA with unit awareness provides an additional layer of security to FEA calculations, and forces the user to carefully think about units. This can help catch some common mistakes.

The Real-ESSI language provides modularity through the `include` directive/command, and user functions. This allows complex analysis cases to be parameterized into modules and functions which can be reused in other models.

Finally, an emphasis is placed on model verification and validation. To this end, Real-ESSI provides an interactive programming environment with all the ESSI syntax available. By using this environment. the user can develop tests to detect errors in the model that are not programming errors. For example, the user can query nodes and elements to see if they are set to appropriate states. Also, several standard tools are provided to check element validity (Jacobian, etc.).

The ESSI language provides reduced model development time by providing the aforementioned features along with meaningful error reporting (of syntax and grammatical errors), a help system, command completion and highlighting for several open source and commercial text editors.

Some additional ideas are given by Dmitriev (2004), Stroustrup (2005), Niebler (2005), Mernik et al. (2005), Ward (2003), etc.

205.3 Domain Specific Language (DSL), English Language Binding

Overview of the language syntax.

- Each command line has to end with a semicolon ";"
- Comment on a line begins with either "//" or "!" and last until the end of current line.
- Units are required (see more below) for all quantities and variables.
- Include statements allow splitting source into several files
- All variables are double precision (i.e. floats) with a unit attached.
- All standard arithmetic operations are implemented, and are unit sensitive.
- Internally, all units are represented in the base SI units (m - s - kg).
- The syntax ignores extra white spaces, tabulations and newlines. Wherever they appear, they are there for code readability only. (This is why all commands need to end with a semicolon).
- The user should be familiar with the list of the reserved keywords from Section 205.7 on page 1163.

205.3.1 Running Real-ESSI

At the command line type "essi", to get to the ESSI prompt and start Real-ESSI in interactive mode.

Command line output

```

  The Finite Element Interpreter Endeavor

  The Real-ESSI Simulator
  Modeling and Simulation of Earthquakes, and Soils, and ↩
     Structures and their Interaction

  Sequential processing mode.

Version Name      : Real-ESSI Global Release, June2018. Release ↩
   date: Jun 13 2018 at 11:02:19. Tag: adc085ae70
```

```
Version Branch    : GLOBAL_RELEASE
Compile Date      : Jun 13 2018 at 14:36:56
Compile User      : jeremic
Compile Sysinfo   : sokocalo 4.13.0-43-generic x86_64 GNU/Linux
Runtime User      : jeremic
Runtime Sysinfo   : sokocalo 4.13.0-43-generic x86_64 GNU/Linux
Time Now          : Jun 13 2018 at 15:32:52
Days From Release : 0
PostProcessing Compatible Version: ParaView 5.1.2
PostProcessing Compatible Version: ESSI-pvESSI Date: Feb 15 2018 ↩
   at 11:00:28. Tag: 58fe430a19

Static startup tips:
 * Remember: Every command ends with a semicolon ';'.
 * Type 'quit;' or 'exit;' to finish.
 * Run 'essi -h' to see available command line options.

ESSI>
```

A number of useful information about Real-ESSI is printed on the screen. From here, commands can be input manually or a file may be included via the `include` command which is as follows.

```
include "foobar.fei";
```

to include the file `foobar.fei`.

A more efficient way to start Real-ESSI and analyze an example is to pass input file name to the command line. Real-ESSI command to execute an input file immediately is done by issuing the following command: `essi -f foobar.fei`. This will execute essi directly on input file `foobar.fei`. After executing the file, the essi interpreter will continue in interactive mode unless the command line flag `-n` or `--no-interactive` is set. A list of command line options is available by calling essi from the command line as `essi -h`.

Command line output

```

  The Finite Element Interpreter Endeavor

  The Real-ESSI Simulator
  Modeling and Simulation of Earthquakes, and Soils, and ↩
     Structures and their Interaction

  Sequential processing mode.

Static startup tips:
 * Remember: Every command ends with a semicolon ';'.
 * Type 'quit;' or 'exit;' to finish.
 * Run 'essi -h' to see available command line options.

The Real-ESSI Simulator
Modeling and Simulation of Earthquakes, and Soils, and Structures ↩
   and their Interaction

Usage: essi [-cfhnsmbe FILENAME]
  -c --cpp-output                : Output cpp version of the model.
  -f --filename [FILENAME]       : run ESSI on a FILENAME.
  -h --help                      : Print this message.
  -n --no-interactive            : Disable interactive mode.
  -s --set-variable              : Set a variable from the ↩
     command line.
  -d --dry-run                   : Do not execute ESSI API calls. ↩
     Just parse.
  -m --model-name [NAME]         : Set the model name from the ↩
     command line.
  -p --profile-report [FILENAME] : Set the filename for the ↩
     profiler report (and activate lightweight profiling)

Example to set a variable name from command line:
    essi -s a=10,b=20,c=30
Runs ESSI with variables a, b, and c set to 10, 20 and 30 ↩
   respectively.
At this time, only ESSIunits::unitless variables can be set.
```

205.3.2 Finishing Real-ESSI Program Run

To properly finish Real-ESSI program run, and save and close all the output files, user has to use final, closure command:

```
bye;
```

Command `bye;` has to be included at the end of input file script, or at the end of each interactive/interpretative session. Command `bye;` ensures that Real-ESSI program gracefully exits simulation, and that all the output files are properly saved and closed. Proper finishing of simulation using Real-ESSI Simulator is very much necessary, while the choice of command `bye;` is done as an homage to Professor Knuth and his Literate Programming endeavor (Knuth, 1984), that is driving much of the Real-ESSI DSL development.

There are a number of alternative final commands, for example:

```
exit;
quit;
zdravo;
vozdra;
dvojka;
voljno;
zaijian;
tschuess;
geia-sou;
tchau;
sair;
khoda-hafez;
doei;
nasvidenje;
ajde-bok;
izhod;
konec;
czesc;
ciao;
hoscakal;
```

These additional, alternative final commands can all be written using original scripts:

zdravo ↔ здраво

vozdra ↔ воздра

dvojka ↔ двојка

voljno ↔ вољно

zaijian ↔ 再见

tschuess ↔ tschüss

geia-sou ↔ γεια σου

khoda-hafez ↔ خداحافظ

hoscakal ↔ hoşçakal

205.3.3 Real-ESSI Variables, Basic Units and Flow Control

Variables are defined using the assignment (=) operator. For example,

```
var_x = 7; //Results in the variable x be set to 7 (unitless)
var_y = 3.972e+2; //Scientific notation is available.
```

The language contains a list of reserved keywords. Throughout this documentation, reserved keywords are highlighted in blue or red.

All standard arithmetic operations are available between variables. These operations can be combined arbitrarily and grouped together with parentheses.

```
var_a = var_x + var_y; // Addition
var_b = var_x - var_y; // Subtraction
var_c = var_x * var_y; // Product
var_d = var_x / var_y; // Quotient
var_e = var_y % var_x; // Modulus (how many times x fits in y)
```

The '`print`' command can be used to display the current value of a variable.

```
print var_x;
print var_y;
print var_a;
print var_b;
print var_c;
print var_d;
print var_e;
```

Command line output

```
var_x = 7 []
var_y = 397.2 []
var_a = 404.2 []
var_b = -390.2 []
var_c = 2780.4 []
var_d = 0.0176234 []
var_e = 5.2 []
```

Here the “unit” (sign) [] means that the quantities are unitless.

The command '`whos`' is used to see all the currently defined variables and their values. After a fresh start of essi, needed to clear up all the previously defined variables, command `whos;`' produces a list of predefined variables:

Command line output

```
ESSI> whos;

Declared variables:
  *      Day =           86400 [s]
```

```
  *      GPa =               1 [GPa]
  *     Hour =            3600 [s]
  *       Hz =               1 [Hz]
  *      MPa =               1 [MPa]
  *   Minute =              60 [s]
  *        N =               1 [N]
  *       Pa =               1 [Pa]
  *     Week =          604800 [s]
  *       cm =               1 [cm]
  *     feet =          0.3048 [m]
  *       ft =          0.3048 [m]
  *        g =            9.81 [m*s^-2]
  *     inch =          0.0254 [m]
  *       kN =               1 [kN]
  *      kPa =               1 [kPa]
  *       kg =               1 [kg]
  *      kip =         4448.22 [N]
  *       km =               1 [km]
  *      ksi =     6.89476e+06 [Pa]
  *      lbf =         4.44822 [N]
  *      lbm =        0.453592 [kg]
  *        m =               1 [m]
  *     mile =         1609.35 [m]
  *       mm =               1 [mm]
  *       pi =         3.14159 []
  *      psi =         6894.76 [Pa]
  *        s =               1 [s]
  *     yard =          0.9144 [m]

    * = locked variable
ESSI>
```

Predefined variables shown above have a preceding asterisk to show they are locked variables which cannot be modified. The purpose of these locked variables are to provide names for units. Imperial units are also supported as shown above.

The units for variable are shown between the brackets. Note that unit variables have the same name as their unit, which is not the case for user defined variables. Variables preceded by a star (*) are locked variables which can't be modified.

For example, the variable 'm' defines 'meter'. So to define a new variable `L1` which has meter units we do:

```
L1 = 1*m; // Defines L1 to 1 m.
L2 = 40*mm; // Defines L2 to be 40 millimeters.
```

Even though L2 was created with millimeter units, it is stored in base units.

`print L2;` displays

Command line output

```
L2 = 0.04 [m]
```

As additional examples, let us define few forces:

```
F1 = 10*kN;
F2 = 300*N;
F3 = 4*kg*g;
```

Here g is the predefined acceleration due to gravity.

Arithmetic operations do check (and enforce) for unit consistency. For example, `foo = L1 + F1;` produces an error because units are not compatible. However, `bar = L1 + L2;` is acceptable. On the other hand, multiplication, division and modulus, always work because the result produces a quantity with new units (except when the adimensional quantity is involved).

```
A = L1*L2;
Stress_n = F1 / A;
```

Units for all variables are internally converted to SI units ($kg-m-s$) and stored in that unit system. Variables can be displayed using different units by using the `[]` operator. This does not change the variable, it just displays the value of variable with required unit. For example,

```
print Stress_n; //Print in base SI units.
print Stress_n in Pa; //Print in Pascal
print Stress_n in kPa; //Print in kilo Pascal
```

Command line output

```
Stress_n = 250000 [kg*m^-1*s^-2]

Stress_n = 250000 [Pa]

Stress_n = 250 [kPa]
```

The DSL provides functions to test the physical units of variables. For example,

`print isForce(F1);`

Will print an adimensional, Boolean `1` because `F1` has units of force. While,

`print isPressure(F);`

will print an adimensional, Boolean `0`. The language also provides comparison of quantities with same units (remember all values are compared in SI Units).

`print F1 > F2;`

will print an adimensional, Boolean `1` since `F1` is greater than `F2`.

The program flow can be controlled with `if` and `while` statements, i.e.:

```
if (isForce(F1))
{
 print F1; // This will be executed
};

if (isForce(L1))
{
 print L1; // This will not.
};
```

Note the necessary semicolon (;) at the closing brace. Unlike C/C++, the braces are always necessary. Closing colon is also always necessary.

The "else" statement is also available:

```
if (isForce(L1))
{
 print L1; // This will not execute
}
else
{
 print L2; // This will execute instead
};
```

While loops are also available:

```
i = 0;
while( i < 10)
{
 print i;
 i = i +1;
};
```

205.3.4 Modeling

This section details ESSI modeling commands. Angle brackets <> are used for quantity or variable placeholder, that is, they indicate where user input goes. Within the angle brackets, the expected unit type is given as well, i.e.. `<L>` means the command expects an input with a value and a length unit. The symbol `<.>` represents the adimensional quantity.

In addition to that, the vertical bar | ("OR" sign)) is used to separate two or more keyword options, i.e. `[a|b|c]` is used indicate keyword options `a` or `b` or `c`. The symbol `|...|` is used to denote where several long options exist and are explained elsewhere (an example of this is available below in a material model definitions).

All commands require unit consistency. Base units, SI or other can be used as indicated below:

- length, symbol L, units [m, inch, ft]
- mass, symbol M, units [kg, lbm],
- time, symbol T, units [s]

Derived units can also be used:

- angle, symbol rad (radian), unit $[dimensionless, L/L]$
- force, symbol N (Newton), units $[N, kN, MN, M * L/T^2]$,
- stress, symbol Pa (Pascal), units $[Pa, kPa, MPa, N/L^2, M/L/T^2]$
- strain, symbol (no symbol), units $[L/L]$
- mass density, symbol (no symbol), units $[M/L^3]$
- force density, symbol (no symbol), units $[M/L^2/T^2]$

All models have to be named: `model name "model_name_string";` This is important as output files are named based on model name.

Each loading stage has to be named as well. A new loading stage[1] is defined like this:

`new loading stage "loading stage name string";`

In addition to model name, loading stage name is used for output file name for given loading stage.

---

[1] See more in section 101.4.5 on page 97 in Jeremić et al. (1989-2025).

205.3.4.1 Modeling, Material Model: Adding a Material Model to the Finite Element Model

Adding constitutive material model to the finite element model/domain is done using command:

```
add material # <.> type |...|
                mass_density = <M/L^3>
                (more model dependent parameters) ;
```

- Material number # (or alternatively `No`) is a distinct integer number used to uniquely identify this material.
- Mass density should be defined for each material (even if only static analysis is performed, for example if self weight is to be used as a loading stage).
- Depending on material model, there will be additional material parameters that are defined for each material model/type below:

Starting with version `03-NOV-2015` all elastic-plastic material models require explicit specification of the constitutive integration algorithm. More information on this can be found in 205.3.5.15. Only the material `linear_elastic_isotropic_3d_LT` ignores this option.

Choices for `material_type` are listed below.

205.3.4.2 Modeling, Material Model: Linear Elastic Isotropic Material Model

The command is:

```
add material # <.> type linear_elastic_isotropic_3d
    mass_density = <M/L^3>
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is an isotropic modulus of elasticity of a material (units: stress)
- `poisson_ratio` is a Poisson's ratio [dimensionless]

More on this material model can be found in Section 104.6.1 on Page 220 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.3 Modeling, Material Model: Cross Anisotropic Linear Elastic Material Model

The command is:

```
add material # <.> <material_number>
            type linear_elastic_crossanisotropic
            mass_density = <M/L^3>
            elastic_modulus_horizontal = <F/L^2>
            elastic_modulus_vertical = <F/L^2>
            poisson_ratio_h_v = <.>
            poisson_ratio_h_h = <.>
            shear_modulus_h_v = <F/L^2>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus_horizontal` is an anisotropic modulus of elasticity for horizontal plane of a material $[F/L^2]$
- `elastic_modulus_vertical` is an anisotropic modulus of elasticity for vertical direction of a material $[F/L^2]$
- `poisson_ratio_h_v` is a Poisson's ratio for horizontal-vertical directions [dimensionless]
- `poisson_ratio_h_h` is a Poisson's ratio for horizontal-horizontal directions [dimensionless]
- `shear_modulus_h_v` is a shear modulus for horizontal-vertical directions $[F/L^2]$

It is assumed that vertical axes is global Z axes.

More on this material model can be found in Section 104.6.1 on Page 220 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.4 Modeling, Material Model: von Mises Associated Material Model with Linear Isotropic and/or Kinematic Hardening

Implements von Mises family of constitutive models, with linear kinematic and/or isotropic hardening.

The command is:

```
add material # <.> type vonMises
  mass_density = <M/L^3>
  elastic_modulus = <F/L^2>
  poisson_ratio = <.>
  von_mises_radius = <F/L^2>
  kinematic_hardening_rate = <F/L^2>
  isotropic_hardening_rate = <F/L^2> ;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `von_mises_radius` is the radius of the deviatoric section of the von Mises yield surface $[F/L^2]$
- `kinematic_hardening_rate` is the rate of the kinematic hardening $[F/L^2]$
- `isotropic_hardening_rate` is the rate of the kinematic hardening $[F/L^2]$

More on this material model can be found in Section 104.6.6 on Page 226 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.5 Modeling, Material Model: von Mises Associated Material Model with Isotropic Hardening and/or Armstrong-Frederic Nonlinear Kinematic Hardening

This command is for von Mises family of constitutive models, with Armstrong-Frederick kinematic and/or isotropic hardening.

The command is:

```
add material # <.> type vonMisesArmstrongFrederick
    mass_density = <M/L^3>
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    von_mises_radius = <.>
    armstrong_frederick_ha = <F/L^2>
    armstrong_frederick_cr = <.>
    isotropic_hardening_rate = <F/L^2> ;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `von_mises_radius` is the radius of the deviatoric section of the von Mises yield surface $[F/L^2]$
- `armstrong_frederick_ha` controls rate of the kinematic hardening $[F/L^2]$
- `armstrong_frederick_cr` controls the saturation limit for kinematic hardening [Dimensionless]
- `isotropic_hardening_rate` is the rate of the kinematic hardening $[F/L^2]$

More on this material model can be found in Section 104.6.6 on Page 226 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.6 Modeling, Material Model: Drucker-Prager Associated Material Model with Linear Isotropic and/or Kinematic Hardening

This command is for Drucker-Prager family of constitutive models, with linear kinematic and/or isotropic hardening. This material uses associate plastic flow rule.

The command is:

```
add material # <.> type DruckerPrager
  mass_density = <M/L^3>
  elastic_modulus = <F/L^2>
  poisson_ratio = <.>
  druckerprager_k = <.>
  kinematic_hardening_rate = <F/L^2>
  isotropic_hardening_rate = <F/L^2>
  initial_confining_stress = <F/L^2> ;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `druckerprager_k` slope of the Drucker-Prager yield surface in p-qm space (equivalent to M parameter) [dimensionless]
- `kinematic_hardening_rate` is the rate of the kinematic hardening $[F/L^2]$
- `isotropic_hardening_rate` is the rate of the isotropic hardening $[F/L^2]$

More on this material model can be found in Section 104.6.7 on Page 232 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.7 Modeling, Material Model: Drucker-Prager Associated Material Model with Isotropic Hardening and/or Armstrong-Frederick Nonlinear Kinematic Hardening

A Drucker-Prager constitutive model with associative plastic-flow rule, Armstrong-Frederick kinematic hardening, and linear isotropic hardening and linear elastic isotropic elasticity law.

The command is:

```
add material # <.> type DruckerPragerArmstrongFrederickLE
   mass_density = <M/L^3>
   elastic_modulus = <F/L^2>
   poisson_ratio = <.>
   druckerprager_k = <.>
   armstrong_frederick_ha = <F/L^2>
   armstrong_frederick_cr = <.>
   isotropic_hardening_rate = <F/L^2>
   initial_confining_stress = <F/L^2>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `druckerprager_k` slope of the Drucker-Prager yield surface in p-qm space (equivalent to M parameter) [Dimensionless]
- `armstrong_frederick_ha` controls rate of the kinematic hardening $[F/L^2]$
- `armstrong_frederick_cr` controls the saturation limit for kinematic hardening [Dimensionless]
- `isotropic_hardening_rate` is the rate of the isotropic hardening $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$

More on this material model can be found in Section 104.6.7 on Page 232 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.8 Modeling, Material Model: Drucker-Prager Associated Material Model with Isotropic Hardening and/or Armstrong-Frederick Nonlinear Kinematic Hardening and Nonlinear Duncan-Chang Elasticity

A Drucker-Prager constitutive model with associative plastic-flow rule, Armstrong-Frederick kinematic hardening, and Duncan-Chang non-linear isotropic elasticity law.

The command is:

```
add material # <.> type DruckerPragerArmstrongFrederickNE
  mass_density = <M/L^3>
  DuncanChang_K = <.>
  DuncanChang_pa = <F/L^2>
  DuncanChang_n = <.>
  DuncanChang_sigma3_max = <F/L^2>
  DuncanChang_nu = <.>
  druckerprager_k = <.>
  armstrong_frederick_ha = <F/L^2>
  armstrong_frederick_cr = <.>
  isotropic_hardening_rate = <F/L^2>
  initial_confining_stress = <F/L^2>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `DuncanChang_K` parameter controlling Young's modulus $[< . >]$
- `DuncanChang_pa` reference pressure $[F/L^2]$
- `DuncanChang_n` exponent $[< . >]$
- `DuncanChang_sigma3_max` maximum value for σ_3 ($\sigma_3 < 0$) elastic properties are constant for greater values of σ_3 $[F/L^2]$
- `DuncanChang_nu` Poisson's ratio $[F/L^2]$
- `druckerprager_k` slope of the Drucker-Prager yield surface in p-qm space (equivalent to M parameter) [Dimensionless]
- `armstrong_frederick_ha` controls rate of the kinematic hardening $[F/L^2]$
- `armstrong_frederick_cr` controls the saturation limit for kinematic hardening [Dimensionless]
- `isotropic_hardening_rate` is the rate of the isotropic hardening $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$

More on this material model can be found in Section 104.6.7 on Page 232 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.9 Modeling, Material Model: Drucker-Prager Nonassociated Material Model with Linear Isotropic and/or Kinematic Hardening

This command defines Drucker-Prager family of constitutive models, with linear kinematic and/or isotropic hardening. This material uses non-associate plastic flow rule.

The command is:

```
add material # <.> type DruckerPragerNonAssociateLinearHardening
    mass_density = <M/L^3>
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    druckerprager_k = <.>
    kinematic_hardening_rate = <F/L^2>
    isotropic_hardening_rate = <F/L^2>
    initial_confining_stress = <F/L^2>
    plastic_flow_xi = <.>
    plastic_flow_kd = <.>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `druckerprager_k` slope of the Drucker-Prager yield surface in p-qm space (equivalent to M parameter) [Dimensionless]
- `kinematic_hardening_rate` is the linear rate of the kinematic hardening $[F/L^2]$
- `isotropic_hardening_rate` is the linear rate of the isotropic hardening $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$
- `plastic_flow_xi` governs the amplitude of plastic volume changes. The higher ξ, the higher the dilatancy. If $\xi = 0$, the material model will only produce deviatoric plastic strains. [.]
- `plastic_flow_kd` governs the size of the dilatancy surface, a cone in the stress space on which no plastic volume changes occur. k_d governs the size of this cone: if k_d is equal to zero, the dilatancy surface shrinks to a line (the hydrostatic axis), so that only dilative soil deformation is possible. [.]

More on this material model can be found in Section 104.6.7 on Page 232 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.10 Modeling, Material Model: Drucker-Prager Nonassociated Material Model with Linear Isotropic and/or Armstrong-Frederick Nonlinear Kinematic Hardening

This command defines Drucker-Prager family of constitutive models, with nonlinear kinematic and/or linear isotropic hardening. This material uses non-associated plastic flow rule.

The command is:

```
add material # <.> type DruckerPragerNonAssociateArmstrongFrederick
    mass_density = <M/L^3>
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    druckerprager_k = <.>
    armstrong_frederick_ha = <F/L^2>
    armstrong_frederick_cr = <.>
    isotropic_hardening_rate = <F/L^2>
    initial_confining_stress = <F/L^2>
    plastic_flow_xi = <.>
    plastic_flow_kd = <.>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `druckerprager_k` slope of the Drucker-Prager yield surface in p-qm space (equivalent to M parameter) [Dimensionless]
- `armstrong_frederick_ha` a kinematic hardening parameter, which governs the initial stiffness after the yield $[F/L^2]$
- `armstrong_frederick_cr` a kinematic hardening parameter. $\frac{h_a}{c_r}$ governs the limit of the back-stress [Dimensionless]
- `isotropic_hardening_rate` is the rate of the kinematic hardening $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$
- `plastic_flow_xi` governs the amplitude of plastic volume changes - the higher ξ, the higher the dilatancy. If $\xi = 0$, the material model will only produce deviatoric plastic strains. [.]
- `plastic_flow_kd` governs the size of the dilatancy surface, a cone in the stress space on which no plastic volume changes occur. k_d governs the size of this cone: if k_d is equal to zero, the

> dilatancy surface shrinks to a line (the hydrostatic axis), so that only dilative soil deformation is possible. [.]

More on this material model can be found in Section 104.6.7 on Page 232 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

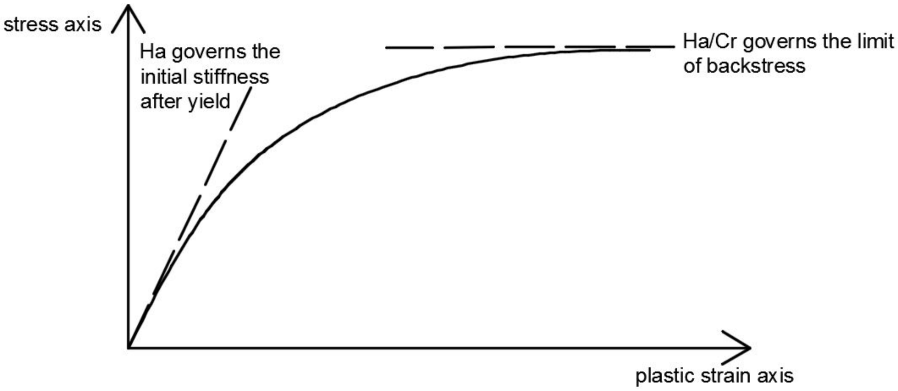

Figure 205.1: The physical meanings of h_a and c_r

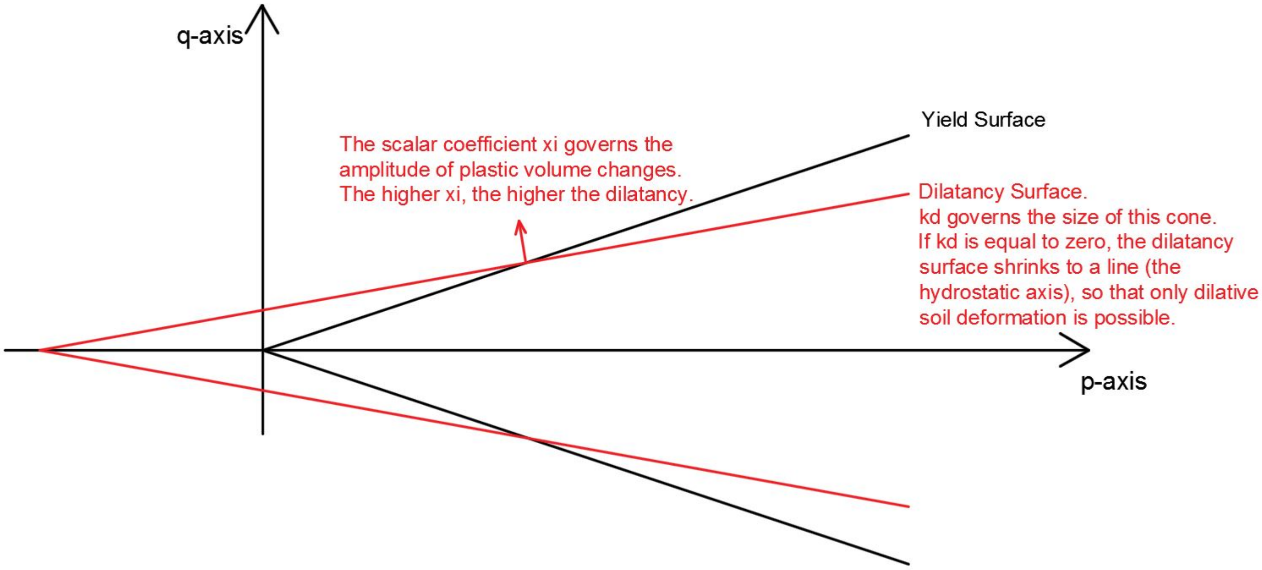

Figure 205.2: The physical meanings of ξ and k_d

The physical meanings of h_a, c_r, ξ, and k_d are shown in Figure (205.1) and Figure (205.2).

205.3.4.11 Modeling, Material Model: Hyperbolic Drucker-Prager Nonassociated Material Model with Linear Isotropic and/or Armstrong-Frederick Nonlinear Kinematic Hardening

This command defines a hyperbolic Drucker-Prager constitutive model, with nonlinear kinematic and/or linear isotropic hardening. This material uses non-associated plastic flow rule.

The command is:

```
add material # <.> type HyperbolicDruckerPragerNonAssociateArmstrongFrederick
   mass_density = <M/L^3>
   elastic_modulus = <F/L^2>
   poisson_ratio = <.>
   friction_angle = <.>
   cohesion = <F/L^2>
   rounded_distance = <F/L^2>
   armstrong_frederick_ha = <F/L^2>
   armstrong_frederick_cr = <.>
   isotropic_hardening_rate = <F/L^2>
   initial_confining_stress = <F/L^2>
   plastic_flow_xi = <.>
   plastic_flow_kd = <.>;
```

where:

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio for material [ ]
- `friction_angle` is the initial friction angle of the material. If isotropic hardening is present, friction angle will evolve. [rad]
- `cohesion` is a material constant that defines the cohesion of the material $[F/L^2]$
- `rounded_distance` is the parameter that controls the shape of the rounded apex of yield surface $[F/L^2]$
- `armstrong_frederick_ha` a kinematic hardening parameter, that governs the initial stiffness after the yield $[F/L^2]$
- `armstrong_frederick_cr` a kinematic hardening parameter. It is noted that ratio $\frac{h_a}{c_r}$ controls the asymptote the back-stress, that can be related to the ultimate shear strength [.]
- `isotropic_hardening_rate` is the rate of the isotropic hardening $[F/L^2]$

- `initial_confining_stress` initial confining (mean) pressure, a small value just get initial stress out of cone zone $[F/L^2]$
- `plastic_flow_xi` governs the amplitude of plastic volume changes - the higher ξ, the higher the dilatancy. If $\xi = 0$, the material model will only produce deviatoric plastic strains. [.]
- `plastic_flow_kd` governs the size of the dilatancy surface, a cone in the stress space on which no plastic volume changes occur. k_d governs the size of this cone: if k_d is equal to zero, the dilatancy surface shrinks to a line (the hydrostatic axis), so that only dilative soil deformation is possible. [.]

More on this material model can be found in Section 104.6.8.5 on Page 247 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.12 Modeling, Material Model: Rounded Mohr-Coulomb Associated Linear Isotropic Hardening Material Model

The command is:

```
add material # <.> type roundedMohrCoulomb
   mass_density = <M/L^3>
   elastic_modulus = <F/L^2>
   poisson_ratio = <.>
   RMC_m = <.>
   RMC_qa = <F/L^2>
   RMC_pc = <F/L^2>
   RMC_e = <.>
   RMC_eta0 = <.>
   RMC_Heta = <F/L^2>
   initial_confining_stress = <F/L^2>
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material [ ]
- `RMC_m` $0 < m < 1$ parameter of the RMC yield function. Controls roundness of apex in p-q space. [ ]
- `RMC_qa` q_a parameter of the RMC yield function. Controls roundness of apex in p-q space. $[F/L^2]$
- `RMC_pc` p pressure offset $[F/L^2]$
- `RMC_e` e parameter controls roundness of the deviatoric cross-section of the yield surface. $0.5 < e <= 1$, $e = 0.5$ results in a triangular deviatoric section while $e = 1$ is round. [ ]
- `RMC_eta0` controls the opening of the yield surface [ ]
- `RMC_Heta` isotropic (linear) hardening of the yield surface $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$

More on this material model can be found in Section 104.6.9 on Page 250 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.13 Modeling, Material Model: Cam Clay Material Model

The command is:

```
add material # <.> type CamClay
  mass_density = <M/L^3>
  M = <.>
  lambda = <.>
  kappa = <.>
  e0 = <.>
  p0 = <F/L^2>
  poisson_ratio = <.>
  initial_confining_stress = <F/L^2>
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `e0` void ratio (e_0) at the reference pressure, [dimensionless]
- `M` Cam-Clay slope of the critical state line in stress space, [dimensionless]
- `lambda` Cam-Clay normal consolidation line slope, (unit: dimensionless)
- `kappa` Cam-Clay unload-reload line slope, (unit: dimensionless)
- `poisson_ratio` Constant Poisson-ratio
- `p0` Cam-Clay parameter (p_0). Tip of the yield surface in q-p space. $[F/L^2]$
- `initial_confining_stress` initial confining (mean) pressure $[F/L^2]$

More on this material model can be found in Section 104.6.10 on Page 251 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.14 Modeling, Material Model: von Mises Associated Multiple Yield Surface Material Model

The command is:

```
add material # <.> type vonMisesMultipleYieldSurface
  mass_density = <M/L^3>
  elastic_modulus = <F/L^2>
  poisson_ratio = <.>
  total_number_of_yield_surface = <.>
  radiuses_of_yield_surface = <string>
  radiuses_scale_unit = <F/L^2>
  hardening_parameters_of_yield_surfaces = <string>
  hardening_parameters_scale_unit = <F/L^2> ;
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of the material $[F/L^2]$
- `poisson_ratio` is the constant Poisson-ratio [dimensionless]
- `total_number_of_yield_surface` is the total number of yield surfaces. [dimensionless]
- `radiuses_of_yield_surface` is the radius list of multiple yield surfaces. This parameter gives the radiuses of each yield surface from the smallest to the biggest. This parameter should be a string which contains the dimensionless radiuses. The radiuses should be separated by a blank space or a comma. [string]
- `radiuses_scale_unit` is the unit of the each yield surface. This parameter also provides a method to scale up or scale down the radiuses of each yield surfaces. $[F/L^2]$
- `hardening_parameters_of_yield_surfaces` is the hardening parameters corresponding to each yield surface. This parameter should be a string which contains the dimensionless hardening parameters. The hardening parameters should be separated by a blank space or a comma. [string]
- `hardening_parameters_scale_unit` The unit of the each hardening parameter. This parameter also provides a method to scale up or scale down the hardening parameter of each yield surfaces. $[F/L^2]$

205.3.4.15 Modeling, Material Model: von Mises Associated Multiple Yield Surface Material Model that Matches G/G_{max} Curves

The command is:

```
add material # <.> type vonMisesMultipleYieldSurfaceGoverGmax
  mass_density = <M/L^3>
  initial_shear_modulus = <F/L^2>
  poisson_ratio = <.>
  total_number_of_shear_modulus = <.>
  GoverGmax = <string>
  ShearStrainGamma = <string> ;
```

Command Example is

```
add material # 1 type vonMisesMultipleYieldSurfaceGoverGmax
   mass_density = 0.0*kg/m^3
   initial_shear_modulus = 3E8 * Pa
   poisson_ratio = 0.0
   total_number_of_shear_modulus = 9
   GoverGmax =
   "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
   ShearStrainGamma =
   "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01";
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `initial_shear_modulus` is the initial maximum shear modulus, namely, the Gmax. $[F/L^2]$
- `poisson_ratio` is the constant Poisson-ratio. [dimensionless]
- `total_number_of_shear_modulus` is the total number of shear modulus, including the initial maximum shear modulus. The total number of yield surface is one less than the total number of shear modulus. Namely, (N+1) areas are divided by N surfaces. [dimensionless]
- `GoverGmax` is the G/Gmax from experiments, including the initial shear modulus. Namely, the first element should be 1.0. Each element is dimensionless. The input should be separated by a blank space or a comma. [string]
- `ShearStrainGamma` is the shear strain γ corresponding to the GoverGmax. Note that $\gamma = 2\varepsilon$ when the input is prepared. The first element should be 0.0 corresponding to the initial shear modulus. Each element is dimensionless. The input should be separated by a blank space or a comma. [string]

205.3.4.16 Modeling, Material Model: Drucker-Prager Nonassociated Multi-Yield Surface Material Model

The command is:

```
add material # <.> type DruckerPragerMultipleYieldSurface
  mass_density = <M/L^3>
  elastic_modulus = <F/L^2>
  poisson_ratio = <.>
  initial_confining_stress = <F/L^2>
  reference_pressure = <F/L^2>
  pressure_exponential_n = <.>
  cohesion = <F/L^2>
  dilation_angle_eta = <.>
  dilation_scale = <.>
  total_number_of_yield_surface = <.>
  sizes_of_yield_surfaces = <string>
  yield_surface_scale_unit = <F/L^2>
  hardening_parameters_of_yield_surfaces = <string>
  hardening_parameters_scale_unit = <F/L^2>;
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of the material $[F/L^2]$
- `poisson_ratio` is the constant Poisson-ratio [dimensionless]
- `initial_confining_stress` is the initial confining (mean) pressure $[F/L^2]$
- `reference_pressure` is the reference pressure for the initial modulus. This parameter is usually 101kPa. $[F/L^2]$
- `pressure_exponential_n` is the exponential number of the pressure dependent modulus. [dimensionless]
- `cohesion` is the attraction force is the soil. $[F/L^2]$
- `dilation_angle_eta` controls the dilation and compaction of the material. When the stress ratio is smaller than this parameter, plastic compaction takes place. When the stress ratio is greater than this parameter, the plastic dilation takes place. [dimensionless]
- `dilation_scale` controls the rate of the dilation or compaction in the plastic flow. [dimensionless]
- `total_number_of_yield_surface` is the total number of yield surfaces. [dimensionless]

- `radiuses_of_yield_surface` is the radius list of multiple yield surfaces. This parameter gives the radiuses of each yield surface from the smallest to the biggest. This parameter should be a string which contains the dimensionless radiuses. The radiuses should be separated by a blank space or a comma. [string]
- `radiuses_scale_unit` is the unit of the each yield surface. This parameter also provides a method to scale up or scale down the radiuses of each yield surfaces. $[F/L^2]$
- `hardening_parameters_of_yield_surfaces` is the hardening parameters corresponding to each yield surface. This parameter should be a string which contains the dimensionless hardening parameters. The hardening parameters should be separated by a blank space or a comma. [string]
- `hardening_parameters_scale_unit` The unit of the each hardening parameter. This parameter also provides a method to scale up or scale down the hardening parameter of each yield surfaces. $[F/L^2]$

205.3.4.17 Modeling, Material Model: Drucker-Prager Nonassociated Material Model that Matches G/G_{max} Curves

The command is:

```
add material # <.> type DruckerPragerMultipleYieldSurfaceGoverGmax
  mass_density = <M/L^3>
  initial_shear_modulus = <F/L^2>
  poisson_ratio = <.>
  initial_confining_stress = <F/L^2>
  reference_pressure = <F/L^2>
  pressure_exponential_n = <.>
  cohesion = <F/L^2>
  dilation_angle_eta = <.>
  dilation_scale = <.>
  total_number_of_shear_modulus = <.>
  GoverGmax = <string>
  ShearStrainGamma = <string>
```

Command Example is

```
add material # 1 type DruckerPragerMultipleYieldSurfaceGoverGmax
  mass_density = 0.0*kg/m^3
  initial_shear_modulus = 3E8 * Pa
  poisson_ratio = 0.0
  initial_confining_stress = 1E5 * Pa
  reference_pressure = 1E5 * Pa
  pressure_exponential_n = 0.5
  cohesion = 0. * Pa
  dilation_angle_eta =1.0
  dilation_scale = 0.0
  total_number_of_shear_modulus = 9
  GoverGmax =
  "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
  ShearStrainGamma =
  "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01";
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of the material $[F/L^2]$
- `poisson_ratio` is the constant Poisson-ratio [dimensionless]
- `initial_confining_stress` is the initial confining (mean) pressure $[F/L^2]$
- `reference_pressure` is the reference pressure for the initial modulus. This parameter is usually 101kPa. $[F/L^2]$

- `pressure_exponential_n` is the exponential number of the pressure dependent modulus. [dimensionless]
- `cohesion` is the attraction force is the soil. $[F/L^2]$
- `dilation_angle_eta` controls the dilation and compaction of the material. When the stress ratio is smaller than this parameter, plastic compaction takes place. When the stress ratio is greater than this parameter, the plastic dilation takes place. [dimensionless]
- `dilation_scale` controls the rate of the dilation or compaction in the plastic flow. For this automatic G/Gmax match, the dilation scale has to be zero, which means only deviatoric plastic flow is allowed. If the users want to have volumetric dilation, they can match the G/Gmax manually with the other DruckerPragerMultipleYieldSurface command. [dimensionless]
- `total_number_of_shear_modulus` is the total number of shear modulus, including the initial maximum shear modulus. The total number of yield surface is one less than the total number of shear modulus. Namely, (N+1) areas are divided by N surfaces. [dimensionless]
- `GoverGmax` is the G/Gmax from experiments, including the initial shear modulus. Namely, the first element should be 1.0. Each element is dimensionless. The input should be separated by a blank space or a comma. [string]
- `ShearStrainGamma` is the shear strain γ corresponding to the GoverGmax. Note that $\gamma = 2\varepsilon$ when the input is prepared. The first element should be 0.0 corresponding to the initial shear modulus. Each element is dimensionless. The input should be separated by a blank space or a comma. [string]

205.3.4.18 Modeling, Material Model: Rounder Mohr-Coulomb Nonassociated Multi-Yield Surface Material Model

The command is:

```
add material # <.> type RoundedMohrCoulombMultipleYieldSurface
  mass_density = <M/L^3>
  elastic_modulus = <F/L^2>
  poisson_ratio = <.>
  initial_confining_stress = <F/L^2>
  reference_pressure = <F/L^2>
  pressure_exponential_n = <.>
  cohesion = <F/L^2>
  RMC_shape_k =<.>
  dilation_angle_eta = <.>
  dilation_scale = <.>
  total_number_of_yield_surface = <.>
  sizes_of_yield_surfaces = <string>
  yield_surface_scale_unit = <F/L^2>
  hardening_parameters_of_yield_surfaces = <string>
  hardening_parameters_scale_unit = <F/L^2>;
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `elastic_modulus` is the elastic modulus of the material $[F/L^2]$
- `poisson_ratio` is the constant Poisson-ratio [dimensionless]
- `initial_confining_stress` is the initial confining (mean) pressure $[F/L^2]$
- `reference_pressure` is the reference pressure for the initial modulus. This parameter is usually 101kPa. $[F/L^2]$
- `pressure_exponential_n` is the exponential number of the pressure dependent modulus. [dimensionless]
- `cohesion` is the attraction force is the soil. $[F/L^2]$
- `RMC_shape_k` controls the shape of the rounded Mohr-Coulomb yield surface. [dimensionless]
- `dilation_angle_eta` controls the dilation and compaction of the material. When the stress ratio is smaller than this parameter, plastic compaction takes place. When the stress ratio is greater than this parameter, the plastic dilation takes place. [dimensionless]
- `dilation_scale` controls the rate of the dilation or compaction in the plastic flow. [dimensionless]

- `total_number_of_yield_surface` is the total number of yield surfaces. [dimensionless]
- `radiuses_of_yield_surface` is the radius list of multiple yield surfaces. This parameter gives the radiuses of each yield surface from the smallest to the biggest. This parameter should be a string which contains the dimensionless radiuses. The radiuses should be separated by a blank space or a comma. [string]
- `radiuses_scale_unit` is the unit of the each yield surface. This parameter also provides a method to scale up or scale down the radiuses of each yield surfaces. $[F/L^2]$
- `hardening_parameters_of_yield_surfaces` is the hardening parameters corresponding to each yield surface. This parameter should be a string which contains the dimensionless hardening parameters. The hardening parameters should be separated by a blank space or a comma. [string]
- `hardening_parameters_scale_unit` The unit of the each hardening parameter. This parameter also provides a method to scale up or scale down the hardening parameter of each yield surfaces. $[F/L^2]$

205.3.4.19 Modeling, Material Model: Tsinghhua Liquefaction Material Model

The command is:

```
add material # <.> type TsinghuaLiquefactionModel
  mass_density = <M/L^3>
  poisson_ratio = <.>
  initial_confining_stress = <F/L^2>
  liquefaction_G0 = <.>
  liquefaction_EXPN = <.>
  liquefaction_c_h0 = <.>
  liquefaction_mfc = <.>
  liquefaction_mdc = <.>
  liquefaction_dre1 = <.>
  liquefaction_Dre2 = <.>
  liquefaction_Dir = <.>
  liquefaction_Alpha = <.>
  liquefaction_gamar = <.>
  liquefaction_pa = <.>
  liquefaction_pmin = <.>
```

Command Example is

```
add material # 1 type TsinghuaLiquefactionModel
  mass_density = 0.0*kg/m^3
  poisson_ratio = 0.1
  initial_confining_stress = 1E5 *Pa
  liquefaction_G0 = 800
  liquefaction_EXPN = 0.5
  liquefaction_c_h0 = 1.0
  liquefaction_mfc = 1.2
  liquefaction_mdc = 0.4
  liquefaction_dre1 = 0.5
  liquefaction_Dre2 = 1500
  liquefaction_Dir = 0.1
  liquefaction_Alpha = 0.01
  liquefaction_gamar = 0.01
  liquefaction_pa = 1E5
  liquefaction_pmin = 100 ;
```

where

- `mass_density` is the mass density of material $[M/L^3]$
- `poisson_ratio` is the constant Poisson ratio [dimensionless]
- `initial_confining_stress` is the initial confining (mean) pressure $[F/L^2]$
- `liquefaction_G0` is initial modulus scale at the reference pressure. For medium dense soil, G0 is 800. [dimensionless]

- `liquefaction_EXPN` is the exponential number of the pressure dependent modulus. [dimensionless]

- `liquefaction_c_h0` is the plastic modulus coefficient. This parameter should be determined by the G/Gmax curve. When the G/Gmax curve is hyperbolic, h is 1.2. The range of h is 0.7-1.2 [dimensionless].

- `liquefaction_mfc` is the slope of the failure surface in p-q plane. The range of $M_{f,c}$ is 1.4-1.8 [dimensionless].

- `liquefaction_mdc` is the slope of the phase transition surface in p-q plane. The range of $M_{d,c}$ is 0.3-1.0 [dimensionless].

- `liquefaction_dre1` is the accumulation coefficient of the reversible dilatancy. This parameter is usually 0.4 [dimensionless].

- `liquefaction_Dre2` is the release coefficient of the reversible dilatancy. This range of $d_{re,2}$ is 1000-1500 [dimensionless].

- `liquefaction_Dir` is the coefficient of irreversible dilatancy. The parameter d_{ir} controls the initial slope of the irreversible strain development with respect to the number of reversible loadings. Intuitively, when d_{ir} is bigger, the soil becomes liquefaction faster. The parameter d_{ir} can be around 0.2 [dimensionless].

- `liquefaction_Alpha` is the limit of the irreversible strain. Intuitively, α controls the maximum strain after the liquefaction. The parameter α can be around 0.03 [dimensionless].

- `liquefaction_gamar` is the maximum shear strain length in one liquefaction loading. Intuitively, this parameter controls the maximum strain size of one loop. This parameter can be around 0.05 [dimensionless].

- `liquefaction_pa` is the reference pressure. Usually, this parameter is 10000 [dimensionless].

- `liquefaction_pmin` is the minimum pressure in the calculation. If the pressure is smaller than p_{min} during the calculation, the pressure will be set to p_{min}. This parameter can be 1. Increasing this parameter can avoid the potential numerical errors on small numbers [dimensionless].

205.3.4.20 Modeling, Material Model: SANISand Material Model, version 2004

The command is:

```
add material # <.> type sanisand2004
  mass_density = <M/L^3>
  e0 = <.>
  sanisand2004_G0 = <.>
  poisson_ratio = <.>
  sanisand2004_Pat = <.>
  sanisand2004_p_cut = <.>
  sanisand2004_Mc = <.>
  sanisand2004_c = <.>
  sanisand2004_lambda_c = <.>
  sanisand2004_xi = <.>
  sanisand2004_ec_ref = <.>
  sanisand2004_m = <.>
  sanisand2004_h0 = <.>
  sanisand2004_ch = <.>
  sanisand2004_nb = <.>
  sanisand2004_A0 = <.>
  sanisand2004_nd = <.>
  sanisand2004_z_max = <.>
  sanisand2004_cz = <.>
  initial_confining_stress = <F/L^2>;
```

where

- `MaterialNumber`: Material tag
- `mass_density` is the mass density of material $[M/L^3]$
- `sanisand2004_e0` initial void ratio [ ]
- `sanisand2004_G0` normalized elastic shear modulus [ ]
- `poisson_ratio` Poisson's ratio [ ]
- `sanisand2004_Pat` atmospheric pressure $[F/L^2]$
- `sanisand2004_p_cut` pressure cut-off ratio $[F/L^2]$
- `sanisand2004_Mc` Critical stress ratio at triaxial compression [ ]
- `sanisand2004_c` tension-compression strength ratio $c = M_e/M_c$ [ ]
- `sanisand2004_lambda_c` parameter for critical state line [ ]
- `sanisand2004_xi` parameter for critical state line [ ]

- `sanisand2004_ec_ref` reference void for critical state line [ ]
- `sanisand2004_m` opening of the yield surface [ ]
- `sanisand2004_h0` bounding surface parameter [ ]
- `sanisand2004_ch` bounding surface parameter [ ]
- `sanisand2004_nb` bounding surface parameter [ ]
- `sanisand2004_A0` dilatancy parameter [ ]
- `sanisand2004_nd` dilatancy parameter [ ]
- `sanisand2004_z_max` maximum z fabric parameter [ ]
- `sanisand2004_cz` fabric hardening parameter [
- `initial_confining_stress` is the initial confining stress $p = -1/3\sigma_{ii}$ and it is positive in compressions (since there is that – (minus) sign in front of sum of normal stresses (σ_{ii} indicial notation summation convention applies) that are positive in tension [stress].

More on this material model can be found in section 104.6.11 on Page 255 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Important note: This material model should be used together with explicit constitutive algorithms, e.g. `Forward_Euler` or `Forward_Euler_Subincrement`. For better result, it is suggested to apply strain increments, or sub-increments, smaller than 1e-4.

205.3.4.21 Modeling, Material Model: SANISand Material Model, version 2008

The command is:

```
add material # <.> type sanisand2008
    mass_density = <M/L^3>
    e0 = <.>
    sanisand2008_G0 = <.>
    sanisand2008_K0 = <.>
    sanisand2008_Pat = <.>
    sanisand2008_k_c = <.>
    sanisand2008_alpha_cc = <.>
    sanisand2008_c = <.>
    sanisand2008_lambda = <.>
    sanisand2008_ec_ref = <.>
    sanisand2008_m = <.>
    sanisand2008_h0 = <.>
    sanisand2008_ch = <.>
    sanisand2008_nb = <.>
    sanisand2008_A0 = <.>
    sanisand2008_nd = <.>
    sanisand2008_p_r = <.>
    sanisand2008_rho_c = <.>
    sanisand2008_theta_c = <.>
    sanisand2008_X = <.>
    sanisand2008_z_max = <.>
    sanisand2008_cz = <.>
    sanisand2008_p0 = <F/L^3>
    sanisand2008_p_in = <F/L^3>
    algorithm = explicit (or) implicit
    number_of_subincrements = <.>
    maximum_number_of_iterations = <.>
    tolerance_1 = <.>
    tolerance_2 = <.>;
```

where

- `MaterialNumber`: Number of the ND material to be used ;
- `Algorithm`: Explicit (=0) or Implicit (=1) ;
- `rho`: density ;
- `e0`: initial void ratio at zero strain ;
- `G0`: Reference elastic shear modulus [stress];
- `K0`: Reference elastic bulk modulus [stress];
- `sanisand2008_Pat`: atmospheric pressure for critical state line ;

- `sanisand2008_k_c`: cut-off factor; for $p < k_c P_{at}$, use $p = k_c P_{at}$ for calculation of G; (a default value of $k_c = 0.01$ should work fine) ;
- `sanisand2008_alpha_cc`: critical state stress ratio ;
- `sanisand2008_c`: tension-compression strength ratio ;
- `sanisand2008_lambda`: parameter for critical state line ;
- `sanisand2008_xi`: parameter for critical state line ;
- `sanisand2008_ec_ref`: reference void for critical state line, ; $e_c = e_r lambda (p_c/P_{at})^x i$;
- `sanisand2008_m`: opening of the yield surface ;
- `sanisand2008_h0`: bounding surface parameter ;
- `sanisand2008_ch`: bounding surface parameter ;
- `sanisand2008_nb`: bounding surface parameter ;
- `sanisand2008_A0`: dilatancy parameter ;
- `sanisand2008_nd`: dilatancy parameter ;
- `sanisand2008_p_r`: LCC parameter ;
- `sanisand2008_rho_c`: LCC parameter ;
- `sanisand2008_theta_c`: LCC parameter ;
- `sanisand2008_X`: LCC parameter ;
- `sanisand2008_z_max`: fabric parameter ;
- `sanisand2008_cz`: fabric parameter ;
- `sanisand2008_p0`: yield surface size ;
- `sanisand2008_p_in` ;
- `number_of_subincrements` number of subincrements in constitutive simulation
- `maximum_number_of_iterations` maximum number of iterations

- `tolerance_1` Explicit: tolerance for intersection point (distance between two consecutive points) Implicit: yield function tolerance
- `tolerance_2` Implicit: residual tolerance

More on this material model can be found in Section 104.6.12 on Page 262 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.22 Modeling, Material Model: Cosserat Linear Elastic Material Model

The command is:

```
add material # <.> type Cosserat_linear_elastic_isotropic_3d
    mass_density = <M/L^3>
    lambda = <F/L^2>
    mu = <F/L^2>
    chi = <F/L^2>
    pi1 = <F>
    pi2 = <F>
    pi3 = <F>
    ;
```

- `MaterialNumber` unique material Number.
- `mass_density` the density of the material.
- `lambda`, `mu`, `chi`, `pi1`, `pi2`, `pi3` are the 6 Cosserat elastic constants (Eringen, 2012).

The relations between elastic constants is as follows Eringen (2012). Note the Young's modulus and the Poisson's ratio are different from the classical elasticity:

- Young's modulus $E = (2\mu + \chi)(3\lambda + 2\mu + \chi)$.
- Shear modulus $G = \mu + 1/2\chi$.
- Poisson's ratio $\nu = \lambda/(2\lambda + 2\mu + \chi)$.
- Characteristic length for torsion $l_t = ((\pi_2 + \pi_3)/(2\mu + \chi))^{1/2}$.
- Characteristic length for bending $l_b = (\pi_3/2(2\mu + \chi))^{1/2}$.
- Coupling number $N = (\chi/2(\mu + \chi))$
- Polar ratio $\Phi = (\pi_2 + \pi_3)/(\pi_1 + \pi_2 + \pi_3)$

According to Eringen Eringen (2012), the 6 elastic constants should satisfy the following conditions

$$\begin{aligned} 3\lambda + 2\mu + \chi \geq 0 \ , \quad & 2\mu + \chi \geq 0 \ , \quad & \chi \geq 0 \ , \\ 3\pi_1 + \pi_2 + \pi_3 \geq 0 \ , \quad & \pi_3 + \pi_2 \geq 0 \ , \quad & \pi_3 - \pi_2 \geq 0 \ . \end{aligned} \tag{205.1}$$

205.3.4.23 Modeling, Material Model: von Mises Cosserat Material Model

The command is:

```
add material # <.> type Cosserat_von_Mises
    mass_density = <M/L^3>
    lambda = <F/L^2>
    mu = <F/L^2>
    chi = <F/L^2>
    pi1 = <F>
    pi2 = <F>
    pi3 = <F>
    plastic_internal_length = <L>
    von_mises_radius = <F/L^2>
    isotropic_hardening_rate = <F/L^2>
    ;
```

- `MaterialNumber` unique material Number.
- `mass_density` the density of the material.
- `lambda`, `mu`, `chi`, `pi1`, `pi2`, `pi3` are the 6 Cosserat elastic constantsEringen (2012).
- `plastic_internal_length` is the characteristic length in the plasticity.
- `von_mises_radius` is radius of the unified yield surface of force-stress and couple-stress.
- `isotropic_hardening_rate` is the rate of isotropic hardening.

205.3.4.24 Modeling, Material Model: Uniaxial Linear Elastic, Fiber Material Model

The command is:

```
add material # <.> type uniaxial_elastic
    elastic_modulus = <F/L^2>
    viscoelastic_modulus = <mass / length / time> ;
```

where

- `MaterialNumber` unique material Number.
- `elastic_modulus` elastic modulus of the material.
- `viscoelastic_modulus` damping tangent.

More on this material model can be found in Section ?? on Page ?? in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

As the name implies, `uniaxiale_elastic` material model works with uniaxial element only. For 3D elements, for example solid brick elements, please use 3D material models, for example, `linear_elastic_isotropic_3d`

205.3.4.25 Modeling, Material Model: Stochastic Uniaxial Linear Elastic Model

The command is:

```
add material # <.> type stochastic_uniaxial_elastic uncertain_elastic_modulus = ↩
    random variable # <.> elastic_modulus_scale_unit = <F/L^2>;
```

where

- `uncertain_elastic_modulus` specify uncertain elastic modulus of the material through a defined random variable.
- `elastic_modulus_scale_unit` specify the unit scale factor that would be multiplied with the polynomial chaos coefficients of the random variable.

As the name implies, `stochastic_uniaxial_elastic` material model works with stochastic uniaxial element only.

For example:

```
add material # 1 type stochastic_uniaxial_elastic uncertain_elastic_modulus = ↩
    random variable # 1 elastic_modulus_scale_unit = 1*Pa;
```

Add material #1 as `stochastic_uniaxial_elastic` material with uncertain elastic modulus characterized by the polynomial chaos coefficients of random variable 1 and scale factor $1 * Pa$.

205.3.4.26 Modeling, Material Model: Stochastic Uniaxial Nonlinear Armstrong Frederick Model

The command is:

```
add material # <.> type stochastic_uniaxial_Armstrong_Frederick
constitutive triple product # <.>
armstrong_frederick_ha = random variable # <.>
armstrong_frederick_ha_scale_unit = <F/L^2>
armstrong_frederick_cr = random variable # <.>
```

or

```
add material # <.> type stochastic_uniaxial_Armstrong_Frederick
constitutive triple product # <.>
armstrong_frederick_ha = random variable # <.>
armstrong_frederick_ha_scale_unit = <F/L^2>
armstrong_frederick_cr = random variable # <.>
polynomial_chaos_terms_ha = <.>
polynomial_chaos_terms_cr = <.>
polynomial_chaos_terms_incremental_strain = <.>;
```

Note that the difference between these two commands is that the first command would by default use the full polynomial chaos (PC) bases defined in the provided `constitutive triple product` for probabilistic constitutive modeling. The second command would support user-specified number of polynomial chaos terms for uncertain `armstrong_frederick_ha`, `armstrong_frederick_cr` and `incremental_strain`. This enables users to perform truncation of PC bases for probabilistic constitutive modeling.

The command input parameters are:

- `constitutive triple product #` specifies the ID of the triple product, that would be used in probabilistic constitutive updating. In stochastic finite element method (FEM), the first and second PC basis for this triple product should come from the joint PC representation of uncertain parameters `armstrong_frederick_ha` and `armstrong_frederick_cr`. The third PC basis for this triple product should come from the PC representation of uncertain FEM system response, e.g., uncertain structural displacement.
- `armstrong_frederick_ha = random variable #` specifies the uncertain Armstrong Frederick parameter ha through a defined random variable.
- `armstrong_frederick_ha_scale_unit` specifies the unit scale factor that would be multiplied with the polynomial chaos coefficients of the random variable of uncertain Armstrong Frederick parameter ha.

- `armstrong_frederick_cr = random variable #` specifies the uncertain Armstrong Frederick parameter cr through a defined random variable.
- `polynomial_chaos_terms_ha` specifies the number of polynomial chaos basis of uncertain ha involved in the probabilistic constitutive updating.
- `polynomial_chaos_terms_cr` specifies the number of polynomial chaos basis of uncertain cr involved in the probabilistic constitutive updating.
- `polynomial_chaos_terms_incremental_strain` specifies the number of polynomial chaos basis of uncertain incremental strain $d\epsilon$ involved in the probabilistic constitutive updating.

As the name implies, `stochastic_uniaxial_Armstrong_Frederick` material model works with stochastic uniaxial element only.

For example:

```
add material # 1 type stochastic_uniaxial_Armstrong_Frederick
constitutive triple product # 1
armstrong_frederick_ha = random variable # 1
armstrong_frederick_ha_scale_unit = 1*Pa
armstrong_frederick_cr = random variable # 2
polynomial_chaos_terms_ha = 10
polynomial_chaos_terms_cr = 10
polynomial_chaos_terms_incremental_strain = 30;
```

Add material # 1 as `stochastic_uniaxial_Armstrong_Frederick` material with triple product # 1 for probabilistic constitutive updating.

Uncertain parameter ha is characterized by random variable # 1 using scale unit $1*$Pa.

Uncertain parameter cr is characterized by random variable # 2. The number of polynomial chaos basis for uncertain parameters ha, cr and incremental strain in probabilistic constitutive updating are 10, 10 and 30, respectively.

205.3.4.27 Modeling, Material Model: Uniaxial Nonlinear Concrete, Fiber Material Model, version 02

The command is:

```
add material # <.> type uniaxial_concrete02
    compressive_strength = <F/L^2>
    strain_at_compressive_strength = <.>
    crushing_strength = <F/L^2>
    strain_at_crushing_strength = <.>
    lambda = <.>
    tensile_strength = <F/L^2>
    tension_softening_stiffness = <F/L^2>;
```

- `compressive_strength` compressive strength.
- `strain_at_compressive_strength` strain at compressive strength.
- `crushing_strength` crushing strength.
- `strain_at_crushing_strength` strain at crushing strength.
- `lambda` ratio between unloading slope at epscu and initial slope.
- `tensile_strength` tensile strength.
- `tension_softening_stiffness` tension softening stiffness (absolute value) (slope of the tension softening branch).

More on this material model can be found in Section ?? on Page ?? in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.28 Modeling, Material Model: Faria-Oliver-Cervera Concrete Material

The command is:

```
add material No (or #) <material_number>
    type FariaOliverCerveraConcrete
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    tensile_yield_strength = <F/L^2>
    compressive_yield_strength = <F/L^2>
    plastic_deformation_rate = <.>
    damage_parameter_Ap = <.>
    damage_parameter_An = <.>
    damage_parameter_Bn = <.>
```

where

- `No (or #)<material_number>` is a unique material integer number (does not have to be sequential, any unique positive integer number can be used).
- `type FariaOliverCerveraConcrete` is the material type.
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material.
- `tensile_yield_strength` is the tensile yield strength $[F/L^2]$
- `compressive_yield_strength` is the compressive yield strength $[F/L^2]$

205.3.4.29 Modeling, Material Model: Plane Stress Layered Material

The command is:

```
add material No (or #) <element_number>
    type PlaneStressLayeredMaterial
    number_of_layers = <.>
    thickness_array = <string>
    thickness_scale_unit = <L>
    with material # <string>
    ;
```

where

- `No (or #)<material_number>` is a unique material integer number (does not have to be sequential, any unique positive integer number can be used).
- `type PlaneStressLayeredMaterial` is the material type.
- `number_of_layers` is the number of layers in this layered material. For reinforced concrete wall element, this will be just 3 layers, inside/confined concrete, reinforcement, and outside/unconfined concrete.
- `thickness_array` is the thickness ratio of each individual material.
- `thickness_scale_unit` set the length unit and the scale factor for the thickness of the layered material.
- `material # <string>` is the string of predefined individual material tags.

205.3.4.30 Modeling, Material Model: Uniaxial Nonlinear Steel, Fiber Material Model, version 01

The command is:

```
add material # <.> type uniaxial_steel01
   yield_strength = <F/L^2>
   elastic_modulus = <F/L^2>
   strain_hardening_ratio = <.>
   a1 = <.>
   a2 = <.>
   a3 = <>
   a4 = <.> ;
```

- `yield_strength` yield strength.
- `elastic_modulus` initial elastic tangent.
- `strain_hardening_ratio` strain-hardening ratio (ratio between post-yield tangent and initial elastic tangent).
- `a1, a2, a3, a4` isotropic hardening parameters
  - a1: isotropic hardening parameter, increase of compression yield envelope as proportion of yield strength after a plastic strain of a2*(fy/Ep). ;
  - a2: isotropic hardening parameter (see explanation under a1) ;
  - a3: isotropic hardening parameter, increase of tension yield envelope as proportion of yield strength after a plastic strain of a4*(fy/Ep) ;
  - a4: isotropic hardening parameter (see explanation under a3) ;

More on this material model can be found in Section ?? on Page ?? in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.31 Modeling, Material Model: Uniaxial Nonlinear Steel, Fiber Material Model, version 02

The command is:

```
add material # <.> type uniaxial_steel02
    yield_strength = <F/L^2>
    elastic_modulus = <F/L^2>
    strain_hardening_ratio = <.>
    R0 = <.>
    cR1 = <.>
    cR2 = <.>
    a1 = <.>
    a2 = <.>
    a3 = <>
    a4 = <.> ;
```

- `yield_strength`: yield strength ;
- `elastic_modulus`: initial elastic tangent ;
- `strain_hardening_ratio`: strain-hardening ratio (ratio between post-yield tangent and initial elastic tangent) ;
- `R0, cR1, cR2`: control the transition from elastic to plastic branches. Recommended values: R0=between 10 and 20, cR1=0.925, cR2=0.15 ;
- `a1, a2, a3, a4`: isotropic hardening parameters ;
  - a1: isotropic hardening parameter, increase of compression yield envelope as proportion of yield strength after a plastic strain of a2*(Fy/E). ;
  - a2: isotropic hardening parameter (see explanation under a1) ;
  - a3: isotropic hardening parameter, increase of tension yield envelope as proportion of yield strength after a plastic strain of a4*(Fy/E) ;
  - a4: isotropic hardening parameter (see explanation under a3) ;

More on this material model can be found in Section ?? on Page ?? in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.32 Modeling, Material Model: Plane Stress Plastic Damage Concrete Material

This is a plane stress version of the plastic damage concrete model developed by Faria et al. (1998). This material was implemented as part of the endeavor to model reinforced concrete shells, plates and shear walls. It should only be used together with Inelastic Layered Shell Section and 4 Node Shell NLDKGQ/Xin-Zheng-Lu, see page 915.

The command is:

```
add material No (or #) <material_number> type PlasticDamageConcretePlaneStress
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    tensile_yield_strength = <F/L^2>
    compressive_yield_strength = <F/L^2>
    plastic_deformation_rate = <.>
    damage_parameter_Ap = <.>
    damage_parameter_An = <.>
    damage_parameter_Bn = <.>
```

where

- `No (or #)<material_number>` is a unique material integer number (does not have to be sequential, any unique positive integer number can be used).
- `elastic_modulus` is the elastic modulus of material $[F/L^2]$
- `poisson_ratio` is the Poisson's ratio material.
- `tensile_yield_strength` is the tensile yield strength $[F/L^2]$
- `compressive_yield_strength` is the compressive yield strength $[F/L^2]$
- `plastic_deformation_rate` governs the post-yield hardening modulus in the effective (undamaged) space and the plastic strain rate
- `damage_parameter_Ap` governs the tensile fracture energy and affects the ductility of the tensile response
- `damage_parameter_An` governs the softening behavior of concrete in compression, it changes the ductility but does not alter the peak strength
- `damage_parameter_Bn` governs the softening behavior of concrete in compression, it changes both the ductility and the peak strength

205.3.4.33 Modeling, Material Model: Plane Stress Rebar Material

This is a plane stress version of the Uniaxial Nonlinear Steel material. This material was implemented as part of the endeavor to model reinforced concrete shells, plates and shear walls. This model should be used together with Inelastic Layered Shell Section and 4 Node Shell NLDKGQ/Xin-Zheng-Lu, see page 915.

The command is:

```
add material No (or #) <material_number> type PlaneStressRebarMaterial
    with uniaxial_material # <.>
    angle = <degree> ;
```

where

- `No (or #)<material_number>` is a unique material integer number (does not have to be sequential, any unique positive integer number can be used).
- `with uniaxial_material #` is the material tag of predefined uniaxial steel material
- `angle` is the angle of uniaxial steel rebars. The angle is 0 along the direction formed by the first two nodes of a 4 Node Shell element.

205.3.4.34 Modeling, Nodes: Adding Nodes

Nodes can be added to the finite element model.

The command is:

```
 add node # <.> at (<L>,<L>,<L>) with <.> dofs;
```

For example:

```
add node No 1 at (1.0*m, 2.5*m, 3.33*m) with 3 dofs;
```

adds a node number 1 at coordinates $x = 1.0m$, $y = 2.5m$ and $z = 3.33m$ with 3 dofs. The nodes can be of 3dofs $[u_x, u_y, u_z]$, 4dofs $[]u_x, u_y, u_z, p]$ (u-p elements) , 6dofs $[u_x, u_y, u_z, r_x, r_y, r_z]$ (beams and shells) and 7 dofs $[u_x, u_y, u_z, p, U_x, U_y, U_z]$ (upU element) types. Description of output for nodes of different dof types can be found in section 206.6

205.3.4.35 Modeling, Nodes: Adding Stochastic Nodes

Nodes can be added to the stochastic finite element model. Different from deterministic finite element analysis, nodes in stochastic FEM should specify the number of polynomial chaos (PC) terms for each physical nodal degree of freedom (dof).

The command is:

```
add node # <.> at (<L>,<L>,<L>) with <.> dofs polynomial_chaos_terms = <.>;
```

Where:

- `polynomial_chaos_terms` specifies the number of polynomial chaos terms for each physical nodal dof.

The stochastic nodes can also be added as:

```
add node # <.> at (<L>,<L>,<L>) with <.> dofs polynomial_chaos_terms as random ↩
   field # <.>;
```

Which specifies the number of polynomial chaos terms for each physical nodal dof using the number of Hermite PC basis of a defined random field.

For example:

```
add node # 1 at (1.0*m, 0.0*m, 0.0*m) with 3 dofs polynomial_chaos_terms = 10;
```

Add a node # 1 at coordinates $x = 1.0m$, $y = 0.0m$ and $z = 0.0m$ with 3 physical dofs. For each physical dof, the number of terms for polynomial chaos expansion is 10.

```
add node # 1 at (1.0*m, 0.0*m, 0.0*m) with 3 dofs polynomial_chaos_terms as ↩
   random field # 2;
```

Add a node # 1 at coordinates $x = 1.0m$, $y = 0.0m$ and $z = 0.0m$ with 3 physical dofs. For each physical dof, the number of terms for polynomial chaos expansion is equal to the number of PC basis of random field # 2.

205.3.4.36 Modeling, Nodes: Define Nodal Physical Group

Physical Group for nodes can be defined as well.

The command is:

```
define physical_node_group "string";
```

For example:

```
define physical_node_group "my_new_node_group";
```

this would create a new physical_node_group with name "my_new_node_group".

Description of output for physical groups can be found in section 206.5.5

205.3.4.37 Modeling, Nodes: Adding Nodes to Nodal Physical Group

Already created nodes can be added to the (any) physical_node_group.

The command is:

```
add nodes (<.>,<.>,...) to physical_node_group "string";
```

For example:

```
add nodes (1,2,3) to physical_node_group "my_new_node_group";
```

this would add node tag (1,2 and 3) to already created physical_node_group "my_new_node_group". Please note that the nodes (1,2 and 3) must be added to the model before they are added to the physical_node_group.

Description of output for physical groups can be found in section 206.5.5

205.3.4.38 Modeling, Nodes: Removing Nodal Physical Group

Already defined node physical group physical_node_group can be removed.

The command is

```
remove physical_node_group "string";
```

For example:

```
remove physical_node_group "my_new_node_group";
```

this would delete the physical_node_group "my_new_node_group".

205.3.4.39 Modeling, Nodes: Print Nodal Physical Group

Printing already defined nodal physical grouop physical_node_group is possible too.

The command is:

```
print physical_node_group "string";
```

For example:

```
print physical_node_group "my_new_node_group";
```

this would print the information about physical_node_group "my_new_node_group".

```
PHYSICAL_NODE_GROUP my_new_node_group
[1 2 3]
```

205.3.4.40 Modeling, Nodes: Removing Nodes

Nodes can be removed from the finite element model, for example during excavation, removal of finite elements.

The command is:

```
remove node No (or #) <.>;
```

For example:

```
remove node # 1;
```

205.3.4.41 Modeling, Nodes: Adding Nodal Mass, for 3DOFs and/or 6DOFs

Nodal mass can be added to nodes with 3 DOFs and/or 6DOFs. This is in addition to nodal mass that is obtained from finite elements.

The command for 3DOFs nodes (truss, solids, wall) is:

```
add mass to node # <.>
mx = <M>
my = <M>
mz = <M>;
```

Simularly, the command for 6DOFs nodes (beams and shells) is:

```
add mass to node # <.>
mx = <M>
my = <M>
mz = <M>
Imx = <M*L^2>
Imy = <M*L^2>
Imz = <M*L^2>;
```

205.3.4.42 Modeling, Finite Element: Adding Finite Elements

The basic structure for adding any finite element is:

```
add element No (or #)
   type <finite_element_type>
   with nodes (<.>, ..., <.>)|
   {element dependent parameters};
```

Choices for `finite_element_type` are listed below

205.3.4.43 Modeling, Finite Element: Define Finite Element Physical Group

Physical group for finite elements can be defined.

The command is:

```
define physical_element_group "string";
```

For example:

```
define physical_element_group "my_new_element_group";
```

this would create a new physical_element_group with name "my_new_element_group".

Description of output for physical groups can be found in Section 206.5.5.

205.3.4.44 Modeling, Finite Element: Adding Elements to Physical Element Group

Finite elements, that already exist in the finite element domain, can be added to the physical_element_group.

The command is:

```
add elements (<.>,<.>,...) to physical_node_group "string";
```

For example:

```
add elements (1,2,3) to physical_node_group "my_new_node_group";
```

this would add elements with tags/numbers (1,2 and 3) to already created physical_element_group "my_new_element_group". Please note that the elements (1,2 and 3) must be added to the model before they are added to the physical_element_group.

Description of output for physical groups can be found in Section 206.5.5.

205.3.4.45 Modeling, Finite Element: Remove Physical Finite Element Group

Finite elements can also be removed from the physical_element_group.

The command is:

```
remove physical_element_group "string";
```

For example:

```
remove physical_element_group "my_new_element_group";
```

this would delete the physical_element_group "my_new_element_group".

205.3.4.46 Modeling, Finite Element: Print Physical Finite Element Group

Details of the physical_element_group can be printed.

The commands is:

```
print physical_element_group "string";
```

For example:

```
print physical_element_group "my_new_element_group";
```

this would print the information about physical_element_group "my_new_element_group".

```
PHYSICAL_ELEMENT_GROUP my_new_element_group
[1 2 3]
```

205.3.4.47 Modeling, Finite Element: Remove Finite Element

Finite elements can be removed, for example if modeling requires excavation, removal of finite elements and nodes.

The command is:

```
remove element # <.>;
```

For example,

```
remove element # 1;
```

205.3.4.48 Modeling, Finite Element: Truss Element

The command is:

```
add element No (or #) <element_number> type truss
            with nodes (n1, n2)
            use material No (or #) <material_number>
            section_area <section_area> [unit];
            mass_density <mass_density> [unit];
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type truss` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `use material No (or #)` is the material number which makes up the element. Material has to be a uniaxial material, and it can be either elastic or one of the elastic-plastic materials defined for uniaxial behavior.
- `section_area` is the cross section area $[L^2]$

Description of output by this element can be found in Section 206.8.1. more on this finite element can be found in Section 102.6 on Page 126 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.49 Modeling, Finite Element: Kelvin-Voigt Element

The command is:

```
add element # <.> type Kelvin_Voigt
    with nodes (<.>, <.>)
    axial_stiffness = <F/L>
    axial_viscous_damping = <F/L*T>;
```

where

- `No (or #)<element_number>` is a unique element integer number, that does not have to be sequential, any unique positive integer number can be used
- `type Kelvin_Voigt` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `axial_stiffness` represents the stiffness in the axial direction, $[F/L]$
- `axial_viscous_damping` represents the viscosity, or viscous damping coefficient, in the axial direction, $[F/L*T]$

Note: Nodes defining this element cannot be at the same location, that is, this is a two node element and direction of this element is calculated from two distinct locations/coordinates of nodes.

205.3.4.50 Modeling, Finite Element: Inerter Element

The command is:

```
add element # <.> type Inerter
    with nodes (<.>, <.>)
    inertance = <M>;
```

where

- `No (or #)<element_number>` is a unique element integer number, that does not have to be sequential, any unique positive integer number can be used
- `type Inerter` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `inertance` represents the inertance in the axial direction, $[M]$

Note: Nodes defining this element cannot be at the same location, that is, this is a two node element and direction of this element is calculated from two distinct locations/coordinates of nodes.

205.3.4.51 Modeling, Finite Element: Shear Beam Element

The command is:

```
add element # <.> type ShearBeam
  with nodes (<.>, <.>)
  cross_section = <l^2>
  use material # <.>;
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element. NOTE: element is supposed to be alligned along vertical, Z direction !!
- `use material No (or #)` is the material (LT-based material) number which makes up the element.
- `section_area` is the cross section area $[L^2]$

Description of output by this element can be found in Section 206.8.3. more on this finite element can be found in Section 102.9 on page 135 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.52 Modeling, Finite Element: Stochastic Shear Beam Element

Add stochastic shear beam element for stochastic finite element analysis.

```
add element # <.> type stochastic_shear_beam with nodes (<.>, <.>)
  use material # <.>
  triple product # <.>
  cross_section = <L^2>
  mass_density = <M/L^3>;
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used).
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element.
- `use material No (or #)` is the stochastic uniaxial material number that makes up the element.
- `triple product #` specifies the ID of the triple product, that would be used in the formation of elemental stochastic stiffness matrix. In stochastic finite element method (FEM), the first PC basis for this triple product should come from the PC representation of uncertain element stiffness. The second and third PC basis for this triple product should come from the PC representation of uncertain FEM system response, e.g., uncertain structural displacement.
- `section_area` is the cross section area $[L^2]$.
- `mass_density` is the density $[M/L^3]$.

For example:

```
add element # 1 type stochastic_shear_beam with nodes (1, 2) use material # 1 ↩
    triple product # 1 cross_section = 1*m^2 mass_density = 2000*kg/m^3;
```

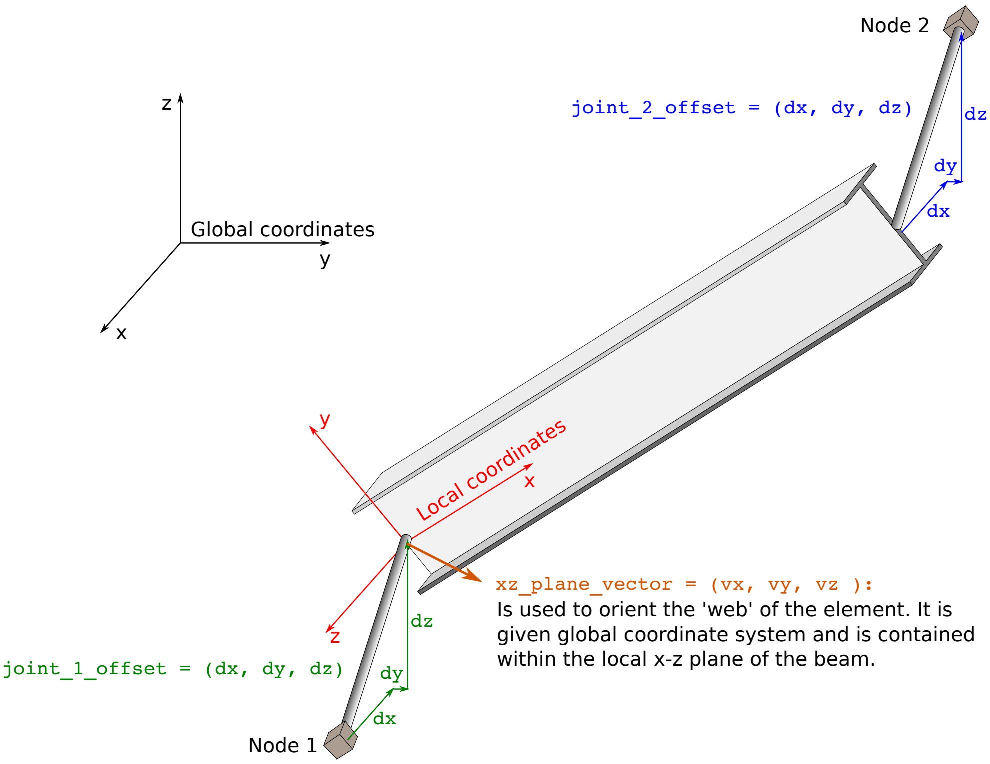
Add a stochastic shear beam element # 1 with stochastic nodes 1 and 2 using stochastic uniaxial material # 1.

The cross section of the element is 1 m^2 and mass density is 2000 kg/m^3.

205.3.4.53 Modeling, Finite Element: Elastic Beam–Column Element

The command is:

```
add element # <.> type beam_elastic with nodes (<.>, <.>)
    cross_section = <L^2>
    elastic_modulus = <F/L^2>
    shear_modulus = <F/L^2>
    torsion_Jx = <length^4>
    bending_Iy = <length^4>
    bending_Iz = <length^4>
    mass_density = <M/L^3>
    xz_plane_vector = (<.>, <.>, <.> )
    joint_1_offset = (<L>, <L>, <L> )
    joint_2_offset = (<L>, <L>, <L> );
```



Is used to orient the 'web' of the element. It is given global coordinate system and is contained within the local x-z plane of the beam.

Figure 205.3: Beam Element, sketch of main geometric components.

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type beam_elastic` is the element type

- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `cross_section` is the cross section area, $[L^2]$
- `elastic_modulus` elastic modulus of the material which makes up the beam, $[F/L^2]$
- `shear_modulus` shear modulus of the material which makes up the beam, $[F/L^2]$
- `torsion_Jx` cross section polar (torsional) moment of inertia, $[L^4]$
- `bending_Iy` cross section moment of inertia about local y axis, $[L^4]$
- `bending_Iz` cross section moment of inertia about local z axis, $[L^4]$
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `xz_plane_vector` a vector which defines the orientation of the local (beam coordinate system) xz plane in global coordinates. NOTE: Please make sure that your `xz_plane_vector` is a bit away from the actuall local x axes, the axes that runs along the beam elelent, in order to prevent numerical problems that might appear when vector cross products are performed inside the program... It is suggested that your `xz_plane_vector` be closer to local z axes... See Figure 205.4 on Page 901 for more in depth explanation of `xz_plane_vector`.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

Description of output by this element can be found in Section 206.8.4

more on this finite element can be found in Section 102.7 on Page 126 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

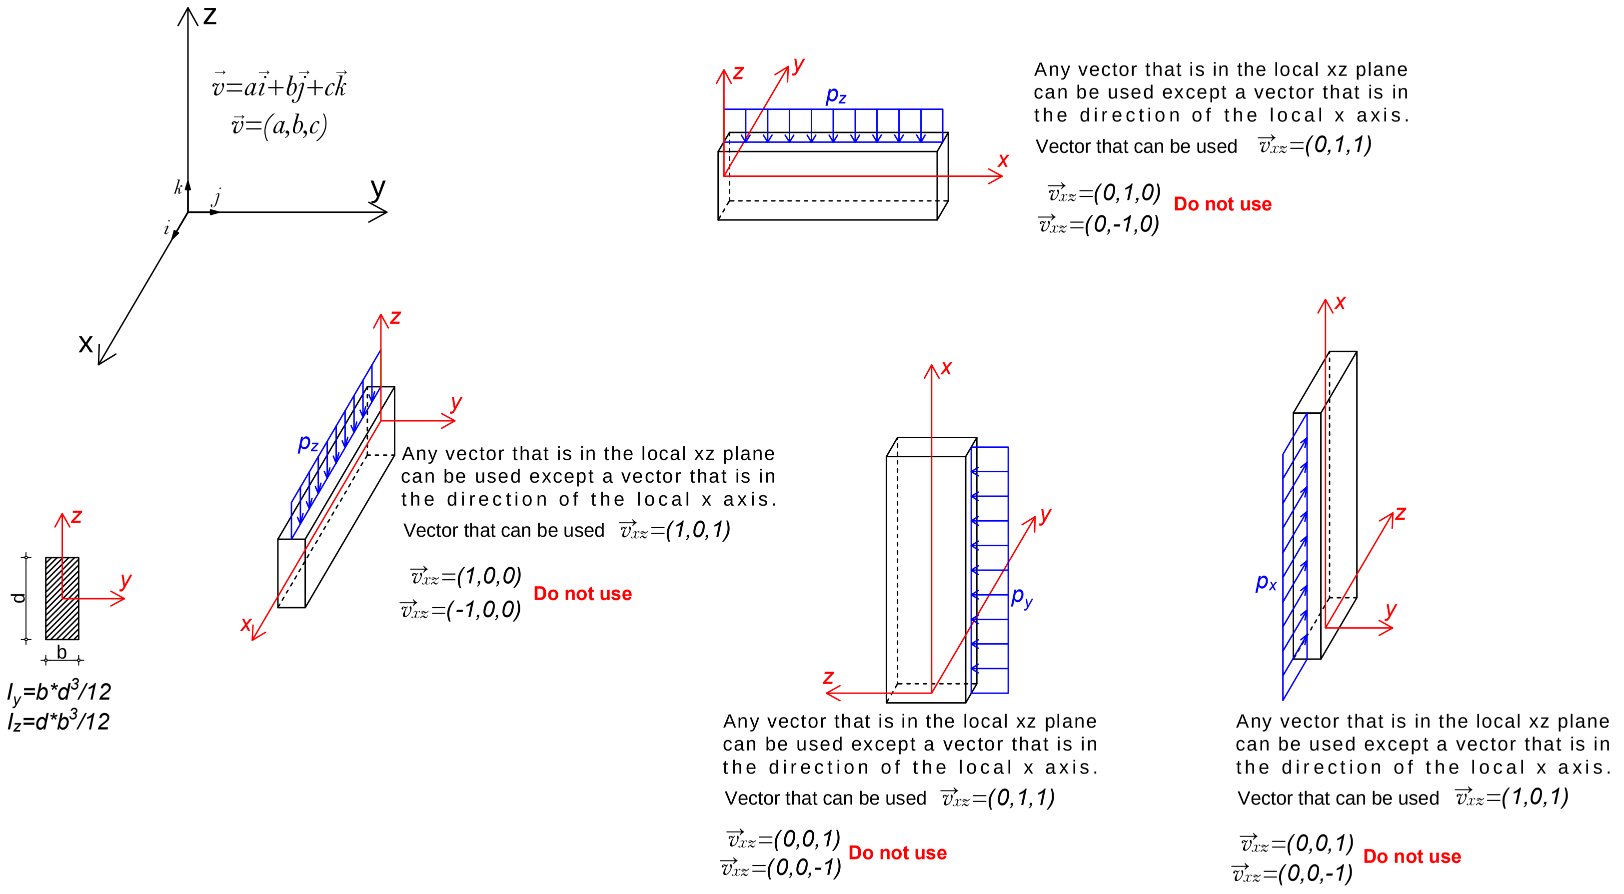


Figure 205.4: Beam Element, details of vector in X-Z plane.

205.3.4.54 Modeling, Finite Element: Large Displacement Elastic Beam–Column Element, with Corotational Transformation

The command is:

```
add element # <.> type beam_elastic_corotational with nodes (<.>, <.>)
   cross_section = <L^2>
   elastic_modulus = <F/L^2>
   shear_modulus = <F/L^2>
   torsion_Jx = <length^4>
   bending_Iy = <length^4>
   bending_Iz = <length^4>
   mass_density = <M/L^3>
   xz_plane_vector = (<.>, <.>, <.> )
   joint_1_offset = (<L>, <L>, <L> )
   joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type beam_elastic` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `cross_section` is the cross section area, $[L^2]$
- `elastic_modulus` elastic modulus of the material which makes up the beam, $[F/L^2]$
- `shear_modulus` shear modulus of the material which makes up the beam, $[F/L^2]$
- `torsion_Jx` cross section polar (torsional) moment of inertia, $[L^4]$
- `bending_Iy` cross section moment of inertia about local y axis, $[L^4]$
- `bending_Iz` cross section moment of inertia about local z axis, $[L^4]$
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `xz_plane_vector` a vector which defines the orientation of the local (beam coordinate system) xz plane in global coordinates.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

205.3.4.55 Modeling, Finite Element: Timoshenko Elastic Beam–Column Element

The command is:

```
add element # <.> type beam_elastic_Timoshenko with nodes (<.>, <.>)
    cross_section = <L^2>
    elastic_modulus = <F/L^2>
    shear_modulus = <F/L^2>
    torsion_Jx = <length^4>
    bending_Iy = <length^4>
    bending_Iz = <length^4>
    mass_density = <M/L^3>
    shear_correction_coefficient = <.>
    xz_plane_vector = (<.>, <.>, <.> )
    joint_1_offset = (<L>, <L>, <L> )
    joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type beam_elastic` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `cross_section` is the cross section area, $[L^2]$
- `elastic_modulus` elastic modulus of the material which makes up the beam, $[F/L^2]$
- `shear_modulus` shear modulus of the material which makes up the beam, $[F/L^2]$
- `torsion_Jx` cross section polar (torsional) moment of inertia, $[L^4]$
- `bending_Iy` cross section moment of inertia about local y axis, $[L^4]$
- `bending_Iz` cross section moment of inertia about local z axis, $[L^4]$
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `shear_correction_coefficient` a parameter for shear correction. When this parameter becomes very large, the Timoshenko beam element becomes Euler-Bernoulli beam. If not specifically calibrated, can use 1.0 for this parameter.
- `xz_plane_vector` a vector which defines the orientation of the local (beam coordinate system) xz plane in global coordinates.

- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

Description of output by this element can be found in Section 206.8.4. more on this finite element can be found in Section 102.7 on Page 126 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.56 Modeling, Finite Element: Timoshenko Elastic Beam–Column Element with Directional Shear Correction Coefficients

The command is:

```
add element # <.> type beam_elastic_Timoshenko_directional with nodes (<.>, <.>)
    cross_section = <L^2>
    elastic_modulus = <F/L^2>
    shear_modulus = <F/L^2>
    torsion_Jx = <length^4>
    bending_Iy = <length^4>
    bending_Iz = <length^4>
    mass_density = <M/L^3>
    shear_correction_coefficient_y = <.>
    shear_correction_coefficient_z = <.>
    xz_plane_vector = (<.>, <.>, <.> )
    joint_1_offset = (<L>, <L>, <L> )
    joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type beam_elastic` is the element type
- `with nodes (n1, n2)` are the 2 nodes (node numbers) defining this element
- `cross_section` is the cross section area, $[L^2]$
- `elastic_modulus` elastic modulus of the material which makes up the beam, $[F/L^2]$
- `shear_modulus` shear modulus of the material which makes up the beam, $[F/L^2]$
- `torsion_Jx` cross section polar (torsional) moment of inertia, $[L^4]$
- `bending_Iy` cross section moment of inertia about local y axis, $[L^4]$
- `bending_Iz` cross section moment of inertia about local z axis, $[L^4]$
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `shear_correction_coefficient_y` parameter for shear correction about local y axis. When this parameter becomes very large, the Timoshenko beam element becomes Euler-Bernoulli beam. If not specifically calibrated, can use 1.0 for this parameter.

- `shear_correction_coefficient_z` parameter for shear correction about local z axis. When this parameter becomes very large, the Timoshenko beam element becomes Euler-Bernoulli beam. If not specifically calibrated, can use 1.0 for this parameter.
- `xz_plane_vector` a vector which defines the orientation of the local (beam coordinate system) xz plane in global coordinates.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

Description of output by this element can be found in Section 206.8.4. more on this finite element can be found in Section 102.7 on Page 126 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.57 Modeling, Finite Element: Adding 1D Fiber to a Beam Cross Section

Fibers can be added to the fiber beam cross section.

The command is:

```
add fiber # <.> using material # <.> to section # <.> fiber_cross_section = ↩
    <area> fiber_location = (<L>,<L>);
```

For example:

```
add fiber # 1 using material # 1 to section # 1 fiber_cross_section = 5*cm^2 ↩
    fiber_location = (10*cm,10*cm);
```

adds a fiber number 1 to section number 1 at coordinates $y = 10\text{cm}$, $z = 10\text{cm}$ with cross section area of 5cm^2 using material number 1.

The material for fiber must be a uniaxial material, for example uniaxial_concrete02, uniaxial_elastic, uniaxial_steel01, and uniaxial_steel02.

205.3.4.58 Modeling, Finite Element: Adding Fiber Section to the Finite Element Model

Fiber section can be added to the finite element model.

The command is:

```
add section # <.> type FiberSection
    TorsionConstant_GJ = <F*L^2);
```

where

- `TorsionConstant_GJ` provides a linear torsional stiffness to the element.

Fibers can be added to the section as described in section 205.3.4.57 on page 907.

The command is:

```
add fiber # <.> using material # <.> to section # <.> fiber_cross_section = <area>
  fiber_location = (<L>,<L>);
```

where

- `fiber_cross_section` is the area of the fiber element. (Total cross section are is the sum of all fiber areas) $[L^2]$
- `fiber_location` location of the fiber in the beam local Y-Z plane.

205.3.4.59 Modeling, Finite Element: 3D Displacement Based Fiber Beam-Column Element

```
add element # <.> type BeamColumnDispFiber3d with nodes (<.>, <.>)
   number_of_integration_points = <.>
   section_number = <.>
   mass_density = <M/L^3>
   xz_plane_vector = (<.>, <.>, <.> )
   joint_1_offset = (<L>, <L>, <L> )
   joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type BeamColumnDispFiber3d` is the element type
- `with nodes (n1, n2)` are the 2 nodes defining this element
- `number_of_integration_points` is number of integration points to be used along the beam element
- `section_number` is the number of predefined section
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `xz_plane_vector` unit vector which defines the orientation of the web of the beam in global coordinates.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

Description of output by this element can be found in Section 206.8.6,

205.3.4.60 Modeling, Finite Element: 3D Displacement Based Fiber Beam-Column Element with Corotational Coordinate Transformation

```
add element # <.> type BeamColumnDispFiber3d_Corotational with nodes (<.>, <.>)
   number_of_integration_points = <.>
   section_number = <.>
   mass_density = <M/L^3>
   xz_plane_vector = (<.>, <.>, <.> )
   joint_1_offset = (<L>, <L>, <L> )
   joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type BeamColumnDispFiber3d_Corotational` is the element type
- `with nodes (n1, n2)` are the 2 nodes defining this element
- `number_of_integration_points` is number of integration points to be used along the beam element
- `section_number` is the number of predefined section
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `xz_plane_vector` unit vector which defines the orientation of the web of the beam in global coordinates.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

Description of output by this element can be found in section 206.8.6.

The co-rotational formulation used in this element is based on Crisfield (1990).

205.3.4.61 Modeling, Finite Element: 3DOF+6DOF=9DOF Beam-Column Element

```
add element # <.> type beam_9dof_elastic
    with nodes (<.>, <.>)
    cross_section = <L^2>
    elastic_modulus = <F/L^2>
    shear_modulus = <F/L^2>
    torsion_Jx = <length^4>
    bending_Iy = <length^4>
    bending_Iz = <length^4>
    mass_density = <M/L^3>
    xz_plane_vector = (<.>, <.>, <.> )
    joint_1_offset = (<L>, <L>, <L> )
    joint_2_offset = (<L>, <L>, <L> );
```

where

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type beam_9dof_elastic` is the element type
- `with nodes (n1, n2)` are the 2 nodes defining this element, where the first node (n1) is the one with 3 DOFs and the second (n2) is the one with 6 DOFs
- `cross_section` is the cross section area, $[L^2]$
- `elastic_modulus` elastic modulus of the material which makes up the beam, $[F/L^2]$
- `shear_modulus` shear modulus of the material which makes up the beam, $[F/L^2]$
- `torsion_Jx` cross section polar (torsional) moment of inertia, $[L^4]$
- `bending_Iy` cross section moment of inertia about local y axis, $[L^4]$
- `bending_Iz` cross section moment of inertia about local z axis, $[L^4]$
- `mass_density` mass per unit volume of the material, $[M/L^3]$
- `xz_plane_vector` unit vector which defines the orientation of the web of the beam in global coordinates.
- `joint_1_offset` vector defining the rigid offset between end of beam and connection node 1, $[L]$
- `joint_2_offset` vector defining the rigid offset between end of beam and connection node 2, $[L]$

This finite element has only 3DOFs (translations) at the first node, and full 6DOFs at the other, second node. Due to missing rotational stiffness on first, 3DOF node, this beam has zero torsional stiffness.

This element is useful for connection of solid (3DOFs per node) and structural (6DOFs per node) elements It his beam element is used on its own, DOF that corresponds to torsion of the second node (DOF number 7), should be fixed as this beam does not provide that stiffness.

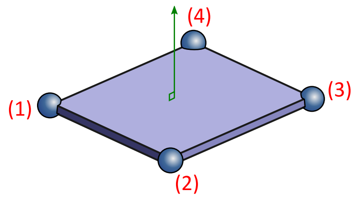
More on this finite element can be found in Section 102.8 on Page 129 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.62 Modeling, Finite Element: 4 Node ANDES Shell with Drilling DOFs

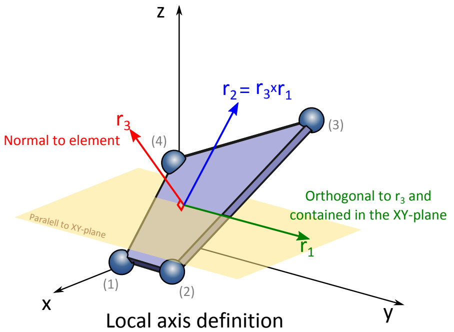
ANDES based 3D shell element including drilling degrees of freedom. Made up by patching together 4 ANDES shell triangle elements (and then averaging two and two squares made up two and two triangles).

The command is:

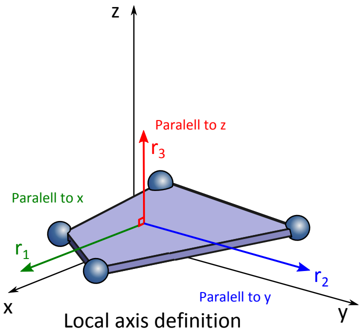
```
add element # <.> type 4NodeShell_ANDES
    with nodes (<.>, <.>, <.>)
    use material # <.>
    thickness = <L> ;
```



Node numbering
is counter-clockwise



Local axis definition
in general



Local axis definition
if r_3 is nearly vertical

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `material # <.>` number of a previously defined material. (see `add material ...`)
- `thickness` shell thickness, $[L]$

Description of output by this element can be found in Section 206.8.5.

More on this finite element can be found in Section 102.10 on page 135 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.63 Modeling, Finite Element: 3 Node ANDES Shell with Drilling DOFs

```
add element # <.> type 3NodeShell_ANDES
    with nodes (<.>, <.>, <.>)
    use material # <.>
    thickness = <L> ;
```

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)

205.3.4.64 Modeling, Finite Element: 4 Node Shell NLDKGQ, or 4 Node Shell Xin-Zheng-Lu

This is a 3D quadrilateral shell element with membrane and drill DOFs based on the theory of generalized conforming element. This element accounts for the geometric nonlinearity of large deformation using a simplified version of updated Lagrangian formulation, where nodal coordinates are updated in each step, however strains and stresses are still calculated with reference to the original, undeformed system. It can be used together with elastic or inelastic sections. This element was originally developed by Professor Xin-Zheng Lu (Tsinghua University) and his students.

The command is:

```
add element # <.> type 4NodeShell_NLDKGQ
    with nodes (<.>, <.>, <.>, <.>)
    section_number = <.>;
```

It can also be called using the alternative command:

```
add element # <.> type 4NodeShell_XinZhengLu_Tsinghua
    with nodes (<.>, <.>, <.>, <.>)
    section_number = <.>;
```

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `with nodes (n1, n2, n3, n4)` are the 4 nodes defining this element
- `section_number` is the number of predefined shell cross section, described on page 916.

205.3.4.65 Modeling, Finite Element: Inelastic Layered Shell Section

This command is used to add a layered shell section. The section is made up of a number of layers with different thicknesses and different material properties (i.e., concrete layers or rebar layers). This type of section is used together with plane stress materials and shell elements.

The command is:

```
add section # <.> type LayeredShellFiber
   number_of_layers = <.>
   thickness_array = "<.>,<.>..."
   with material # "<.>,<.>..."
   thickness_scale_unit = <L>
   outofplane_shear_modulus = <F/L^2>;
```

where

- `number_of_layers` is the number of layers that the section has
- `thickness_array` is the relative thickness of each layer
- `with material #` is the material tag of each layer, only plane stress materials can be used here, see pages 878 and 879.
- `thickness_scale_unit` is the total thickness of the section
- `outofplane_shear_modulus` is the out-of-plane shear modulus of the section

205.3.4.66 Modeling, Finite Element: ElasticMembranePlaneStress Element (to be removed!)

NOTE: this element is being removed, and will not be available after Real ESSI version 19.07 (current). This is a 2D finite element, and we only maintain 3D finite elements. This element is replaced by a 3D 27 node elastic and/or elastic-plastic wall/plate/shell brick element.

The command is:

```
add element No (or #) <element_number>
    type ElasticMembranePlaneStress
    with nodes (n1, n2, n3, n4)
    use material No (or #) <material_number>
    thickness = <L> ;
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used).
- `type ElasticMembranePlaneStress` is the element type.
- `with nodes (n1, n2, n3, n4)` are the 4 nodes (node numbers) defining this element.
- `use material No (or #)` is the material number for linear elastic material that makes up the element.
- `thickness` is the thickness of the membrane.

205.3.4.67 Modeling, Finite Element: InelasticMembranePlaneStress Element (to be removed!)

NOTE: this element is being removed, and will not be available after Real ESSI version 19.07 (current). This is a 2D finite element, and we only maintain 3D finite elements. This element is replaced by a 3D 27 node elastic or elastic-plastic wall/plate/shell brick element or elastic-plastic shell element.

The command is:

```
add element No (or #) <element_number>
   type InelasticMembranePlaneStress
   with nodes (n1, n2, n3, n4)
   use material No (or #) <material_number>
   ;
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used).
- `type InelasticMembranePlaneStress` is the element type.
- `with nodes (n1, n2, n3, n4)` are the 4 nodes (node numbers) defining this element.
- `use material No (or #)` is the material number for inelastic material that makes up the element. Since this is a plane stress element, material needs to have plane stress constitutive integration algorithm available. In addition, this material should specify thickness of the element. Different layers and their thicknesses for different materials (for example concrete and steel) will be defined within material definition. `PlaneStressLayeredMaterial` is a material of this type.

205.3.4.68 Modeling, Finite Element: SuperElementLinearElasticImport

The command is:

```
add element No (or #) <element_number>
    type SuperElementLinearElasticImport
    with hdf5_file = <string>
    ;
```

where

- `No (or #)<element_number>` is a unique element integer number (does not have to be sequential, any unique positive integer number can be used).
- `type SuperElementLinearElasticImport` is the element type.
- `hdf5_file` specifies the HDF5 filename of the SuperElement with SuperElement data. The HDF5 file should contain the following datasets:
  - `Node` dataset within HDF5 file is organized in a column (a 1D dataset), and it specifies the node tags/numbers of nodes that make up the SuperElement.
  - `DofList` dataset within HDF5 file is a organized in a column, and it specifies the number of DOFs per each `Node`. For example if nodes are representing structural elements, they usually have 6 DOFs per node, while solids will have 3 DOFs per node. `DofList` dataset has to have the same number of entries as `Node` dataset, as each entry in `DofList` corresponds to one node from `Node` dataset.
  - `MassMatrix` is a matrix, that sets masses/numbers for a mass matrix of the SuperElement.
  - `StiffnessMatrix` is a matrix, that sets stiffness/numbers for a stiffness matrix of the SuperElement.
  - `ConnectNode` dataset within HDF5 file is organized in a column (a 1D dataset), and it specifies the node tags/numbers of nodes that are going to be connected to Real-ESSI mesh.
  - `ConnectNodeCoordinate` dataset within HDF5 file is organized in a matrix (a 2D dataset), and it specifies the nodal coordinates for nodes that are going to be connected to Real-ESSI mesh. Since each node has 3 coordinates, the length of `ConnectNodeCoordinate` is the same as the length of `ConnectNode` and each line has three entries, for X, Y and Z coordinates of given node.

In addition to the minimum dataset requirements above, users can get more output from Real-ESSI:

- Results for individual finite elements (internal forces, etc.), can be obtained if node, DofList, mass matrix and stiffness matrix for each finite element within the super element are provided.
- Graphical post-processing can be obtained if coordinates for all nodes and their connectivity into finite elements are provided (a mesh data).

205.3.4.69 Modeling, Finite Element: 8 Node Brick Element

The command is:

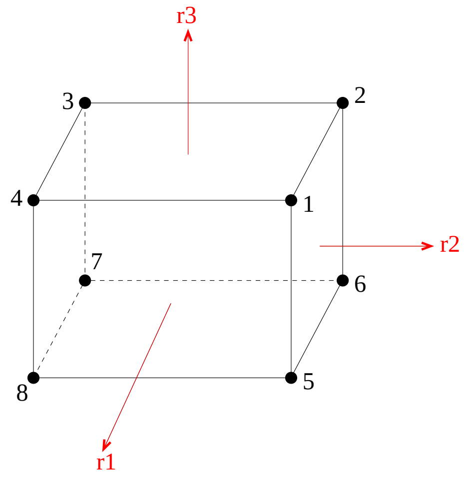
```
add element # <element_number> type 8NodeBrick
   using <.> Gauss points each direction
   with nodes (n1, n2, n3, n4, n5, n6, n7, n8)
   use material No (or #) <material_number>;
```

and/or;

```
add element # <element_number> type 8NodeBrick
   with nodes (n1, n2, n3, n4, n5, n6, n7, n8)
   use material No (or #) <material_number>;
```

where:

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type 8NodeBrick` is the element type.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8)` are the 8 nodes for this element, in the order as per figure below



- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility.

For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$),

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.

Description of output by this element can be found in section 206.8.2.

More on this finite element can be found in Section 102.4.1 on page 114 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.70 Modeling, Finite Element: 20 Node Brick Element

The command is:

```
add element No (or #) <element_number> type 20NodeBrick
   using <.> Gauss points each direction
   with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
            n9, n10, n11, n12, n13, n14, n15, n16,
            n17, n18, n19, n20 )
   use material No (or #) <material_number>;
```

and/or

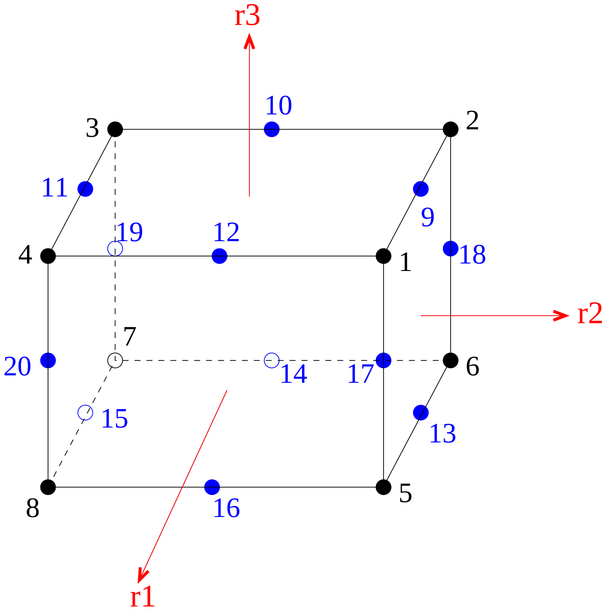
```
add element No (or #) <element_number> type 20NodeBrick
   with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
            n9, n10, n11, n12, n13, n14, n15, n16,
            n17, n18, n19, n20 )
   use material No (or #) <material_number>;
```

where:

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type 20NodeBrick` is the element type. `20NodeBrick_elastic` can be used if elastic material is used. It this case, the stiffness and mass matrices will not be updated at each step.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8, n9, n10, n11, n12, n13, n14, n15, n16, n17, n18, n19, n20)` are the 20 nodes for this element, written in the order defined as per figure below
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$),
- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms)

Description of output by this element can be found in Section 206.8.2.

More on this finite element can be found in Section 102.4.3 on page 116 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).



205.3.4.71 Modeling, Finite Element: 27 Node Brick Element

The command is:

```
add element # <element_number>
          type 27NodeBrick
          using <.> Gauss points each direction
          with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
                    n9, n10, n11, n12, n13, n14, n15, n16,
                    n17, n18, n19, n20, n21, n22, n23,
                    n124, n25, n26, n27 )
          use material # <material_number>;
```

and/or

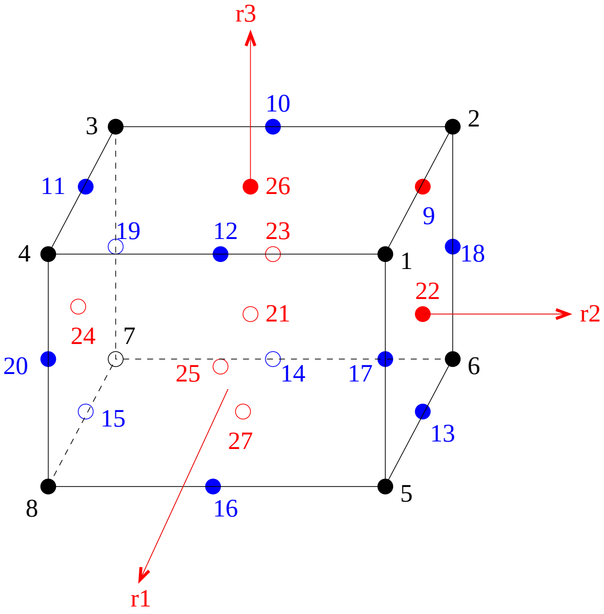
```
add element # <element_number>
          type 27NodeBrick
          with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
                    n9, n10, n11, n12, n13, n14, n15, n16,
                    n17, n18, n19, n20, n21, n22, n23,
                    n124, n25, n26, n27 )
          use material # <material_number>;
```

where:

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type 27NodeBrick` is the element type.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8,`
  `n9, n10, n11, n12, n13, n14, n15, n16, n17, n18, n19, n20)`
  `n21, n22, n23, n24, n25, n26, n27)` are the 27 nodes for this element, written in the order defined as per this figure
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$),
- `use material No (or #)` is the material number which makes up the element (nonlinear elastic and/or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms).

Description of output by this element can be found in Section 206.8.2.

More on this finite element can be found in Section 102.4.4 on page 118 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).



205.3.4.72 Modeling, Finite Element: Variable 8-27 Node Brick Element

The command is:

```
add element No (or #) <element_number> type variable_node_brick_8_to_27
          using <.> Gauss points each direction
          with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
                    n9, n10, n11, n12, n13, n14, n15, n16,
                    n17, n18, n19, n20, n21, n22, n23, n24, n25, n26, n27)
          use material No (or #) <material_number>;
```

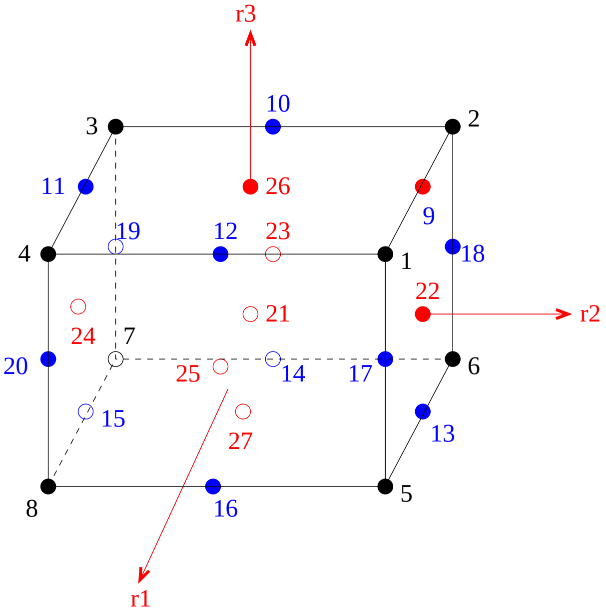
and/or

```
add element No (or #) <element_number> type variable_node_brick_8_to_27
          using <.> Gauss points each direction
          with nodes (n1, n2, n3, n4, n5, n6, n7, n8,
                    n9, n10, n11, n12, n13, n14, n15, n16,
                    n17, n18, n19, n20, n21, n22, n23, n24, n25, n26, n27)
          use material No (or #) <material_number>;
```

where:

- `No (or #)<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type variable_node_brick_8_to_27` is the element type
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8,`
  `n9, n10, n11, n12, n13, n14, n15, n16, n17, n18, n19, n20,`
  `n21, n22, n23, n24, n25, n26, n27)`
  are the 8 to 27 nodes for this element, written in the order defined as per this figure. Nodes 1-8 are obligatory, while any other nodes can be used but do not have to, the element will automatically pick proper shape functions. This element is good for transitions in meshing.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$),
- `material No (or #)` is the material number which makes up the element (nonlinear elastic and/or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms)

Description of output by this element can be found in Section 206.8.2.



205.3.4.73 Modeling, Finite Element: 8 Node Brick u-p Element

The command is:

```
add element # <.> type 8NodeBrick_up
   using <.> Gauss points each direction
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

and/or

```
add element # <.> type 8NodeBrick_up
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

where:

- `No (or #)<element_number>` is the unique element integer number that does not have to be sequential, any unique positive integer number can be used.
- `type 8NodeBrick_up` is the element type/name.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8)` are the 8 nodes for this element, is specified order.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility.

For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$).

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.
- `porosity` is the porosity ($n = V_{voids}/V_{total}$) of material in this element.
- `alpha` is the parameter controlling level of effective stress analysis. For soils, usually $\alpha = 1$ is used, while for other materials (saturated concrete, bone material, etc.) lower values are used ($0 \leq \alpha \leq 1$).
- `rho_s` is the density of particles of the solid phase. It is important to note that this is a density of the actual mineral that makes up solid particles!.
- `rho_f` is the density of pore fluid. It is usually density of water, however, for unsaturated and partially saturated materials, this density will be different, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).
- `k_x` is the permeability in the x direction (global x) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_y` is the permeability in the y direction (global y) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_z` is the permeability in the z direction (global z) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `K_s` is the bulk modulus of the soil phase particles. It is important to note that this is a bulk modulus of the actual mineral that makes up solid particles!
- `K_f` is the bulk modulus of the fluid phase that is found in porous material pores. It is usually bulk modulus of the fluid (physical value of the bulk modulus of fluid, for example water), however, for unsaturated and partially saturated materials, this density is a density of a mixture, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Note: the permeability k_x, k_y, k_z is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e. $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured.

More on theory for this finite element can be found in Section 102.12.3.3 on page 156 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Description of output by this element can be found in Section 206.8.2 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.74 Modeling, Finite Element: 20 Node Brick u-p Element

The command is:

```
add element # <.> type 20NodeBrick_up
   using <.> Gauss points each direction
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, ↩
      <.>, <.>, <.>,<.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

and/or

```
add element # <.> type 20NodeBrick_up
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, ↩
      <.>, <.>, <.>,<.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

where:

- `No (or #)<element_number>` is the unique element integer number that does not have to be sequential, any unique positive integer number can be used.
- `type 8NodeBrick_up` is the element type/name.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8, n9, n10, n11, n12, n13, n14, n15,` ↩ `n16, n17, n18, n19, n20)` are the 20 nodes for this element, is specified order.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the

brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$).

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.
- `porosity` is the porosity ($n = V_{voids}/V_{total}$) of material in this element.
- `alpha` is the parameter controlling level of effective stress analysis. For soils, usually $\alpha = 1$ is used, while for other materials (saturated concrete, bone material, etc.) lower values are used ($0 \leq \alpha \leq 1$).
- `rho_s` is the density of particles of the solid phase. It is important to note that this is a density of the actual mineral that makes up solid particles!.
- `rho_f` is the density of pore fluid. It is usually density of water, however, for unsaturated and partially saturated materials, this density will be different, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).
- `k_x` is the permeability in the x direction (global x) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_y` is the permeability in the y direction (global y) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_z` is the permeability in the z direction (global z) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `K_s` is the bulk modulus of the soil phase particles. It is important to note that this is a bulk modulus of the actual mineral that makes up solid particles!
- `K_f` is the bulk modulus of the fluid phase that is found in porous material pores. It is usually bulk modulus of the fluid (physical value of the bulk modulus of fluid, for example water), however, for unsaturated and partially saturated materials, this density is a density of a mixture, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Note: the permeability k_x, k_y, k_z is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e. $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured.

More on theory for this finite element can be found in section 102.12.3.3 on page 156 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.75 Modeling, Finite Element: 27 Node Brick u-p Element

The command is:

```
add element # <.> type 27NodeBrick_up
   using <.> Gauss points each direction
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, ↩
      <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

and/or

```
add element # <.> type 27NodeBrick_up
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, ↩
      <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

where:

- `No (or #)<element_number>` is the unique element integer number that does not have to be sequential, any unique positive integer number can be used.
- `type 8NodeBrick_up` is the element type/name.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8, n9, n10, n11, n12, n13, n14, n15, ↩ n16, n17, n18, n19, n20, n21, n22, n23, n24, n25, n26, n27)` are the 27 nodes for this element, is specified order.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can

be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$).

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.
- `porosity` is the porosity ($n = V_{voids}/V_{total}$) of material in this element.
- `alpha` is the parameter controlling level of effective stress analysis. For soils, usually $\alpha = 1$ is used, while for other materials (saturated concrete, bone material, etc.) lower values are used ($0 \leq \alpha \leq 1$).
- `rho_s` is the density of particles of the solid phase. It is important to note that this is a density of the actual mineral that makes up solid particles!.
- `rho_f` is the density of pore fluid. It is usually density of water, however, for unsaturated and partially saturated materials, this density will be different, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).
- `k_x` is the permeability in the x direction (global x) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_y` is the permeability in the y direction (global y) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_z` is the permeability in the z direction (global z) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `K_s` is the bulk modulus of the soil phase particles. It is important to note that this is a bulk modulus of the actual mineral that makes up solid particles!
- `K_f` is the bulk modulus of the fluid phase that is found in porous material pores. It is usually bulk modulus of the fluid (physical value of the bulk modulus of fluid, for example water), however, for

unsaturated and partially saturated materials, this density is a density of a mixture, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Note that, the permeability $\mathbf{k}$ is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e. $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured.

More on theory for this finite element can be found in Section 102.12.3.3 on page 156 of the main document. Description of output by this element can be found in Section 206.8.2.

205.3.4.76 Modeling, Finite Element: 8 Node Brick u-p-U Element

The command is:

```
add element # <.> type 8NodeBrick_upU
   using <.> Gauss points each direction
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

and/or

```
add element # <.> type 8NodeBrick_upU
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>
   alpha = <.>
   rho_s = <M/L^3>
   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

where:

- `No (or #)<element_number>` is the unique element integer number that does not have to be sequential, any unique positive integer number can be used.
- `type 8NodeBrick_up` is the element type/name.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8)` are the 8 nodes for this element, is specified order.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility.

For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$).

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.
- `porosity` is the porosity ($n = V_{voids}/V_{total}$) of material in this element.
- `alpha` is the parameter controlling level of effective stress analysis. For soils, usually $\alpha = 1$ is used, while for other materials (saturated concrete, bone material, etc.) lower values are used ($0 \leq \alpha \leq 1$).
- `rho_s` is the density of particles of the solid phase. It is important to note that this is a density of the actual mineral that makes up solid particles!.
- `rho_f` is the density of pore fluid. It is usually density of water, however, for unsaturated and partially saturated materials, this density will be different, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).
- `k_x` is the permeability in the x direction (global x) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_y` is the permeability in the y direction (global y) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_z` is the permeability in the z direction (global z) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `K_s` is the bulk modulus of the soil phase particles. It is important to note that this is a bulk modulus of the actual mineral that makes up solid particles!
- `K_f` is the bulk modulus of the fluid phase that is found in porous material pores. It is usually bulk modulus of the fluid (physical value of the bulk modulus of fluid, for example water), however, for unsaturated and partially saturated materials, this density is a density of a mixture, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Note that, the permeability $\mathbf{k}$ is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e. $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured.

Please note that the $u-p-U$ element, and the $u-p-U$ formulation is a dynamic formulation and is meant to be used with dynamic analysis, and not static analysis, so that all the element matrices, as described in theory section, noted below, are developed and used.

More on theory for this finite element can be found in Section 102.12.1.7 on page 152 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL). Description of output by this element can be found in Section 206.8.2 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.77 Modeling, Finite Element: 20 Node Brick u-p-U Element

The command is:

```
add element # <.> type 20NodeBrick_upU
   using <.> Gauss points each direction
   with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>,<.>, <.>, <.>, <.>, <.>, ↩
      <.>, <.>, <.>,<.>, <.>, <.>, <.>)
   use material # <.>
   porosity = <.>

   rho_f = <M/L^3>
   k_x = <L^3*T/M>
   k_y = <L^3*T/M>
   k_z = <L^3*T/M>
   K_s = <F/L^2>
   K_f = <F/L^2>;
```

where:

- `No (or #)<element_number>` is the unique element integer number that does not have to be sequential, any unique positive integer number can be used.
- `type 8NodeBrick_up` is the element type/name.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8, n9, n10, n11, n12, n13, n14, n15, ↩ n16, n17, n18, n19, n20, n21, n22, n23, n24, n25, n26, n27)` are the 27 nodes for this element, is specified order.
- `using <.> Gauss points each direction` is the number of Gauss points to be used in each direction (r1, r2, and r3) for integration of finite element matrices (mass and stiffness). There can

be from 1 to 6 Gauss points used (uniformly) in each direction (r1, r2, and r3). Command for the brick finite element (above) without number of Gauss points control is kept for back compatibility. For 8 node bricks 2 Gauss points are used in each direction ($2 \times 3 \times 3$), while for 20 nodes, 8-20 node and 8-27 node bricks 3 Gauss points are used in each direction ($3 \times 3 \times 3$).

- `use material No (or #)` is the material number which makes up the element (nonlinear elastic or elastic-plastic material properties for each integration (Gauss) point will evolve independently as the element deforms). Use LT version with LT materials.
- `porosity` is the porosity ($n = V_{voids}/V_{total}$) of material in this element.
- `alpha` is the parameter controlling level of effective stress analysis. For soils, usually $\alpha = 1$ is used, while for other materials (saturated concrete, bone material, etc.) lower values are used ($0 \leq \alpha \leq 1$).
- `rho_s` is the density of particles of the solid phase. It is important to note that this is a density of the actual mineral that makes up solid particles!.
- `rho_f` is the density of pore fluid. It is usually density of water, however, for unsaturated and partially saturated materials, this density will be different, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).
- `k_x` is the permeability in the x direction (global x) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_y` is the permeability in the y direction (global y) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `k_z` is the permeability in the z direction (global z) of the element. It is also important to note about the units used for permeability, as noted below. With isotropic permeability, usually the case, $k_x = k_y = k_z$.
- `K_s` is the bulk modulus of the soil phase particles. It is important to note that this is a bulk modulus of the actual mineral that makes up solid particles!
- `K_f` is the bulk modulus of the fluid phase that is found in porous material pores. It is usually bulk modulus of the fluid (physical value of the bulk modulus of fluid, for example water), however, for

unsaturated and partially saturated materials, this density is a density of a mixture, as described in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Note that, the permeability $\mathbf{k}$ is used with dimensions of $[length]^3[time]/[mass]$, which is different from the usual soil mechanics convention, where the permeability has the dimension of velocity, i.e. $[length]/[time]$. Their values are related by $k = K/\rho_f g$, where g is the gravitational acceleration at which the permeability is measured.

Please note that the $u-p-U$ element, and the $u-p-U$ formulation is a dynamic formulation and is meant to be used with dynamic analysis, and not static analysis, so that all the element matrices, as described in theory section, noted below, are developed and used.

More on theory for this finite element can be found in Section 102.12.1.9 on page 152 of the main document. Description of output by this element can be found in Section 206.8.2.

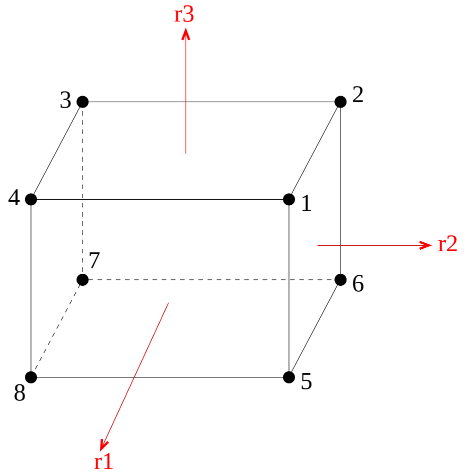
205.3.4.79 Modeling, Finite Element: 8 Node Cosserat Brick Element

The command is:

```
add element # <element_number> type Cosserat8NodeBrick
  with nodes (<.>, <.>, <.>, <.>, <.>, <.>, <.>, <.>)
  use material # <.>;
```

where:

- `<element_number>` is the unique element integer number (does not have to be sequential, any unique positive integer number can be used)
- `type Cosserat8NodeBrick` is the element type.
- `with nodes (n1, n2, n3, n4, n5, n6, n7, n8)` are the 8 nodes for this element. Each node should have 6 DOFs for this element. The element should be in the order as per figure below



- `use material No (or #)` is the material number which makes up the element. The element can use materials `Cosserat_linear_elastic_isotropic_3d` and `Cosserat_von_Mises`.

205.3.4.80 Modeling, Finite Element: Bonded Contact/Interface/Joint Element

The command is:

```
add element # <.> type BondedContact
    with nodes (<.>, <.>)
    penalty_stiffness = <F/L>
```

where

- `penalty_stiffness` represents the penalty stiffness in the three orthogonal x, y and z directions, that connects two nodes of this element.

205.3.4.81 Modeling, Finite Element: Coupled Bonded Contact/Interface/Joint Element

The command is:

```
add element # <.> type CoupledBondedContact
    with nodes (<.>, <.>)
    penalty_stiffness = <F/L>
    axial_viscous_damping = <F/L>
    shear_viscous_damping = <F/L>
    contact_plane_vector = (<.>, <.>, <.> );
```

where

- `penalty_stiffness` represents the penalty stiffness in the three orthogonal x, y and z directions, that connects two nodes of this element. The penalty stiffness is used for both solid and fluid DOFs.
- `axial_viscous_damping` is the viscous damping in axial.
- `shear_viscous_damping` is the viscous damping in shear.
- `contact_plane_vector` defines the normal to the contact/interface/joint plane.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

205.3.4.82 Modeling, Finite Element: Force Based Dry Hard Contact/Interface/Joint Element

The command is:

```
add element # <.> type ForceBasedHardContact
   with nodes (<.>, <.>)
   axial_stiffness = <F/L>
   shear_stiffness = <F/L>
   axial_viscous_damping = <F/L>
   shear_viscous_damping = <F/L>
   friction_ratio = <.>
   contact_plane_vector = (<.>, <.>, <.> );
```

The axial force F_a and axial stiffness E_a in defined as

$$F_a = E_a * \delta_a \tag{205.2}$$

where

δ_a refers to the axial relative displacement in axial contact/interface/joint direction,

E_a refers to the axial stiffness in axial contact direction, and

- `axial_stiffness (b)` represents the stiffness in the axial/axial direction (local x axis).
- `shear_stiffness` Is the stiffness in the tangential (shear, local y or z axis) directions.
- `axial_viscous_damping` Is the viscous damping in axial/axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `friction_ratio` Coulomb friction ratio.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.83 Modeling, Finite Element: Force Based Dry Soft Contact/Interface/Joint Element

The command is:

```
add element # <.> type ForceBasedSoftContact
    with nodes (<.>, <.>)
    initial_axial_stiffness = <F/L>
    stiffening_rate = <1/m>
    max_axial_stiffness = <F/L>
    shear_stiffness = <F/L>
    axial_viscous_damping = <F/L>
    shear_viscous_damping = <F/L>
    friction_ratio = <.>
    contact_plane_vector = (<.>, <.>, <.> );
```

The axial force F_a and axial stiffness E_a in defined as

$$\begin{aligned} F_a &= b * exp(a * \delta_a) * \delta_a \\ E_a &= max(b * exp(a * \delta_a) * (1 + a * \delta_a), E_{max}) \end{aligned} \tag{205.3}$$

where

δ_a refers to the axial relative displacement in axial contact/interface/joint direction,

b refers to the axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact/interface/joint direction,

E_{max} refers to the maximum axial stiffness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(a * \delta_a)$ in axial direction.
- `max_axial_stiffness` (E_{max}) Defines the maximum stiffness in the axial direction (local x axis).
- `shear_stiffness` Is the stiffness in the tangential (shear, local y or z axis) directions.
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `friction_ratio` Coulomb friction ratio.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.84 Modeling, Finite Element: Force Based Coupled Hard Contact/Interface/Joint Element

The command is:

```
add element # <.> type ForceBasedCoupledHardContact
   with nodes (<.>, <.>)
   axial_stiffness = <F/L>
   axial_penalty_stiffness = <F/L>
   shear_stiffness = <F/L>
   axial_viscous_damping = <F/L>
   shear_viscous_damping = <F/L>
   friction_ratio = <.>
   contact_plane_vector = (<.>, <.>, <.> );
```

The axial force F_a and axial stiffness E_a in defined as

$$
\begin{aligned}
F_a &= b * \delta_a \\
E_a &= b
\end{aligned}
\tag{205.4}
$$

where

δ_a refers to the axial relative displacement in axial contact/interface/joint direction,

b refers to the axial stiffness in axial contact/interface/joint direction, and

- `axial_stiffness (b)` represents the axial stiffness in the axial direction (local x axis).
- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.
- `shear_stiffness` Is the stiffness in the tangential (shear, local y or z axis) directions.
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `friction_ratio` Coulomb friction ratio.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.85 Modeling, Finite Element: Force Based Coupled Soft Contact/Interface/Joint Element

The command is:

```
add element # <.> type ForceBasedCoupledSoftContact
   with nodes (<.>, <.>)
   initial_axial_stiffness = <F/L>
   stiffening_rate = <1/m>
   max_axial_stiffness = <F/L>
   axial_penalty_stiffness = <F/L>
   shear_stiffness = <F/L>
   axial_viscous_damping = <F/L>
   shear_viscous_damping = <F/L>
   friction_ratio = <.>
   contact_plane_vector = (<.>, <.>, <.> );
```

The axial force F_a and axial stiffness E_a in defined as

$$\begin{aligned} F_a &= b * exp(a * \delta_a) * \delta_a \\ E_a &= max(b * exp(a * \delta_a) * (1 + a * \delta_a), E_{max}) \end{aligned} \tag{205.5}$$

where

δ_a refers to the axial relative displacement in axial contact/interface/joint direction,

b refers to the axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact/interface/joint direction,

E_{max} refers to the maximum axial stiffness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(a * \delta_a)$ in axial direction.
- `max_axial_stiffness` (E_{max}) Defines the maximum stiffness in the axial direction (local x axis).
- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.
- `shear_stiffness` Is the stiffness in the tangential (shear, local y or z axis) directions.
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.

- `friction_ratio` Coulomb friction ratio.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.86 Modeling, Finite Element: Stress Based Dry Hard Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior

The command is:

```
add element # <.> type StressBasedHardContact_ElPPlShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedHardContact_ElPPlShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * \epsilon_a \\ E_a &= b \end{aligned} \tag{205.6}$$

where

$E_a = b$ refers to the axial stiffness in axial contact/interface/joint direction,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress described in Section 104.7.3.2
- `axial_viscous_damping` Is the viscous damping in axial.

- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual friction coefficient described in Section 104.7.3.2.
- `shear_zone_thickness` h Is the shear zone thickness.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.87 Modeling, Finite Element: Stress Based Dry Hard Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior

The command is:

```
add element # <.> type StressBasedHardContact_NonLinHardShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedHardContact_NonLinHardShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * \epsilon_a \\ E_a &= b \end{aligned} \tag{205.7}$$

where

$E_a = b$ refers to the axial stiffness in axial contact/interface/joint direction,

ϵ_a refers to the axial strain in axial contact direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact/interface/joint axial direction,

h is the shear zone thickness, and

- `axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101 kPa$ axial stress, described in Section 104.7.3.4
- `axial_viscous_damping` Is the viscous damping in axial.

- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.3
- `shear_zone_thickness` h Is the shear zone thickness.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.88 Modeling, Finite Element: Stress Based Dry Hard Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior

The command is:

```
add element # <.> type StressBasedHardContact_NonLinHardSoftShear
    with nodes (<.>, <.>)
    axial_stiffness = <Pa>
    initial_shear_stiffness = <Pa>
    rate_of_softening = <>
    size_of_peak_plateau = <>
    axial_viscous_damping = <Pa*s>
    shear_viscous_damping = <Pa*s>
    peak_friction_coefficient_limit = <>
    peak_friction_coefficient_rate_of_decrease = <.>
    residual_friction_coefficient = <.>
    shear_zone_thickness = <m>
    contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedHardContact_NonLinHardSoftShear
    with nodes (<.>, <.>)
    axial_stiffness = <Pa>
    initial_shear_stiffness = <Pa>
    rate_of_softening = <>
    size_of_peak_plateau = <>
    axial_viscous_damping = <Pa*s>
    shear_viscous_damping = <Pa*s>
    peak_friction_coefficient_limit = <>
    peak_friction_coefficient_rate_of_decrease = <.>
    residual_friction_coefficient = <.>
    shear_zone_thickness = <m>
    surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * \epsilon_a \\ E_a &= b \end{aligned} \tag{205.8}$$

where

$E_a = b$ refers to the axial stiffness in axial contact/interface/joint direction,

ϵ_a refers to the axial strain in axial contact direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact/interface/joint axial direction,

h is the shear zone thickness, and

- `axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).

- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress, described in Section 104.7.3.4

- `rate_of_softening` (R_s) Is the parameter to control the rate of frictional softening described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as

$$\Delta\mu = -\frac{n * R_s(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta\Delta\gamma^p \tag{205.9}$$

$$\theta = \frac{\mu_p - \mu}{\mu_p - \mu_r}(\pi/2)^n \tag{205.10}$$

  where, R_s is the frictional softening rate parameter, $\Delta\gamma^p$ is the plastic shear strain and n represents the size of the peak plateau.

$$\Delta\gamma^p = \sqrt{\Delta\epsilon^p_{ij}\Delta\epsilon^p_{ij}} \tag{205.11}$$

- `size_of_peak_plateau` (n) Is the frictional softening parameter to control the size of plateau as described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as shown in Equation 205.17.

- `axial_viscous_damping` Is the viscous damping in axial.

- `shear_viscous_damping` Is the viscous damping in shear.

- `peak_friction_coefficient_limit` (μ_{p0}) Is the limit to the peak frictional hardening parameter μ_p.

- `peak_friction_coefficient_rate_of_decrease` (k) Is the rate of decrease of peak frictional hardening parameter μ_p with axial stress, described in Section 104.7.3.4

$$\mu_p = max(\mu_{p0}, \mu_{p0} - k * log(\sigma_a/P_0)) \tag{205.12}$$

  where μ_{p0} is the peak frictional hardening limit, k is the peak frictional parameter rate of decrease and P_0 is the reference stress of $P_0 = 101kPa$.

- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.4

- `shear_zone_thickness` h Is the shear zone thickness.

- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.89 Modeling, Finite Element: Stress Based Dry Soft Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior

The command is:

```
add element # <.> type StressBasedSoftContact_ElPPlShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedSoftContact_ElPPlShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * exp(a * \epsilon_a) * \epsilon_a \\ E_a &= max(b * exp(a * \epsilon_a) * (1 + a * \epsilon_a), E_{max}) \end{aligned} \tag{205.13}$$

where

b refers to the initial axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact direction,

E_{max} refers to the maximum axial stiffness,

E_a refers to the axial stiffness,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis).
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(a * \epsilon_a)$ in axial direction.
- `max_axial_stiffness`(E_{max}) Defines the maximum stiffness in the axial direction (local x axis) for the contact/interface/joint element.
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101 kPa$ axial stress described in Section 104.7.3.2
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual friction coefficient described in Section 104.7.3.2
- `shear_zone_thickness` h Is the shear zone thickness
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.90 Modeling, Finite Element: Stress Based Dry Soft Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior

The command is:

```
add element # <.> type StressBasedSoftContact_NonLinHardShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedSoftContact_NonLinHardShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned}\sigma_a &= b * exp(a * \epsilon_a) * \epsilon_a \\ E_a &= max(b * exp(a * \epsilon_a) * (1 + a * \epsilon_a), E_{max})\end{aligned} \tag{205.14}$$

where

b refers to the initial axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact direction,

E_{max} refers to the maximum axial stiffness,

E_a refers to the axial stiffness,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis) for 1m penetration.
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(sr * \epsilon_a)$ in axial direction.
- `max_axial_stiffness`(E_{max}) Defines the maximum stiffness in the axial direction (local x axis) for the contact/interface/joint element.
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress described in Section 104.7.3.3
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.3
- `shear_zone_thickness` h Is the shear zone thickness
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.91 Modeling, Finite Element: Stress Based Dry Soft Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior

The command is:

```
add element # <.> type StressBasedSoftContact_NonLinHardSoftShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>

   size_of_peak_plateau = <>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   peak_friction_coefficient_limit = <>
   peak_friction_coefficient_rate_of_decrease = <.>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedSoftContact_NonLinHardSoftShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   rate_of_softening = <>
   size_of_peak_plateau = <>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   peak_friction_coefficient_limit = <>
   peak_friction_coefficient_rate_of_decrease = <.>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned}
\sigma_a &= b * exp(a * \epsilon_a) * \epsilon_a \\
E_a &= max(b * exp(a * \epsilon_a) * (1 + a * \epsilon_a), E_{max})
\end{aligned} \tag{205.15}$$

where

b refers to the initial axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact direction,

E_{max} refers to the maximum axial stiffness,

E_a refers to the axial stiffness,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis) for 1m penetration.
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(sr * \epsilon_n)$ in axial direction.
- `max_axial_stiffness`(E_{max}) Defines the maximum stiffness in the axial direction (local x axis) for the contact/interface/joint element.
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress, described in Section 104.7.3.4
- `rate_of_softening` (R_s) Is the parameter to control the rate of frictional softening described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as

$$\Delta\mu = -\frac{n * R_s(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta \Delta\gamma^p \tag{205.16}$$

$$\theta = \frac{\mu_p - \mu}{\mu_p - \mu_r}(\pi/2)^n \tag{205.17}$$

where, R_s is the frictional softening rate parameter, $\Delta\gamma^p$ is the plastic shear strain and n represents the size of the peak plateau.

$$\Delta\gamma^p = \sqrt{\Delta\epsilon^p_{ij}\Delta\epsilon^p_{ij}} \tag{205.18}$$

- `size_of_peak_plateau` (n) Is the frictional softening parameter to control the size of plateau as described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as shown in Equation 205.17.
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `peak_friction_coefficient_limit` (μ_{p0}) Is the limit to the peak frictional hardening parameter μ_p.

- `peak_friction_coefficient_rate_of_decrease` (k) Is the rate of decrease of peak frictional hardening parameter μ_p with axial stress, described in Section 104.7.3.4

  $$\mu_p = max(\mu_{p0}, \mu_{p0} - k * log(\sigma_a/P_0)) \tag{205.19}$$

  where μ_{p0} is the peak frictional hardening limit, k is the peak frictional parameter rate of decrease and P_0 is the reference stress of $P_0 = 101kPa$.

- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.4

- `shear_zone_thickness` h Is the shear zone thickness

- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.

- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.92 Modeling, Finite Element: Stress Based Coupled Hard Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior

The command is:

```
add element # <.> type StressBasedCoupledHardContact_ElPPlShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   axial_penalty_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedCoupledHardContact_ElPPlShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   axial_penalty_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * \epsilon_a \\ E_a &= b \end{aligned} \tag{205.20}$$

where

$E_a = b$ refers to the axial stiffness in axial contact/interface/joint direction,

ϵ_a refers to the axial strain in axial contact direction $\epsilon_a = \delta_a / h$,

δ_a is the relative axial penetration in contact/interface/joint axial direction,

h is the shear zone thickness, and

- `axial_stiffness` (b) represents the stiffness in the axial direction (local x axis).
- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is

useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.

- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress described in Section 104.7.3.2
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual friction coefficient described in Section 104.7.3.2
- `shear_zone_thickness` h Is the shear zone thickness
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.93 Modeling, Finite Element: Stress Based Coupled Hard Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior

The command is:

```
add element # <.> type StressBasedCoupledHardContact_NonLinHardShear
   with nodes (<.>, <.>)
   axial_stiffness = <Pa>
   axial_penalty_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );
```

and/or;

```
add element # <.> type StressBasedCoupledHardContact_NonLinHardShear
   with nodes (<.>, <.>)

    shear_zone_thickness = <m>
    surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * \epsilon_a \\ E_a &= b \end{aligned} \tag{205.22}$$

where

$E_a = b$ refers to the axial stiffness in axial contact/interface/joint direction,

ϵ_a refers to the axial strain in axial contact direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact/interface/joint axial direction,

h is the shear zone thickness, and

- `axial_stiffness` (b) represents the stiffness in the axial direction (local x axis) for 1m penetration.

- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.

- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress, described in Section 104.7.3.4

- `rate_of_softening` (R_s) Is the parameter to control the rate of frictional softening described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as

$$\Delta\mu = -\frac{n * R_s(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta\Delta\gamma^p \tag{205.23}$$

$$\theta = \frac{\mu_p - \mu}{\mu_p - \mu_r}(\pi/2)^n \tag{205.24}$$

  where, R_s is the frictional softening rate parameter, $\Delta\gamma^p$ is the plastic shear strain and n represents the size of the peak plateau.

$$\Delta\gamma^p = \sqrt{\Delta\epsilon^p_{ij}\Delta\epsilon^p_{ij}} \tag{205.25}$$

- `size_of_peak_plateau` (n) Is the frictional softening parameter to control the size of plateau as described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as shown in Equation 205.24.

- `axial_viscous_damping` Is the viscous damping in axial.

- `shear_viscous_damping` Is the viscous damping in shear.

- `peak_friction_coefficient_limit` (μ_{p0}) Is the limit to the peak frictional hardening parameter μ_p.

- `peak_friction_coefficient_rate_of_decrease` (k) Is the rate of decrease of peak frictional hardening parameter μ_p with axial stress, described in Section 104.7.3.4

$$\mu_p = max(\mu_{p0}, \mu_{p0} - k * log(\sigma_a/P_0)) \tag{205.26}$$

  where μ_{p0} is the peak frictional hardening limit, k is the peak frictional parameter rate of decrease and P_0 is the reference stress of $P_0 = 101kPa$.

- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.4
- `shear_zone_thickness` h Is the shear zone thickness.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.95 Modeling, Finite Element: Stress Based Coupled Soft Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior

The command is:

```
add element # <.> type StressBasedCoupledSoftContact_ElPPlShear
   with nodes (<.>, <.>)
   initial_axial_stiffness = <Pa>
   stiffening_rate = <>
   max_axial_stiffness = <Pa>
   axial_penalty_stiffness = <Pa>
   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   contact_plane_vector = (<.>, <.>, <.> );

   initial_shear_stiffness = <Pa>
   axial_viscous_damping = <Pa*s>
   shear_viscous_damping = <Pa*s>
   residual_friction_coefficient = <.>
   shear_zone_thickness = <m>
   surface_vector_relative_tolerance = <.>;
```

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned} \sigma_a &= b * exp(a * \epsilon_a) * \epsilon_a \\ E_a &= max(b * exp(a * \epsilon_a) * (1 + a * \epsilon_a), E_{max}) \end{aligned} \tag{205.27}$$

where

b refers to the initial axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact direction,

E_{max} refers to the maximum axial stiffness,

E_a refers to the axial stiffness,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `initial_axial_stiffness (b)` represents the stiffness in the axial direction (local x axis) for 1m penetration.
- `stiffening_rate (a)` Represents exponential stiffening rate $exp(sr * \epsilon_n)$ in axial direction.
- `max_axial_stiffness`(E_{max}) Defines the maximum stiffness in the axial direction (local x axis) for the contact/interface/joint element.
- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101 kPa$ axial stress described in Section 104.7.3.2
- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `residual_friction_coefficient` (μ_r) Is the residual friction coefficient described in Section 104.7.3.2
- `shear_zone_thickness` h Is the shear zone thickness
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section ??.

205.3.4.96 Modeling, Finite Element: Stress Based Coupled Soft Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior

The command is:

```
add element # <.> type StressBasedCoupledSoftContact_NonLinHardShear

The axial stress σ_a and axial stiffness E_a in defined as

$$\begin{aligned}\sigma_a &= b * exp(a * \epsilon_a) * \epsilon_a \\ E_a &= max(b * exp(a * \epsilon_a) * (1 + a * \epsilon_a), E_{max})\end{aligned} \tag{205.29}$$

where

b refers to the initial axial stiffness in axial contact/interface/joint direction,

a refers to the stiffening rate in axial contact direction,

E_{max} refers to the maximum axial stiffness,

E_a refers to the axial stiffness,

ϵ_a refers to the axial strain in axial contact/interface/joint direction $\epsilon_a = \delta_a/h$,

δ_a is the relative axial penetration in contact axial direction,

h is the shear zone thickness, and

- `initial_axial_stiffness` (b) represents the stiffness in the axial direction (local x axis) for 1m penetration.
- `stiffening_rate` (a) Represents exponential stiffening rate $exp(sr * \epsilon_n)$ in axial direction.
- `max_axial_stiffness`(E_{max}) Defines the maximum stiffness in the axial direction (local x axis) for the contact/interface/joint element.
- `axial_penalty_stiffness` (E_p) defines the penalty stiffness between U_i degree of freedom (DoF) (saturated, coupled u-p-U element) and u_i DoF (dry u element) to enforce movement of fluid in u-p-U element with solid in u element in contact/interface/joint axial direction. This is useful for pumping action, gap opens and draws the fluid from u-p-U element and then gap closes and pumps, pushes fluid into u-p-U element.
- `initial_shear_stiffness` (E_s) Is the stiffness in the tangential (shear, local y or z axis) directions at $101kPa$ axial stress, described in Section 104.7.3.4
- `rate_of_softening` (R_s) Is the parameter to control the rate of frictional softening described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as

  $$\Delta\mu = -\frac{n * R_s(\mu_p - \mu_r)}{(\pi/2)^n \theta^{1/n-1}} * cos^2\theta\Delta\gamma^p \tag{205.30}$$

  $$\theta = \frac{\mu_p - \mu}{\mu_p - \mu_r}(\pi/2)^n \tag{205.31}$$

  where, R_s is the frictional softening rate parameter, $\Delta\gamma^p$ is the plastic shear strain and n represents the size of the peak plateau.

  $$\Delta\gamma^p = \sqrt{\Delta\epsilon^p_{ij}\Delta\epsilon^p_{ij}} \tag{205.32}$$

- `size_of_peak_plateau` (n) Is the frictional softening parameter to control the size of plateau as described in Section 104.7.3.4. The frictional softening function is an inverse tangent function raised to power n with incremental form as shown in Equation 205.31.

- `axial_viscous_damping` Is the viscous damping in axial.
- `shear_viscous_damping` Is the viscous damping in shear.
- `peak_friction_coefficient_limit` (μ_{p0}) Is the limit to the peak frictional hardening parameter μ_p.
- `peak_friction_coefficient_rate_of_decrease` (k) Is the rate of decrease of peak frictional hardening parameter μ_p with axial stress, described in Section 104.7.3.4

  $$\mu_p = max(\mu_{p0}, \mu_{p0} - k * log(\sigma_a/P_0)) \tag{205.33}$$

  where μ_{p0} is the peak frictional hardening limit, k is the peak frictional parameter rate of decrease and P_0 is the reference stress of $P_0 = 101kPa$.
- `residual_friction_coefficient` (μ_r) Is the residual frictional parameter as described in Section 104.7.3.4
- `shear_zone_thickness` h Is the shear zone thickness.
- `contact_plane_vector` Vector defining the normal to the contact/interface/joint plane.
- `surface_vector_relative_tolerance` defines the relative tolerance to find all the contact/interface/joint normals and create multiple contact elements for a given contact node pairs for a conforming surface-to-surface mesh.

IMPORTANT NOTE No. 1: `contact_plane_vector` defines a direction from Node I to Node J, that is, from the first to the second node. If this normal vector is reversed, the contact/interface/joint element behaves as a hook and is likely to create convergence issues.

IMPORTANT NOTE No. 2: Two nodes that form the Contact/Interface/Joint Element, need to be placed at the same physical location, coordinates in order to prevent convergence issues when nodes are separated and element tries to close the gap in the very first step.

Description of output by this element can be found in Section 206.8.8.

205.3.4.98 Modeling, Finite Element: Neoprene Isolator Finite Element

(command syntax is in development),

. . .

more on this finite element can be found in Section 102.11 on Page 136 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.99 Modeling, Finite Element: Lead Core Rubber Isolator/Dissipator Element

(command syntax is in development),

. . .

more on this finite element can be found in Section 102.11 on Page 136 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.100 Modeling, Finite Element: Frictional Pendulum Isolator/Dissipator Finite Element version01

(command syntax is in development),

. . .

more on this finite element can be found in Section 102.11 on Page 136 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.101 Modeling, Finite Element: Frictional Pendulum Isolator/Dissipator Finite Element version03

(command syntax is in development),

more on this finite element can be found in Section 102.11 on Page 136 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

205.3.4.102 Modeling, Damping: Adding Rayleigh Damping

First, define the Rayleigh damping.

```
add damping # <.> type Rayleigh with a0 = <1/T> a1 = <T> stiffness_to_use = ↩
    <Initial_Stiffness|Current_Stiffness|Last_Committed_Stiffness>;
```

then apply it to element or node.

```
add damping # <.> to element # <.>;
```

```
add damping # <.> to node # <.>;
```

NOTE:

- If the simulation model is a distributed mass system (e.g. using solid brick elements with nonzero density), users should add damping to elements. In other words, if no additional mass were added to nodes, the command add damping to nodes won't have any effect in ESSI.
- If the simulation model is a lumped mass model (e.g. using the massless beam/truss with lumped mass at nodes), users should add damping to nodes.

205.3.4.103 Modeling, Damping: Adding 3rd Order Caughey Damping

First, define the 3rd-order Caughey damping

```
add damping # <.> type Caughey3rd
with a0 = <T> a1 = <1/T> a2 = <T^3> stiffness_to_use = ↩
    <Initial_Stiffness|Current_Stiffness|Last_Committed_Stiffness>;
```

then apply it to element or node.

```
add damping # <.> to element # <.>;
```

```
add damping # <.> to node # <.>;
```

NOTE:

- If the simulation model is a distributed mass system (e.g. using solid brick elements with nonzero density), users should add damping to elements. In other words, if no additional mass were added to nodes, the command add damping to nodes won't have any effect in ESSI.
- If the simulation model is a lumped mass model (e.g. using the massless beam/truss with lumped mass at nodes), users should add damping to nodes.

205.3.4.104 Modeling, Damping: Adding 4th Caughey Damping

First, define the 4th-order Caughey damping

```
add damping # <.> type Caughey4th
with a0 = <1/T> a1 = <T> a2 = <T^3> a3 = <T^5> stiffness_to_use = ↩
    <Initial_Stiffness|Current_Stiffness|Last_Committed_Stiffness>;
```

then apply it to element or node.

```
add damping # <.> to element # <.>;
```

```
add damping # <.> to node # <.>;
```

NOTE:

- If the simulation model is a distributed mass system (e.g. using solid brick elements with nonzero density), users should add damping to elements. In other words, if no additional mass were added to nodes, the command add damping to nodes won't have any effect in ESSI.
- If the simulation model is a lumped mass system (e.g. using the massless beam/truss with lumped mass at nodes), users should add damping to nodes.

205.3.4.105 Modeling, Constraints and Supports: Adding Constraints or Supports

```
fix node # <.> dofs [ux uy uz p Ux Uy Uz rx ry rz all];
```

where at least one of the DOF fixity codes (`ux uy uz p Ux Uy Uz rx ry rz all`) has to be invoked. These codes are

- `ux`, translation in x direction, for structures and solids (solid phase only in $u-p-U$ and $u-p$ elements)
- `uy`, translation in y direction, for structures and solids (solid phase only in $u-p-U$ and $u-p$ elements)
- `uz`, translation in z direction, for structures and solids (solid phase only in $u-p-U$ and $u-p$ elements)
- `p`, pore fluid pressure (for fluid phase in $u-p-U$ and $u-p$ elements))
- `Ux`, translation of pore fluid phase in x direction (for $u-p-U$ elements)
- `Uy`, translation of pore fluid phase in y direction (for $u-p-U$ elements)
- `Uz`, translation of pore fluid phase in z direction (for $u-p-U$ elements)
- `rx`, rotation around x axes (for structural elements)
- `ry`, rotation around y axes (for structural elements)
- `rz`, rotation around z axes (for structural elements)
- `all`, all applicable DOFs for a given node

Example fix translation x and y for node #3 `fix node # 3 dofs ux uy;`

Example fix all appropriate DOFs for node #7. `fix node # 7 dofs all;`

205.3.4.106 Modeling, Constraints and Supports: Adding Stochastic Constraints or Supports

Define fixities, boundary conditions for a stochastic node. The command would fix all the polynomial chaos expanded dofs associated with the specified physical dof.

```
fix node # <.> stochastic dofs [ux uy uz all];
```

where at least one of the DOF fixity codes (`ux uy uz all`) has to be invoked. These codes are

- `ux`, translation in x direction, including all the associated polynomial chaos expanded dofs.
- `uy`, translation in y direction, including all the associated polynomial chaos expanded dofs.
- `uz`, translation in z direction, including all the associated polynomial chaos expanded dofs.
- `all`, all applicable DOFs for a given node, including all the associated polynomial chaos expanded dofs.

For example,

```
fix node # 3 stochastic dofs ux uy;
```

Fix translation dofs ux and uy, including all the associated polynomial chaos expanded dofs, for stochastic node # 3.

205.3.4.107 Modeling, Constraints and Supports: Free Constraint or Support

Free the specified DOFs on a designated node.

```
free node # <.> dofs [ux uy ux p Ux Uy Uz rx ry rz];
```

205.3.4.108 Modeling, Constraints and Supports: Add Tied/Connected Main-Fillower Nodes for the Same DOFs

Add the equal dof for tied/connected nodes for the same degree of freedom.

```
add constraint equal_dof with
master node # <.> and
slave node # <.>
dof to constrain <.>;
```

205.3.4.109 Modeling, Constraints and Supports: Adding Tied/Connected, Main-Follower Nodes for Different DOFs

Add the equal dof for tied/connected nodes for different degree of freedom.

```
add constraint equal_dof with node # <.> dof <.> master and node # <.> dof <.> ↩
   slave;
```

205.3.4.110 Modeling, Constraints and Supports: Remove Tied/Connected Main-Follower equal DOFs

Remove the tied/connected nodes equal_dofs.

```
remove constraint equal_dof node # <.>
```

205.3.4.111 Modeling, Constraints and Supports: Adding Single Point Constraint to Nodes

Define the single point constraint to nodes on a particular degree of freedom for a specified value.

```
add single point constraint to node # <.>
dof to constrain <dof_type>
constraint value of <.>
```

205.3.4.112 Modeling, Acceleration Field: Adding Acceleration/Inertia Field

```
add acceleration field # <.>
    ax = <acceleration in x direction>*[L/T^2]
    ay = <acceleration in y direction>*[L/T^2]
    az = <acceleration in z direction>*[L/T^2];
```

Example adding acceleration induced loading field for (some) elements

```
add acceleration field # 1
ax = 0*m/s^2
ay = 0*m/s^2
az = -9.81*m/s^2;
```

NOTE: see note on page 1004 for command

```
add load # <.> to element # <.> type self_weight use acceleration field # <.>;
```

205.3.4.113 Modeling, Loads: Nodal Loads

The general signature to add loads is

```
add load # <.> to node # <.>
    type <load type> <direction> = <force_amplitude>
    {more parameters};
```

The load # is a unique number assigned to each load. The node # is the number of a node which has already been defined. The load type refers to the functional form in time or pseudo-time (for static analysis) and can be any of the list

- `linear` Constant rate time dependence.
- `path` Use an arbitrary function defined in an external file.

Each force type except linear have additional parameters which will be explained later.

The force direction refers to the degree of freedom the force will be added to. These force directions are the conjugate in energy of the DOFs defined earlier. These are,

- `Fx`, force in x direction [1]
- `Fy`, force in y direction [1]
- `Fz`, force in z direction [1]
- `F_fluid_x`, force to the pore fluid phase in x direction [2]
- `F_fluid_y`, force to the pore fluid phase in y direction [2]
- `F_fluid_z`, force to the pore fluid phase in z direction [2]
- `Mx`, moment about x axes [3]
- `My`, moment about y axes [3]
- `Mz`, moment about z axes [3]

Example command for adding three linear forces ($fx = -10 * kN, fy = -10 * kN, fz = -10 * kN$) to node # 1:

---

[1] Applies to solid phase only when connected to coupled elements

[1] Applies to fluid phase when connected to coupled elements. HOWEVER, please note that these are NOT pore fluid pressures, see section 102.12.1.5 on page 148, in Lecture Notes (Jeremić et al., 1989-2025) (Lecture Notes URL).

[1] For elements with rotational DOFs, i.e. beams, shells

```
add load # 1 to node #1 type linear Fx = -10*kN;
add load # 2 to node #1 type linear Fy = -10*kN;
add load # 3 to node #1 type linear Fz = -10*kN;
```

The force `type` refers to the functional dependence in time (or pseudo-time) that the force will have. The possible functional forms have been listed before. Listed are additional parameters which define these forces.

1. `linear`

   Receives no extra parameters. In this case the magnitude of the force is interpreted as the magnitude of the force after one second of time (or pseudo-time) has passed.

2. `path`

   How to add path loads is in the next page.

205.3.4.114 Modeling, Loads: Nodal Path Loads

To add forces which follow a path other than linear, we have the `path_series`, for equally spaced time series data, and `path_time_series` for variable spaced time series data.

The commands are:

```
add load # <.> to node # <.> type path_series
  FORCETYPE = <force or moment scale factor>
  time_step = <T>
  series_file = "STRING";
```

```
add load # <.> to node # <.> type path_time_series
  FORCETYPE = <force or moment scale factor>
  series_file = "STRING";
```

As before, `FORCETYPE` can be `Fx`, `Fy`, `Fz`, `Mx`, `My`, `Mz`, `F_fluidx`, `F_fluidy`, `F_fluidz`.

The format of the series_file is one column of text for the equally spaced case (`path_series`) and double column, one for time and second one for data values, for (`path_time_series`).

205.3.4.115 Modeling, Loads: Nodal Loads From Reactions

Loads can be added from reactions.

The command is:

```
add load # <.> to node # <.> type from_reactions;
add load # <.> to all nodes type from_reactions;
```

The load # is a unique number assigned to each load. The node # is the number of a node which has already been defined. This DSL applies an external load equal to the reaction calculated at that node. It is useful, for stage loading where a constrained dof gets relaxed. The first command add load for a specified node whereas, the second command applies load for all nodes.

For example:

```
add load # 3 to node #5 type from_reactions;
```

Adds an external load to node 5 from its reaction force calculated in previous stage.

```
add load # 3 to all nodes type from_reactions;
```

Adds an external load to all nodes from their reaction force calculated in previous stage.

205.3.4.116 Modeling, Loads: Selfweight Element Load

```
add load # <.>
to element # <.>
type self_weight
use acceleration field # <.>;
```

NOTE: since the gravity acceleration field is $g = 9.81\mathrm{m/s}^2$, meaning that there is an increment of $9.81\mathrm{m/s}$ of velocity each second (please note that this defines a rate of increase in velocity), gravity is then applied in 1 second! This is sometimes (most of the time) too harsh numerically! It helps if one defines an acceleration field of say $0.0981\mathrm{m/s}^2$ and then apply it in 100 seconds. This is to be done in command `add acceleration field ...` on page 999.

205.3.4.117 Modeling, Loads: Selfweight Nodal Load

```
add load # <.> to node # <.> type self_weight use acceleration field # <.>;
```

NOTE: For this command to take effect, there should be concentrated mass defined at the node.

205.3.4.118 Modeling, Loads: 8 Node Brick Surface Load with the Constant Pressure

Surface of 8 node brick element with same pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>) ↩
    with magnitude <Pa>;
```

Note: This command works for the dry `8NodeBrick` element and the coupled `8NodeBrick_upU` element. For the coupled upU element, this command applies all surface load on the solid phase, simulating a drained surface loading condition.

A new command for undrained surface loading on upU element will be added soon...

205.3.4.119 Modeling, Loads: 8 Node Brick Surface Load with Variable Pressure

Surface of 8 node brick element with variable pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>) ↩
   with magnitudes ( <Pa> , <Pa> , <Pa> , <Pa>);
```

205.3.4.120 Modeling, Loads: 20Node Brick Surface Load with the Constant Pressure

Surface of 20 node brick element with same pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>, ↩
    <.>, <.>, <.>, <.>) with magnitude <Pa>;
```

205.3.4.121 Modeling, Loads: 20 Node Brick, Surface Load with Variable Pressure

Surface of 20 node brick element with variable pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>, ↩
    <.>, <.>, <.>, <.>) with magnitudes ( <Pa> , <Pa> , <Pa> , <Pa>, <Pa>, ↩
    <Pa>, <Pa>, <Pa>);
```

205.3.4.122 Modeling, Loads: 27 Node Brick Surface Load with the Constant Pressure

Surface of 27 node brick element with same pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>, ↩
    <.>, <.>, <.>, <.>, <.>) with magnitude <Pa>;
```

205.3.4.123 Modeling, Loads: 27 Node Brick Surface Load with Variable Pressure

Surface of 27 node brick element with variable pressure magnitudes at all nodes:

```
add load # <.> to element # <.> type surface at nodes (<.> , <.> , <.> , <.>, ↩
    <.>, <.>, <.>, <.>, <.>) with magnitudes ( <Pa> , <Pa> , <Pa> , <Pa>, <Pa>, ↩
    <Pa>, <Pa>, <Pa>, <Pa>);
```

205.3.4.124 Modeling, Loads: Removing Loads

Loads can be removed using:

```
remove load # <.>
```

205.3.4.125 Modeling, Loads: Domain Reduction Method, DRM

```
add load # <.> type domain reduction method hdf5_file = <string>;
add load # <.> type domain reduction method hdf5_file = <string> scale_factor = ↩
    <.>;
```

- `hdf5_file` HDF5 file with information for the DRM specification. See section....
- `scale_factor` Factor to linearly scale the motion.

Creating DRM input in HDF5 format. As shown in Fig.(205.5), eight components are required for the DRM input.

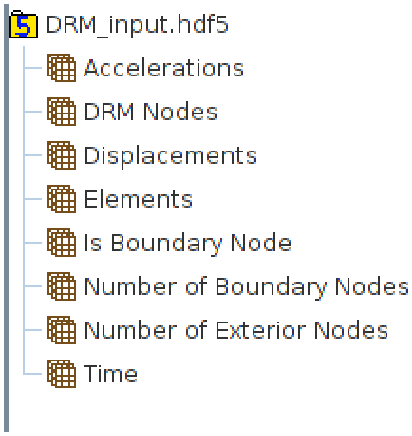

Figure 205.5: Components of DRM input in HDF5 format.

The name of the sub-folders must be exactly the same as shown here.

1. Elements: element numbers for DRM elements, a single layer of elements used to add the earthquake motion.
2. DRM Nodes: Node numbers for DRM elements.
3. Is Boundary Node: used to describe whether each of nodes in "DRM Nodes" is a boundary node or an exterior node.
    - If this value is "1", the corresponding node in "DRM Nodes" is a boundary node.
    - If this value is "0", the corresponding node in "DRM Nodes" is an exterior node in the DRM element.
4. Number of Boundary Nodes: the number of boundary nodes.

5. Number of Exterior Nodes: the number of exterior nodes.
6. Displacements: the displacement components of input earthquake motion on corresponding DRM Nodes. Displacements are a 2D array,
    - column number represents a time-step,
    - rows represents the displacement in one direction.

      If every node has 3 degrees of freedom (DOFs, say ux, uy, and uz), the first three rows represent the input displacements on first DRM node in directions of ux, uy, and uz. Then, next three rows represent the input displacements for the next node. So the total row number should be three times of the number of DRM Nodes.
7. Accelerations: same data structure as displacements, above.
8. Time: real time for each time-step in the input earthquake motion.

Python example script to generate the DRM HDF5-based input is given below. Please note that script only generates simplest possible rigid body motion, and that for any realistic motions, those will have to be created using 1C or 3C seismic motions codes, for example, SW4, SynAcc, fk, Hisada, EDT, MS ESSI, or even SHAKE for 1C motions.

```
# Created by Jose Antonio Abell Mena
# This file reads old-format DRM input files and translates them into new
# HDF5-based format.
#

# This file produces a rigid body input to the DRM layer. That is, all DRM
# nodes have same X-direction displacement and acceleration. In this case a
# sine wave is used. This is not realistic, its just for demonstration
# purposes. DRM won't work in this case but can be used to verify input if a
# pseudo-static analysis is done (zero density on all elements and apply loads
# with transient analysis.)
# For real input motions, produced using some other means, say SW4, fk,
# Hisada or MS ESSI program, this simple program can be used as an example,
# where DRM input file format used here can be (re) used, while those real
# motions are read form output of above mentioned programs.

import scipy as sp
import h5py
import time

# Write elements and nodes data
elements = sp.loadtxt("DRMelements.txt",dtype=sp.int32)
exterior_nodes = sp.loadtxt("DRMexterior.txt",dtype=sp.int32)
boundary_nodes = sp.loadtxt("DRMbound.txt",dtype=sp.int32)
```

```

Ne = sp.array(exterior_nodes.size)
Nb = sp.array(boundary_nodes.size)

Nt = Ne+Nb

all_nodes = sp.hstack((boundary_nodes, exterior_nodes))
is_boundary_node = sp.zeros(Nt, dtype=sp.int32)
is_boundary_node[0:Nb] = 1

h5file = h5py.File("small.h5.drminput","w")

h5file.create_dataset("Elements", data=elements)
h5file.create_dataset("DRM Nodes", data=all_nodes)

# This array has 1 if the node at the corresponding position in "DRM nodes"
# array is a boundary node and zero if not
h5file.create_dataset("Is Boundary Node", data=is_boundary_node)

h5file.create_dataset("Number of Exterior Nodes", data=Ne)
h5file.create_dataset("Number of Boundary Nodes", data=Nb)

# Write timestamp (time format used is that of c "asctime" Www Mmm dd
# hh:mm:ss yyyy example: Tue Jan 13 10:17:09 2009)
localtime = time.asctime( time.localtime(time.time()) )
h5file.create_dataset("Created",data=str(localtime))

# Generate motions
t = sp.linspace(0,10,1001)
w = 2*sp.pi/0.5
d = sp.sin(w*t)
a = -w**2*sp.sin(w*t)

# Output accelerations, displacements and time-vector

# Format is:
#
# Array/matrix for Accelerations and Displacements has the following shape
# [3*(N_boundary_nodes + N_exterior_nodes) , Ntimesteps]
#
# where component
# A[3*n], A[3*n+1], A[3*n+2]
# correspond to accelerations/displacements in X, Y, and Z directions
# at node n.
# The location corresponding to node n is that of the n-th component of array
# "DRM Nodes"

# Time vector

h5file.create_dataset("Time", data=t)

acc = h5file.create_dataset("Accelerations", (3*Nt,len(t)), dtype=sp.double)
dis = h5file.create_dataset("Displacements", (3*Nt,len(t)), dtype=sp.double)

for node_index in range(Nt):
 acc[3*node_index,:] = a
 acc[3*node_index+1,:] = 0*a #Zero acceleration in y and z
 acc[3*node_index+2,:] = 0*a
 dis[3*node_index,:] = d
 dis[3*node_index+1,:] = 0*d #Zero displacement in y and z
 dis[3*node_index+2,:] = 0*d

h5file.close()
```

205.3.4.126 Modeling, Wave Field for Creating DRM Loads: Add Wave Field

```
add wave field # <.> with
    acceleration_filename = <string>
    unit_of_acceleration = <L/T^2>
    displacement_filename = <string>
    unit_of_displacement = <L>
    add_compensation_time = <T>
    motion_depth = <L>
    monitoring_location = <within_soil_layer|equivalent_rock_outcropping>
    soil_profile_filename = <string>
    unit_of_Vs = <L/T>
    unit_of_rho = <M/L^3>
    unit_of_damping = <absolute|percent>
    unit_of_thickness = <L>
    ;
```

Example adding a wave field

```
add wave field # 1 with
    acceleration_filename = "acc.txt"
    unit_of_acceleration = 1 * m/s^2
    displacement_filename = "dis.txt"
    unit_of_displacement = 1 * m
    add_compensation_time = 0.5 * s
    motion_depth = 0 * m
    monitoring_location = within_soil_layer
    soil_profile_filename = "soil_profile.txt"
    unit_of_Vs = 1 * m/s
    unit_of_rho = 1 * kg/m^3
    unit_of_damping = absolute
    unit_of_thickness = 1*m
    ;
```

where:

- `No (or #)<.>` is the unique wave field ID. The wave field ID does not have to be sequential, any unique positive integer number can be used. Each wave field is a 1C wave field. The wave field does not have a direction. Later, if users want to add load with the wave field, users should specify the direction with each wave field.
- `acceleration_filename` is the filename of a plain text file, which contains the acceleration of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding acceleration. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field does NOT conduct any base correction on the input

motion, so the simulation results may have permanent deformation after the earthquake. If users want to have base corrections, users should pre-process the earthquake motion by themselves.

- `displacement_filename` is the filename of a plain text file, which contains the displacement of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding displacement. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field does NOT conduct any base correction on the input motion, so the simulation results may have permanent deformation after the earthquake. If users want to have base corrections, users should pre-process the earthquake motion by themselves.

- `add_compensation_time` is a feature to add zero-motion in the beginning and at the end of the earthquake motion. Since the wave propagation theory is solving the wave equation in frequency domain (steady state), without additional zeros, the beginning and the end of wave may be mixed up. If the user does not want to add the additional zeros, user can specify 0*s.

- `motion_depth` is the depth of the input motion. Usually, the `motion_depth` is at the surface (namely, 0*m). Later, users can specify the request depth for deconvolution. However, users can also specify a specific depth of the input motion. In this case, users can request both convolution and deconvolution.

  - If the request depth is deeper than this input acceleration depth, the wave propagation will generate the deconvolution results.
  - If the request depth is shallower than this input acceleration depth, the wave propagation will generate the convolution results. It is recommended to add a small damping for wave convolution.

  The acceleration depth is the relative depth to the soil surface, so both negative and positive depth are acceptable and result in the same results.

- `monitoring_location` is the location of the earthquake monitoring station. When the monitoring location is within soil layer, the wave propagation is conducted inside the soil layer directly. When the monitoring location is equivalent rock outcropping, wave deconvolution is conducted back to the bedrock first and then propagate into the soil layers.

- `soil_profile_filename` contains the soil properties for each layer. The soil profile file should have four columns, which are the shear wave velocity, density, damping ratio and thickness of each layer respectively. The soil layers should be from the soil surface to the bedrock. The last layer is bedrock, which has three columns only. User should NOT give the thickness of the last layer.

One Example of soil profile file is given below.

```
// Vs rho damp thickness
200 2000 0.03 35
250 2000 0.04 35
2000 2400 0.05
```

205.3.4.127 Modeling, Wave Field for Creating DRM Loads: Deconvolution

This command performs deconvolution or convolution of given motions at surface or certain depth and writes accelerations, velocities and displacements in 3 directions, in files, that can then be used to create DRM loads.

```
generate wave propagation results of wave field
  # <.> at depth <L> to file <output_filename_prefix>
```

One example of deconvolution is

```
generate wave propagation results of wave field
  # 1 at depth -60*m to file "Northridge_record" ;
```

where

- `wave field # <.>` specifies the wave field number which will be used for wave propagation.
- `depth <L>` is the request depth of the output motion.
  - If the request depth is deeper than the input motion that defined in the wave field, this command will generate the deconvolution results.
  - If the request depth is shallower than the input motion that defined in the wave field, this command will generate the convolution results. It is recommended to add a small damping for wave convolution.

  The depth specifies the *relative* location between the soil surface and the request depth, which means both positive and negative depth are acceptable and will result in the same results.
- `output_filename_prefix` specified the prefix of the output filenames. This command will generate 3 output files, whose suffix are `at_str(depth)_acc.txt` , `at_str(depth)_vel.txt` , `at_str(depth)_dis.txt` .

205.3.4.128 Modeling, Wave Field for Creating DRM Input: Motions

This command performs deconvolution or convolution of given motions at surface or certain depth and directly generates DRM motions in 1, 2, or 3 directions.

```
generate DRM motion file from wave field
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

```
generate DRM motion file from wave field
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

```
generate DRM motion file from wave field
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

One example of deconvolution to DRM is

```
generate DRM motion file from wave field
  # 1 in direction ux
  soil_surface at z = 0*m
  hdf5_file = "input.hdf5" ;
```

where:

- `in direction <ux,uy,uz>` specifies the direction of the wave field. Each wave field is a 1C wave field. At most 3 wave fields can be associated with the load.
- `soil_surface` specifies the relation between the FEM coordinate systems and the soil profile depths inside the wave field. The soil surface should always be above the DRM nodes. Namely, soil surface is generally the surface between the soil and the structure, NOT the bedrock surface.
- `hdf5_file` specifies the HDF5 file which contain the information about the DRM elements and DRM nodes.

205.3.4.129 Modeling, Wave Field for Creating DRM Input: Forces

This command performs deconvolution or convolution of given motions at surface or certain depth and directly generates DRM motions and forces in 1, 2, or 3 directions.

```
generate DRM force file from wave field
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

```
generate DRM force file from wave field
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

```
generate DRM force file from wave field
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  # <.> in direction <ux|uy|uz>
  soil_surface at z = <L>
  hdf5_file = <string> ;
```

One example of deconvolution to DRM is

```
generate DRM force file from wave field
  # 1 in direction ux
  soil_surface at z = 0*m
  hdf5_file = "input.hdf5" ;
```

where:

- `in direction <ux,uy,uz>` specifies the direction of the wave field. Each wave field is a 1C wave field. At most 3 wave fields can be associated with the load.
- `soil_surface` specifies the relation between the FEM coordinate systems and the soil profile depths inside the wave field. The soil surface should always be above the DRM nodes. Namely, soil surface is generally the surface between the soil and the structure, NOT the bedrock surface.
- `hdf5_file` specifies the HDF5 file which contain the information about the DRM elements and DRM nodes.

205.3.4.130 Modeling, Wave Field for Creating DRM Loads: Add Inclined Plane Wave Field from Incident SV Wave Potential Magnitude

```
add wave field # <.> type inclined_plane_wave with
   anticlockwise_angle_of_SV_wave_plane_from <x|y|z> = <degrees>
   SV_incident_magnitude = <L^2>
   SV_incident_angle = <degrees>
   SV_incident_frequency = <1/T>
   motion_time_step = <T>
   number_of_time_steps = <.>
   soil_profile_filename = <string>
   soil_surface at <x|y|z> = <L>
   unit_of_vs_and_vp = <L/T>
   unit_of_rho = <M/L^3>
   unit_of_damping = <absolute|percent>
   unit_of_thickness = <L>
   ;
```

Example of adding an inclined plane wave field

```
add wave field # 1 type inclined_plane_wave with
  anticlockwise_angle_of_SV_wave_plane_from x= 30
  SV_incident_magnitude = 2*m^2
  SV_incident_angle = 60
  SV_incident_frequency = 5/s
  motion_time_step = 0.01*s
  number_of_time_steps = 600
  soil_profile_filename = "soil.txt"
  soil_surface at z = 0*m
  unit_of_vs_and_vp = 1*m/s
  unit_of_rho = 1*kg/m^3
  unit_of_damping = absolute
  unit_of_thickness = 1*m;
```

where:

- `No (or #)<.>` is the unique wave field ID/number. The wave field ID does not have to be sequential, any unique positive integer number can be used. Each wave field is an inclined plane SV wave field.
- `anticlockwise_angle_of_SV_wave_plane_from <x|y|z>` specifies the orientation of the inclined wave field propagation plane. User should give the anticlockwise angle in degrees between the wave propagation plane and the specified reference axis. The reference axis could be x or y or z. As shown in figure 205.7, the `anticlockwise_angle_of_SV_wave_plane_from` x axis is α.
- `SV_incident_magnitude` specifies the incident SV wave potential magnitude. The displacement magnitude of incident SV wave is related to the potential magnitude as follows: $|u| = \phi\omega/V_s$, where

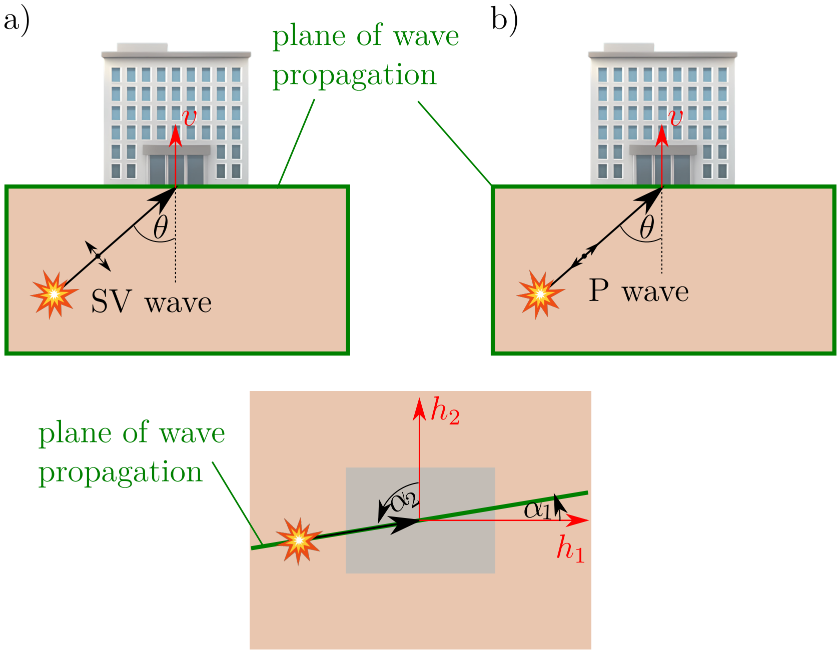

Figure 205.6: Orientation of an inclined plane wave with respect to the vertical, v, and horizontal, h_1, h_2, directions: a) a SV wave and b) a P-wave. The user defines v, h_1, h_2 directions. Either α_1 or α_2 can be input into the DSL command.

$|u|$ is the displacement magnitude, ϕ is potential magnitude, ω is incident angular frequency and V_s is the shear wave velocity of the incident soil/rock layer.

- `SV_incident_angle` specifies the inclination angle of incident SV wave, measured from vertical axis of wave plane to the wave propagation axis. In figure 205.7, the incident angle of SV wave is θ.
- `motion_time_step` is the time step/interval used for discretizing the harmonic motion into time domain.
- `number_of_time_steps` is the number of total time steps for the discretized harmonic motion.
- `soil_profile_filename` is a file name for a file that contains the soil properties for each layer. The soil profile file should have fives columns: (i) shear wave velocity, (ii) compressional wave velocity, (iii) density, (iv) damping ratio and (v) thickness of each layer respectively. The soil layers count from the soil surface to the bedrock. The last layer is bedrock, which has four columns only. User should NOT give the thickness of the last layer, as it extends into halfspace.

  One Example of soil profile file is given below.

```
// Vs Vp rho damp thickness
  200 333 2000 0.02 100
  250 408 2000 0.02 200
 2000 3400 2400 0.02
```

- `soil_surface at <x|y|z>` defines the location of soil surface in the global coordinate system of Real-ESSI.

205.3.4.131 Modeling, Wave Field for Creating DRM Loads: Add Inclined Plane Wave Field from Incident SV Wave Time Series Signal

```
add wave field # <.> type inclined_plane_wave with
   anticlockwise_angle_of_SV_wave_plane_from <x|y|z> = <degrees>
   SV_incident_acceleration_filename = <string>
   unit_of_acceleration = <L/T^2>
   SV_incident_displacement_filename = <string>
   unit_of_displacement = <L>
   SV_incident_angle = <degrees>
   add_compensation_time = <T>
   source_location = (<T>, <T>, <T>)
   soil_profile_filename = <string>
   soil_surface at <x|y|z> = <L>
   unit_of_vs_and_vp = <L/T>
   unit_of_rho = <M/L^3>
   unit_of_damping = <absolute|percent>
   unit_of_thickness = <L>
   ;
```

Example of adding an inclined plane wave field

```
add wave field # 1 type inclined_plane_wave with
  anticlockwise_angle_of_SV_wave_plane_from x = 0
  SV_incident_acceleration_filename = "Kobe_acc.txt"
  unit_of_acceleration = 1*m/s^2
  SV_incident_displacement_filename = "Kobe_disp.txt"
  unit_of_displacement = 1*m
  SV_incident_angle = 15
  add_compensation_time = 0.5*s
  source_location = (-150*m, 0*m, -100*m)
  soil_profile_filename = "soil_profile.txt"
  soil_surface at z = 0*m
  unit_of_vs_and_vp = 1*m/s
  unit_of_rho = 1*kg/m^3
  unit_of_damping = absolute
  unit_of_thickness = 1*m;
```

where:

- `No (or #)<.>` is the unique wave field ID/number. The wave field ID does not have to be sequential, any unique positive integer number can be used. Each wave field is an inclined plane SV wave field.
- `anticlockwise_angle_of_SV_wave_plane_from <x|y|z>` specifies the orientation of the inclined wave field propagation plane. User should give the anticlockwise angle in degrees between the wave propagation plane and the specified reference axis. The reference axis could be x or y or

z. As shown in figure 205.7, the `anticlockwise_angle_of_SV_wave_plane_from` x axis is α.

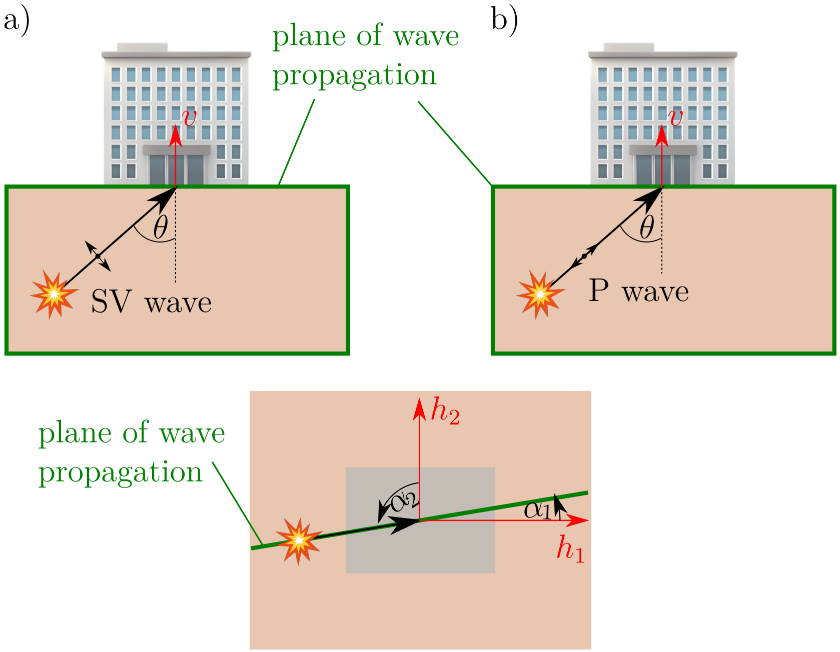

Figure 205.7: Orientation of an inclined plane wave with respect to the vertical, v, and horizontal, h_1, h_2, directions: a) a SV wave and b) a P-wave. The user defines v, h_1, h_2 directions. Either α_1 or α_2 can be input into the DSL command.

- `SV_incident_acceleration_filename` is the filename of a plain text file, which contains the acceleration of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding acceleration. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field implementation in Real-ESSI does NOT conduct any baseline correction on the input motion. The users should perform baseline correction for earthquake motions by themselves.

- `SV_incident_displacement_filename` is the filename of a plain text file, which contains the displacement of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding displacement. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field implementation in Real-ESSI does NOT conduct any baseline correction on the input motion. The users should perform baseline correction for earthquake motions by themselves.

- `SV_incident_angle` specifies the inclination angle of incident SV wave, measured from vertical axis of wave plane to the wave propagation axis. In figure 205.7, the incident angle of SV wave is θ.

- `add_compensation_time` is a feature to add zero-motion in the beginning and at the end of the earthquake motion. If the user does not want to add the additional zeros, user can specify compensation time as 0*s.

- `source_location` specify the location of seismic source, where the seismic motion is input as in `SV_incident_acceleration_filename` and `SV_incident_displacement_filename`, it is used for determining phase of the wave, and the source location can be inside or outside of the model.

- `soil_profile_filename` is a file name for a file that contains the soil properties for each layer. The soil profile file should have fives columns: (i) shear wave velocity, (ii) compressional wave velocity, (iii) density, (iv) damping ratio and (v) thickness of each layer respectively. The soil layers count from the soil surface to the bedrock. The last layer is bedrock, which has four columns only. User should NOT give the thickness of the last layer, as it extends into half-space.

  One Example of soil profile file is given below.

```
 // Vs Vp rho damp thickness
   200 333 2000 0.02 100
   250 408 2000 0.02 200
  2000 3400 2400 0.02
```

- `soil_surface at <x|y|z>` defines the location of soil surface in the global coordinate system of Real-ESSI.

205.3.4.132 Modeling, Wave Field for Creating DRM Loads: Add Inclined Plane Wave Field from Incident P Wave Potential Magnitude

```
add wave field # <.> type inclined_plane_wave with
    anticlockwise_angle_of_P_wave_plane_from <x|y|z> = <degrees>
    P_incident_magnitude = <L^2>
    P_incident_angle = <degrees>
    P_incident_frequency = <1/T>
    motion_time_step = <T>
    number_of_time_steps = <.>
    soil_profile_filename = <string>
    soil_surface at <x|y|z> = <L>
    unit_of_vs_and_vp = <L/T>
    unit_of_rho = <M/L^3>
    unit_of_damping = <absolute|percent>
    unit_of_thickness = <L>
    ;
```

Example adding an inclined plane wave field

```
add wave field # 1 type inclined_plane_wave with
  anticlockwise_angle_of_P_wave_plane_from x= 30
  P_incident_magnitude = 2*m^2
  P_incident_angle = 60
  P_incident_frequency = 5/s
  motion_time_step = 0.01*s
  number_of_time_steps = 600
  soil_profile_filename = "soil.txt"
  soil_surface at z = 0*m
  unit_of_vs_and_vp = 1*m/s
  unit_of_rho = 1*kg/m^3
  unit_of_damping = absolute
  unit_of_thickness = 1*m;
```

where:

- `No (or #)<.>` is the unique wave field ID/number. The wave field ID does not have to be sequential, any unique positive integer number can be used. Each wave field is an inclined plane P wave field.

- `anticlockwise_angle_of_P_wave_plane_from <x|y|z>` specifies the orientation of the inclined wave propagation plane. User should give the anticlockwise angle in degrees between the wave propagation plane and the specified reference axis. The reference axis could be x or y or z. As shown in figure 205.7, the `anticlockwise_angle_of_P_wave_plane_from` x axis is α.

- `P_incident_magnitude` specifies the incident P wave potential magnitude. The displacement magnitude of incident P wave is related to the potential magnitude as following: $|u| = \phi\omega/V_p$, where $|u|$ is the displacement magnitude, ϕ is potential magnitude, ω is incident angular frequency and V_p is the compressional wave velocity of the incident layer.

- `P_incident_angle` specifies the inclination of incident P wave. The angle is measured from vertical axis of wave plane to the wave propagation axis. In figure 205.7, the incident angle of P wave is θ.
- `motion_time_step` is the time interval when discretized the harmonic motion into time domain.
- `number_of_time_steps` is the number of total time steps for the discretized harmonic motion.
- `soil_profile_filename` is a file name for a file that contains the soil properties for each layer. The soil profile file should have fives columns: (i) shear wave velocity, (ii) compressional wave velocity, (iii) density, (iv) damping ratio and (v) thickness of each layer respectively. The soil layers count from the soil surface to the bedrock. The last layer is bedrock, which has four columns only. User should NOT give the thickness of the last layer, as it extends into halfspace.

  One Example of soil profile file is given below.

```
// Vs Vp rho damp thickness
  200 333 2000 0.02 100
  250 408 2000 0.02 200
 2000 3400 2400 0.02
```

- `soil_surface at <x|y|z>` defines the location of soil surface in the global coordinate system of Real-ESSI.

205.3.4.133 Modeling, Wave Field for Creating DRM Loads: Add Inclined Plane Wave Field from Incident P Wave Time Series Signal

```
add wave field # <.> type inclined_plane_wave with
   anticlockwise_angle_of_P_wave_plane_from <x|y|z> = <degrees>
   P_incident_acceleration_filename = <string>
   unit_of_acceleration = <L/T^2>
   P_incident_displacement_filename = <string>
   unit_of_displacement = <L>
   P_incident_angle = <degrees>
   add_compensation_time = <T>
   source_location = (<T>, <T>, <T>)
   soil_profile_filename = <string>
   soil_surface at <x|y|z> = <L>
   unit_of_vs_and_vp = <L/T>
   unit_of_rho = <M/L^3>
   unit_of_damping = <absolute|percent>
   unit_of_thickness = <L>
   ;
```

Example of adding an inclined plane wave field

```
add wave field # 1 type inclined_plane_wave with
  anticlockwise_angle_of_P_wave_plane_from x = 0
  P_incident_acceleration_filename = "Kobe_acc.txt"
  unit_of_acceleration = 1*m/s^2
  P_incident_displacement_filename = "Kobe_disp.txt"
  unit_of_displacement = 1*m
  P_incident_angle = 15
  add_compensation_time = 0.5*s
  source_location = (-150*m, 0*m, -100*m)
  soil_profile_filename = "soil_profile.txt"
  soil_surface at z = 0*m
  unit_of_vs_and_vp = 1*m/s
  unit_of_rho = 1*kg/m^3
  unit_of_damping = absolute
  unit_of_thickness = 1*m;
```

where:

- `No (or #)<.>` is the unique wave field ID/number. The wave field ID does not have to be sequential, any unique positive integer number can be used. Each wave field is an inclined plane P wave field.
- `anticlockwise_angle_of_P_wave_plane_from <x|y|z>` specifies the orientation of the inclined wave field propagation plane. User should give the anticlockwise angle in degrees between the wave propagation plane and the specified reference axis. The reference axis could be x or y or

z. As shown in figure 205.7, the `anticlockwise_angle_of_P_wave_plane_from` x axis is α.

- `P_incident_acceleration_filename` is the filename of a plain text file, which contains the acceleration of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding acceleration. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field implementation in Real-ESSI does NOT conduct any baseline correction on the input motion. The users should perform baseline correction for earthquake motions by themselves.

- `P_incident_displacement_filename` is the filename of a plain text file, which contains the displacement of the input motion. The file should have two columns, where the first column is the accumulated time and the second column is the corresponding displacement. For the DRM loading from a wave field, if the simulation time is longer than the earthquake motion, the remaining simulation will continue with zero motions. The wave field implementation in Real-ESSI does NOT conduct any baseline correction on the input motion. The users should perform baseline correction for earthquake motions by themselves.

- `P_incident_angle` specifies the inclination angle of incident P wave, measured from vertical axis of wave plane to the wave propagation axis. In figure 205.7, the incident angle of P wave is θ.

- `add_compensation_time` is a feature to add zero-motion in the beginning and at the end of the earthquake motion. If the user does not want to add the additional zeros, user can specify compensation time as 0*s.

- `source_location` specify the location of seismic source, where the seismic motion is input as in `P_incident_acceleration_filename` and `P_incident_displacement_filename`, it is used for determining phase of the wave, and the source location can be inside or outside of the model.

- `soil_profile_filename` is a file name for a file that contains the soil properties for each layer. The soil profile file should have fives columns: (i) shear wave velocity, (ii) compressional wave velocity, (iii) density, (iv) damping ratio and (v) thickness of each layer respectively. The soil layers count from the soil surface to the bedrock. The last layer is bedrock, which has four columns only. User should NOT give the thickness of the last layer, as it extends into half-space.

  One Example of soil profile file is given below.

```
// Vs Vp rho damp thickness
  200 333 2000 0.02 100
  250 408 2000 0.02 200
```

```
  2000 3400 2400 0.02
```

- `soil_surface at <x|y|z>` defines the location of soil surface in the global coordinate system of Real-ESSI.

205.3.4.134 Modeling, Wave Field for Creating DRM Loads: DRM Inclined Motion

This command generates inclined DRM motion with pre-defined inclined wave field.

```
generate DRM motion file from wave field # <.> hdf5_file = <string>;
```

One example of generating inclined DRM motion is:

```
generate DRM motion file from wave field # 1 hdf5_file = "DRMinput.hdf5";
```

where

- `wave field # <.>` specifies the inclined plane wave field number which will be used for wave propagation.
- `hdf5_file` specifies the HDF5 file which contains the geometric information about the DRM elements and DRM nodes.

205.3.4.135 Modeling, Imposed Motions: through Loads, Motion Time History, Constant Time Step

Impose motions (displacements, velocities and accelerations) through loads. This one is used if time increment is constant during the analysis. Input files have one column only, corresponding file for displacements, velocities, and accelerations.

```
add load # <.> type imposed motion to node # <.> dof DOFTYPE
time_step = <T>
displacement_scale_unit = <L>
displacement_file = "filename"
velocity_scale_unit = <L/T>
velocity_file = "filename"
acceleration_scale_unit = <L/L^2>
acceleration_file = "filename";
```

The above command generates load to the corresponding node to get the applied imposed motion.

205.3.4.136 Modeling, Imposed Motions: through Loads, Stochastic Motion Time History, Constant Time Step

Impose stochastic motions (uncertain displacements, velocities and accelerations) through stochastic loads. This one is used if time increment is constant during the analysis.

```
add load # <.> type imposed random motions to node # <.> dof DOFTYPE
time_step = <T>
displacement_scale_unit = <L>
displacement_file = "filename"
velocity_scale_unit = <L/T>
velocity_file = "filename"
acceleration_scale_unit = <L/L^2>
acceleration_file = "filename"
penalty_stiffness = <N/L>
using double product # <.>;
```

where

- `DOFTYPE` specify the dof to impose the uncertain motion. It can be either `ux`, `uy` or `uz`.
- `time_step` specify the time step of the imposed uncertain motion.
- `displacement_scale_unit` specify the scale unit of the imposed uncertain displacement polynomial chaos (PC) coefficients.
- `displacement_file` specify the filename of a text file containing PC coefficients of uncertain displacement random process. The number of rows of the file content should be equal to total number of polynomial chaos basis of the displacement random process. The number of columns of the file content should be equal to total number of time steps of the displacement random process. The value at the i^{th} row and j^{th} column of the file gives the PC coefficient of the i^{th} PC basis of the displacement random process at the j^{th} time step.
- `velocity_scale_unit` specify the scale unit of the imposed uncertain velocity polynomial chaos (PC) coefficients.
- `velocity_file` specify the filename of a text file containing PC coefficients of uncertain velocity random process. The number of rows of the file content should be equal to total number of polynomial chaos basis of the velocity random process. The number of columns of the file content should be equal to total number of time steps of the velocity random process. The value at the i^{th} row and j^{th} column of the file gives the PC coefficient of the i^{th} PC basis of the velocity random process at the j^{th} time step.

- `acceleration_scale_unit` specify the scale unit of the imposed uncertain acceleration polynomial chaos (PC) coefficients.

- `acceleration_file` specify the filename of a text file containing PC coefficients of uncertain acceleration random process. The number of rows of the file content should be equal to total number of polynomial chaos basis of the acceleration random process. The number of columns of the file content should be equal to total number of time steps of the acceleration random process. The value at the i^{th} row and j^{th} column of the file gives the PC coefficient of the i^{th} PC basis of the acceleration random process at the j^{th} time step.

- `penalty_stiffness` specify the penalty stiffness for the input of uncertain motion using penalty method. The penalty stiffness is expected to be several magnitudes, e.g., $10^3 \sim 10^6$, larger than the elemental stiffness.

- `double product #` specify the ID of the double product that would be used in the formation of stochastic force. In stochastic finite element method (FEM), the first PC basis for this double product should come from the PC representation of uncertain FEM system response, e.g., uncertain structural displacement. The second PC basis for this double product should come from the uncertain imposed motion representation.

205.3.4.137 Modeling, Imposed Motions: through Loads, Stochastic Random Process Motions, Constant Time Step

Impose a defined random process motions.

This one is used if time increment is constant during the analysis.

```
add load # <.> type imposed random motions to node # <.> dof DOFTYPE
time_step = <T>
uncertain_displacement = random field # <.>
displacement_scale_unit = <L>
penalty_stiffness = <N/L>
using double product # <.>;
```

where

- `DOFTYPE` specify the dof to impose the uncertain motion. It can be either `ux`, `uy` or `uz`.
- `time_step` specify the time step of the imposed uncertain motion.
- `uncertain_displacement` specify the imposed uncertain motion through a defined random field-/process.
- `displacement_scale_unit` specify the scale unit of the imposed uncertain displacement.
- `penalty_stiffness` specify the penalty stiffness for the input of uncertain motion using penalty method. The penalty stiffness is expected to be several magnitudes, e.g., $10^3 \sim 10^6$, larger than the elemental stiffness.
- `double product #` specify the ID of the double product that would be used in the formation of stochastic force. In stochastic finite element method (FEM), the first PC basis for this double product should come from the PC representation of uncertain FEM system response, e.g., uncertain structural displacement. The second PC basis for this double product should come from the uncertain imposed motion representation.

205.3.4.138 Modeling, Imposed Motions: through Loads, Motion Time History, Variable Time Step

Impose motions (displacements, velocities and accelerations) through loads. This one is used if time increment is variable during the analysis. Input files have two columns, first column is time and the second column in corresponding file for displacements, velocities, and accelerations. Time steps have to be the same in each file.

```
add load # <.> type imposed motion to node # <.> dof DOFTYPE
displacement_scale_unit = <displacement>
displacement_file = "filename"
velocity_scale_unit = <velocity>
velocity_file = "filename"
acceleration_scale_unit = <acceleration>
acceleration_file = "filename";
```

The above command generates load to the corresponding node to get the applied imposed motion.

205.3.4.139 Modeling, Imposed Motions: Adding Load for Uniform Acceleration Time History

Defines a non-inertial reference frame from which all displacements are measured. This reference frame (fixed to the base of the model) accelerates according to a given acceleration record. All output quantities are derived from this relative coordinate system (not-inertial). To get total displacements, the twice-integrated acceleration record must be added to the results.

The command is:

```
add load # <.> type uniform acceleration to all nodes dof <.>
  time_step = <T>
  scale_factor = <L/T^2>
  initial_velocity = <L/T>
  acceleration_file = <string>;
```

Where

- `time_step` Is the time step of the record in time units.
- `scale_factor` Is a dimensionless factor with which the record is scaled before it's applied.
- `initial_velocity` Initial velocity for all translational DOFs of the system.
- `acceleration_file` String containing the path (relative or absolute) to the record text file.

File format is a single value of the record in acceleration units (m/s/s) per line for each time step. If a time-step different from the record is used for analysis, then the record is interpolated linearly.

205.3.4.140 Modeling, Imposed Motions: Remove Imposed Motions

Motions can be removed using:

```
remove imposed motion # <.>
```

205.3.4.141 Modeling, Random Variable: Adding Gaussian Random Variables

Gaussian random variable can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Gaussian distribution mean = <.> ↩
    standard_deviation = <.>;
```

where:

- `mean` is the mean of the Gaussian random variable
- `standard_deviation` is the standard deviation of the Gaussian random variable

For example:

```
add random variable # 1 with Gaussian distribution mean = 3.0 ↩
    standard_deviation = 1.0;
```

Adds a Gaussian random variable 1 with mean equal to 3.0 and standard deviation equal to 1.0.

205.3.4.142 Modeling, Random Variable: Adding Gaussian Random Variables with Location

Gaussian random variable with spatial location can be added for probabilistic analysis. The location information of the defined random variable is important to calculate the correlation structure of random field, that can consist of many random variables.

The command is:

```
add random variable # <.> with Gaussian distribution mean = <.> ↩
   standard_deviation = <.> at (<L>, <L>, <L>);
```

where:

- `mean` is the mean of the Gaussian random variable
- `standard_deviation` is the standard deviation of the Gaussian random variable

For example:

```
add random variable # 1 with Gaussian distribution mean = 3.0 ↩
   standard_deviation = 1.0 at (3*m, 0*m, 0*m);
```

Adds a Gaussian random variable 1 with mean equal to 3.0 and standard deviation equal to 1.0 at location $x = 3$m, $y = 0$m and $z = 0$m.

205.3.4.143 Modeling, Random Variable: Adding Lognormal Random Variables

Lognormal random variable can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Lognormal distribution mean = <.> ↩
    standard_deviation = <.>;
```

where:

- `mean` is the mean of the lognormal random variable
- `standard_deviation` is the standard deviation of the lognormal random variable

For example:

```
add random variable # 1 with Lognormal distribution mean = 3.0 ↩
    standard_deviation = 1.0;
```

Adds a Lognormal random variable 1 with mean equal to 3.0 and standard deviation equal to 1.0.

205.3.4.144 Modeling, Random Variable: Adding Lognormal Random Variables with Location

Lognormal random variable with spatial location can be added for probabilistic analysis. The location information of the defined random variable is important to calculate the correlation structure of random field, that can consist of many random variables.

The command is:

```
add random variable # <.> with Lognormal distribution mean = <.> ↩
    standard_deviation = <.> at (<L>, <L>, <L>);
```

where:

- `mean` is the mean of the lognormal random variable
- `standard_deviation` is the standard deviation of the lognormal random variable

For example:

```
add random variable # 1 with Lognormal distribution mean = 3.0 ↩
    standard_deviation = 1.0 at (3*m, 0*m, 0*m);
```

Adds a Lognormal random variable 1 with mean equal to 3.0 and standard deviation equal to 1.0 at location $x = 3$m, $y = 0$m and $z = 0$m.

205.3.4.145 Modeling, Random Variable: Adding Lognormal Random Variables using Logarithmic Input

Lognormal random variable can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Lognormal distribution lognormal_mean = <.> ↩
    lognormal_standard_deviation = <.>;
```

where:

- `lognormal_mean`: μ is the mean of the natural logarithm of the lognormal random variable X
- `lognormal_standard_deviation`: σ is the standard deviation of the natural logarithm of the lognormal random variable X

In other words, for lognormal distributed random variable X with parameters μ and σ, we have:

$$ln(X) \sim N(\mu, \sigma) \tag{205.34}$$

It is noted that the mean m and variance v of lognormal random variable X is related to parameters μ and σ as follows:

$$m = e^{\mu+\sigma^2/2} \tag{205.35}$$

$$v = e^{2\mu+\sigma^2}(e^{\sigma^2} - 1) \tag{205.36}$$

For example:

```
add random variable # 1 with Lognormal distribution lognormal_mean = 3.0 ↩
    lognormal_standard_deviation = 1.0;
```

adds a Lognormal random variable 1. The natural logarithm of such random variable follows Gaussian distribution with mean equal to 3.0 and standard deviation equal to 1.0.

205.3.4.146 Modeling, Random Variable: Adding Lognormal Random Variables using Logarithmic Input with Location

Lognormal random variable with spatial location can be added for probabilistic analysis. The location information of the defined random variable is important to calculate the correlation structure of random field, which can consist of many random variables.

The command is:

```
add random variable # <.> with Lognormal distribution lognormal_mean = <.> ↩
    lognormal_standard_deviation = <.> at (<L>, <L>, <L>);
```

where:

- `lognormal_mean`: μ is the mean of the natural logarithm of the lognormal random variable X
- `lognormal_standard_deviation`: σ is the standard deviation of the natural logarithm of the lognormal random variable X

In other words, for lognormal distributed random variable X with parameters μ and σ, we have:

$$ln(X) \sim N(\mu, \sigma) \tag{205.37}$$

It is noted that the mean m and variance v of lognormal random variable X is related to parameters μ and σ as follows:

$$m = e^{\mu+\sigma^2/2} \tag{205.38}$$

$$v = e^{2\mu+\sigma^2}(e^{\sigma^2} - 1) \tag{205.39}$$

For example:

```
add random variable # 1 with Lognormal distribution lognormal_mean = 3.0 ↩
    lognormal_standard_deviation = 1.0 at (3*m, 0*m, 0*m);
```

Adds a Lognormal random variable 1 at location $x = 3$m, $y = 0$m and $z = 0$m. The natural logarithm of such random variable follows Gaussian distribution with mean equal to 3.0 and standard deviation equal to 1.0.

205.3.4.147 Modeling, Random Variable: Adding Gamma Random Variables using Shape and Scale Parameters

Random variable following Gamma distribution can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Gamma distribution shape_parameter = <.> ↩
    scale_parameter = <.>;
```

where:

- `shape_parameter` is the shape parameter of the Gamma random variable
- `scale_parameter` is the scale parameter of the Gamma random variable

For example:

```
add random variable # 1 with Gamma distribution shape_parameter = 5.0 ↩
    scale_parameter = 2.0;
```

Adds a Gamma random variable 1 with the shape parameter equal to 5.0 and scale parameter equal to 2.0.

205.3.4.148 Modeling, Random Variable: Adding Gamma Random Variables using Shape and Scale Parameters with Location

Random variable following Gamma distribution can be added for probabilistic analysis.

The location information of the defined random variable is important to calculate the correlation structure of random field, that can consist of many random variables.

The command is:

```
add random variable # <.> with Gamma distribution shape_parameter = <.> ↩
    scale_parameter = <.> at (<L>, <L>, <L>);
```

where:

- `shape_parameter` is the shape parameter of the Gamma random variable
- `scale_parameter` is the scale parameter of the Gamma random variable

For example:

```
add random variable # 1 with Gamma distribution shape_parameter = 5.0 ↩
    scale_parameter = 2.0 at (3*m, 0*m, 0*m);
```

Adds a Gamma random variable 1 with the shape parameter equal to 5.0 and scale parameter equal to 2.0 at location $x = 3$m, $y = 0$m and $z = 0$m.

205.3.4.149 Modeling, Random Variable: Adding Gamma Random Variables using Mean and Standard Deviation Parameters

Random variable for given mean and standard deviation parameter following Gamma distribution can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Gamma distribution mean = <.> standard_deviation ↩
    = <.>;
```

where:

- `mean` is the mean of the Gamma random variable
- `standard_deviation` is the standard deviation of the Gamma random variable

For example:

```
add random variable # 1 with Gamma distribution mean = 5.0 standard_deviation = ↩
    2.0;
```

Adds a Gamma random variable 1 with mean equal to 5.0 and standard deviation equal to 2.0.

205.3.4.150 Modeling, Random Variable: Adding Gamma Random Variables using Mean and Standard Deviation Parameters with Location

Random variable for given mean and standard deviation parameter following Gamma distribution can be added for probabilistic analysis.

The location information of the defined random variable is important to calculate the correlation structure of random field, that can consist of many random variables.

The command is:

```
add random variable # <.> with Gamma distribution mean = <.> standard_deviation ↩
    = <.> at (<L>, <L>, <L>);
```

where:

- `mean` is the mean of the Gamma random variable
- `standard_deviation` is the standard deviation of the Gamma random variable

For example:

```
add random variable # 1 with Gamma distribution mean = 5.0 standard_deviation = ↩
    2.0 at (3*m, 0*m, 0*m);
```

Adds a Gamma random variable 1 with mean equal to 5.0 and standard deviation equal to 2.0 at location $x = 3$m, $y = 0$m and $z = 0$m.

205.3.4.151 Modeling, Random Variable: Adding Weibull Random Variables using Shape and Scale Parameters

Random variable following Weibull distribution can be added for probabilistic analysis.

The command is:

```
add random variable # <.> with Weibull distribution shape_parameter = <.> ↩
    scale_parameter = <.>;
```

where:

- `shape_parameter` is the shape parameter of the Weibull random variable
- `scale_parameter` is the scale parameter of the Weibull random variable

For example:

```
add random variable # 1 with Weibull distribution shape_parameter = 5.0 ↩
    scale_parameter = 2.0;
```

Adds a Weibull random variable 1 with the shape parameter equal to 5.0 and scale parameter equal to 2.0.

205.3.4.152 Modeling, Random Variable: Adding Weibull Random Variables using Shape and Scale Parameters with Location

Random variable following Weibull distribution can be added for probabilistic analysis.

The location information of the defined random variable is important to calculate the correlation structure of random field, which can consist of many random variables.

The command is:

```
add random variable # <.> with Weibull distribution shape_parameter = <.> ↩
    scale_parameter = <.> at (<L>, <L>, <L>);
```

where:

- `shape_parameter` is the shape parameter of the Weibull random variable
- `scale_parameter` is the scale parameter of the Weibull random variable

For example:

```
add random variable # 1 with Weibull distribution shape_parameter = 5.0 ↩
    scale_parameter = 2.0 at (3*m, 0*m, 0*m);
```

adds a Weibull random variable 1 with the shape parameter equal to 5.0 and scale parameter equal to 2.0 at location $x = 3$m, $y = 0$m and $z = 0$m.

205.3.4.153 Modeling, Random Variable: Remove Random Variables

Remove random variables.

The command is:

```
remove random variable # <.> ;
```

For example:

```
remove random variable # 2;
```

Remove random variable 2 from the analysis.

205.3.4.154 Modeling, Random Variable: Hermite Polynomial Chaos Expansion

Hermite polynomial chaos expansion Xiu (2010) can be performed for random variable with any type of distribution.

The command is:

```
Hermite polynomial chaos expansion to random variable # <.> with order <.>;
```

where:

- `order` specifies the order of Hermite polynomial chaos expansion

For example:

```
Hermite polynomial chaos expansion to random variable # 1 with order 6;
```

Performs Hermite polynomial chaos expansion to random variable 1 using Hermite polynomial chaos up to order 6.

205.3.4.155 Modeling, Random Variable: Output Hermite Polynomial Chaos Expansion Result

A HDF5 (.hdf5) file contains computed polynomial chaos coefficients of Hermite polynomial chaos expansion for random variable can be generated.

The command is:

```
generate Hermite polynomial chaos expansion file from random variable # <.> ↩
   hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the output hdf5 file.

The generated hdf5 file contains two datasets:

- Dataset PC is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis. $\boldsymbol{PC_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} multi-dimensional Hermite PC basis.
- Dataset PC Coefficients is a column vector. The i^{th} component of PC Coefficients is the polynomial chaos coefficient corresponding to the i^{th} PC base as described by PC.

For example:

```
generate Hermite polynomial chaos expansion file from random variable # 2 ↩
   hdf5_file = "PC_RV1.hdf5";
```

Generate HDF5 file named "PC_RV2.hdf5" that contains the computed polynomial chaos coefficients of Hermite polynomial chaos expansion of random variable 2.

205.3.4.156 Modeling, Random Variable: Hermite Polynomial Chaos Expansion & Output Results

Hermite polynomial chaos expansion Xiu (2010) can be performed for random variable with any type of distribution. A HDF5 (.hdf5) file contains computed polynomial chaos coefficients of Hermite polynomial chaos expansion for random variable can be generated.

The command is:

```
generate Hermite polynomial chaos expansion file from random variable # <.> ↩
    with order <.> hdf5_file = "file_name";
```

where:

- `order` specifies the order of Hermite polynomial chaos expansion
- `file_name` is a string that specifies the name of the output hdf5 file.

The generated hdf5 file contains two datasets:

- Dataset PC is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis. $\boldsymbol{PC_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} multi-dimensional Hermite PC basis.
- Dataset PC Coefficients is a column vector. The i^{th} component of PC Coefficients is the polynomial chaos coefficient corresponding to the i^{th} PC base as described by PC.

For example:

```
generate Hermite polynomial chaos expansion file from random variable # 1 with ↩
    order 6 hdf5_file = "PC_RV1.hdf5";
```

Perform Hermite polynomial chaos expansion to random variable 1 using Hermite polynomial chaos up to order 6 and generate HDF5 file named "PC_RV1.hdf5" that contains the computed polynomial chaos coefficients.

205.3.4.157 Modeling, Random Field: Adding Random Field with Dimension and Order

Random field with specific Hermite polynomial chaos dimension and order can be added for probabilistic analysis.

The command is:

```
add random field # <.> with Hermite polynomial chaos dimension <.> order <.>;
```

where:

- `dimension` defines the dimension of Hermite polynomial chaos expansion of the random field
- `order` defines the order of Hermite polynomial chaos expansion of the random field

For example:

```
add random field # 1 with Hermite polynomial chaos dimension 4 order 3;
```

adds random field 1 with Hermite polynomial chaos expansion of dimension 4 and order 3.

205.3.4.158 Modeling, Random Field: Define Global Dimension Index of Random Field

Define the global dimension index of local Hermite polynomial chaos (PC) dimension for the uncertainty characterization of the random field.

If the global dimension index is not specified, by default Real-ESSI takes the ID of local Hermite polynomial chaos (PC) dimension as the global dimension index.

Please note that correctly specifying global dimension index for local Hermite PC dimensions of the random field is very important, especially when there are multiple random fields exist in the system and need to compute the triple products of Hermite PC basis of these random fields.

The command is:

```
define random field # <> Hermite polynomial chaos dimension # <> as global ↩
   dimension # <>;
```

where:

- `Hermite polynomial chaos dimension` defines the local dimension ID for Hermite polynomial chaos (PC) basis of the random field. It should be an integer no more than the total number of dimensions adopted in the Hermite polynomial chaos (PC) Karhunen Loève expansion of the random field.
- `global dimension` defines the corresponding global dimension index for the local Hermite PC dimension

For example:

```
define random field # 1 Hermite polynomial chaos dimension # 1 as global ↩
   dimension # 10;
```

defines the global dimension index of local Hermite PC dimension 1 of random field 1 is 10.

205.3.4.159 Modeling, Random Field: Define Global Dimension Index of Random Field from File Input

Define the global dimension index of local Hermite polynomial chaos (PC) dimension for the uncertainty characterization of the random field using inputs from a text file.

If the global dimension index is not specified, by default Real-ESSI takes the ID of local Hermite polynomial chaos (PC) dimension as the global dimension index.

Please note that correctly specifying global dimension index for local Hermite PC dimensions of the random field is very important, especially when there are multiple random fields exist in the system and need to compute the triple products of Hermite PC basis of these random fields.

The command is:

```
define random field # <.> Hermite polynomial chaos dimension from ↩
    dimension_file = "file_name";
```

where:

- `dimension_file` specifies the name of a text file that contains two columns: The first column is local dimension ID of Hermite PC basis; The second column is corresponding global dimension ID for the local dimension of Hermite PC basis. Comments lines starts with "//"

For example:

```
define random field # 1 Hermite polynomial chaos dimension from dimension_file ↩
    = "dimension_info_RF1.txt";
```

defines the global dimension index of local Hermite PC dimensions for random field 1 with input from a text file "dimension_info_RF1.txt".

An example file of "dimension_info_RF1.txt" is provided below:

```
//====================================================================
// This file specify the global dimension index of local dimensions
// of Hermite PC basis
// File should have two columns separated by spaces:
// The first column is local KL dimension ID
// The second column is the global KL dimension ID
//====================================================================
1 10
2 11
3 12
4 13
```

205.3.4.160 Modeling, Random Field: Set Number of Polynomial Chaos Terms of Random Field

Specify the number of polynomial chaos terms of a random field involved in the stochastic finite element analysis. By default, the full polynomial chaos basis of a random field would be used for uncertainty propagation. The specified number of polynomial chaos terms in this command is used for truncation of polynomial chaos basis.

The command is:

```
set random field # <.> polynomial_chaos_terms = <.>;
```

where:

- `polynomial_chaos_terms` defines the number of truncated Hermite polynomial chaos basis of the random field

For example:

```
set random field # 1 polynomial_chaos_terms = 100;
```

Set the number of truncated Hermite polynomial chaos basis of random field 1 to be 100.

205.3.4.161 Modeling, Random Field: Adding Random Field with Zero Correlation

Random field with uncorrelated random variables can be added for probabilistic analysis.

The command is:

```
add random field # <.> with zero correlation;
```

205.3.4.162 Modeling, Random Field: Adding Random Field with Exponential Correlation

Random field with exponential correlation can be added for probabilistic analysis.

The command is:

```
add random field # <.> with exponential correlation correlation_length = <L> ;
```

where:

- `correlation_length` l_c defines the correlation length of random field such that the correlation $\rho(RV_i, RV_j)$ of any two random variables RV_i and RV_j is given as:

$$\rho(RV_i, RV_j) = exp(-d/l_c) \tag{205.40}$$

Variable d is the Euclidean distance between RV_i and RV_j, that is calculated from the spatial locations of random variables within the random field.

For example:

```
add random field # 1 with exponential correlation correlation_length = 10*m;
```

adds an exponentially correlated random field number 1 with correlation length 10m.

205.3.4.163 Modeling, Random Field: Adding Random Field with Triangular Correlation

Random field with triangular correlation can be added for probabilistic analysis.

The command is:

```
add random field # <.> with triangular correlation correlation_length = <L> ;
```

where:

- `correlation_length` l_c defines the correlation length of random field such that the correlation $\rho(RV_i, RV_j)$ of any two random variables RV_i and RV_j is given as:

$$\rho(RV_i, RV_j) = \max\{1 - \mathrm{d}/\mathrm{l_c},\ 0\} \tag{205.41}$$

Variable d is the Euclidean distance between RV_i and RV_j, that is calculated from the spatial locations of random variables within the random field.

For example:

```
add random field # 1 with triangular correlation correlation_length = 10*m;
```

Adds an triangular correlated random field number 1 with correlation length 10m.

205.3.4.164 Modeling, Random Field: Adding Random Field with Exponentially Damped Cosine Correlation

Random field with exponentially damped cosine correlation can be added for probabilistic analysis.

The command is:

```
add random field # <.> with exponentially damped cosine correlation ↩
   correlation_length = <L> ;
```

where:

- `correlation_length` l_c defines the correlation length of random field such that the correlation $\rho(RV_i, RV_j)$ of any two random variables RV_i and RV_j is given as:

$$\rho(RV_i, RV_j) = exp(-d/l_c) * cos(d/l_c) \tag{205.42}$$

Variable d is the Euclidean distance between RV_i and RV_j, that is calculated from the spatial locations of random variables within the random field.

For example:

```
add random field # 1 with exponentially damped cosine correlation ↩
   correlation_length = 10*m;
```

adds an exponentially damped cosine correlated random field number 1 with correlation length 10m.

205.3.4.165 Modeling, Random Field: Adding Random Field with Gaussian Correlation

Random field with Gaussian correlation can be added for probabilistic analysis.

The command is:

```
add random field # <.> with Gaussian correlation correlation_length = <L> ;
```

where:

- `correlation_length` l_c defines the correlation length of random field such that the correlation $\rho(RV_i, RV_j)$ of any two random variables RV_i and RV_j is given as:

$$\rho(RV_i, RV_j) = exp(-d^2/l_c^2) \tag{205.43}$$

Variable d is the Euclidean distance between RV_i and RV_j, that is calculated from the spatial locations of random variables within the random field.

For example:

```
add random field # 1 with Gaussian correlation correlation_length = 10*m;
```

adds a random field number 1 with Gaussian correlation and correlation length 10m.

205.3.4.166 Modeling, Random Field: Remove Random Fields

Remove random Fields.

The command is:

```
remove random field # <.> ;
```

For example:

```
remove random field # 2;
```

Remove random field 2 from the analysis.

205.3.4.167 Modeling, Random Field: Adding Random Variable to Random Field

Add random variable to random field.

The command is:

```
add random variable # <.> to random field # <.>;
```

For example:

```
add random variable # 2 to random field # 1;
```

Adds random variable 2 to random field 1.

205.3.4.168 Modeling, Random Field: Remove Random Variable From Random Field

Remove random variable from random field.

The command is:

```
remove random variable # <.> from random field # <.>;
```

For example:

```
remove random variable # 2 from random field # 1;
```

Remove random variable 2 from random field 1.

205.3.4.169 Modeling, Random Field: Hermite Polynomial Chaos Karhunen Loève Expansion

Perform Hermite polynomial chaos Karhunen Loève expansion for random field of any arbitrary marginal distribution and correlation structure according to Sakamoto and Ghanem (2002).

The command is:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
   Hermite polynomial chaos dimension <.> order <.>;
```

Where:

- `dimension`: specifies the number of dimensions of Hermite polynomial chaos to capture the correlation structure of the random field
- `order`: specifies the order of Hermite polynomial chaos to capture the marginal distribution of the random field

For example:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # 1 with ↩
   Hermite polynomial chaos dimension 4 order 3;
```

Perform the Hermite polynomial chaos Karhunen Loève expansion for random field 1 using Hermite polynomial chaos of dimension 4 and order 3.

205.3.4.170 Modeling, Random Field: Hermite Polynomial Chaos Karhunen Loève Expansion with Inverse Order

Perform Hermite polynomial chaos Karhunen Loève expansion for random field of any arbitrary marginal distribution and correlation structure according to Sakamoto and Ghanem (2002).

The user can explicitly state the order used in the inversion of underlying Gaussian correlation kernel. The command is:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
    Hermite polynomial chaos dimension <.> order <.> ↩
    correlation_kernel_inverse_order = <.>;
```

Where:

- `dimension`: specifies the number of dimensions of Hermite polynomial chaos to capture the correlation structure of the random field
- `order`: specifies the order of Hermite polynomial chaos to capture the marginal distribution of the random field
- `correlation_kernel_inverse_order`: specifies the order used in the inversion of underlying Gaussian correlation kernel. For the exact Gaussian kernel inversion, set up `correlation_kernel_inverse_order` equal to order of Hermite polynomial chaos. `correlation_kernel_inverse_order` should not exceed `order` of Hermite polynomial chaos. If `correlation_kernel_inverse_order` is not stated, by default linear Gaussian kernel inversion, i.e., `correlation_kernel_inverse_order` equal to 1, is performed as the approximation of higher order inversion. See Sakamoto and Ghanem (2002) for more details.

For example:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # 1 with ↩
    Hermite polynomial chaos dimension 4 order 2 ↩
    correlation_kernel_inverse_order = 2;
```

Perform the Hermite polynomial chaos Karhunen Loève expansion for random field 1 using Hermite polynomial chaos of dimension 4 and order 2. The 2^{nd} order Gaussian correlation kernel inversion is adopted.

205.3.4.171 Modeling, Random Field: Hermite Polynomial Chaos Karhunen Loève Expansion with Number of FE Elements Larger than Dimension of Hermite Polynomials

Perform Hermite polynomial chaos Karhunen Loève expansion for random field described by either Gaussian or lognormal distribution and Gaussian auto-correlation coefficient function. The PCE coefficients are computed using Eq. (11) from Sakamoto and Ghanem (2002).

This command should be used when the number of Gauss points (GPs), i.e., integration points, is much larger than the number of discrete locations needed to solve the eigenproblem of auto-covariance, that is, than the dimension of Hermite polynomials. This allows to save some computation time. In such case, the eigenproblem of auto-covariance function will be solved instead of the eigenproblem of auto-covariance matrix.

Here, "shear beam" element is used. It has only one GP, in the middle of an element. Hence the number of GPs is here equal to the number of FE elements. It is easier for a user to input the number of FE elements than to input the number of GPs.

The command is:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
   Hermite polynomial chaos dimension <.> order <.> ↩
   correlation_kernel_inverse_order = 1 number_of_FE_elements = <.>;
```

Where:

- `dimension`: specifies the number of dimensions of Hermite polynomial chaos to capture the correlation structure of the random field, in other words, it is the number of discrete points used in the solution of the eigenproblem of auto-covariance
- `order`: specifies the order of Hermite polynomial chaos to capture the marginal distribution of the random field
- `correlation_kernel_inverse_order = 1`: does not specify anything and must be equal to 1
- `number_of_FE_elements`: here, "shear beam" element is used and it has only one GP, in the middle of an element, hence the number of FE elements is here equal to the number of GPs, the user must provide (via command `add random variable...`) the type of distribution (here, either Gaussian or lognormal), mean and standard deviation in the middle of each FE element (mean and standard deviation at discrete points used in the solution of the eigenproblem of auto-covariance function are interpolated using the values at GPs), they should be sorted for increasing coordinates in 1D

  `number_of_FE_elements = dimension` is equivalent to:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> ↩
   with Hermite polynomial chaos dimension <.> order <.> ;
```

and:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> ↩
   with Hermite polynomial chaos dimension <.> order <.> ↩
   correlation_kernel_inverse_order = 1;
```

For example:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # 1 with ↩
   Hermite polynomial chaos dimension 4 order 2 ↩
   correlation_kernel_inverse_order = 1 number_of_FE_elements = 20;
```

Perform the Hermite polynomial chaos Karhunen Loève expansion for random field 1 using Hermite polynomial chaos of dimension 4 and order 2 with number of FE elements 20 (i.e., with 20 GPs, in the middle of elements).

Command:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
   Hermite polynomial chaos dimension <.> order <.> number_of_FE_elements = <.>;
```

with optional argument `number_of_FE_elements` cannot be defined because

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
   Hermite polynomial chaos dimension <.> order <.> ↩
   correlation_kernel_inverse_order = <.>;
```

with optional argument `correlation_kernel_inverse_order` exists already.

205.3.4.172 Modeling, Random Field: Hermite Polynomial Chaos Karhunen Loève Expansion Using HDF5 Input

Add a random field with marginal distribution and correlation information defined in a given HDF5 (.hdf5) file. Perform Hermite polynomial chaos Karhunen Loève expansion for the random field.

The command is:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
   Hermite polynomial chaos dimension <.> order <.> hdf5_file = "file_name";
```

Where:

- `dimension`: specifies the number of dimensions of Hermite polynomial chaos to capture the correlation structure of the random field
- `order`: specifies the order of Hermite polynomial chaos to capture the marginal distribution of the random field
- `hdf5_file`: specifies the filename of the input HDF5 file that defines the marginal distribution and correlation information of the random field

The input HDF5 file should contain the following datasets:

- Dataset Random Field contains a single integer, which is the ID of the random field.
- Dataset Marginal Mean is a column vector specifying marginal mean of the random field corresponding to each random variable.
- Dataset Marginal Variance is a column vector specifying marginal variance of the random field for each random variable.
- Dataset Marginal Distributions is a column vector integers specifying the marginal distribution IDs of the random field for each random variable. Specifically, the ID is 1 for Gaussian distribution, 2 for Lognormal distribution, 3 for Gamma distribution and 4 for Weibull distribution.
- Dataset Correlation is a 2D array specifying correlation of the random field among random variables.
- Dataset PC Order contains a single integer, which specifies the order of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset PC Dimension contains a single integer, which specifies the dimension of Hermite polynomial chaos (PC) Karhunen Loève expansion.

- Dataset Index to Global Dimension contains a column vector of integers, which specifies the index of corresponding global PC dimension for each local PC dimension used in the uncertainty expansion of the random field.

For example:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # 1 with ↩
   Hermite polynomial chaos dimension 4 order 4 hdf5_file = "PC_RF1.hdf5";
```

Perform the Hermite polynomial chaos Karhunen Loève expansion for random field 1 using Hermite polynomial chaos of dimension 4 and order 4 with input marginal distribution and correlation information defined in HDF5 file "PC_RF1.hdf5".

205.3.4.173 Modeling, Random Field: Hermite Polynomial Chaos Karhunen Loève Expansion with Inverse Order Using HDF5 Input

Add a random field with marginal distribution and correlation information defined in a given HDF5 (.hdf5) file. Perform Hermite polynomial chaos Karhunen Loève expansion for the random field.

The user can explicitly state the order used in the inversion of underlying Gaussian correlation kernel.

The command is:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # <.> with ↩
    Hermite polynomial chaos dimension <.> order <.> ↩
    correlation_kernel_inverse_order = <.> hdf5_file = "file_name";
```

Where:

- `dimension`: specifies the number of dimensions of Hermite polynomial chaos to capture the correlation structure of the random field
- `order`: specifies the order of Hermite polynomial chaos to capture the marginal distribution of the random field
- `correlation_kernel_inverse_order`: specifies the order used in the inversion of underlying Gaussian correlation kernel. For the exact Gaussian kernel inversion, set up `correlation_kernel_inverse_order` equal to `order` of Hermite polynomial chaos. `correlation_kernel_inverse_order` should not exceed `order` of Hermite polynomial chaos. If `correlation_kernel_inverse_order` is not stated, by default linear Gaussian kernel inversion, i.e., `correlation_kernel_inverse_order` equal to 1, is performed as the approximation of higher order inversion. See Sakamoto and Ghanem (2002) for more details.
- `hdf5_file`: specifies the filename of the input HDF5 file that defines the marginal distribution and correlation information of the random field

The input HDF5 file should contain the following datasets:

- Dataset Random Field contains a single integer, which is the ID of the random field.
- Dataset Marginal Mean is a column vector specifying marginal mean of the random field corresponding to each random variable.
- Dataset Marginal Variance is a column vector specifying marginal variance of the random field for each random variable.

- Dataset Marginal Distributions is a column vector integers specifying the marginal distribution IDs of the random field for each random variable. Specifically, the ID is 1 for Gaussian distribution, 2 for Lognormal distribution, 3 for Gamma distribution and 4 for Weibull distribution.
- Dataset Correlation is a 2D array specifying correlation of the random field among random variables.
- Dataset PC Order contains a single integer, which specifies the order of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset PC Dimension contains a single integer, which specifies the dimension of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset Index to Global Dimension contains a column vector of integers, which specifies the index of corresponding global PC dimension for each local PC dimension used in the uncertainty expansion of the random field.

For example:

```
Hermite polynomial chaos Karhunen Loeve expansion to random field # 1 with ↩
   Hermite polynomial chaos dimension 4 order 4 ↩
   correlation_kernel_inverse_order = 3 hdf5_file = "PC_RF1.hdf5";
```

Perform the Hermite polynomial chaos Karhunen Loève expansion for random field 1 using Hermite polynomial chaos of dimension 4 and order 4. The 3^{rd} order Gaussian correlation kernel inversion is adopted. The input marginal distribution and correlation information are defined in HDF5 file ”PC_RF1.hdf5”.

205.3.4.174 Modeling, Random Field: Output Hermite Polynomial Chaos Karhunen Loève Expansion Result

A HDF5 (.hdf5) file contains all the information for Hermite polynomial chaos Karhunen Loève expansion for random field can be generated.

The command is:

```
generate Hermite polynomial chaos Karhunen Loeve expansion file from random ↩
   field # <.> hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the output hdf5 file.

The generated hdf5 file contains the following datasets:

- Dataset Random Field contains a single integer, which is the ID of the random field.
- Dataset Random Variables contains a column vector of integers, which are the IDs of the random variables that constitute the random field.
- Dataset Marginal Mean is a column vector specifying marginal mean of the random field corresponding to each random variable.
- Dataset Marginal Variance is a column vector specifying marginal variance of the random field for each random variable.
- Dataset Marginal Distributions is a column vector integers specifying the marginal distribution IDs of the random field for each random variable. Specifically, the ID is 1 for Gaussian distribution, 2 for Lognormal distribution, 3 for Gamma distribution and 4 for Weibull distribution.
- Dataset Correlation is a 2D array specifying correlation of the random field among random variables.
- Dataset PC Order contains a single integer, which specifies the order of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset PC Dimension contains a single integer, which specifies the dimension of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset Index to Global Dimension contains a column vector of integers, which specifies the index of corresponding global PC dimension for each local PC dimension used in the uncertainty expansion of the random field.

- Dataset PC is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis. $\boldsymbol{PC_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} multi-dimensional Hermite PC basis.
- Dataset PC Coefficients is a 2D array. The j^{th} component of the i^{th} row is the polynomial chaos coefficient corresponding to the j^{th} PC base as described by PC for the i^{th} random variable specified in Random Variables.
- Dataset PC Variance is a column vector specifying the variances of Hermite PC basis.

For example:

```
generate Hermite polynomial chaos Karhunen Loeve expansion file from random ↩
    field # 1 hdf5_file = "PC_RF1.hdf5";
```

Generate HDF5 file named “PC_RF1.hdf5” that contains all the information for Hermite polynomial chaos Karhunen Loève expansion of random field 1.

205.3.4.175 Modeling, Random Field: Adding Random Field from Hermite Polynomial Chaos Karhunen Loève Expansion HDF5 File

Add a random field with marginal distribution, correlation information and multi-dimensional Hermite polynomial chaos (PC) coefficients specified in a given HDF5 (.hdf5) file.

The command is:

```
add random field # <.> with Hermite polynomial chaos Karhunen Loeve expansion ↩
   hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the input hdf5 file.

The input hdf5 file should contain the following datasets:

- Dataset Random Field contains a single integer, that represents the ID of the random field.
- Dataset Random Variables contains a column vector of integers, that are the IDs of the random variables that constitute the random field.
- Dataset Marginal Mean is a column vector specifying marginal mean of the random field corresponding to each random variable.
- Dataset Marginal Variance is a column vector specifying marginal variance of the random field for each random variable.
- Dataset Marginal Distributions is a column vector of integers specifying the marginal distribution IDs of the random field for each random variable. Specifically, the ID is 1 for Gaussian distribution, 2 for Lognormal distribution, 3 for Gamma distribution and 4 for Weibull distribution.
- Dataset Correlation is a 2D array specifying correlation of the random field among random variables.
- Dataset PC Order contains a single integer, that specifies the order of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset PC Dimension contains a single integer, that specifies the dimension of Hermite polynomial chaos (PC) Karhunen Loève expansion.
- Dataset Index to Global Dimension contains a column vector of integers, that specify the index of corresponding global PC dimension for each local PC dimension used in the uncertainty expansion of the random field.

- Dataset PC is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis. $\boldsymbol{PC_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} multi-dimensional Hermite PC basis.
- Dataset PC Coefficients is a 2D array. The j^{th} component of the i^{th} row is the polynomial chaos coefficient corresponding to the j^{th} PC base as described by PC for the i^{th} random variable specified in Random Variables.
- Dataset PC Variance is a column vector specifying the variances of Hermite PC basis.

For example:

```
add random field # 1 with Hermite polynomial chaos Karhunen Loeve expansion ↩
   hdf5_file = "PC_RF1.hdf5";
```

Add random field 1 with the marginal distribution, correlation structure and Hermite polynomial chaos Karhunen Loève expansion information defined in HDF5 file named “PC_RF1.hdf5”.

205.3.4.176 Modeling, Random Field: Adding Random Field from Marginal Distribution and Correlation

Add a random field with specified marginal distribution and correlation information.

The command is:

```
add random field # <.> with <distribution_type> distribution
marginal_mean_file = "file_name"
marginal_standard_deviation_file = "file_name"
correlation_file = "file_name";
```

where:

- `distribution_type` is a string specifying the marginal distribution type of the random field, can be `Gaussian`, `Lognormal`, or `Gamma`.
- `marginal_mean_file` is a string specifying the name of a plain text file that contains a single column of marginal mean of the random field.
- `marginal_standard_deviation_file` is a string specifying the name of a plain text file that contains a single column of marginal standard deviation of the random field.
- `correlation_file` is a string specifying the name of a plain text file that contains a 2D array of the correlation structure of the random field.

205.3.4.177 Modeling, Random Field: Add Triple Product of Hermite Polynomial Chaos Basis

Compute and add triple product of Hermite polynomial chaos basis from three different random fields.

The command is:

```
add triple product # <.> with Hermite polynomial chaos from random field (<.>, ↩
   <.>, <.>);
```

For example:

```
add triple product # 1 with Hermite polynomial chaos from random field (1, 2, 3);
```

Compute and add triple product #1 with Hermite polynomial chaos basis from random field 1, 2 and 3;

205.3.4.178 Modeling, Random Field: Add Double Product of Hermite Polynomial Chaos Basis

Compute and add double product of Hermite polynomial chaos basis from two different random fields.

The command is:

```
add double product # <.> with Hermite polynomial chaos from random field (<.>, ↩
    <.>);
```

For example:

```
add double product # 1 with Hermite polynomial chaos from random field (2, 3);
```

Compute and add double product #1 with Hermite polynomial chaos basis from random field 2 and 3;

205.3.4.179 Modeling, Random Field: Generate Triple Product of Hermite Polynomial Chaos Basis

The computation of triple product of Hermite polynomial chaos basis for different random fields is a key part for stochastic finite element analysis.

A HDF5 (.hdf5) file contains triple product of Hermite polynomial chaos basis for random fields can be generated.

The command is:

```
generate triple product of Hermite polynomial chaos from random field (<.>, ↩
    <.>, <.>) hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the output HDF5 file.

The generated HDF5 file contains the following datasets:

- Dataset PC1 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC1_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC1.
- Dataset PC1 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC1.
- Dataset PC1 Variance is a column vector specifying the variances of basis PC1.
- Dataset PC2 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC2_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC2.
- Dataset PC2 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC2.
- Dataset PC2 Variance is a column vector specifying the variances of basis PC2.
- Dataset PC3 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC3_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC3.
- Dataset PC3 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC3.

- Dataset PC3 Variance is a column vector specifying the variances of basis PC3.
- Dataset Triple Product is a column vector containing the non-zero triple products of polynomial chaos basis from PC1, PC2 and PC3.
- Dataset Triple Product PC1 Index is a column vector containing the indexes of polynomial chaos basis from PC1 that contributes to the non-zero triple products in dataset Triple Product.
- Dataset Triple Product PC2 Index is a column vector containing the indexes of polynomial chaos basis from PC2 that contributes to the non-zero triple products in dataset Triple Product.
- Dataset Triple Product PC3 Index is a column vector containing the indexes of polynomial chaos basis from PC3 that contributes to the non-zero triple products in dataset Triple Product.

For example:

```
generate triple product of Hermite polynomial chaos from random field (1, 2, 3) ↩
    hdf5_file = "Triple_product_4(3)_4(3)_4(3).hdf5";
```

Compute the triple product of Hermite polynomial chaos basis of random field 1, 2 and 3 and write all the results into a HDF5 file named "Triple_product_4(3)_4(3)_4(3).hdf5";

205.3.4.180 Modeling, Random Field: Generate Double Product of Hermite Polynomial Chaos Basis

The computation of double product of Hermite polynoial chaos basis for different random fields is a key part for stochastic finite element analysis.

A HDF5 (.hdf5) file contains double product of Hermite polynomial chaos basis for random fields can be generated.

The command is:

```
generate double product of Hermite polynomial chaos from random field (<.>, ↩
    <.>) hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the output HDF5 file.

The generated HDF5 file contains the following datasets:

- Dataset PC1 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC1_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC1.
- Dataset PC1 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC1.
- Dataset PC1 Variance is a column vector specifying the variances of basis PC1.
- Dataset PC2 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC2_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC2.
- Dataset PC2 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC2.
- Dataset PC2 Variance is a column vector specifying the variances of basis PC2.
- Dataset Double Product is a column vector containing the non-zero double products of polynomial chaos basis from PC1 and PC2.
- Dataset Double Product PC1 Index is a column vector containing the indexes of polynomial chaos basis from PC1 that contributes to the non-zero double products in dataset Double Product.

- Dataset Double Product PC2 Index is a column vector containing the indexes of polynomial chaos basis from PC2 that contributes to the non-zero double products in dataset Double Product.

For example:

```
generate double product of Hermite polynomial chaos from random field (1, 2) ↩
   hdf5_file = "doubleproduct_153(2)_150(1).hdf5";
```

Compute the triple product of Hermite polynomial chaos basis of random field 1 and 2 and write all the results into a HDF5 file named "doubleproduct_153(2)_150(1).hdf5";

205.3.4.181 Modeling, Random Field: Add Triple Product of Hermite Polynomial Chaos Basis Using HDF5 Input

Add triple product of Hermite polynomial chaos basis using HDF5 input.

The command is:

```
add triple product # <.> from hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the input HDF5 file.

The input HDF5 file should contain the following datasets:

- Dataset PC1 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC1_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC1.
- Dataset PC1 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC1.
- Dataset PC1 Variance is a column vector specifying the variances of basis PC1.
- Dataset PC2 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC2_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC2.
- Dataset PC2 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC2.
- Dataset PC2 Variance is a column vector specifying the variances of basis PC2.
- Dataset PC3 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC3_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC3.
- Dataset PC3 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC3.
- Dataset PC3 Variance is a column vector specifying the variances of basis PC3.
- Dataset Triple Product is a column vector containing the non-zero triple products of polynomial chaos basis from PC1, PC2 and PC3.

- Dataset Triple Product PC1 Index is a column vector containing the indexes of polynomial chaos basis from PC1 that contributes to the non-zero triple products in dataset Triple Product.
- Dataset Triple Product PC2 Index is a column vector containing the indexes of polynomial chaos basis from PC2 that contributes to the non-zero triple products in dataset Triple Product.
- Dataset Triple Product PC3 Index is a column vector containing the indexes of polynomial chaos basis from PC3 that contributes to the non-zero triple products in dataset Triple Product.

For example:

```
add triple product # 1 from hdf5_file = "tripleproduct_3(2)_153(2)_153(2).hdf5";
```

Add triple product #1 using HDF5 input file named "tripleproduct_3(2)_153(2)_153(2).hdf5".

205.3.4.182 Modeling, Random Field: Add Double Product of Hermite Polynomial Chaos Basis Using HDF5 Input

Add double product of Hermite polynomial chaos basis using HDF5 input.

The command is:

```
add double product # <.> from hdf5_file = "file_name";
```

where:

- `file_name` is a string that specifies the name of the input HDF5 file.

The input HDF5 file should contain the following datasets:

- Dataset PC1 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC1_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC1.
- Dataset PC1 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC1.
- Dataset PC1 Variance is a column vector specifying the variances of basis PC1.
- Dataset PC2 is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) basis of the first random field. $\boldsymbol{PC2_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} basis of PC2.
- Dataset PC2 Index to Global Dimension contains a column vector of integers, which specifies the global dimension index of each local PC dimension in basis PC2.
- Dataset PC2 Variance is a column vector specifying the variances of basis PC2.
- Dataset Double Product is a column vector containing the non-zero double products of polynomial chaos basis from PC1 and PC2.
- Dataset Double Product PC1 Index is a column vector containing the indexes of polynomial chaos basis from PC1 that contributes to the non-zero double products in dataset Double Product.
- Dataset Double Product PC2 Index is a column vector containing the indexes of polynomial chaos basis from PC2 that contributes to the non-zero double products in dataset Double Product.

For example:

```
add double product # 1 from hdf5_file = "doubleproduct_153(2)_150(1).hdf5";
```

Add double product #1 using HDF5 input file named "doubleproduct_153(2)_150(1).hdf5".

205.3.4.183 Modeling, Solid-Fluid Interaction: Adding Solid-Fluid Interface

For solid-fluid interaction analysis, solid fluid interface should be defined and added to the analysis domain.

The command is:

```
add solid fluid interface <string>
```

where:

- `<string>` specifies the name of the boundary of fluid domain that is solid fluid interface. It is noted that the boundary name should be consistent with the definition in the OpenFOAM input file at *constant/polyMesh/boundary*. More information about the organization and format of OpenFOAM input files can be found at OpenFOAM User Guide (OpenCFD Ltd, 2019).

For example:

```
add solid fluid interface "bottom_fluid_surface";
```

Adds fluid boundary named “bottom_fluid_surface” as one of the interface boundaries between solid domain and fluid domain.

205.3.4.184 Modeling, Solid-Fluid Interaction: Defining Solid-Fluid Interface, ESSI Element Nodes

For solid-fluid interaction analysis, solid fluid interface contains information about the Real-ESSI solid interface and OpenFOAM fluid interface. The Real-ESSI solid interface defines Real-ESSI interface nodes and faces.

Real-ESSI interface nodes can be defined as the following:

```
define solid fluid interface ESSI nodes <string>;
```

where:

- `<string>` specifies the plain text file name that contains the information about Real-ESSI interface nodes.

The format of such text file containing Real-ESSI interface nodes information is:

- Comment line starts with "//"
- Each line defining a Real-ESSI interface node has four entries separated by space(s):
  - 1^{st} entry: Real-ESSI node ID;
  - 2^{nd} entry: x coordinate of Real-ESSI interface node;
  - 3^{rd} entry: y coordinate of Real-ESSI interface node;
  - 4^{th} entry: z coordinate of Real-ESSI interface node;

For example:

```
define solid fluid interface ESSI nodes "ESSI_nodes_info.fei";
```

Defines Real-ESSI nodes at solid fluid interface with file named "ESSI_nodes_info.fei". An example file of "ESSI_nodes_info.fei" is provided below:

```
//=====================================================
// Files contains information about ESSI nodes at solid fluid interface, have 4 ↩
   columns
// 1st column: ESSI node ID
// 2nd column: coordinate x
// 3rd column: coordinate y
// 4th column: coordinate z
//======================================================
1 0.00 0.00 0.00
12 30.00 0.00 0.00
33 0.00 0.00 10.00
...
```

205.3.4.185 Modeling, Solid-Fluid Interaction: Defining Solid-Fluid Interface, ESSI Element Faces

For solid-fluid interaction analysis, solid fluid interface contains information about Real-ESSI solid interface and OpenFOAM fluid interface. The Real-ESSI solid interface defines Real-ESSI interface nodes and faces.

Real-ESSI interface faces are quads that can be defined as:

```
define solid fluid interface ESSI faces <string>;
```

where:

- `<string>` specifies the plain text file name that contains the information about Real-ESSI interface elements faces.

The format of such text file containing Real-ESSI interface element faces information is:

- Comment line starts with "//"
- Each line defining a Real-ESSI interface element face, i.e., a face of a brick element, in effect a quad consisting of four Real-ESSI interface nodes. Each line has six entries separated by spaces:
  - 1^{st} entry: Real-ESSI interface face ID;
  - 2^{nd} entry: Real-ESSI element ID that contains the Real-ESSI interface face;
  - 3^{rd} entry: Real-ESSI node ID for Real-ESSI interface face, i.e., a brick face, a quad, vertex 1;
  - 4^{th} entry: Real-ESSI node ID for Real-ESSI interface face, i.e., a brick face, a quad, vertex 2;
  - 5^{th} entry: Real-ESSI node ID for Real-ESSI interface face, i.e., a brick face, a quad, vertex 3;
  - 6^{th} entry: Real-ESSI node ID for Real-ESSI interface face, i.e., a brick face, a quad, vertex 4;

  It is noted that the ordering of the four vertex Real-ESSI nodes is very important. The ordering should be taken such that the face normal vector points outwards to the fluid domain following the convention of right hand rule.

For example:

```
define solid fluid interface ESSI faces "ESSI_faces_info.fei";
```

Defines Real-ESSI faces at solid fluid interface with file named "ESSI_faces_info.fei". An example file of "ESSI_faces_info.fei" is provided below:

```
//===================================================
// Files contains information about ESSI faces (quads) at solid fluid ↩
   interface, have 6 columns
// 1st column: ESSI face ID
// 2nd column: ESSI Element ID that ESSI face belongs to
// 3rd column: ESSI node ID for quad vertex 1
// 4th column: ESSI node ID for quad vertex 2
// 5th column: ESSI node ID for quad vertex 3
// 6th column: ESSI node ID for quad vertex 4
//===================================================
1 276 1 25 272 5
2 277 25 26 273 272
3 278 26 27 274 273
4 279 27 28 275 274
...
```

205.3.4.186 Modeling, Solid-Fluid Interaction: Defining Solid-Fluid Interface FOAM Nodes

For solid-fluid interaction analysis, solid fluid interface contains information about the Real-ESSI solid interface and OpenFOAM fluid interface. The OpenFOAM fluid interface needs to define OpenFOAM interface nodes and faces.

OpenFOAM interface nodes can be defined as the following:

```
define solid fluid interface FOAM nodes <string>;
```

where:

- `<string>` specifies the plain text file name that contains the information about OpenFOAM interface nodes.

The format of such text file containing OpenFOAM interface nodes information is:

- Comment line starts with "//"
- Each line defining a OpenFOAM interface node has four entries separated by space(s):
  - 1^{st} entry: OpenFOAM node ID;
  - 2^{nd} entry: x coordinate of OpenFOAM interface node;
  - 3^{rd} entry: y coordinate of OpenFOAM interface node;
  - 4^{th} entry: z coordinate of OpenFOAM interface node;

For example:

```
define solid fluid interface FOAM nodes "foam_nodes_info.fei";
```

Defines OpenFOAM nodes at solid fluid interface with file named "foam_nodes_info.fei". An example file of "foam_nodes_info.fei" can be:

```
//=====================================================
// Files contains information about Foam nodes at solid fluid interface, have 4 ↩
   columns
// 1st column: Foam node ID
// 2nd column: coordinate x
// 3rd column: coordinate y
// 4th column: coordinate z
//=====================================================
1 0.00 0.00 0.00
12 30.00 0.00 0.00
33 0.00 0.00 10.00
...
```

205.3.4.187 Modeling, Solid-Fluid Interaction: Defining Solid-Fluid Interface FOAM Faces

For solid-fluid interaction analysis, solid fluid interface contains information about the Real-ESSI solid interface and OpenFOAM fluid interface. The OpenFOAM fluid interface needs to define OpenFOAM interface nodes and faces.

OpenFOAM interface faces are quads that can be defined as the following:

```
define solid fluid interface FOAM faces <string>;
```

where:

- `<string>` specifies the plain text file name that contains the information about OpenFOAM interface faces.

The format of such text file containing OpenFOAM interface faces information is:

- Comment line starts with "//"
- Each line defining a OpenFOAM interface face, i.e., a quad consisting of four OpenFOAM interface nodes. Each line has five entries separated by space(s):
  - 1^{st} entry: OpenFOAM face ID;
  - 2^{nd} entry: OpenFOAM node ID for OpenFOAM interface face, i.e., a quad, vertex 1;
  - 3^{rd} entry: OpenFOAM node ID for OpenFOAM interface face, i.e., a quad, vertex 2;
  - 4^{th} entry: OpenFOAM node ID for OpenFOAM interface face, i.e., a quad, vertex 3;
  - 5^{th} entry: OpenFOAM node ID for OpenFOAM interface face, i.e., a quad, vertex 4;

  It is noted that the ordering of the four vertex OpenFOAM nodes is very important. The ordering should be consistent with the OpenFOAM faces definition in the OpenFOAM input file at *constant/polyMesh/faces*. Detailed information about the organization and format of OpenFOAM input files can be found at OpenFOAM User Guide (OpenCFD Ltd, 2019).

For example:

```
define solid fluid interface FOAM faces "foam_faces_info.fei";
```

Defines OpenFOAM faces at solid fluid interface with file named "foam_faces_info.fei". An example file of "foam_faces_info.fei" can be:

```
//=============================================
// Files contains information about Foam faces (quads) at solid fluid ↩
   interface, have 5 columns
// 1st column: Foam face ID
// 2rd column: Foam node ID for quad vertex 1
// 3th column: Foam node ID for quad vertex 2
// 4th column: Foam node ID for quad vertex 3
// 5th column: Foam node ID for quad vertex 4
//=============================================
50 8 0 4 404
51 9 8 404 405
52 10 9 405 406
53 11 10 406 407
54 12 11 407 408
55 13 12 408 409
...
```

205.3.5 Simulation

205.3.5.1 Simulation, Solvers: Sequential Solvers

```
define solver sequential <profilespd|umfpack >;
```

Available sequential solvers are:

- `ProfileSPD` is used for symmetric matrices
- `UMFPack` is used for non-symmetric matrices and indefinite matrices

NOTE: USE THE SAME SOLVER FOR EACH ANALYSIS, FOR ALL LOAD STAGES!

Use the same solver, parallel or sequential, with same solver options, for all loading stages in an analysis. System matrices, mass, damping and stiffness and packaged in a different way for different solvers, and different solver options, so changing solver type between different stages will affect access to those matrices, and will affect results...

205.3.5.2 Simulation, Solvers: Parallel Solvers

```
define solver parallel petsc <petsc_options> ;
```

NOTE: USE THE SAME SOLVER FOR EACH ANALYSIS, FOR ALL LOAD STAGES!

Use the same solver, parallel or sequential, with same solver options, for all loading stages in an analysis. System matrices, mass, damping and stiffness and packaged in a different way for different solvers, and different solver options, so changing solver type between different stages will affect access to those matrices, and will affect results...

Direct Solvers

Command Example for a direct solver:

```
define solver parallel petsc "-ksp_type preonly -pc_type lu" ;
define solver parallel petsc "-pc_type lu -pc_factor_mat_solver_package mumps" ;
define solver parallel petsc "-pc_type lu -pc_factor_mat_solver_package ↩
    superlu" ;
```

As shown in the Command Example, "-ksp_type" represents the solver type, "-pc_type" represents the preconditioner types. By defining "preonly", petsc will use the direct solver, and its type is defined in the preconditioner types. In addition, "lu" represents LU factorization in the direct solver. The solver package "mumps" is designed for finite-element methods, and can interleave Gauss elimination process with the assembly process of global stiffness from the local element stiffness matrices. It is also noted that "mumps" can solve symmetric indefinite matrices.

The solver package "superlu" pivots the large-scale sparse matrices to numerous small-scale dense matrices for acceleration.

Iterative Solvers

Command Example for an iterative solver:

```
define solver parallel petsc "-ksp_type gmres -pc_type jacobi";
define solver parallel petsc "-ksp_type cg -pc_type ilu";
```

PETSc contains many iterative solvers and preconditioner for large-scale problems, and they are all available in with Real-ESSI.

Tables 205.1 and 205.2 on next pages present a full set of options for iterative solvers and preconditioners.

Table 205.1: Available Parallel Iterative Solvers

Solver Name	Method
"richardson"	Richardson
"chebyshev"	Chebyshev
"cg"	Conjugate Gradient
"bicg"	BiConjugate Gradient
"gmres"	Generalized Minimal Residual
"fgmres"	Flexible Generalized Minimal Residual
"dgmres"	Deflated Generalized Minimal Residual
"gcr"	Generalized Conjugate Residual
"bcgs"	BiCGSTAB
"cgs"	Conjugate Gradient Squared
"tfqmr"	Transpose-Free Quasi-Minimal Residual (1)
"tcqmr"	Transpose-Free Quasi-Minimal Residual (2)
"cr"	Conjugate Residual
"lsqr"	Least Squares Method

Table 205.2: Available Parallel Iterative Preconditioners

Preconditioner Name	Method
jacobi	Jacobi
bjacobi	Block Jacobi
sor	SOR (and SSOR)
eisenstat	SOR with Eisenstat trick
icc	Incomplete Cholesky
ilu	Incomplete LU
asm	Additive Schwarz
gasm	Generalized Additive Schwarz
gamg	Algebraic Multigrid
bddc	Balancing Domain Decomposition by Constraints
ksp	Linear solver
composite	Combination of preconditioners

For more available solver options please consult the PETSc documentation (`http://www.mcs.anl.gov/petsc/petsc-current/docs/manual.pdf`).

205.3.5.3 Simulation: Static Solution Advancement

```
simulate <.> steps using static algorithm;
```

205.3.5.4 Simulation: Dynamic Solution Advancement with the Constant Time Step

```
simulate <.> steps using transient algorithm time_step = <T>;
```

205.3.5.5 Simulation: Dynamic Solution Advancement with Variable Time Step

```
simulate <.> steps using variable transient algorithm
  time_step = <T>
  minimum_time_step = <.>
  maximum_time_step = <.>
  number_of_iterations = <.>
```

205.3.5.6 Simulation: Generalized Eigenvalue Analysis

At any given point in an analysis a generalized eigenvalue analysis of the system can be performed, based on the current mass and tangent stiffness matrices. The command to do this is:

```
simulate using eigen algorithm number_of_modes = <.>;
```

The first `number_of_modes` eigenvalues are displayed on screen after the analysis is performed. If more eigenvalues are requested than degrees-of-freedom the system has, the excess reported values are set to NaN (not a number).

Description of output for nodes of different dof types can be found in section 206.5.6.

205.3.5.7 Simulation: Displacement Control

```
define static integrator displacement_control using node # <.> dof DOFTYPE ↩
   increment <L>;
```

205.3.5.8 Simulation: Load, Control, Factor Increment

```
define load factor increment <.>;
```

205.3.5.9 Simulation: Dynamic Integrator, Newmark Method

```
define dynamic integrator Newmark with gamma = <.> beta = <.>;
```

See also the list of the reserved keywords from Section 205.7 on page 1163.

205.3.5.10 Simulation: Dynamic Integrator, Hilber Hughes Taylor, HHT, α Method

```
define dynamic integrator Hilber_Hughes_Taylor with alpha = <.>;
```

See also the list of the reserved keywords from Section 205.7 on page 1163.

205.3.5.11 Simulation: Absolute Convergence Criteria

```
define convergence test
  < Absolute_Norm_Unbalanced_Force | Absolute_Norm_Displacement_Increment >
  tolerance = <.>
  maximum_iterations = <.>;
```

This command sets the convergence criteria for global iterative solvers. If the system-of-equation to be solved is

$$K_T \Delta U = \Delta R$$

where K_T is the current tangent stiffness operator/matrix, ΔU is the displacement increment, and ΔR is the residual. The convergence criteria is based on:

- The l^2 norm of the displacement increment: $\|\Delta U\|_2 < TOL$.
- The l^2 norm of the unbalanced force: $\|\Delta R\|_2 < TOL$.

The convergence test should be defined before the algorithms.

205.3.5.12 Simulation: Average Convergence Criteria

```
define convergence test ↩
    <Average_Norm_Unbalanced_Force|Average_Norm_Displacement_Increment>
tolerance = <.>
maximum_iterations = <.> ;
```

This command sets the convergence criteria for global iterative solvers. If the system-of-equation to be solved is

$$K_T \Delta U = \Delta R$$

Where K_T is the current tangent stiffness operator (dynamic tangent for dynamic analysis), ΔU is the displacement increment, and ΔR is the residual. The convergence criteria can be based off

- The average l^2 norm of the displacement increment: $\|\Delta U\|_2/\sqrt{N} < TOL$.
- The average l^2 norm of the unbalanced force: $\|\Delta R\|_2/\sqrt{N} < TOL$.

where N is the number of DOFs in the system-of-equations.

The convergence test should be defined before the algorithms.

205.3.5.13 Simulation: Relative Convergence Criteria

```
define convergence test ↩
    <Relative_Norm_Unbalanced_Force|Relative_Norm_Displacement_Increment>
tolerance = <.>
minimum_absolute_tolerance = <.>
maximum_iterations = <.> ;
```

This command sets the convergence criteria for global iterative solvers. If the system-of-equation to be solved is

$$K_T \Delta U = \Delta R$$

Where K_T is the current tangent stiffness operator (dynamic tangent for dynamic analysis), ΔU is the displacement increment, and ΔR is the residual. The convergence criteria can be based on

- The relative l^2 norm of the displacement increment: $\|\Delta U\|_2 / \|U_0\|_2 < TOL$ or $\|\Delta U\|_2 < MIN\_ABS\_TOL$.
- The relative l^2 norm of the unbalanced force: $\|\Delta R\|_2 / \|R_0\|_2 < TOL$ or $\|\Delta R\|_2 < MIN\_ABS\_TOL$.

Where,
R_0 is the external force in the beginning
U_0 is the solution after the first iteration.
Since U_0 is zero before the first iteration, the relative norm of the displacement increment in the first iteration would be equal to 1.

The convergence test should be defined before the algorithms.

205.3.5.14 Simulation: Solution Algorithms

```
define algorithm < With_no_convergence_check | linear_elastic | Newton | ↩
    Modified_Newton | Newton_With_LineSearch >;
```

```
define algorithm < Newton_With_Subincrement >
  using minimum_time_step = <.> ;
```

If the current specified load factor $\Delta\lambda$ (for static) or time step Δt (for dynamic) fails to achieve the convergence in the specified maximum number of iterations, the algorithm `Newton_With_Subincrement` will subdivide the current step into two sub steps of load increment $\Delta\lambda^{new} = \Delta\lambda/2$ (for static) or time step $\Delta t^{new} = \Delta t/2$ (for dynamic).

- `minimum_time_step` specifies the allowed minimum load factor $\Delta\lambda$ (for static) or time step Δt (for dynamic), that the algorithm should sub-divide to achieve convergence. If the subdivided step size becomes less than the `minimum_time_step`, the algorithm returns failure to convergence.

Note: If any Newton algorithm is used, the convergence test should be defined before the algorithms.

205.3.5.15 Simulation: Constitutive Integration Algorithm

Starting with version 03-NOV-2015, NDMaterial class of materials require explicit specification of the constitutive integration algorithm. This is done with the command:

```
define NDMaterial constitutive integration algorithm Forward_Euler;
```

```
define NDMaterial constitutive integration algorithm Forward_Euler_Subincrement
  number_of_subincrements = <.> ;
```

```
define NDMaterial constitutive integration algorithm Backward_Euler
  yield_function_relative_tolerance = <.>
  stress_relative_tolerance = <.>
  maximum_iterations = <.>;
```

```
define NDMaterial constitutive integration algorithm Backward_Euler_Subincrement
  yield_function_relative_tolerance = <.>
  stress_relative_tolerance = <.>
  maximum_iterations = <.>
  allowed_subincrement_strain = <.> ;
```

The command specifies the method, tolerances and maximum number of iterations used to do material point integrations. The parameters are:

- `number_of_subincrements` Specify the number of subincrements in forward Euler subincrement algorithm.
- `yield_function_relative_tolerance` Specify the relative tolerance of the yield surface value in the family of backward Euler algorithm.
- `stress_relative_tolerance` Specify the relative stress tolerance in the family of backward Euler algorithm. The stress increment is within this tolerance for each step unless the integration fails. Frobenius norm is used to calculate the stress norm.
- `maximum_iterations` Specify the maximum number of iterations in backward Euler algorithm.
- `allowed_subincrement_strain` defines the maximum value of allowed strain increment in backward Euler subincrement method. If one of strain component increments is greater than the user-defined allowed strain increment, strain increment will be divided into subincrements based on the allowed subincrement. For example, if the `strain_increment` is 0.05, and the `allowed_subincrement_strain` is 0.01. The number of subincrements will be $0.05/0.01 = 5$. A small allowed subincrement leads to more accurate results, however, it takes more time. For the simple nonlinear materials, like

von Mises linear hardening, the allowed subincrement can be as big as 5 percent. For the complicated nonlinear materials, like hyperbolic Drucker-Prager Armstrong-Frederick hardening material, the allowed subincrement should be much smaller in the range of 1E-4.

205.3.5.16 Simulation: Status Check

All simulate commands set the variable `SIMULATE_EXIT_FLAG` automatically upon exit. This flag can be used to check whether the simulation concluded normally (`SIMULATE_EXIT_FLAG` = 0), failed (`SIMULATE_EXIT_FLAG < 0`), or finished with warnings (`SIMULATE_EXIT_FLAG > 0`).

For example, the following simulations will fail.

```
atmospheric_pressure = 101325*Pa;

pstart = 3000*kPa;

//SAniSand 2004 calibration for Toyoura Sand.
add material # 1 type sanisand2004
    mass_density = 2100.0 * kg / m^3
    e0 = 0.735
    sanisand2004_G0 = 125. poisson_ratio = 0.05
    sanisand2004_Pat = atmospheric_pressure
    sanisand2004_p_cut = 0.1*atmospheric_pressure
    sanisand2004_Mc = 1.25 sanisand2004_c = 0.712
    sanisand2004_lambda_c = 0.019 sanisand2004_xi = 0.7
    sanisand2004_ec_ref = 0.934 sanisand2004_m = 0.01
    sanisand2004_h0 = 7.05 sanisand2004_ch = 0.968
    sanisand2004_nb = 1.1 sanisand2004_A0 = 0.704
    sanisand2004_nd = 3.5 sanisand2004_z_max = 4.
    sanisand2004_cz = 600.
    initial_confining_stress = 1*Pa ;

simulate constitutive testing DIRECT_STRAIN
    use material # 1
    scale_factor = 1.
    series_file = "increments.txt"
    sigma0 = ( -pstart*kPa , -pstart*kPa , -pstart*kPa , 0*Pa , 0*Pa , 0*Pa )
    verbose_output = 1;

if(SIMULATE_EXIT_FLAG == 0)
{
    print "All Good!";
}
else
{
    print "Something went wrong. Error code = ";
    print SIMULATE_EXIT_FLAG;
}

bye;
```

The above simulation fails because the integration method for the constitutive model is not set (see 205.3.5.15). Therefore, the second branch of the 'if' statement will execute.

205.3.5.17 Simulation: Save State

Save ESSI system state to a file, to prepare for a restart.

```
 save model;
```

This command will save the state of a model, an ESSI system, in file. Filename for the save file will be created from a model name, loading stage name, and current loading time.

For example, for a model that contains the following commands in the input file:

```
model name "ESSI_model";
. . .
new loading stage "Loading_stage_2";
. . .
simulate 100 steps using transient algorithm time_step = 0.005*s;

save model;
```

will be saved in file with the following name:

```
ESSI_model_Loading_stage_2_at_time_0.5second_RESTART.essi
```

since there were 100 steps with $\Delta t = 0.005$s, and that advances the solution to $t = 0.5$s.

205.3.5.18 Simulation: Restart Simulation

Restart simulation after stage or a step, from a saved ESSI system model file.

```
restart model using file "filename";
```

Here, ESSI system model is saved in a file `filename`, see command for saving model on page 1120.

For example, to restart simulation from a saved file described above, restart will be initiated in a new input file by using the following command:

```
restart model using file ←↩
   "ESSI_model_Loading_stage_2_at_time_0.5second_RESTART.essi";
```

All the results from previous loading stages will be saved in the restart file. From here on, analyst can start new loading stages, etc.

205.3.5.19 Simulation: Return Value for `simulate` Command

Simulate command, `simulate`, returns status of simulation progress. For each successful step, `simulate` returns value 0 while for a failed step it returns -1. This is useful as analyst can control solution process, and change algorithm if predefined algorithm fails to converge.

For example the example if listing 205.8, simulation part of a larger examples, will perform a change of stepping algorithm from the load control to displacement control upon failure of load control to converge.

```
step=0;
Nsteps = 100;
define load factor increment 0.01; // Start with load-control

simulation_status=simulate 1 steps using static algorithm;

while (step<(Nsteps-1))
  {
    if(simulation_status>=0) // Converged, continue using load-control
      {
        simulation_status=simulate 1 steps using static algorithm;
      }
    else // Not converged, so change to displacement-control
     {
       define static integrator displacement_control using node # 1 dof ux ↩
           increment 1E-3*m;
       simulate 1 steps using static algorithm;
     }
    step=step+1;
  }
```

Figure 205.8: Interactive simulation control using feedback (return value) from the `simulate` command.

It should be noted that the idea for interactive control of simulation process comes from FEAP (Zienkiewicz and Taylor, 1991b) and later from OpenSEES (Mazzoni et al., 2002) where it was implemented with early extension of OpenSees command language with using Tcl in early 2000s.

An example of the above feedback mechanism is provided below

```
model name "vm";
add material # 1 type vonMises
    mass_density = 0.0*kg/m^3
    elastic_modulus = 2E7*N/m^2
    poisson_ratio = 0.0
    von_mises_radius = 1E5*Pa
    kinematic_hardening_rate = 0*Pa
    isotropic_hardening_rate = 0*Pa;
// define the node:
add node # 1 at (0*m,0*m,1*m) with 3 dofs;
add node # 2 at (1*m,0*m,1*m) with 3 dofs;
add node # 3 at (1*m,1*m,1*m) with 3 dofs;
add node # 4 at (0*m,1*m,1*m) with 3 dofs;
add node # 5 at (0*m,0*m,0*m) with 3 dofs;
add node # 6 at (1*m,0*m,0*m) with 3 dofs;
add node # 7 at (1*m,1*m,0*m) with 3 dofs;
add node # 8 at (0*m,1*m,0*m) with 3 dofs;
// Define the element.
add element # 1 type 8NodeBrick using 2 Gauss points each direction with nodes ↩
    (1, 2, 3, 4, 5, 6, 7, 8) use material # 1;

new loading stage "shearing";
//fix the bottom totally
fix node # 5 dofs all;
fix node # 6 dofs all;
fix node # 7 dofs all;
fix node # 8 dofs all;
// Fix the other 2 directions on the top.
fix node # 1 dofs uy uz ;
fix node # 2 dofs uy uz ;
fix node # 3 dofs uy uz ;
fix node # 4 dofs uy uz ;
add load # 101 to node # 1 type linear Fx = 40 * kN;
add load # 102 to node # 2 type linear Fx = 40 * kN;
add load # 103 to node # 3 type linear Fx = 40 * kN;
add load # 104 to node # 4 type linear Fx = 40 * kN;
define solver UMFPack;
//define algorithm With_no_convergence_check ↩
    ;Norm_Displacement_Increment;Norm_Unbalance
define convergence test Absolute_Norm_Displacement_Increment
    tolerance = 1E-3
    maximum_iterations = 5
    ;
define algorithm Newton;
define NDMaterial constitutive integration algorithm Backward_Euler
    yield_function_relative_tolerance = 1E-7
    stress_relative_tolerance = 1E-7
    maximum_iterations = 100;

// ****************************************************************************
step=0;
```

```
Nsteps = 10;
define load factor increment 1/Nsteps; // Start with load-control
// ***************************************************************************
// Simulate with status check:
// ***************************************************************************
mystatus=simulate 1 steps using static algorithm;
while (step<(Nsteps-1)){
    step=step+1;
    if(mystatus>=0){ // Converged, so continue using load-control
        mystatus=simulate 1 steps using static algorithm;
    }
    else{ // Not converged, so change to displacement-control
        define static integrator displacement_control using node # 1 dof ux ↩
            increment 1E-3*m ;
        simulate 1 steps using static algorithm;
    }
}

bye;
```

Resulting terminal output, showing a switch between two solution control mechanisms is provided below:

```

  The Finite Element Interpreter

  MS ESSI
  Earthquake Soil Structure Interaction Simulator

  Sequential processing mode.

Version Name : Academic Version. Release date: Apr 14 2017 at 17:19:55. Tag: ↩
    c24e557a56
Version Branch : yuan
Compile Date : Apr 15 2017 at 20:28:11
Compile User : yuan
Compile Sysinfo: cml01 4.4.0-72-generic x86_64 GNU/Linux
Runtime User : Runtime Sysinfo: Time Now : Apr 15 2017 at 21:15:40

Static startup tips:
 * Remember: Every command ends with a semicolon ';'.
 * Type 'quit;' or 'exit;' to finish.
 * Run 'essi -h' to see available command line options.

Including: "main.fei"

Model name is being set to "vm"

```

How polite! Bye, have a nice day!
```

205.3.5.20 Simulation: New Elastic Loading Case

For design applications, linear elastic analysis cases are performed and later combined, using factors of safety (see section 205.3.5.21 on page 1133) to obtain sectional forces for design.

The command for elastic analysis is:

```
new elastic loading case <string> ;
```

One example is

```
new elastic loading case "case1" ;
```

In a new elastic loading case, all previous loads, load patterns are removed.

To guarantee a fresh start, all commit-displacement at nodes are reset to 0, and all commit-stress/strain at Gauss points are reset to 0.

The following components are kept unchanged in a new elastic loading case:

- material properties.
- mesh connectivity
- boundary conditions.
- acceleration fields.
- damping.

If users want to modify the mesh, a new model is suggested instead of a new elastic loading case.

205.3.5.21 Simulation: Combine Elastic Load Cases

For design applications, elastic load cases, that have been analyzed beforehand, can be superimposed, combined using factors of safety, to obtain internal forces that used for design.

The command for this is

```
combine elastic load cases
  hdf5_filenames_list = <string>
  load_factors_list = <string>
  output_filename = <string>
  ;
```

One example is

```
combine elastic load cases
  hdf5_filenames_list = "test_case1.h5.feioutput test_case2.h5.feioutput"
  load_factors_list = "1.2 1.5"
  output_filename = "combine.h5.feioutput"
  ;
```

- `hdf5_filenames_list` specifies the list of HDF5 output filenames. The list should be separated by either space or comma.
- `load_factors_list` specifies the list of scale factors for each loading case. The list should be separated by either space or comma.
- `output_filename` specifies one output filename of the combined loading cases.

The number of specified files in `hdf5_filenames_list` should be equal to the number of scale factors (factors of safety) in `load_factors_list`.

205.3.5.22 Simulation, Dynamic Solution Advancement for Solid-Fluid Interaction

Dynamic analysis of solid-fluid interaction can be performed using:

```
simulate <.> steps using solid fluid interaction transient algorithm time_step ↩
    = <T>;
```

where:

- `<.>` is an integer specifying total number of time steps in transient solid fluid interaction analysis.
- `time_step = <T>` defines the time step for solid fluid interaction transient analysis.

For example:

```
simulate 300 steps using solid fluid interaction transient algorithm time_step ↩
    = 0.01*s;
```

Performs transient solid fluid interaction analysis for 300 steps with time step 0.01 s.

205.3.5.23 Simulation, Dynamic Solution Advancement for Stochastic Finite Element Method

Dynamic analysis of stochastic finite element modeling can be performed using:

```
simulate <.> steps using stochastic transient algorithm time_step = <T>;
```

where:

- `<.>` is an integer specifying total number of time steps in transient stochastic finite element analysis.
- `time_step = <T>` defines the time step for stochastic finite element transient analysis.

Please note that the stochastic transient algorithm is different from the general transient algorithm in section 205.3.5.4 in the formulation of unbalanced load for each time step. The stochastic transient algorithm uses directly the incremental external loads to compute the incremental displacements, while the general transient algorithm accounts for the correction from resisting forces in the formulation of unbalanced forces.

For deterministic and probabilistic, linear elastic problems, both transient algorithms would produce the same response. Stochastic transient algorithm is more efficient because there is no need to compute resisting forces.

For deterministic, nonlinear inelastic problems, the general transient algorithm is more accurate due to the corrections from resisting forces. The accuracy of stochastic transient algorithm can be improved using smaller loading increments. For probabilistic, nonlinear inelastic problems, the accuracy of the general transient algorithm can only be guaranteed if the number of polynomial chaos terms used in probabilistic constitutive modeling is equal or close enough to the number of polynomial chaos terms in global level. Otherwise, it is recommended to use the stochastic transient algorithm for dynamic analysis of stochastic finite element modeling.

For example:

```
simulate 300 steps using stochastic transient algorithm time_step = 0.01*s;
```

Performs transient stochastic finite element analysis for 300 steps with time step 0.01s.

205.3.5.24 Simulation, Sobol Sensitivity Analysis

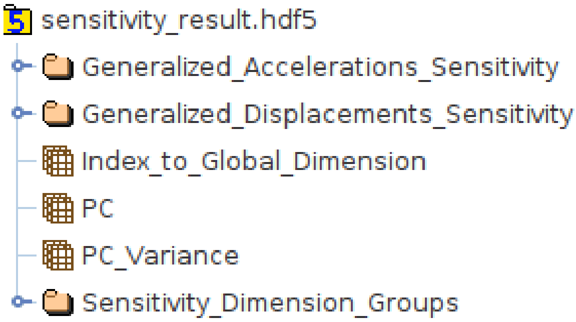
Sobol sensitivity analysis can be performed using:

```
Sobol sensitivity analysis of node # <.> dof DOFTYPE peak response from random field # <.>
pc_coefficient_hdf5 = "pc_coefficient_hdf5_file_name"
output_hdf5 = "output_hdf5_file_name";
```

where:

- `node #` specify the node tag.
- `DOFTYPE` specify the dof to perform sensitivity analysis. It can be either `ux`, `uy` or `uz`.
- `random field #` specify the random field polynomial chaos bases of the stochastic nodal response.
- `pc_coefficient_hdf5` specify the name of a hdf5 file that contains simulation results of polynomial chaos coefficients.
- `output_hdf5` specify the name of the output hdf5 file for sensitivity analysis.

The output hdf5 format for sensitivity analysis is given as below:



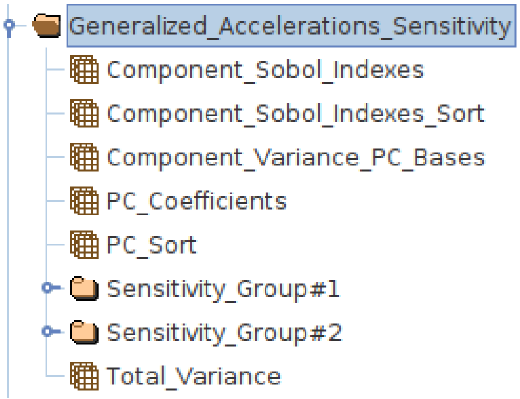
sensitivity_result.hdf5
Generalized_Accelerations_Sensitivity
Generalized_Displacements_Sensitivity
Index_to_Global_Dimension
PC
PC_Variance
Sensitivity_Dimension_Groups

Figure 205.9: Overall data structure of output hdf5 file for sensitivity analysis.

Figure 205.9 shows the overall data structure organization of the output hdf5 file of sensitivity analysis.

- Generalized_Accelerations_Sensitivity data group:

  Contains Sobol sensitivity analysis results for stochastic nodal acceleration response. It contains the following datasets and data groups as shown in Figure 205.10.



Generalized_Accelerations_Sensitivity
- Component_Sobol_Indexes
- Component_Sobol_Indexes_Sort
- Component_Variance_PC_Bases
- PC_Coefficients
- PC_Sort
- Sensitivity_Group#1
- Sensitivity_Group#2
- Total_Variance

Figure 205.10: Datasets and data groups in Generalized_Accelerations_Sensitivity data group.

- Component_Sobol_Indexes dataset:

  Is a column vector containing the computed Sobol Indexes for each component of polynomial chaos (PC) bases.

- Component_Sobol_Indexes_Sort dataset:

  Is a column vector containing the computed Sobol Indexes for each component of polynomial chaos (PC) bases, in descending order.

- Component_Variance_PC_Bases dataset:

  Is a column vector containing the computed variance for each component of polynomial chaos (PC) bases.

- PC_Coefficients dataset:

  Is a column vector containing the polynomial chaos coefficients corresponding to PC bases specified in PC dataset.

- PC_Sort dataset:

  Is a 2D array that describes the sorted PC bases corresponding to Component_Sobol_Indexes_Sort dataset. PC_Sort$_{ij}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} sorted, PC basis.

- Total_Variance dataset:

  Is a scalar, variance of nodal stochastic response.

In addition to the above datasets, there will be sub data group(s) containing sensitivity analysis results corresponding to each of the defined sensitivity dimension groups. For example, we have two sub data groups Sensitivity_Group#1 and Sensitivity_Group#2 for this specific hdf5 output for sensitivity analysis. Within these sub data groups, taking Sensitivity_Group#1 as an example, the output data is organized as shown in Figure 205.11.

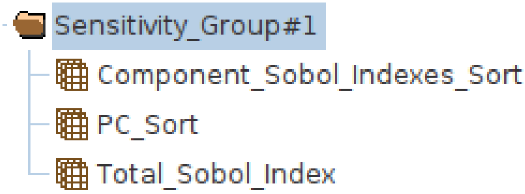


Figure 205.11: Datasets in Sensitivity_Group#1.

It includes the following datasets:

  - Component_Sobol_Indexes_Sort dataset:

    Is a column vector containing the computed Sobol Indexes for part of polynomial chaos (PC) bases specified through the sensitivity dimension group, in descending order.

  - PC_Sort dataset:

    Is a 2D array that describes the sorted, part of PC bases specified through the sensitivity dimension group, corresponding to Component_Sobol_Indexes_Sort dataset. PC_Sort$_{\boldsymbol{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} sorted, PC basis.

  - Total_Sobol_Index dataset:

    Is a scalar, total Sobol sensitivity index for PC bases specified in the sensitivity dimension group.

- Generalized_Displacements_Sensitivity data group:

  Contains Sobol sensitivity analysis results for stochastic nodal displacement response. The configuration of data structure for Generalized_Displacements_Sensitivity data group is the same as Generalized_Accelerations_Sensitivity data group.

- Index_to_Global_Dimension dataset:

  Contains a column vector of integers, which specifies the global dimension IDs for the polynomial chaos bases used to represent the nodal stochastic response.

- PC dataset:

Is a 2D array that describes the multi-dimensional Hermite polynomial chaos (PC) bases for representing the nodal stochastic response. $\boldsymbol{PC_{ij}}$ denotes the order of polynomial chaos dimension ξ_j that contributes to the i^{th} multidimensional Hermite PC basis.

- PC_Variance dataset:

  Is a column vector specifying the variances of Hermite PC basis.

- Sensitivity_Dimension_Groups data group:

  Contains the information about the sensitivity dimension groups defined for sensitivity analysis. Each sensitivity dimension group would be defined by a dataset within the data group as shown in Figure 205.12. Each dataset contains a column vector of integers, specifying the dimension IDs in specific sensitivity dimension group.

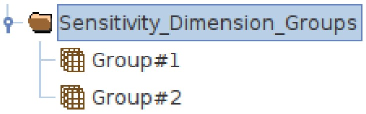

Figure 205.12: Datasets in Sensitivity_Dimension_Groups data group.

205.3.5.25 Simulation: 3D 3C Wave Field Inversion

```
generate domain reduction method motion file from 3D_3C_wave_field_inversion
    target_nodes_filename = <string>
    target_motions_filename = <string>
    time_step = <T>
    hdf5_file = <string>;
```

Example:

```
generate domain reduction method motion file from 3D_3C_wave_field_inversion
    target_nodes_filename = "Target_Nodes.txt"
    target_motions_filename = "Target_Motions.txt"
    time_step = 0.01*s
    hdf5_file = "DRM_Input_from_Inverse_Motion.hdf5";
```

where:

- `target_nodes_filename` is the file name for a file that contains the list of nodes, represented by their tags, where target motions are designated.

  One example of target nodes file is given below.

  ```
  5
  15
  25
  35
  46
  48
  50
  52
  ```

- `target_motions_filename` is the file name for a file that contains the list of target motions at the corresponding target nodes. Note that the length, or number of rows, and the ordering of the target motions file must be the same as those of the target nodes file.

  One example of target motions file is given below.

  ```
  Displacement_1000steps_with_CT.txt
  Displacement_1000steps_with_CT.txt
  Displacement_1000steps_with_CT.txt
  Displacement_1000steps_with_CT.txt
  Zero_Displacement_1000steps_with_CT.txt
  Zero_Displacement_1000steps_with_CT.txt
  Zero_Displacement_1000steps_with_CT.txt
  Zero_Displacement_1000steps_with_CT.txt
  ```

  Time series of target motion is defined in each of the file listed in `target_motions_filename`.

- `time_step` is the time step/interval corresponding to the target motions.
- `hdf5_file` specifies the HDF5 file which contains the geometric information about the DRM elements and DRM nodes. This is also the file in which the DRM forces obtained from 3D wave field inversion are stored. Then this file can be used in future simulations as the DRM input. See previous DRM-related DSLs for the format of this file.

205.3.6 Output Options

Real-ESSI Simulator outputs total displacements at all the nodes, as well total stress, total strain and total plastic strain at all the Gauss points of the element in each time step of each stage of loading. Real-ESSI also outputs any/all other element output in addition to the integration/Gauss point output. Generally, 3-D elements have only integration/Gauss point outputs and structure elements have only element output. The output options are reset to the default options in the beginning of each loading stage. More information about output organization is given in section 206.2.

205.3.6.1 Output Options: Enable/Disable Output

This option is used to enable or disable the outputting of results from all nodes and elements to HDF5 (.feioutput) output file.

Note:- By default output is always enabled for each loading stage.

Command to disable output is

```
disable all output;
```

Command to enable output is

```
enable all output;
```

205.3.6.2 Output Options: Enable/Disable Element Output

This option is used to enable or disable the outputting of element results from all elements to HDF5 (.feioutput) output file, per stage of loading.

Note:- By default all results from elements are output for each loading stage, so this option can be used to enable or disable output per loading stage.

Command to disable element output is

```
disable element output;
```

Command to enable element output is

```
enable element output;
```

205.3.6.3 Output Options: Enable/Disable Displacement Output

This option is used to enable or disable the displacement output at nodes to HDF5 (.feioutput) file.

Note:- By default displacement output is enabled.

Command to disable displacement output is

```
disable displacement output;
```

Command to enable displacement output is

```
enable displacement output;
```

205.3.6.4 Output Options: Enable/Disable Acceleration Output

This option is used to enable or disable the acceleration output at nodes to HDF5 (.feioutput) file.

Note:- By default acceleration output is disabled.

Command to disable acceleration output is

```
disable acceleration output;
```

Command to enable acceleration output is

```
enable acceleration output;
```

205.3.6.5 Output Options: Enable/Disable Asynchronous Output

This option is used to enable or disable the asynchronous method of writing output to HDF5 (.feioutput) file.

Note:- By default asynchronous output is disabled. Asynchronous output is an advanced output feature. Asynchronous output is suitable for I/O-bound simulation.

Command to disable asynchronous output is

```
disable asynchronous output;
```

Command to enable asynchronous output is

```
enable asynchronous output;
```

205.3.6.6 Output Options: Output Every n Steps

This option is used to output results at intervals of n time steps.

Note:- By default results are output for every time step.

Command to enable output only at n^{th} time step interval

```
output every <.> steps;
```

For example: To output only at interval of two time steps for a simulation of 100 steps. One can write

```
output every 2 steps;
```

This will only output for steps 2,4,6,... until 100th step.

205.3.6.7 Output Options: Output Support Reactions

This option is used to output reactions at constrained supports.

Note:- By default output reactions at constrained supports are disabled.

Command to enable reactions for support is

```
output support reactions;
```

205.4 Checking the Model

Real-ESSI provides model check capability:

```
check model ;
```

This command will cycle over all the domain components, including Nodes, Elements, Loads, Constraints, etc. and execute the `checkModel()` function for each. Each domain component writes/reports to the terminal and to the *essi.log* file, if an error is found. For example, bricks will report when the computed Jacobian is negative and other similar errors. Nodes that are not connected will be reported as well. If the diagnostic log is empty, it means that the mesh has passed all tests. Additionally, an output HDF5 file is produced that can be used to display the mesh and do further visual inspections of the model. This file will have initial conditions as outputs for element sand nodes.

Command `check model;` represents a dry run through the model that is used to check the model before a full analysis. Model check is highly recommended before initial stages of a full analysis are executed.

205.5 Constitutive Testing

Material models can be tested using constitutive drivers which exercise single material models. RealE-SSI implements two such drivers.

1. Bardet Driver. Bardet-type constraints can be used to simulate conditions such as drained or undrained triaxial testing with strain or stress control or direct shear testing with shear control.
2. Direct Strain Driver. This driver applies a given strain history (specified by the user) to a material model.

Both these drivers produce identical output: the files `Stress.feioutput` and `Strain.feioutput` which contain stress and strain tensor components at each step. Additionally, the drivers may print out material internal information to the file `Material_Output.feioutput`. For the stress and strain files, each line of these files contain the stresses and strains organized in the following manner:

`Stress.feioutput` → σ_{11} σ_{22} σ_{33} σ_{12} σ_{13} σ_{23}.

`Strain.feioutput` → ϵ_{11} ϵ_{22} ϵ_{33} ϵ_{12} ϵ_{13} ϵ_{23}.

The Bardet driver has the following format.

```
simulate constitutive testing BARDETMETHOD use material # <.>
  scale_factor = <.>
  series_file = <string>
  sigma0 = ( <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> )
  verbose_output = <.>
```

Where,

- `BARDETMETHOD` can have any one of the following values:
  - `CONSTANT_P_TRIAXIAL_LOADING_STRAIN_CONTROL`: Triaxial loading with p kept constant. In this case the input file is interpreted as strain increments in the ϵ_{11} component.
  - `DRAINED_TRIAXIAL_LOADING_STRESS_CONTROL`: Drained Triaxial loading. In this case the input file is interpreted as stress increments in the σ_{11} component.
  - `DRAINED_TRIAXIAL_LOADING_STRAIN_CONTROL`: Drained Triaxial loading. In this case the input file is interpreted as strain increments in the ϵ_{11} component.
  - `UNDRAINED_TRIAXIAL_LOADING_STRAIN_CONTROL`: Undrained Triaxial loading. In this case the input file is interpreted as strain increments in the ϵ_{11} component.
  - `UNDRAINED_TRIAXIAL_LOADING_STRESS_CONTROL`: Undrained Triaxial loading. In this case the input file is interpreted as stress increments in the σ_{11} component.

  - `UNDRAINED_SIMPLE_SHEAR_LOADING_STRAIN_CONTROL`: Undrained simple-shear loading. In this case the input file is interpreted as angular strain increments in the $\gamma_{12} = 2\epsilon_{12}$ component.

- `scale_factor`: Can be used to scale the series file arbitrarily.

- `series_file`: String specifying the path to the file containing the increments (might be interpreted as strain or stress depending on the method chosen). Each line of the file contains one increment.

- `sigma0`: Components of the initial stress for the material, given in the order: $(\sigma_{11}, \sigma_{22}, \sigma_{33}, \sigma_{12}, \sigma_{13}, \sigma_{23})$.

- `verbose_output(=N)` Whether the driver should print extra information about the material model every N steps. If Takes value 0 (no output) or N (do output every N increments). Each material implements its own output, so the format of the `Material_Output.feioutput` file is variable and material dependent.

The direct strain driver has the following format.

```
simulate constitutive testing DIRECT_STRAIN use material # <.>
  scale_factor = <.>
  series_file = <string>
  sigma0 = ( <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> , <F/L^2> )
  verbose_output = <.>
```

Where al the arguments are the same as the Bardet driver. In this case each line of the file contains all six components of the strain increment to be applied. For example:
`series_file = "increments.txt"` where each line in `increments.txt` contains $d\epsilon_{11}$ $d\epsilon_{22}$ $d\epsilon_{33}$ $d\epsilon_{12}$ $d\epsilon_{13}$ $d\epsilon_{23}$.

205.6 List of Available Commands (tentative, not up to date)

```
add acceleration field # <.> ax = <accel> ay = <accel> az = <aaccel> ;

205.8 Integrated Development Environment (IDE) for DSL

205.9 Mesh Generation using GiD

1. Download the latest version of GiD from `http://www.gidhome.com/`, and also get a temporary license (or purchase it...).
2. Download essi.gid.tar.gz, unpack it (`tar -xvzf essi.gid.tar.gz`) in `problemtypes` directory that is located in GiD's root directory.
3. When you run GiD, you will see `essi` in "Data > Problem types", and can start using it...
4. A simple movie with instructions for mesh generation is available: (Link to a movie, 11MB).

205.10 Model Development and Mesh Generation using gmesh

205.11 Model Input File Editing using Sublime

`http://www.sublimetext.com/`

Chapter 206

Output Formats

(2012-2014-2017-2019-2021-)

(In collaboration with Prof. José Abell, Prof. Sumeet Kumar Sinha and Dr. Yuan Feng, and Prof. Han Yang)

206.1 Chapter Summary and Highlights

206.2 Introduction

All output from ESSI simulator is stored inside a database format, specifically designed for handling scientific array-oriented data, called HDF5 (Group, 2020). HDF stands for 'Hierarchical Data Format' and is a self-describing data format suitable for portable sharing of scientific data. The format was created and is maintained by the HDF group (`http://www.hdfgroup.org/`)

Data is stored within the file using a hierarchy similar to a unix filesystem, with groups to store related data and the actual data stored in so-called 'datasets' within each group.

HDF5 was chosen because it meets our design goals of provides:

- A simplified output format. Output is a single HDF5 file per analysis stage.
- An efficient binary (possibly compressed) file format that optimizes random access to data.
- A data format that is amenable to store output from parallel computations.
- Has a reasonable API exposed in several languages so that users can easily and customizably access simulation data.

One very convenient tool for the basic exploration of HDF5 files is the viewer 'hdfview' (`http://www.hdfgroup.org/products/java/hdfview/index.html`).

206.3 Output Filename and Format

On running any simulation on Real-ESSI simulator output files are produced for each analysis stage. The number of outputs and the filename is slightly different for sequential and parallel runs. Each output file, contains the information about the model mesh, nodal displacements, elements output, boundary conditions, material tags.. etc. The output files are designed as completely independent files containing all the data for the loading stage. In parallel each of the follower compute process outputs contains all the data corresponding to only the follower compute process. This is done to make the visualization and output process efficient.

206.3.1 Sequential

For sequential runs a single output file is produced per analysis stage. The files are named according to `model` and `stage names`, not by the filename that runs the analysis. The extension is set to be '`.h5.feioutput`', to distinguish from future possible alternative output formats.

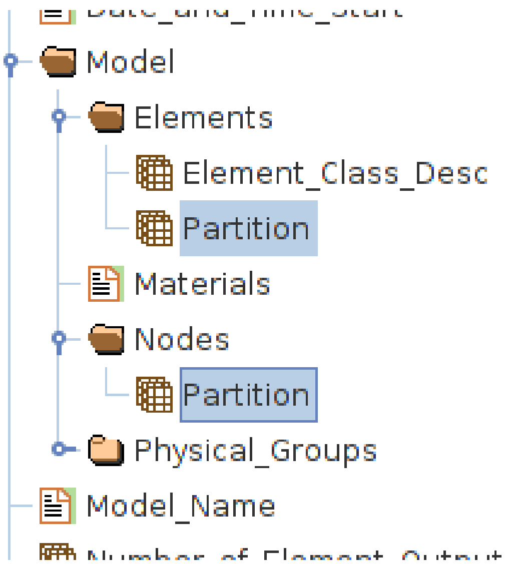

Figure 206.1: Partition info in output file produced by main compute node in parallel run

For example, if the model name is ‘`site_response`’ and the stage name is ‘`earthquake_shaking`’ the corresponding output filename will be ‘`site_response_earthquake_shaking.h5.feioutput`’.

206.3.2 Parallel

In parallel, for each stage, output files produced are equal to the number of CPU’s used. For example, a simulation run of 8 CPU’s will produce 8 output files per stage for each corresponding CPU’s (cores).The filename remains the same as sequential output each CPU (process id) used, but the extension is set to be as ‘`.h5.pid.feioutput`’, where *pid* refers to the process id of the CPU. However, the main compute process having *pid* equal to 0 follows the extension ‘`.h5.feioutput`’.

For example, In parallel, if the model name is ‘`site_response`’ and the stage name is ‘`earthquake_shaking`’ and the analysis is run on n CPU’s, the corresponding output filename for the main compute process ($pid = 0$) would be ‘`site_response_earthquake_shaking.h5.feioutput`’. All the follower compute process having $pid > 0$ would have output filename ‘`site_response_earthquake_shaking.h5.pid.feioutput`’.

The main compute process usually does not contain any nodes and element once the partition is achieved and nodes and elements are transfered to their respective CPU’s or cores. Thus, the output produced by main compute process does not contain any mesh or output results. However, it contains the partition data as shown in Figure 206.1 describing the process id on which any node or element is assigned. This information is quite useful, during post processing when the result of a particular node or element needs to be extracted. The main compute output can be read to find out the follower compute process id on which the data is located and then the output of that process id can be read to get the data of interest.

206.4 Output Units

Real-ESSI `.feioutput` file stores all the results in standard units. The table below shows the units of all the data stored in HDF5 file.

Quantity	Unit
Force F_x, F_y, F_z	N
Moments M_x, M_y, M_z	$N-m$
Pressure p	Pa
Displacement u_x, u_y, u_z	m
Rotation r_x, r_y, r_z	$radian$
Stress σ	Pa
Strain ϵ	unit less
Acceleration a_x, a_y, a_z	m/s^2
Time t	s

206.5 Data organization

In HDF5 jargon a multidimensional array is called a dataset. Datasets are indexed arrays (up to 32 dimensions) that can contain different types of data. Supported data types are: integers (various sizes), floating point numbers (`float`, `float`, `long double`, etc.), strings of text (fixed and variable size `char *`), and arbitrary structures of data (similar to C language `struct`). A file can contain as many independent datasets as needed. Datasets can be organized into 'groups', which are like folders in a file system. HDF5 provides additionally convenience data-types such as 'references', which provide views (slices) into diferent datasets or portions of them.

In the particular case of the ESSI HDF5 output, the files are designed with the contents and structure explained hereafter and depicted in Figure 206.3.

206.5.1 The `Root` group

The root of the HDF5 file contains information about each stage of loading. In parallel simulations, the information corresponds to the process Id (follower compute node) involved in that stage. The objects under this group are shown in Figure 206.4 and described in List 206.5.1

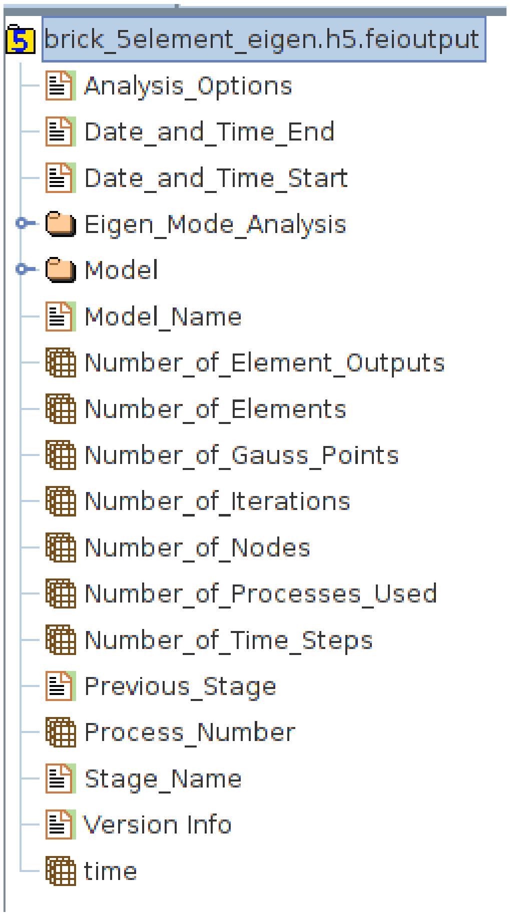

Figure 206.2: Output from a typical analysis.

- `time` : (`float`) A floating point array named which contains the available time steps for this analysis.
- `Number_of_Time_Steps`: (`int`) A single scalar integer array with the number of times steps.
- `Model_Name`: (`string`) A single string with the model name.
- `Stage_Name`: (`string`) A single string with the stage name.
- `Previous_Stage`: (`string`) A single string containing previous stage name.
- `Process_Number`: (`int`) An integer representing the *process id* by which output was generated. For sequential runs, *process id* would be zero. In parallel runs, *process id* corresponds to the *mpi rank* or *follower compute id* of processor involved in computation.
- `Number_of_Processes_Used`: (`int`) An integer representing total number of processors/CPU/nodes used in the simulation. For sequential runs, it is equal to one whereas for parallel runs, it is

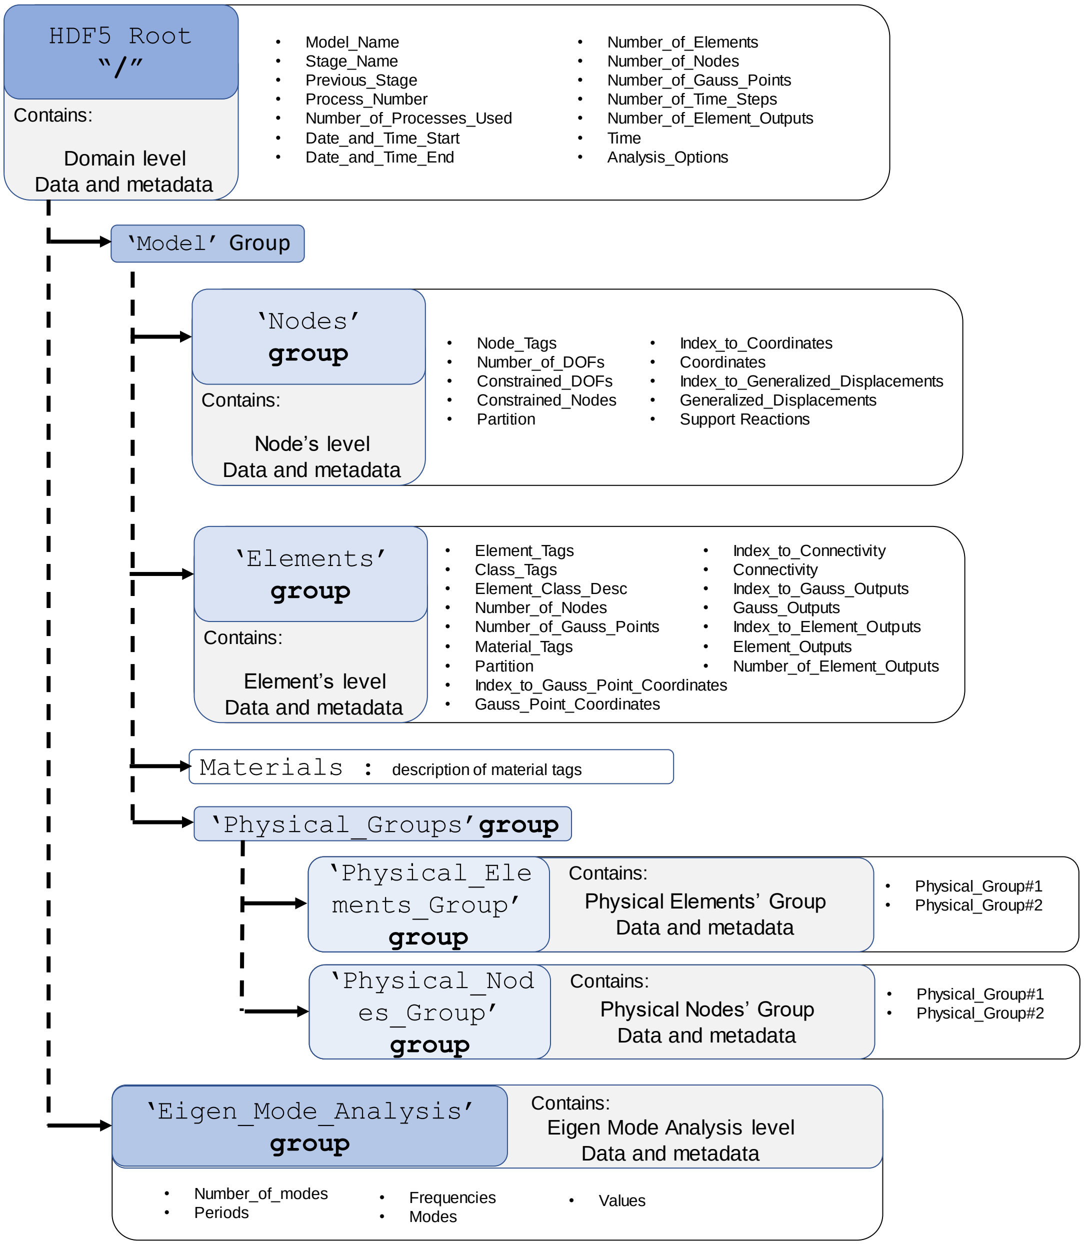

Figure 206.3: Design of the ESSI `.h5.feioutput` data format.

equal to the number of CPU's/Cores used.

- `Number_of_Nodes`: (`int`) A single scalar integer array with the number of nodes defined in that domain.
- `Number_of_Elements`: (`int`) A single scalar integer array with the number of elements defined in that domain.

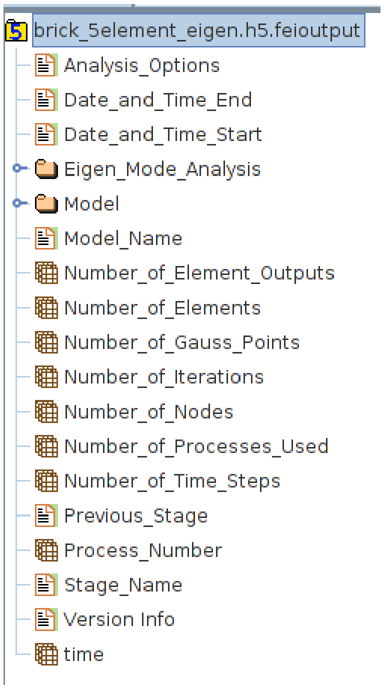

Figure 206.4: Data accessible in the `Root` directory of HDF5 file.

- `Number_of_Gauss_Points`: (`int`) A single scalar integer array with the number of gauss points in that domain.
- `Number_of_Element_Outputs`: (`int`) A single scalar integer array with stores the total length of `Element_Output` array in that domain.
- `Analysis_Options`: (`string`) An array of strings with the analysis options selected for the current analysis.
- `Date_and_Time_Start`: (`string`) A single string with the Date and Time of the start of the analysis. (In Coordinated Universal Time, UTC)
- `Date_and_Time_End`: (`string`) A single string with the Date and Time of the end of the analysis. (In Coordinated Universal Time, UTC)

  item `Version_Info`:(`string`) A Long string containing the version information of Real-ESSI simulator.
- `Model`: A group that contains the `Nodes` and `Elements` groups. It contains essential information about the mesh and analysis results for nodes and elements. See Section 206.5.2

- `Eigen_Mode_Analysis`: A group that contains the information about the the eigen mode analysis results of the doamin. See Section 206.5.6

206.5.2 The `Model` group

The `Model` group contains information about the mesh and analysis outputs. It contains the following groups as shown in Figure 206.5 and is also described below

- `Nodes`: A group that contains the information about the defined nodes and their output for this analysis. See Section 206.5.3
- `Elements`: A group that contains the information about the defined Elements and their output for this analysis. See Section 206.5.4
- `Physical_Groups`: A group that contains the information physical group of elements and nodes defined in that domain. See Section 206.5.5
- `Material`: (`string`) A string array which contains information about the material tag defined in the analysis for that loading stage. Section 206.5.7

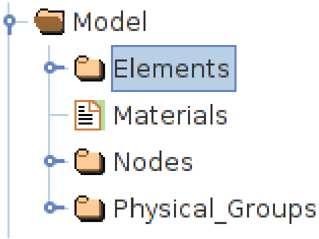

Figure 206.5: `Model` group directory of HDF5 file.

Subgroups `Nodes` and `Elements` store several integer and double precision arrays, that contain all necessary information for post processing.

206.5.3 The `Nodes` group

The `Nodes` group contains information about the nodal coordinates of the model, their tags, the number of DOFs defined at each node, and the corresponding solution variables (DOF results or generalized displacements) for each time step.

The format used to store the data is designed to give the fastest possible access time to the data of interest. Stored within the `Nodes` groups (and also in `Elements`) are two types of arrays: *data arrays* and *index arrays*.

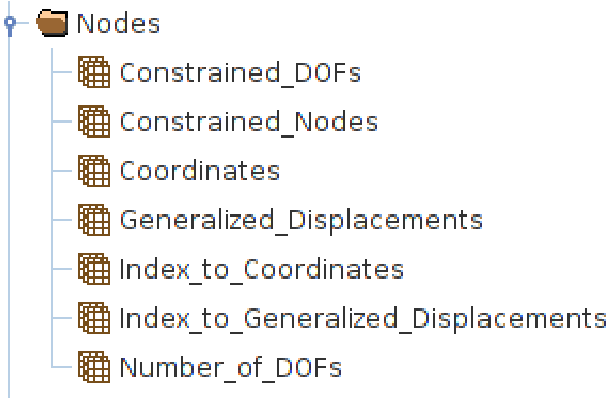
- Data Arrays :: Data arrays might be floating-point arrays or integer arrays and have names not starting with '`Index_to_`'.
- Index Arrays :: All index arrays are integer arrays and have names starting with the word '`Index_to_`' followed by the name of the array which this array indexes.

The concept of *index array* is an important one regarding speed of access to data. These arrays map the integer tag number of the nodes (or elements) to the data. This allows fast access to components which minimizes searching within arrays to find the data of interest.

The `Nodes` group contains the following index arrays.

- `Index_to_Coordinates`: (`int`) Indexes the coordinates of nodes. See section 206.5.3.6
- `Index_to_Generalized_Displacements`: (`int`) Indexes the outputs of nodes (generalized displacements). See section 206.5.3.7

The following are the data arrays available in the `Nodes` group (shown in Figure ?? along with their respective indexing array:



Nodes
Constrained_DOFs
Constrained_Nodes
Coordinates
Generalized_Displacements
Index_to_Coordinates
Index_to_Generalized_Displacements
Number_of_DOFs

Figure 206.6: `Nodes` group directory of HDF5 file.

- `Coordinates`: (`float`) 1-D array containing nodal coordinates fixed in time. [Indexed by `Index_to_Coordinates` array]. See section 206.5.3.6
- `Generalized_Displacements`: (`float`) 2-D array containing the DOF values for the solution at each time step. [Indexed by `Index_to_Generalized_Displacements` array]. See section 206.5.3.7
- `Number_of_DOFs`: (`int`) 1-D array mapping the integer tag of each node to the number of DOFs at that node. See section 206.5.3.1

- `Constrained_Nodes`: (`int`) 1-D array mapping the integer tag of each node to the number of DOFs at that node. See section 206.5.3.3
- `Constrained_DOFs`: (`int`) 1-D array mapping the integer tag of each node to the number of DOFs at that node. See section 206.5.3.4
- `Partition`: (`int`) 1-D array mapping the integer tag of each node to the number of DOFs at that node. See section 206.5.3.2
- `Support_Reactions`: (`float`) 1-D array mapping the integer tag of each node to the number of DOFs at that node. See section 206.5.3.5

For example, lets imagine that the user has defined 4 nodes and applied the following constrained as shown below :

Listing 206.1: Node_Example

```
// defining nodes
add node # 2 at (0*m, 0*m, 0*m) with 3 dofs;
add node # 4 at (1*m, 1*m, 1*m) with 6 dofs;
add node # 5 at (2*m, 2*m, 2*m) with 3 dofs;
add node # 6 at (1*m, 0*m, 5*m) with 3 dofs;

// applying constraints
fix node # 2 dofs ux uy;
fix node # 4 rx ry rz;
fix node # 6 Ux p;
```

The index and the data arrays for the given example would look like the following as shown in the subsections ahead.

206.5.3.1 `Number_of_DOFs`

`Number_of_DOFs` array defines the number of degrees of freedom for each node defined in the model. It is an `integer` array of length equal to the maximum node tag + 1 (including tag 0). If a node tag does not exists, the corresponding dofs is output as -1. Figure 206.7 shows how to read `Number_of_DOFs` array. In the given example Listing 206.1 , node tag 2 has 3 degrees of freedom. Similarly, node tag 4 has 6 degrees of freedom and so on.

206.5.3.2 `Partition`

`Partition` array contains the domain or process id on which nodes tags were defined in case of a parallel simulation. For sequnetial runs, this dataset is not available. If a node tag does not exists, the corresponding partition process id is output as -1. Figure 206.7 shows how to read `Partition` array. In the given example Listing 206.1, node tag 2 is assigned to process id 1. Similarly, node tag 4 is assigned to process id 2 and so on.

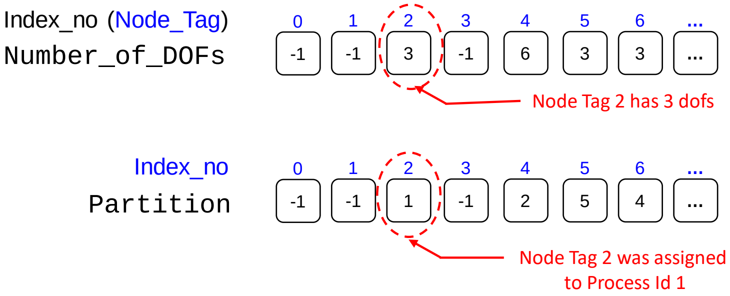


Figure 206.7: Arrays describing node information in `Nodes` group directory of HDF5 file.

206.5.3.3 Constrained_Nodes

`Constrained_Nodes` array contains a list of node tags for each dof on which fixities were applied. Figure 206.8 shows how to read `Constrained_Nodes`. In the given example Listing 206.1, dof ux and uy of node tag 2 is fixed. Similarly, for node tag 4 dofs rx ry and rz are fixed. Thats why in the `Constrained_Nodes` array contains node tags 2,2,4,4,4 and so on multiple times for each dof of the corresponding node tag fixed.

206.5.3.4 Constrained_DOFs

`Constrained_DOFs` array contains a list of dofs of the corresponding node tag on which fixities were applied. Figure 206.8 shows how to read `Constrained_DOFs`. In the given example Listing 206.1, dof ux (0) and uy (1) of node tag 2 is fixed. Similarly, for node tag 4 dofs rx (3) ry (4) and rz (5) are fixed. Figure 206.8 also show the DOF if numbering for different dof types i.e. for 3dof, 4dof, 6dof and 7dof nodes.

206.5.3.5 Support_Reactions

`Support_Reactions` contains a (`float`) array of reaction forces for the constrained degree of freedoms (DOFs). Figure 206.8 shows how to read `Constrained_DOFs`. In the given example Listing 206.1, dof ux (0) and uy (1) of node tag 2 has support reactions 1N and -5N respectively. Similarly, for node tag 4 dofs rx (3) ry (4) and rz (5) have reactions 45, 3 and -5 $N-m$ respectively. The reaction forces for displacement dofs (u_x, u_y, u_z) are forces in units of N, for rotational dofs (r_x, r_y, r_z) are moments in units

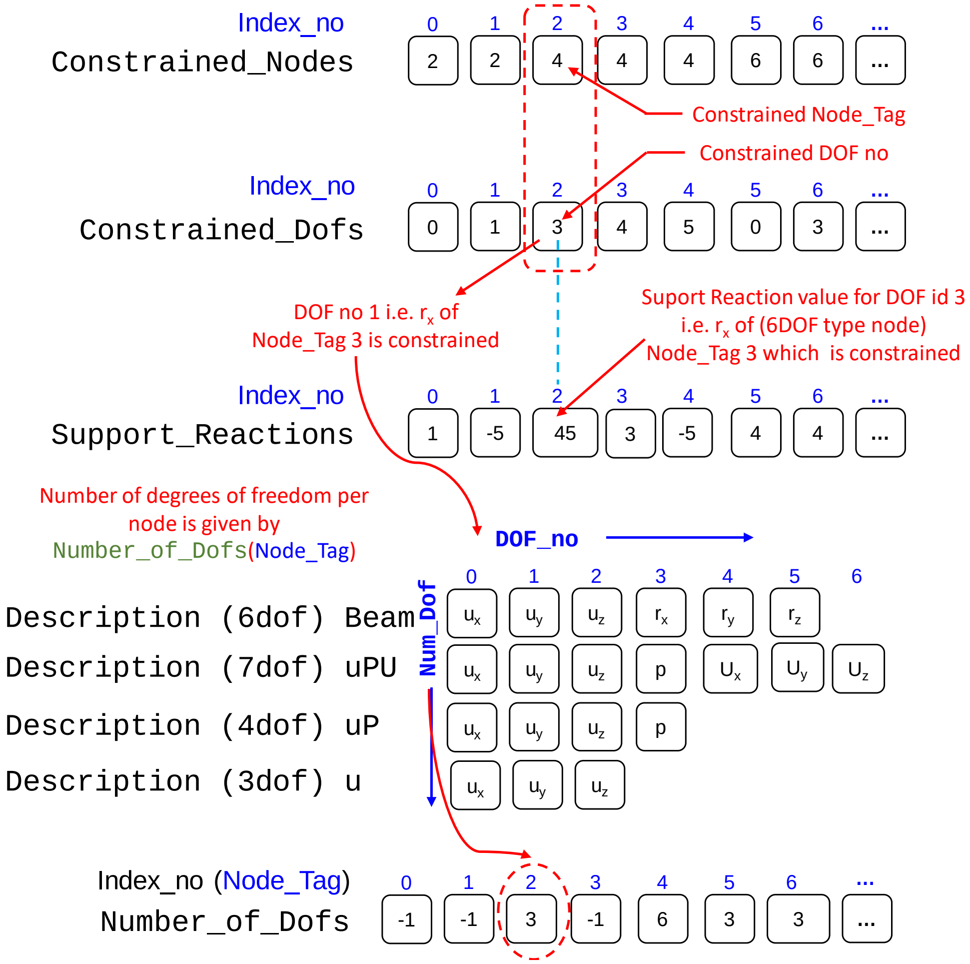

Figure 206.8: Arrays describing constrained nodes and reaction information in `Nodes` group directoory of HDF5 file.

of $N-m$ and for pressure dof (p) is pascal (Pa). Section 206.6 describes the output definitions for nodes with different dof-types.

206.5.3.6 `Coordinates`

The `Coordinates` array is a vertical stack of the nodal coordinate values. it is indexed by the `Index_to_Coordinates`, which relates the integer tag of each nodes (defined at the moment of creation of every node) with the position on this array of the 3 nodal coordinates. If the node with a given tag is not defined (if a tag number or several are skipped) this array will contain a negative number (-1) for that tag value. Figure 206.9 shows how to read `Coordinates` and `index_to_Coordinates` of nodes.

The size of `Index_to_Coordinates` is always the maximum tag defined plus one (zero can be a tag too). The size of the `Coordinates` array is three times the number of nodes defined. In the given

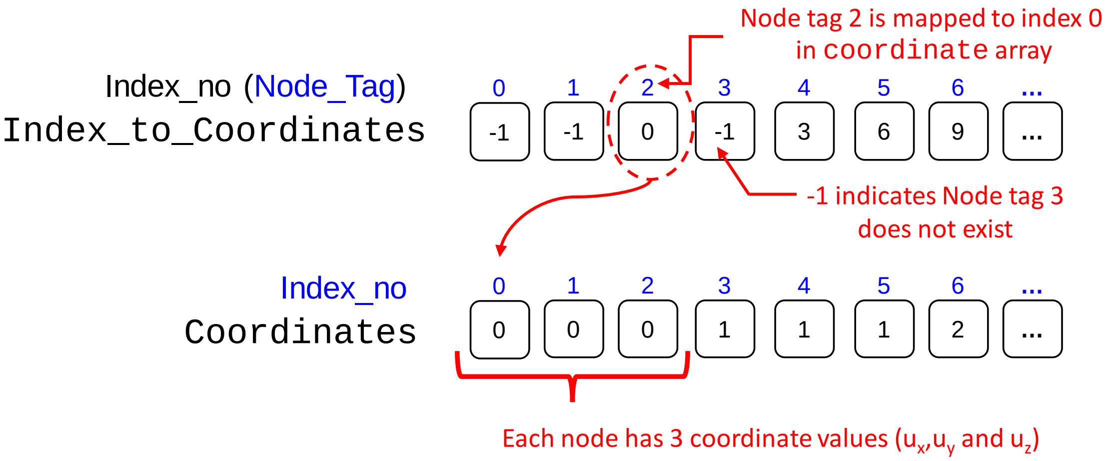

Figure 206.9: `Coordinates` and `Index_to_Coordinates` arrays in `Nodes` group directory of HDF5 file.

example Listing 206.1, the coordinates of node tag 2 is (0*m,0*m,0*m). The coordinate of node tag 4 is (1*m,1*m,1*m) and so on. The coordinates have unit of meter (m).

206.5.3.7 `Generalized_Displacements`

The `Generalized_Displacements` array is a 2-D array containing the computed solution at the nodal degrees of freedom for all nodes and all times steps. It is indexed by the `Index_to_Generalized_Displacements` array (first index) and time (second index). Figure 206.10 shows how to read `Generalized_Displacements` and `index_to_Generalized_Displacements` of nodes.

Output for displacement dofs (u_x, u_y, u_z) are in units of m, for rotational dofs (r_x, r_y, r_z) are in units of $radian$ and for pressure dof (p) is in pascal (Pa).

With every time step, another column is added to the `Generalized_Displacements` array. This means that the time index (starting at 0) is directly related to the `time` array at the root of the HDF5 file.

The rows of the `Generalized_Displacements` array contain the results for each DOF of the current node. For a 3-DOF node these will be displacement in X, Y, and Z (u_x, u_y, and u_z) respectively. For higher number-of-dof nodes the first three components are the same but the remaining ones are going to depend on the connecting elements. For example, 6-DOF nodes might carry information on nodal rotations (beams and shells) or might be fluid displacements in case the elements connecting are u–U coupled fluid-porous-solid elements as shown in Figure 206.8. Section 206.6 describes the output definitions for nodes with different dof-types.

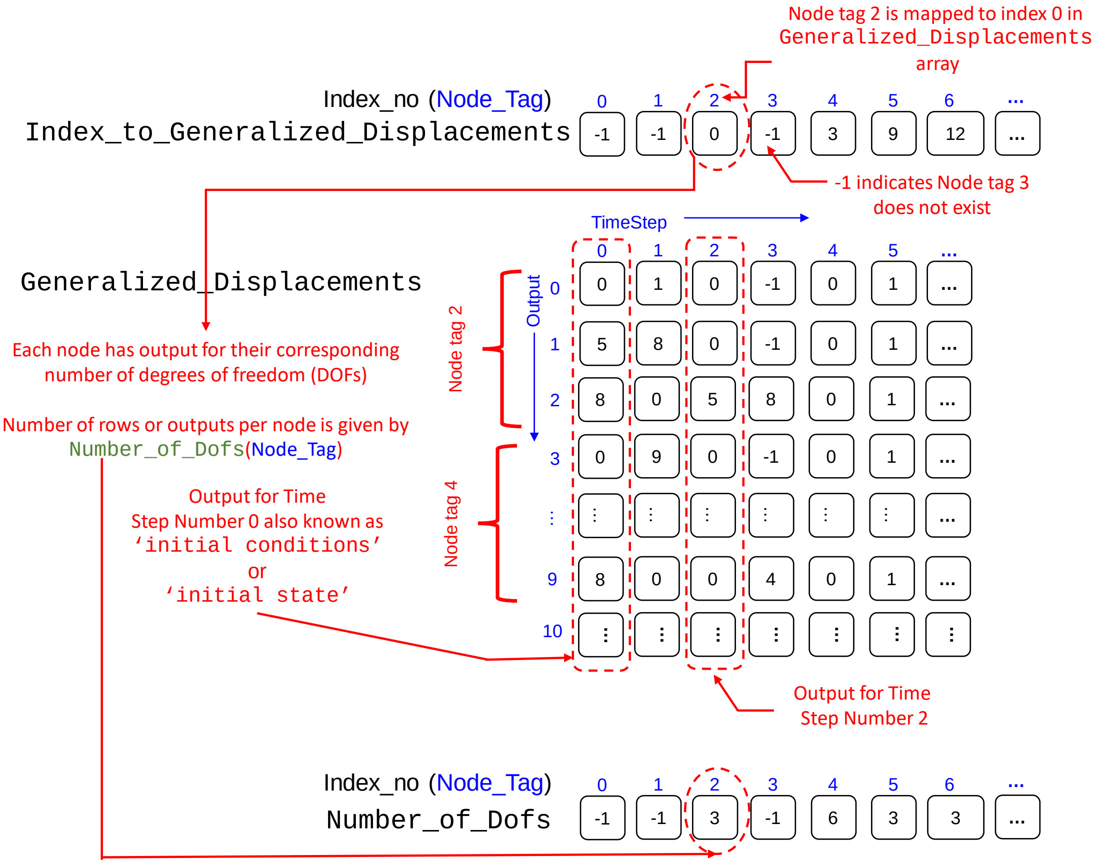

Figure 206.10: The `Index_to_Generalized_Displacements` and `Generalized_Displacements` in `Nodes` group directory of HDF5 file.

206.5.4 The `Elements` group

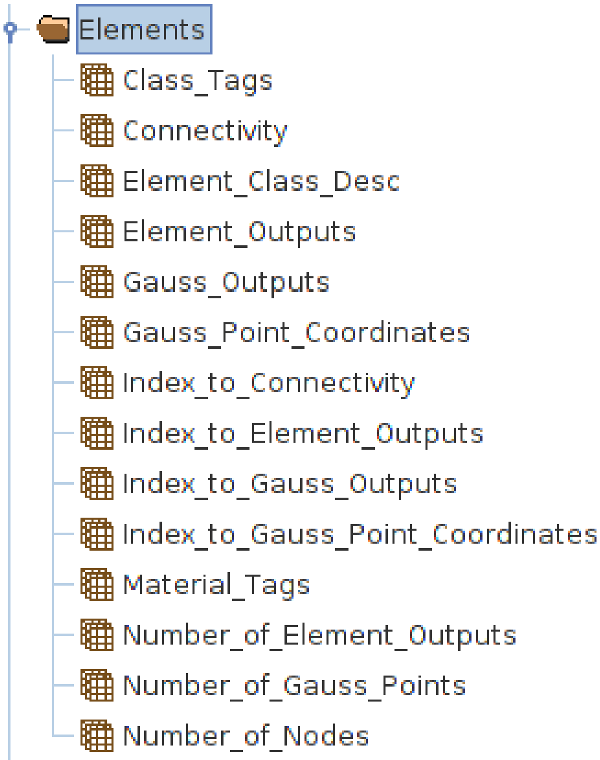
The `Elements` group contains information on the finite element mesh such as: connectivity array, element types, location of Gauss-point integration coordinates (global), materials defined at each element, and all available output from the elements. At this point it is important to note that the kind and amount of output contained in the element output arrays are dependent on element implementation as it is the elements who are in charge of controlling their output. For information on the specific output of each element, consult the documentation for the respective element.

The idea and organization of the datasets contained herein is analogous to the of the `Nodes` group. This group contains the following *index arrays*.

- `Index_to_Connectivity`: (`int`) Maps element tag to location within the `Connectivity` array.
- `Index_to_Gauss_Point_Coordinates`: Maps element tag to location of Gauss-point coordinates in the `Gauss_Point_Coordinates` array.

- `Index_to_Gauss_Outputs`: (`int`) Maps element tag to location of gauss output of element in the `Gauss_Outputs` array.
- `Index_to_Element_Outputs`: (`int`) Maps element tag to location of output in the `Elements_Outputs` array.

The following are the data arrays available in the `Elements` group (shown in Figure ?? along with their respective indexing array:



Elements
Class_Tags
Connectivity
Element_Class_Desc
Element_Outputs
Gauss_Outputs
Gauss_Point_Coordinates
Index_to_Connectivity
Index_to_Element_Outputs
Index_to_Gauss_Outputs
Index_to_Gauss_Point_Coordinates
Material_Tags
Number_of_Element_Outputs
Number_of_Gauss_Points
Number_of_Nodes

Figure 206.11: `Elements` group directory of HDF5 file.

- `Class_Tags`: (`int`) It is an array that contains the integer ids for each elements tag defined in the model and present in thet domain. See section 206.5.4.4
- `Number_of_Nodes`: (`int`) Maps element tag number to number of nodes in the element (-1 if element tag is not defined). See section 206.5.4.1.
- `Number_of_Gauss_Points`: (`int`) Maps tag number to the number of Gauss-integration points in that element (-1 if not element tag is not defined). It stores 0 in case of no gauss points (mostly for structural elements). See section 206.5.4.3

- `Material_Tags`: (`int`) Maps tag number to the tag number of the material contained in that element (-1 if element tag is not defined or material for that element is not defined). See section 206.5.4.6
- `Partition`: (`int`) Maps tag number to the tag number of the processor id on which it is assigned (-1 if element tag is not defined). See section 206.5.4.5
- `Connectivity`:(`int`) Contains the nodes tags which are connected by this element [indexed by the `Index_to_Connectivity` array] (-1 if element tag is not defined). See section 206.5.4.7
- `Gauss_Point_Coordinates`: (`float`) Contains the coordinates of all the gauss pints of that element tag [indexed by the `Index_to_Gauss_Point_Coordinates` array] (-1 if element tag is not defined) . See section 206.5.4.8
- `Gauss_Outputs`: (`float`) Contains the stress, strain and plastic strain outputs for each gauss point present in the corresponding element tag[indexed by the `Index_to_Gauss_Outputs` array]. See section 206.5.4.9
- `Element_Outputs`: (`float`) Contains output other than gauss points by the [indexed by the `Index_to_Element_Outputs` array]. See section 206.5.4.2

For example, lets imagine that the user has defined 4 elements and some materials as shown below :

Listing 206.2: Element_Example

```

// defining materials

add material #1 type uniaxial_elastic elastic_modulus = 1*Pa ↩
    viscoelastic_modulus = 0*Pa*s;
add material #2 type linear_elastic_isotropic_3d mass_density = 2000*kg/m^3 ↩
    elastic_modulus = 200*MPa poisson_ratio = 0.3;

// defining elements
add element #2 type truss with nodes (1,2) use material # 1 cross_section = ↩
    1*m^2 mass_density = 0*kg/m^3;
add element #4 type 8NodeBrick with nodes (1,8,6, 4, 3, 9, 2, 5) use material #2;
add element #5 type HardContact with nodes (3,2) normal_stiffness =1e10*N/m ↩
    tangential_stiffness = 1e4*Pa*m normal_damping = 0*kN/m*s ↩
    tangential_damping = 0*N/m*s friction_ratio = 1 contact_plane_vector = ↩
    (0,0,1);
add element #6 type 8NodeBrick with nodes (11,18,61,14, 3,19,22,15) use ↩
    material #2;
```

The index and the data arrays for the given example would look like the following as shown in the subsections ahead.

206.5.4.1 `Number_of_Nodes`

`Number_of_Nodes` array defines the number of nodes for each element defined in the model. It is an `integer` array of length equal to the maximum element tag + 1 (including tag 0). If a element tag does not exists, the corresponding number of nodes is output as -1. Figure 206.12 shows how to read `Number_of_Nodes` array. In the given example Listing 206.2 , element tag 2 has 2 nodes. Similarly, element tag 4 has 8 nodes and so on.

206.5.4.2 `Number_of_Element_Outputs`

`Number_of_Element_Outputs` array defines the number of outputs for each element defined in the model. It is an `integer` array of length equal to the maximum element tag + 1 (including tag 0). If a element tag does not exists, the corresponding number of outputs is stored as-1. Figure 206.12 shows how to read `Number_of_Element_Outputs` array. In the given example Listing 206.2 , element tag 2 has 2 outputs. Similarly, element tag 5 has 9 outputs but element tag 4 has 0 outputs and so on.

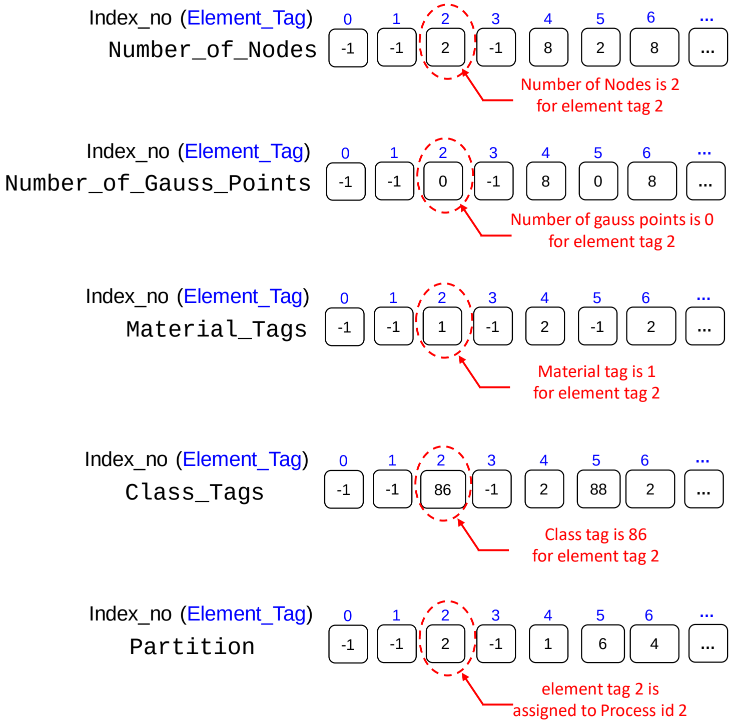


Figure 206.12: Arrays describing element information in `Elements` group directory of HDF5 file.

206.5.4.3 Number_of_Gauss_Points

`Number_of_Gauss_Points` array defines the number of gauss points for each element defined in the model. It is an `integer` array of length equal to the maximum element tag + 1 (including tag 0). If a element tag does not exists, the corresponding number of outputs is stored as-1. Figure 206.12 shows how to read `Number_of_Gauss_Points` array. In the given example Listing 206.2 , element tag 2 and 5 has 0 gauss points. Similarly, element tag 4 has 8 gauss points and so on.

206.5.4.4 Class_Tags

`Class_Tags` array defines an (unique) element type for each of the element defined in the model. It is an `integer` array of length equal to the maximum element tag + 1 (including tag 0). If a element tag does not exists, the corresponding number of outputs is stored as-1. Figure 206.12 shows how to read `Class_Tags` array. In the given example Listing 206.2 , element tag 2 has class tag of 88 (i.e. truss element) . Similarly, element tag 5 has class tag 2 (i.e. 8 node brick element) and so on. Table 206.1 and Table 206.2 shows class tags for different element types.

206.5.4.5 Partition

`Partition` array contains the domain or process id on which element tags were defined in case of a parallel simulation. For sequential runs, this dataset is not available. If a element tag does not exists, the corresponding partition process id is output as -1. Figure 206.12 shows how to read `Partition` array. In the given example Listing 206.2, element tag 2 is assigned to process id 2. Similarly, element tag 4 is assigned to process id 1 and so on.

206.5.4.6 `Material_Tags`

`Material_Tags` array defines the material tag number for each element defined in the model. It is an `integer` array of length equal to the maximum element tag + 1 (including tag 0). If a element tag does not exists, the corresponding number of outputs is stored as-1. Figure 206.12 shows how to read `Material_Tags` array. In the given example Listing 206.2 , element tag 2 has material tag of 1. Similarly, element tag 4 has material tag 2. Whereas, element tag 5 have material tag of -1.

Table 206.2: Class Tags for Real-ESSI Elements (Part -2)

206.5.4.7 `Connectivity`

`Connectivity` array stores the list of node tags in the same order as they were defined along with element declaration in the model. It is an `integer`. It is indexed by the `Index_to_Connectivity` array and the number of rows is defined by `Number_of_Nodes`. Figure 206.14 shows how to read `Connectivity` array for a particular element. In the given example Listing 206.2 , element tag 2 includes node tag 1 and 2. Similarly, element tag 4 includes 8 node tas 1,8,6, 4, 3, 9, 2 and 5 respectively.

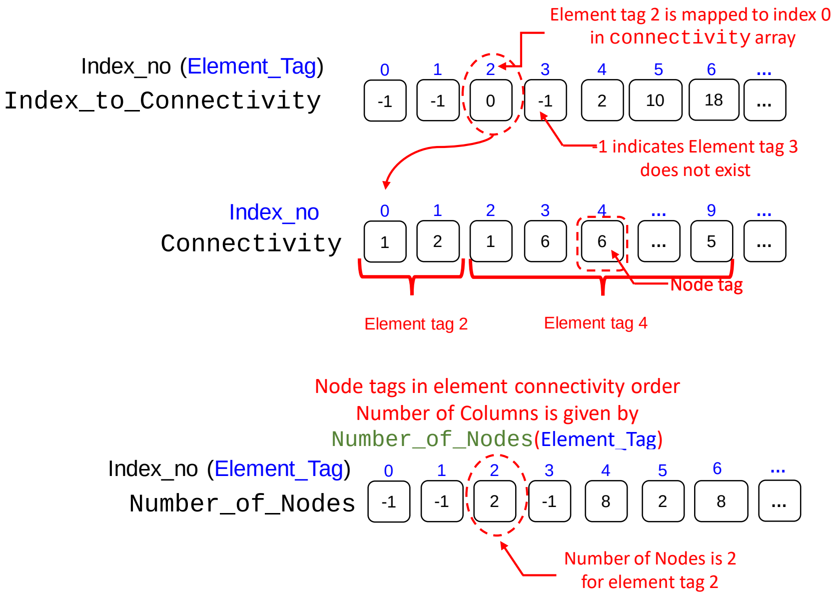

Figure 206.14: Arrays describing connectivity information in `Elements` group directory of HDF5 file.

206.5.4.8 `Gauss_Point_Coordinates`

`Gauss_Point_Coordinates` array stores the coordinates of the gauss points declared inside for each element defined in the model. It is a `float` array indexed by the `Index_to_Gauss_Point_Coordinates` array and the number of rows is defined by 3 (x, y, z) times `Number_of_Gauss_Points`. Figure 206.15 shows how to read `Gauss_Point_Coordinates` array for a particular element. In the given example Listing 206.2, element tag 2 and 5 has no gauss points. Since, element tag 4 has 8 gauss points, the total length of gauss point coordinates output for that element is $8 \times 3 = 24$. The index from which the coordinates information start is 0. Coordinate values for first 3 index $(0, 1, 2)$ corresponds to gauss point 1 and next 3 index $(3, 4, 5)$ corresponds to gauss point 2 and so on.

206.5.4.9 `Gauss_Output`

`Gauss_Outputs` array stores the coordinates of the gauss points declared inside for each element defined in the model. It is a 2D `float` array indexed by the `Index_to_Gauss_Outputs` array and the number of rows is defined by 18 (6 total strain, 6 plastic strain and 6 stress) times `Number_of_Gauss_Points`. The column index is represented by the time step of the simulation. Time index 0 represents initial state conditions, i.e. the state before the start of new stage and end of previous stage.

Figure 206.16 shows how to read `Gauss_Outputs` array for a particular element. In the given example Listing 206.2, element tag 2 and 5 has no gauss points. Since, element tag 4 has 8 gauss points, the

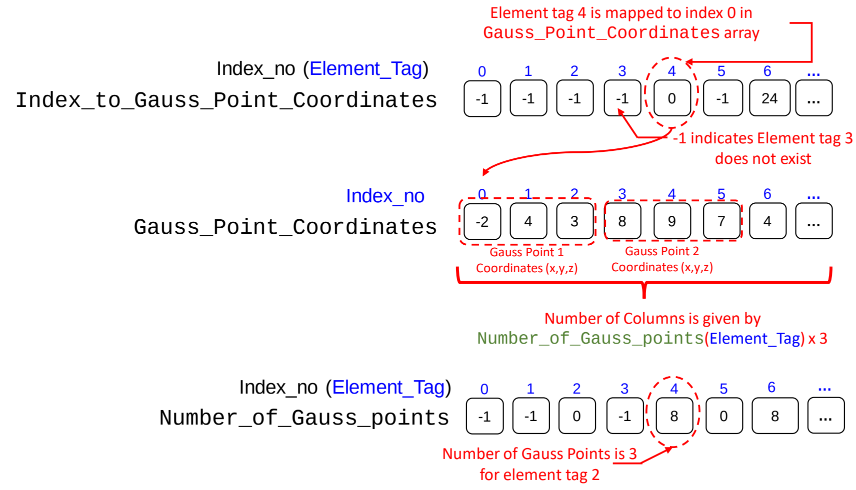

Figure 206.15: Arrays describing gauss coordinates information in `Elements` group directory of HDF5 file.

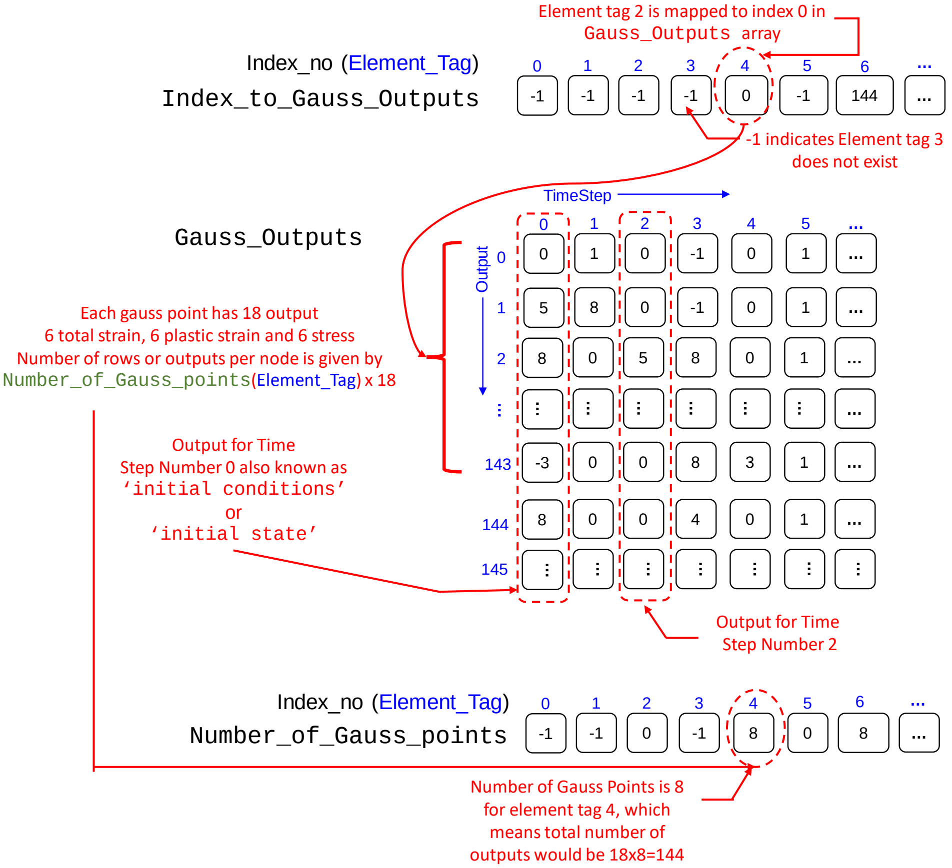

Figure 206.16: Arrays describing gauss output information in `Elements` group directory of HDF5 file.

total length of gauss output for that element is $8 \times 18 = 144$. The index from which the coordinates information start is 0. gauss values for first 18 index $(0, 1..17)$ corresponds to gauss point 1 and next 18 index $(18..35)$ corresponds to gauss point 2 and so on. For gauss point 1, first 6 index $(0, 1..5)$ corresponds to total strain, next 6 index $(6..11)$ corresponds to plastic strain and next 6 index $(12..17)$ corresponds to stress. Section 206.7 describes how gauss output is stored and what are the units and meaning of those outputs.

206.5.4.10 `Element_Outputs`

`Element_Outputs` array stores output for the elements except those stored at gauss points (i.e. stress, total strain and plastic strain). It is a 2D `float` array indexed by the `Index_to_Element_Outputs` array and the number of rows is defined `Number_of_Element_Outputs`. he column index is represented by the time step of the simulation. Time index 0 represents initial state conditions, i.e. the state before the start of new stage and end of previous stage.

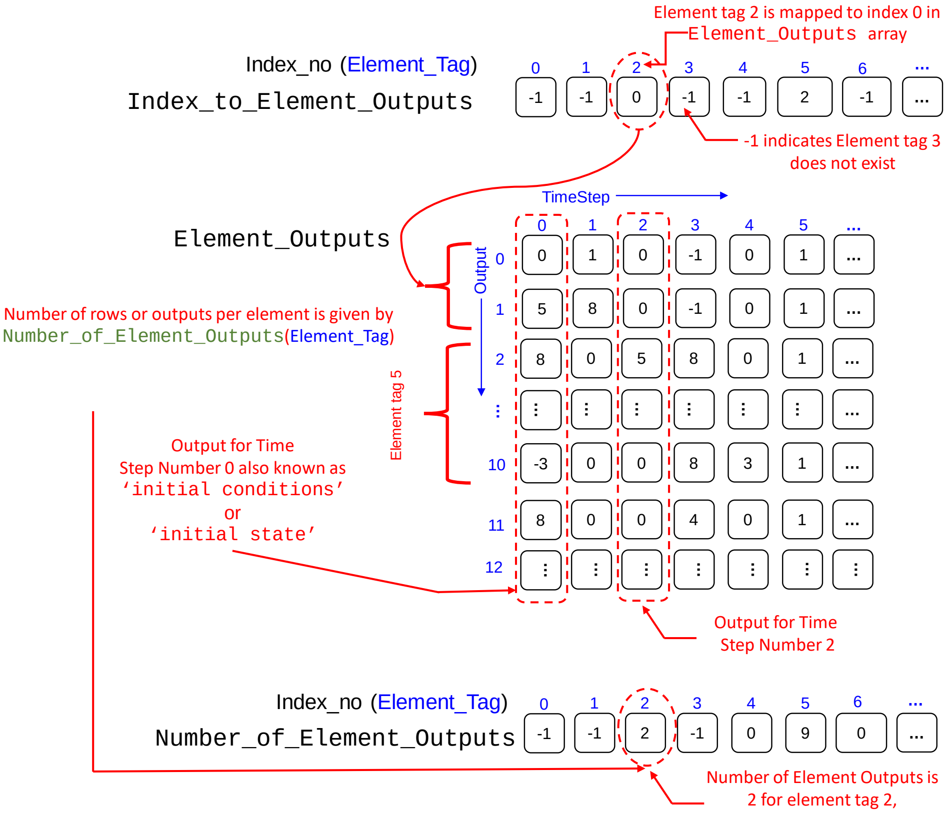

Figure 206.17: Arrays describing output information in `Elements` group directory of HDF5 file.

Figure 206.17 shows how to read `Element_Outputs` array for a particular element and particular time step. In the given example Listing 206.2, element tag 2 has two outputs. Similarly, element tag 5 has 9 outputs. On the other hand element tag 4 has no output. For element 2, the output starts at row index 0 and ends at 1. Similarly, for element tag 4, the output is stored in row index $2..10$.

Since the `Element_Outputs` array format depends on the elements present in the model, one must refer to each element specifically (Section 206.8) to identify what each output component means.

206.5.5 The `Physical_Groups` group

`Physical_Groups` group contains the physical groups of nodes or elements defined in the analysis. It contains two subgroups: `Physical_Node_Groups` and `Physical_Element_Groups` as shown in Figure 206.18 and is described in the following sections.

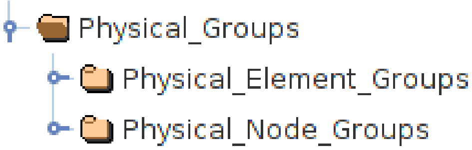

Figure 206.18: `Physical_Groups` group directory of HDF5 file.

For example, lets imagine that the user has defined one phyical group of nodes and elements respectively as shown below :

Listing 206.3: PhyGrp_Example

```
// defining physical groups
define physical_node_group ``Physical_Node_Group#1'';
define physical_element_group ``Physical_Element_Group#1'';

// adding items to allready defined physical groups
add nodes (1,4,5,7,2,30,42) to physical_node_group ``Physical_Node_Group#1''
add elements (1,4,5,7,2,30,42) to physical_node_group ``Physical_Element_Group#1''
```

The data arrays for the given example would look like the following as shown in the subsections ahead.

206.5.5.1 The `Physical_Element_Groups`

This group contains information about physical groups of elements defined in the analysis. For each of the physical group defined, a new `integer` data array is created inside `Physical_Element_Groups` which stored the element tags belonging to that group. Figure 206.19 shows how to read `Physical_Element_Groups` dataset array for a particular defined physical group.

In the given example Listing 206.3, a physical group array with name ``Physical_Element_Group#1'' is created which contains the list of element tags that were part of that physical group. Figure 206.19 shows that ``Physical_Element_Group#1'' contains element tags 1,4,5,7, and so on;

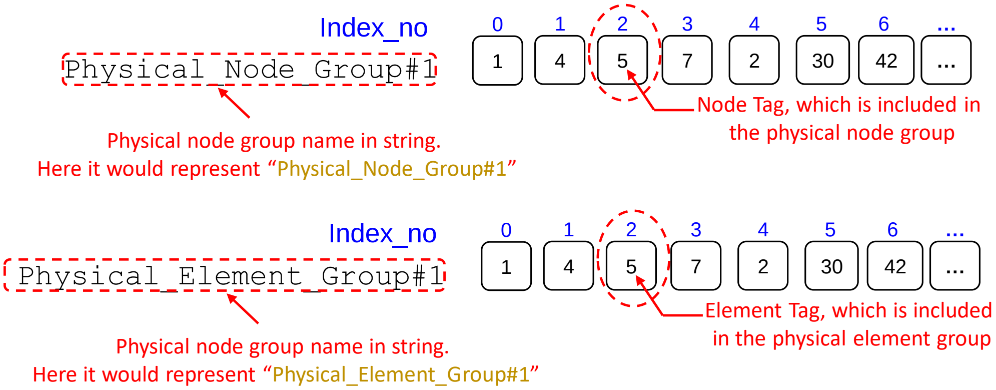

Figure 206.19: Arrays describing physical groups information in `Physical_Groups` group directory of HDF5 file.

206.5.5.2 The `Physical_Node_Groups`

This group contains information about physical groups of nodes defined in the analysis. For each of the physical group defined, a new `integer` data array is created inside `Physical_Node_Groups` which stored the node tags belonging to that group. Figure 206.19 shows how to read `Physical_Node_Groups` dataset array for a particular defined physical group.

In the given example Listing 206.3, a physical group array with name ``Physical_Node_Group#1'' is created which contains the list of node tags that were part of that physical group. Figure 206.19 shows that ``Physical_Node_Group#1'' contains node tags 1,4,5,7, and so on;

206.5.6 The `Eigen_Mode_Analysis` group

`Eigen_Mode_Analysis` group gets created in HDF5 .feioutput file after an eigen mode analysis. The data arrays available inside this group are described below and is also shown in Figure 206.20.

206.5.6.1 `Number_of_Eigen_Modes`

`Number_of_Modes` is an `integer` that stores information about the number of modes solved for the eigen problem. Figure 206.21 shows how to read it.

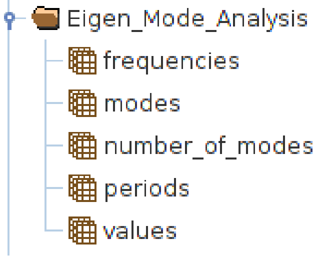

Figure 206.20: `Eigen_Mode_Analysis` group directory of HDF5 file.

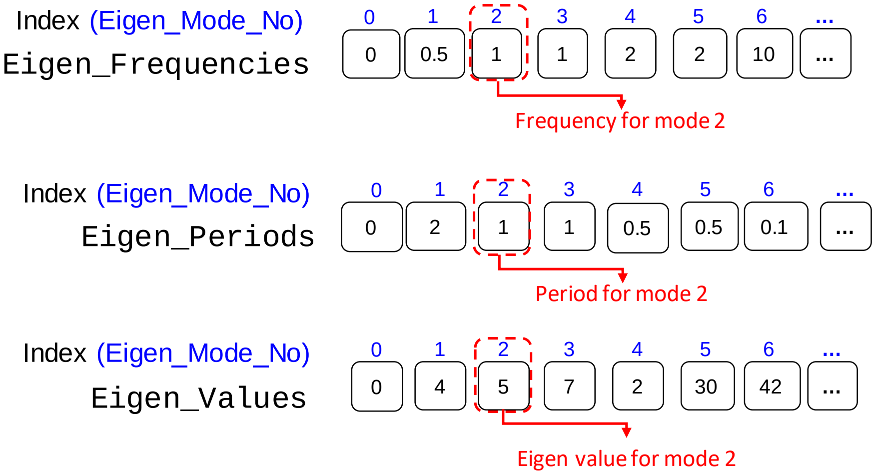
206.5.6.2 `Eigen_Frequencies`

`Frequencies` is an `float` array that stores the natural frequencies of the model corresponding to different modes. The length of the array is number of modes + 1. Index '0' does not correspond to any eigen mode and thus stores -1. Figure 206.21 shows how to read it.



Index (Eigen_Mode_No)	0	1	2	3	4	5	6	...
Eigen_Frequencies	0	0.5	1	1	2	2	10	...

Frequency for mode 2

Index (Eigen_Mode_No)	0	1	2	3	4	5	6	...
Eigen_Periods	0	2	1	1	0.5	0.5	0.1	...

Period for mode 2

Index (Eigen_Mode_No)	0	1	2	3	4	5	6	...
Eigen_Values	0	4	5	7	2	30	42	...

Eigen value for mode 2

Figure 206.21: `Eigen_Mode_Analysis` group directory of HDF5 file.

206.5.6.3 `Eigen_Periods`

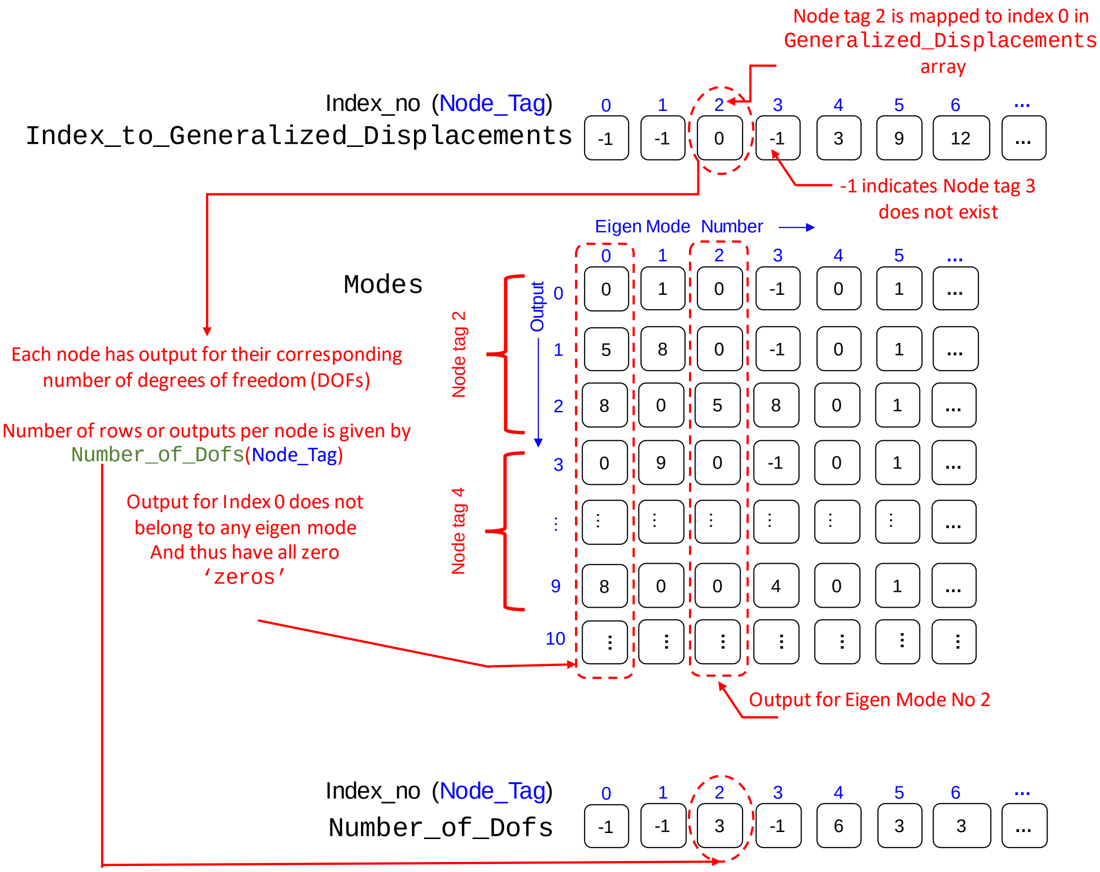
`Frequencies` is an `float` array that stores the natural periods of the model corresponding to different modes. The length of the array is number of modes + 1. Index '0' does not correspond to any eigen mode and thus stores -1. Figure 206.21 shows how to read it.

206.5.6.4 `Eigen_Values`

`Frequencies` is an `float` array that stores the natural eigen values of the model corresponding to different modes. The length of the array is number of modes + 1. Index '0' does not correspond to any eigen mode and thus stores -1. Figure 206.21 shows how to read it.

206.5.6.5 `Modes`

`Modes` is a 2-D `float` array that stores the generalized displacements of the nodes defined in the model corresponding to different modes. The column index no. n this 2-D array defines the mode no i.e. column index 1 corresponds to mode number 1 and so on. Figure ?? shows how to read it.



Index_no (Node_Tag)	0	1	2	3	4	5	6	...
Index_to_Generalized_Displacements	-1	-1	0	-1	3	9	12	...

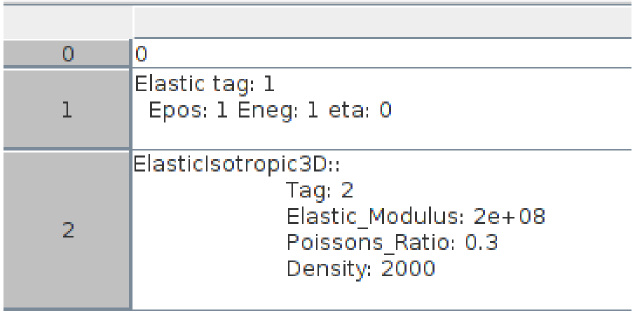
Output	0	1	2	3	4	5	...
0	0	1	0	-1	0	1	...
1	5	8	0	-1	0	1	...
2	8	0	5	8	0	1	...
3	0	9	0	-1	0	1	...
⋮	⋮	⋮	⋮	⋮	⋮	⋮	...
9	8	0	0	4	0	1	...
10	⋮	⋮	⋮	⋮	⋮	⋮	⋮

Index_no (Node_Tag)	0	1	2	3	4	5	6	...
Number_of_Dofs	-1	-1	3	-1	6	3	3	...

Figure 206.22: `Eigen_Mode_Analysis` group directory of HDF5 file.

206.5.7 The `Material` data array

Material is a 1-D `string` array that stores information about all materials defined in the model. The length of the array is the maximum material tag + 1 (including tag 0). The index of this array corresponds to the `material tag`. A value of '-1' means that the material tag was not defined. Figure 206.23 shows the `Material` data array for the example Listing 206.2. Here, index no 1 and index no 2 stores the information corresponding to material tag 1 and 2 respectively.



0	0
1	Elastic tag: 1 Epos: 1 Eneg: 1 eta: 0

Figure 206.23: `Materials` data array in `Model` directory of HDF5 file.

206.6 Node-specific output format

In Real-ESSI simulator, nodes can be defined with different number of degree of freedoms (DOFs). Nodes with with different dofs can be thought of different types of nodes. As a result, their corresponding output also changes. Here is described, all the different node types available and the output format and their descriptions for each of them. The following subsections would describe the definition of outputs that are expected in `Generalized_Displacements` and `Support_Reactions` data arrays in `Nodes` group of HDF5 output file for node tags of different dof types.

206.6.1 3DOF

Nodes defined with 3DOF type has u_x, u_y, u_z degrees of freedom. They correspond to the displacement degrees of freedom in x, y and z direction respectively. The dof id, generalized_displacement and support reactions for 3dof type node are summarized in the Table 206.6.1.

DOF Id	Description	`Generalized_Displacements`	`Support_Reactions`
0	disp. in x-dir	$u_x[m]$	$F_x[N]$
1	disp. in y-dir	$u_y[m]$	$F_y[N]$
2	disp. in z-dir	$u_z[m]$	$F_z[N]$

Table 206.3: DOF id and output for 3DOF type node

206.6.2 4DOF

Nodes defined with 3DOF type has u_x, u_y, u_z, p degrees of freedom. They correspond to the displacement degrees of freedom in x, y and z direction and pressure respectively. The dof id, generalized_displacement and support reactions for 4dof type node are summarized in the Table 206.6.2. up elements have nodes with 4 dofs.

DOF Id	Description	`Generalized_Displacements`	`Support_Reactions`
0	disp. in x-dir	$u_x[m]$	$F_x[N]$
1	disp. in y-dir	$u_y[m]$	$F_y[N]$
2	disp. in z-dir	$u_z[m]$	$F_z[N]$
3	pressure	$p[Pa]$	$p[Pa]$

Table 206.4: DOF id and output for 4DOF type node

206.6.3 6DOF

Nodes defined with 6DOF type has $u_x, u_y, u_z, r_x, r_y, r_z$ degrees of freedom. They correspond to the displacement and rotational degrees of freedom in x, y and z direction respectively. The dof id, generalized_displacement and support reactions for 6 dof type node are summarized in the Table 206.6.3. Beam and Shell elements have nodes with 6 dofs.

DOF Id	Description	`Generalized_Displacements`	`Support_Reactions`
0	disp. in x-dir	$u_x[m]$	$F_x[N]$
1	disp. in y-dir	$u_y[m]$	$F_y[N]$
2	disp. in z-dir	$u_z[m]$	$F_z[N]$
3	rotation about x-axis	$r_x[radian]$	$M_x[N-m]$
4	rotation about y-axis	$r_y[radian]$	$M_y[N-m]$
5	rotation about z-axis	$r_z[radian]$	$M_z[N-m]$

Table 206.5: DOF id and output for 6DOF type node

206.6.4 7DOF

Nodes defined with 6DOF type has $u_x, u_y, u_z, p, U_x, U_y, U_z$ degrees of freedom. They correspond to the solid-displacement , pore-fluid pressure and and fluid-displacement in x, y and z direction respectively. The dof id, generalized_displacement and support reactions for 7dof type node are summarized in the Table 206.6.3. upU elements have nodes with 7 dofs.

DOF Id	Description	`Generalized_Displacements`	`Support_Reactions`
0	solid disp. in x-dir	$u_x[m]$	$F^s{}_x[N]$
1	solid disp. in y-dir	$u_y[m]$	$F^s{}_y[N]$
2	solid disp. in z-dir	$u_z[m]$	$F^s{}_z[N]$
3	pore-pressure	$p[Pa]$	$p[Pa]$
4	fluid disp. in x-dir	$U_x[m]$	$F^f{}_x[N]$
5	fluid disp. in y-dir	$U_y[m]$	$F^f{}_y[N]$
6	fluid disp. in z-dir	$U_z[m]$	$F^f{}_z[N]$

Table 206.6: DOF id and output for 7DOF type node

206.7 Element-gauss output format

`Gauss_Outputs` array stores the coordinates of the gauss points declared inside for each element defined in the model. It is a 2D `float` array indexed by the `Index_to_Gauss_Outputs` array and the number of rows is defined by 18 (6 total strain, 6 plastic strain and 6 stress) times `Number_of_Gauss_Points`. The column index is represented by the time step of the simulation. Time index 0 represents initial state conditions, i.e. the state before the start of new stage and end of previous stage.

Figure 206.24 shows how to read `Gauss_Outputs` array for a particular element. In the given example Listing 206.2, element tag 2 and 5 has no gauss points. Since, element tag 4 has 8 gauss points, the total length of gauss output for that element is $8 \times 18 = 144$. The index from which the coordinates information start is 0. gauss values for first 18 index $(0, 1..17)$ corresponds to gauss point 1 and next 18 index $(18..35)$ corresponds to gauss point 2 and so on. For gauss point 1, first 6 index $(0, 1..5)$ corresponds to total strain, next 6 index $(6..11)$ corresponds to plastic strain and next 6 index $(12..17)$ corresponds to stress. Table 206.7 shows how data is stored for each gauss points. The strains are unit less and stress have unit of Pascal Pa.

In the Table 206.7 `start` corresponds to the starting position for the elements output as determined with reference to the `Index_to_Element_Outputs` for the element of interest. To this number we add the corresponding `offset` as determined by each table below and interpret the row according to the meaning established below.

For each gauss outputs there are 6 components of strain tensor, 6 components of plastic-strain tensor and 6 components of stress tensor. This makes a total of $3 \times 6 \times NumGauss$ rows of output per element. The specific meaning of the rows is as follows. For Gauss-point 1 (with starting index given in the `Index_to_Gauss_Outputs` array), the outputs are stored as the following

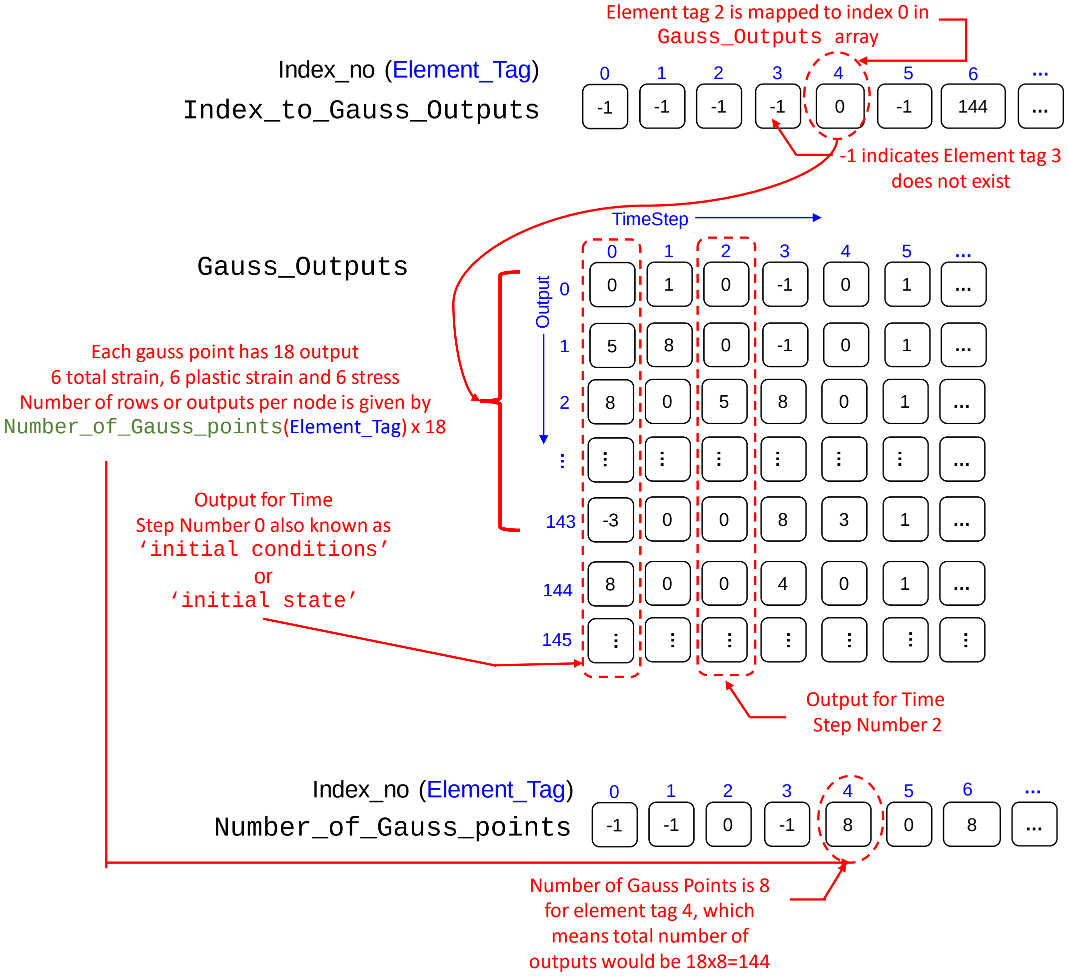

Figure 206.24: Arrays describing gauss output information in `Elements` group directory of HDF5 file.

Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+0`	$\epsilon_{xx}[]$	`start+6`	$\epsilon^{\text{plastic}}_{xx}[]$	`start+12`	$\sigma_{xx}[Pa]$
`start+1`	$\epsilon_{yy}[]$	`start+7`	$\epsilon^{\text{plastic}}_{yy}[]$	`start+13`	$\sigma_{yy}[Pa]$
`start+2`	$\epsilon_{zz}[]$	`start+8`	$\epsilon^{\text{plastic}}_{zz}[]$	`start+14`	$\sigma_{zz}[Pa]$
`start+3`	$\epsilon_{xy}[]$	`start+9`	$\epsilon^{\text{plastic}}_{xy}[]$	`start+15`	$\sigma_{xy}[Pa]$
`start+4`	$\epsilon_{xz}[]$	`start+10`	$\epsilon^{\text{plastic}}_{xz}[]$	`start+16`	$\sigma_{xz}[Pa]$
`start+5`	$\epsilon_{yz}[]$	`start+11`	$\epsilon^{\text{plastic}}_{yz}[]$	`start+17`	$\sigma_{yz}[Pa]$

Table 206.7: Output Format for each gauss point defined inside element

Gauss-point 2 will then start at position 18 through 36 with the same meaning for each row. And so-on for the other Gauss-points.

206.8 Element-specific output format

`Element_Outputs` array stores output for the elements except those stored at gauss points (i.e. stress, total strain and plastic strain). It is a 2D `float` array indexed by the `Index_to_Element_Outputs` array and the number of rows is defined `Number_of_Element_Outputs`. he column index is represented by the time step of the simulation. Time index 0 represents initial state conditions, i.e. the state before the start of new stage and end of previous stage.

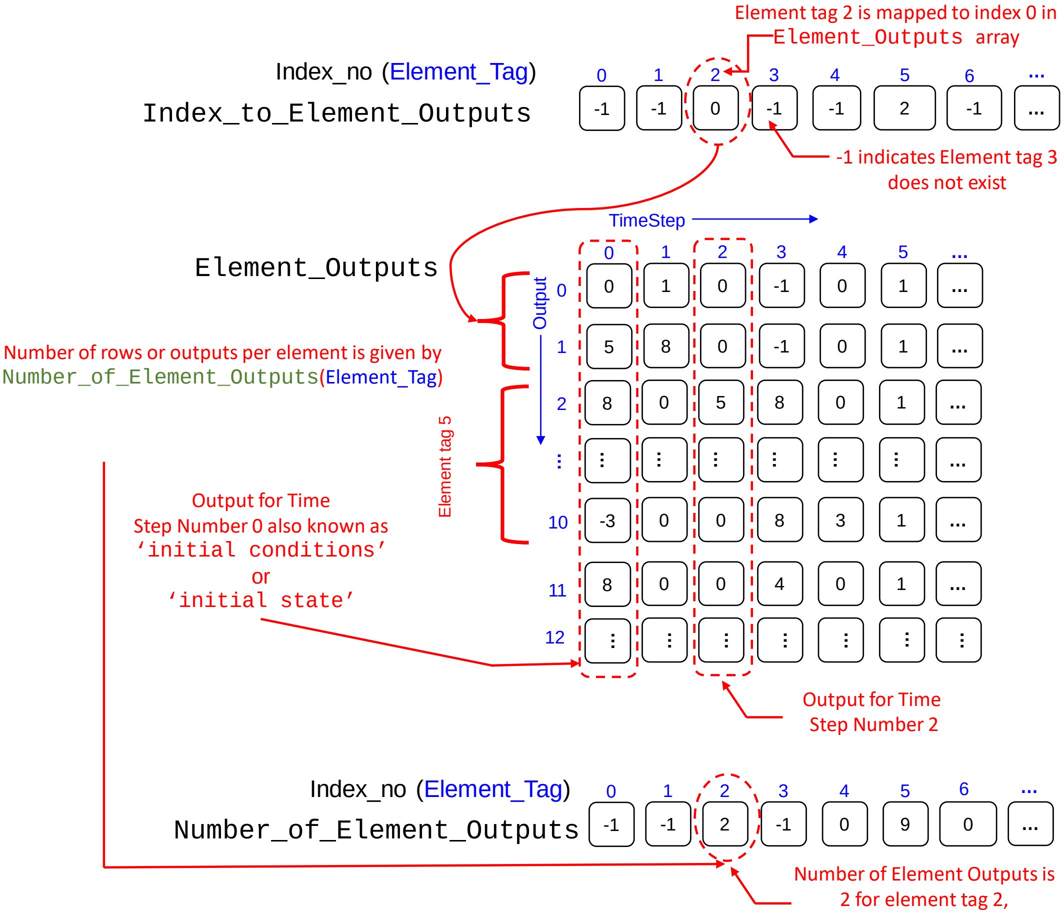

Figure 206.25: Arrays describing output information in `Elements` group directory of HDF5 file.

Figure 206.25 shows how to read `Element_Outputs` array for a particular element and particular time step. In the given example Listing 206.2, element tag 2 has two outputs. Similarly, element tag 5 has 9 outputs. On the other hand element tag 4 has no output. For element 2, the output starts at row index 0 and ends at 1. Similarly, for element tag 4, the output is stored in row index $2..10$.

Since the `Element_Outputs` array format depends on the elements present in the model, one must refer to each element specifically. Each element writes information into the `Element_Outputs` array in a different way. The user can determine the rows of the `Element_Outputs` array that belong to a given element by looking into the `Index_to_Element_Outputs` array which relates element tag to the starting position of that element's output within the `Element_Outputs` array. Additionally, the `Number_of_Element_Outputs` tells the user how many rows after the starting position correspond to the given element output.

The actual meaning of each row is element dependent and is detailed in the following pages. Please note that elements not in this list have no output defined at the moment.

In what follows `start` corresponds to the starting position for the elements output as determined with reference to the `Index_to_Element_Outputs` for the element of interest. To this number we add the corresponding `offset` as determined by each table below and interpret the row according to the meaning established below.

206.8.1 Truss

This element outputs 2 rows in total. First row is the uniaxial change in length while second component is the axial force. Truss does not have any gauss points and thus do not have any gauss outputs. The description of each of these rows are shown in Table 206.8:

Position (`start+offset`)	Content meaning
`start+0`	$\Delta L[m]$
`start+1`	$Force F[N]$

Table 206.8: Element Output description for Truss

206.8.2 Brick Elements

All the bricks (u, up, upU and variable) have 0 element outputs. But, they do output total strain, plastic strain and stress for all their corresponding number of gauss points involved in elasto-plastic integration. The format in which gauss outputs are stored for each gauss point is described in Section 206.8

206.8.3 ShearBeam

Like brick elements, Shear Beam element also does not have any element output. But it does output for the *one* gauss point it has. Thus, in total it has 18 outputs for the only one gauss point. The format in which gauss outputs are stored for each gauss point is described in Section 206.8

206.8.4 ElasticBeam

This element outputs 6 components of local nodal displacements at each of its two nodes, and 6 components of end forces at each of its two nodes. Total number of outputs is thus $2 \times 6 \times 2 = 24$ rows per element. The description of each of these rows are shown in Table 206.9:

Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+0`	$u_x^{\text{local},1}[m]$	`start+6`	$u_x^{\text{local},2}[m]$
`start+1`	$u_y^{\text{local},1}[m]$	`start+7`	$u_y^{\text{local},2}[m]$
`start+2`	$u_z^{\text{local},1}[m]$	`start+8`	$u_z^{\text{local},2}[m]$
`start+3`	$\theta_x^{\text{local},1}[radian]$	`start+9`	$\theta_x^{\text{local},2}[radian]$
`start+4`	$\theta_y^{\text{local},1}[radian]$	`start+10`	$\theta_y^{\text{local},2}[radian]$
`start+5`	$\theta_z^{\text{local},1}[radian]$	`start+11`	$\theta_z^{\text{local},2}[radian]$
Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+12`	$F_x^{\text{local},1}[N]$	`start+18`	$F_x^{\text{local},2}[N]$
`start+13`	$F_y^{\text{local},1}[N]$	`start+19`	$F_y^{\text{local},2}[N]$
`start+14`	$F_z^{\text{local},1}[N]$	`start+20`	$F_z^{\text{local},2}[N]$
`start+15`	$M_x^{\text{local},1}[N-m]$	`start+21`	$M_x^{\text{local},2}[N-m]$
`start+16`	$M_y^{\text{local},1}[N-m]$	`start+22`	$M_y^{\text{local},2}[N-m]$
`start+17`	$M_z^{\text{local},1}[N-m]$	`start+23`	$M_z^{\text{local},2}[N-m]$

Table 206.9: Element Output description for Elastic Beam

206.8.5 4NodeShell_ANDES

This element currently does not have any gauss or element outputs.

206.8.6 BeamColumnDispFiber3d

This element outputs 6 components of end forces at each of its two nodes. Each row is described in Table 206.10:

Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+0`	$F_x^{\text{local},1}[N]$	`start+6`	$F_x^{\text{local},2}[N]$
`start+1`	$F_y^{\text{local},1}[N]$	`start+7`	$F_y^{\text{local},2}[N]$
`start+2`	$F_z^{\text{local},1}[N]$	`start+8`	$F_z^{\text{local},2}[N]$
`start+3`	$M_x^{\text{local},1}[N-m]$	`start+9`	$M_x^{\text{local},2}[N-m]$
`start+4`	$M_y^{\text{local},1}[N-m]$	`start+10`	$M_y^{\text{local},2}[N-m]$
`start+5`	$M_z^{\text{local},1}[N-m]$	`start+11`	$M_z^{\text{local},2}[N-m]$

Table 206.10: Element Output description for displacement based fiber beams

206.8.7 Force Based Contact/Interface Elements

This element outputs 9 components: 3 components of gap displacement and 3 components of contact/interface forces and 3 components of incremental slip in the local axis definition. The first two components of gap are transverse components (g_{t1}, g_{t2}), while the third is the normal gap component g_n. Similarly, the first two components of force (F_{t1}, F_{t2}) are transverse (shear on contact/interface plane) while the third is the normal contact/interface force F_n. The last three components are incremental slip $\Delta g^{inc_s lip}{}_1, \Delta g^{inc_s lip}{}_2$ in the local transverse direction and total uplift Δn in local normal vector direction. If $\Delta n > 0$, there is uplift i.e. loss of contact/interface else it is in contact. Each row is described in Table 206.12:

Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+0`	$g_{t1}[m]$	`start+3`	$F_{t1}[N]$	`start+6`	$\Delta g^{inc_s lip}{}_1[m]$
`start+1`	$g_{t2}[m]$	`start+4`	$F_{t2}[N]$	`start+7`	$\Delta g^{inc_s lip}{}_2[m]$
`start+2`	$g_n[m]$	`start+5`	$F_n[N]$	`start+8`	$Uplift \Delta g_n[m]$

Table 206.11: Element Output description for force based contact/interface elements

206.8.8 Stress Based Contact/Interface Elements

This element outputs 9 components: 3 components of gap displacement and 3 components of contact/interface forces and 3 components of incremental slip in the local axis definition. The first two components of gap are transverse components (g_{t1}, g_{t2}), while the third is the normal gap component g_n. Similarly, the first two components of stress $(\sigma_{t1}, \sigma_{t2})$ are transverse (shear on contact/interface plane) while the third is the normal contact/interface stress σ_n. The last three components are incremental slip $\Delta g^{inc_s lip}{}_1, \Delta g^{inc_s lip}{}_2$ in the local transverse direction and total uplift Δn in local normal vector direction. If $\Delta n > 0$, there is uplift i.e. loss of contact/interface else it is in contact. Each row is described in Table 206.12:

Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning	Position (`start+offset`)	Content meaning
`start+0`	$g_{t1}[m]$	`start+3`	$\sigma_{t1}[N/m^2]$	`start+6`	$\Delta g^{inc_s lip}{}_1[m]$
`start+1`	$g_{t2}[m]$	`start+4`	$\sigma_{t2}[N/m^2]$	`start+7`	$\Delta g^{inc_s lip}{}_2[m]$
`start+2`	$g_n[m]$	`start+5`	$\sigma_n[N/m^2]$	`start+8`	$Uplift \Delta g_n[m]$

Table 206.12: Element Output description for stress based contact/interface elements

206.9 Energy Output Format

`Energy` folder in the output file stores simulation results for energy-related quantities. Energy density quantities are calculated at element integration points. Averaged energy density quantities are calculated for each element. Energy quantities are calculated for each element. Nodal input energy values are calculated at each node. All energy terms are calculated and stored at each time step.

Under the `Energy` folder, there are currently seven datasets. Four of them contain energy calculation results. The other three are index datasets, which can be used to find energy output for specific elements or nodes.

In general, energy output datasets are 2D float arrays. The column index is represented by the time step of the simulation. The row index represents various energy quantities that are calculated and stored. The three index datasets are used to locate the row index for specific energy quantities.

206.9.1 Input Energy

All types of nodal load, including DRM, are applied at nodes. Elemental loads are automatically converted to nodal loads, then also applied at nodes. Therefore, input energy or input work from all types of external load can be calculated at each node.

Under the `Energy` folder, the `Nodal_Input_Energy` dataset stores input energy at each node. Note that this is input energy accumulated from the start of simulation to the current time step. To find the input energy time history at a specific node, find the index in the `Index_to_Nodal_Input_Energy` dataset then find the corresponding entry in the `Nodal_Input_Energy` dataset.

For example, here are the steps to get the input energy time history at the node with node tag 73, Go to `Index_to_Nodal_Input_Energy`, find the index for node 73 to be 105. Then the accumulated input energy at your chosen node is stored at row 105 in `Nodal_Input_Energy`.

206.9.2 Energy Density Quantity at Gauss Point

`Energy_Density_GP` dataset stores energy density quantities at each Gauss point. To find the energy density time history at a specific Gauss point, find the index in the `Index_to_Energy_Density_GP` dataset then find the corresponding entry in the `Energy_Density_GP` dataset.

For each Gauss point, 12 data slots are occupied in the following order:

- Incremental kinetic energy density
- Accumulated kinetic energy density
- Incremental strain energy density

- Accumulated strain energy density
- Incremental plastic free energy density
- Accumulated plastic free energy density
- Incremental plastic dissipation density
- Accumulated plastic dissipation density
- The last 4 slots are currently empty, reserved for potential future use

Note that "incremental" means the change of energy density during the time step, "accumulated" means current cumulative energy density at the time step.

Here is an example showing how to obtain the energy density evolution at a specific Gauss point. Say you are interested in looking at the accumulated plastic dissipation density at the third Gauss point of an `8NodeBrick` element with element tag 73. Go to `Index_to_Energy_Density_GP`, find the index for element 73 to be 3904. Since each Gauss point occupies 12 slots in `Energy_Density_GP`, the energy outputs for the third Gauss point starts at index 3904+(3-1)*12=3928. Finally, since accumulated plastic dissipation density is the 8th entry among the 12 slots, the row index for the data of your interest is 3928+(8-1) = 3935. This means that the accumulated plastic dissipation density at your chosen location is stored at row 3935 of `Energy_Density_GP`.

206.9.3 Average Energy Density Quantity for Element

`Energy_Density_Element_Average` dataset stores averaged energy density quantities of each element. To find the energy density time history of a specific element, find the index in the `Index_to_Energy_Element` dataset then find the corresponding entry in the `Energy_Density_Element_Average` dataset.

For each element, 12 data slots are occupied in the following order:

- Incremental kinetic energy density
- Accumulated kinetic energy density
- Incremental strain energy density
- Accumulated strain energy density
- Incremental plastic free energy density
- Accumulated plastic free energy density

- Incremental plastic dissipation density
- Accumulated plastic dissipation density
- The last 4 slots are currently empty, reserved for potential future use

Note that "incremental" means the change of energy density during the time step, "accumulated" means current cumulative energy density at the time step.

Here is an example showing how to obtain the energy density evolution of a specific element. Say you are interested in looking at the accumulated plastic dissipation density of an `8NodeBrick` element with element tag 73. Go to `Index_to_Energy_Element`, find the index for element 73 to be 612. Since accumulated plastic dissipation density is the 8th entry among the 12 slots, the row index for the data of your interest is 612+(8-1) = 619. This means that the accumulated plastic dissipation density of your chosen element is stored at row 619 of `Energy_Density_Element_Average`.

206.9.4 Energy Quantity for Element

`Energy_Element` dataset stores averaged energy density quantities of each element. To find the energy time history of a specific element, find the index in the `Index_to_Energy_Element` dataset then find the corresponding entry in the `Energy_Element` dataset.

For each element, 12 data slots are occupied in the following order:

- Incremental kinetic energy
- Accumulated kinetic energy
- Incremental strain energy
- Accumulated strain energy
- Incremental plastic free energy
- Accumulated plastic free energy
- Incremental plastic dissipation
- Accumulated plastic dissipation
- Incremental viscous energy dissipation
- Accumulated viscous energy dissipation
- The last 2 slots are currently empty, reserved for potential future use

Note that "incremental" means the change of energy density during the time step, "accumulated" means current cumulative energy density at the time step.

Here is an example showing how to obtain the energy evolution of a specific element. Say you are interested in looking at the accumulated plastic dissipation of an `8NodeBrick` element with element tag 73. Go to `Index_to_Energy_Element`, find the index for element 73 to be 612. Since accumulated plastic dissipation is the 8th entry among the 12 slots, the row index for the data of your interest is 612+(8-1) = 619. This means that the accumulated plastic dissipation of your chosen element is stored at row 619 of `Energy_Element`.

Chapter 207

Real-ESSI Pre Processing and Model Development Methods

(2010-2015-2017-2020-2021-)

(In collaboration with Prof. Sumeet Kumar Sinha, Dr. Hexiang Wang and Dr. Yuan Feng)

207.1 Introduction

207.2 Model Development Using gmsh

207.2.1 Introduction to gmESSI

The gmESSI, pronounced as *[gm-ESSI]*, is a translator that converts mesh file from gmsh (a three-dimensional finite element mesh generator with built-in pre- and post-processing facilities) to Real-ESSI DSL format. The primary aim of this program is to provide an efficient pre-processing tool to develop Finite Element (FE) models in gmsh and make them interface with various Real-ESSI functionalities. The gmESSI translator package contains the translator, sublime plugin and the manual.

The gmESSI package is available at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Pre_Processing/Real-ESSI_gmESSI.tgz`.

The text editor sublime plugin *[gmESSI-Tools]* can be downloaded here: `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Pre_Processing/fei-syntax-n-snippets.tar.gz`.

207.2.1.1 Getting Started

The translator utilizes the physical and entity group concept of *Gmsh* (`http://geuz.org/gmsh/doc/texinfo/gmsh.html`) (Geuzaine and Remacle, 2009), which gets imprinted in the mesh ".msh" file. The translator then manipulates these groups to convert the whole mesh to ESSI commands. Thus, making physical groups is the essential, key for conversion. The Translator basically provides some strict syntax for naming these Physical Groups which provides gmESSI information about the elements or (nodes) on which the translation operates. The translator is made so general that any other FEM program can use it with little tweaks to have their own conversion tool. A quick look at some important features of the program are:

- It has a lot of predefined commands which do the conversion at the blink of an eye. These commands make it easier to define elements, boundary conditions, contacts/interfaces, fixities, loads ....
- It provides a python module "gmessi". The users can import this modulue and can extend the functional capability of gmESSI.
- The *[gmESSI-Tools]* sublime plugin makes it easy by providing syntax coloring and auto-text-completion for gmESSI commands. *[gmsh-Tools]* sublime plugin can also be installed for gmsh syntax coloring and auto-completion.

- The translator uses a *mapping.fei* file to check for its command syntax and conversion. A user can easily add a command in *mapping.fei* and it would get reflected automatically in the translation.
- It automatically optimizes the Real-ESSI tags (node, element, load) for space and time efficiency while running simulation.

Installation Process: The Translator have its dependencies on Octave (3.2 or higher), Boost(1.58 or higher), (Python 2.7 or higher). One should make sure to have them before compiling it. On Linux Ubuntu distros the dependencies can be installed as

```
sudo apt-get install liboctave-dev
# Boost version should be higher than 1.48
sudo apt-get install libboost-all-dev
sudo apt-get install python-dev
```

Installation of the gmESSI translator is easy, just follow steps below.

```
## go to folder where you want to store and build gmESSI application

## download the package from main Real-ESSI repository
## this line below should be all one line
## HOWEVER it had to be broken in two lines to be readable
## so please make a single command out of two lines below
##
#
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
wget {http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/\
_Chapter_SoftwareHardware_Pre_Processing/Real-ESSI_gmESSI.tgz}
##
# make directory, move files, expand archive
mkdir Real-ESSI-gmESSI
mv _all_files_gmESSI_.tgz Real-ESSI-gmESSI
cd Real-ESSI-gmESSI
tar -xvzf _all_files_gmESSI_.tgz

## build the package
make # builds the application in curr_dir/build

## install the package
# -- by default the pacakage is installed in /usr/local
make install # installs the package in /usr/local
# -- to change the install directory
make install INSTALL_DIR=install_dir_specified_by_user

############## For installation of gmESSI plugin in sublime ##############
# open sublime-text
```

```
# make sure you have installed package control
# if not then install it first from
# {https://packagecontrol.io/installation}
# go to Preferences->PackageControl->InstallPackage
# search for [gmESSI-Tools] and install it
# also install [gmsh-Tools] following the same steps
# restart sublime
############################################################################
```

207.2.1.2 Running gmESSI

gmESSI can be invoked from the bash terminal by typing *gmessy*. It can take one or multiple *xyz.gmessi* files as an argument and convert them to Real-ESSI files in their respective simulation directory defined by the user. By default, the 'gmessi' python module is automatically imported and available as 'gmESSI' in '.gmeesi' input file.

gmessy is a top level python script that parses the .gmessi file and categories commands in the following order as

- gmESSI Command: gmESSI Commands are one line commands. They start and end with '[' and ']' respectively. Section 207.2.3 describes the syntax.
- gmESSI Comments: The lines that start with '//' are considered as gmESSI comments. It gets translated and copied to the main file (See Section 207.2.4.6).
- Singular Commands: The lines that start with '!' are directly copied to the main file (See Section 207.2.4.6 and Section 207.2.5.1). Real-ESSI domain specific language (DSL) are written following the exclamation mark '!' sign.
- Python Comments: The lines that start with '#' are considered as python comments.
- Python Commands: Whatever lines left are considered as python commands. This option is only for the advanced user and is not documented to make the manual simple. Only some useful commands required are explained in the manual.

The categorized commands then generates an equivalent python (.py) script, which gets finally run in python interpretor. The generated equivalent python script can be seen by adding '-l' or '–logfile= LOG_FILE' option during execution. It is important to note that nodes, coordinates, element no etc generated from the translator have a precision associated with them. By default the precision is up-to '6' significant digits. The user can change the precision anywhere in the .gmessi file as

```
gmESSI.setPrecision(10);
```

This will set the precision to ‘10’ significant digits. Lowering precision can be helpful in generating same coordinates for contact/interface node pairs. See [Example_4.gmessi] for its usage.

The full description of *gmessy* can be invoked from the terminal as

```
$gmessy --help

usage: gmessy [-h] [-l] [-nm] [-em] [-ne] [--logfile= LOG_FILE]
[--nodemap= NM_FILE] [--elemap= ELM_FILE]
gmessi_filename

positional arguments:
gmessi_filename filename containing semantics of conversion

optional arguments:
-h, --help show this help message and exit
-l generate the log file at the current location
-nm generate the node map file at the current location
-em generate the element map file at the current location
-ne don't carry out the conversion
--logfile= LOG_FILE generate the log file at specified location
--nodemap= NM_FILE generate the node-map (gmsh-to-Real_ESSI) file at specified ↩
    location
--elemap= ELM_FILE generate the element-map (gmsh-to-Real_ESSI) file at ↩
    specified location
```

Since gmESSI optimizes the ‘node’ and ‘element’ tag for Real-ESSI, it provides an interface to retrieve the node map and element map containing mapping from gmsh_tag to Real_ESSI_Tag.

Running gmESSI requires, the *.gmessi* input file and the gmsh mesh (.msh) mesh file containing physical groups. Let’s go and run an example to see how gmESSI works. [Example_1] can be obtained here.

Alternatively in the gmESSI directory, navigate to the Examples directory and then to Example_1 directory.

```
$cd ./Examples/Example_1
$ls
Example_1.geo # geometry file [gmsh]
Example_1.msh # mesh file [gmsh]
Example_1.gmessi # gmessi input file [gmESSI]
```

Contents of Example_1.gmessi input file: As described above, the .gmessi input file contains gmESSI commands, singular commands and python commands. Also, it can contain comments followed by // or #.

At the beginning of the input file, the simulation directory, main, node, element, load filenames must be specified. Also, before adding any gmESSI command, mesh must be loaded using 'gmESSI.loadGmshFile' command.

```
$ cat Example_1.gmessi

### loading the msh file
gmESSI.loadGmshFile("Example_1.msh")

### Physical Groups defined in the msh file.
#2 2 "Base_Surface"
#2 3 "Top_Surface"
#3 1 "Soil"

### Defining the Simulation Directory
gmESSI.setSimulationDir("./Example_1_ESSI_Simulation")
gmESSI.setMainFile(gmESSI.SimulationDir+ "main.fei")
gmESSI.setNodeFile(gmESSI.SimulationDir+ "node.fei")
gmESSI.setElementFile(gmESSI.SimulationDir+ "element.fei")
gmESSI.setLoadFile(gmESSI.SimulationDir+ "load.fei")

// My new model
! model name "Soil_Block";

[Add_All_Node{ unit:= m, nof_dofs:= 3}]

// Adding Material layer wise and also assigning it to elements
[Vary_Linear_Elastic_Isotropic_3D{Physical_Group#Soil, ElementCommand:= ↩
    [Add_8NodeBrick{}], Density:= 1600+10*(10-z)\ 0 \kg/m^3, ElasticModulus:= ↩
    20e9+10e8*(10-z)\-8\Pa, PoissonRatio:= 0.3}]

! include "node.fei";
! include "element.fei";
! new loading stage "Stage1_Surface_Loading";

# Applying Fixities
[Fix_Dofs{Physical_Group#Base_Surface, all}]

#### For applying Surface load on the Top Surface of the Soil Block
#[Add_8NodeBrick_SurfaceLoad{Physical_Group#1,Physical_Group#3,10*Pa}]

#### For applying Nodal loads to all the nodes of the top surface
[Add_Node_Load_Linear{Physical_Group#Top_Surface, ForceType:= Fx, Mag:= 10*kN}]

#### For applying Self-Weight Load to the soil elements
! add acceleration field # 1 ax = 0*g ay = 0*g az = -1*g ;
! add load #18 to all elements type self_weight use acceleration field # 1;

# Updating the tag inside gmESSI as user entered by himself load tag
gmESSI.setESSITag("load",19)
```

```

! include "load.fei";
! NumStep = 10;
!
! define algorithm With_no_convergence_check;
! define solver UMFPack;
! define load factor increment 1/NumStep;
! simulate NumStep steps using static algorithm;
! bye;
```

Running Example_1 in Terminal:

```
$ gmessy Example_1.gmessi
Message:: newDirectory created as ./Example_1_ESSI_Simulation

Add_All_Node{ unit:= m, nof_dofs:= 3}
   Found!!
   Successfully Converted

Vary_Linear_Elastic_Isotropic_3D{Physical_Group#Soil, ElementCommand:= ↩
    [Add_8NodeBrick{}], Density:= 1600+10*(10-z)\ 0 \kg/m^3, ElasticModulus:= ↩
    20e9+10e8*(10-z)\-8\Pa, PoissonRatio:= 0.3}
   Found!!
   Successfully Converted

Fix_Dofs{Physical_Group#Base_Surface, all}
   Found!!
   Successfully Converted

Add_Node_Load_Linear{Physical_Group#Top_Surface, ForceType:= Fx, Mag:= 10*kN}
   Found!!
   Successfully Converted

*********************** Updated New Tag Numbering *********************
damping = 1
displacement = 1
element = 28
field = 1
load = 17
material = 4
motion = 19
node = 65
nodes = 65
Gmsh_Elements = 46
Gmsh_Nodes = 65
```

It must be noted that the terminal only displays information about gmESSI commands. The singular commands are directly copied to the main file. The translator creates a user defined directory *Example_1_ESSI_Simulation* and places

1. node.fei
2. element.fei
3. load.fei
4. main.fei
5. Example_1.msh

The terminal displays the WARNING, ERROR messages and log of command conversions as shown above. At the end, it displays the *Available ESSITag's* numbering, which can be refereed and used for further conversion.

ESSITags are explained later in this manual in Section 207.2.4.8.

The Real-ESSI input files produced can be tweaked a little if required. Once all is set, the model can be run through Real-ESSI Simulator

```
cd Example_1_ESSI_Simulation

### To run ESSI in sequential
# -- assuming sequential executable name is 'essi'
essi -f main.fei

### To run ESSI in parallel
# -- assuming parallel executable name is 'pessi'
mpirun -np 4 pessi -f main.fei
```

207.2.2 Gmsh Physical Groups and Geometrical Entities

207.2.2.1 Geometrical Entities

Geometrical entities are the most elementary group in Gmsh. Each point, line, surface and volume is a geometrical entity and possess a unique identification number. Elementary geometrical entities can then be manipulated in various ways, for example using the *Translate, Rotate, Scale or Symmetry* commands. They can be deleted with the *Delete* command, provided that no higher-dimension entity references them. Example_2.geo shows description of a geometry (.geo) file in gmsh for creating a *cantilever beam*. The files can be downloaded here. Alternatively, it can be located in the gmESSI directory by navigating to the Examples/Example_2 directory.

```
$ cat Example_2.geo
// Creating a point
Point(1) = {0,0,0};

// Dividing the beam length in 5 parts
Extrude (4,0,0) {Point{1}; Layers{5};}

// Dividing the beam width in 2 parts
Extrude (0,1,0) {Line{1}; Layers{2};Recombine;}

// Dividing the beam depth in 2 parts
Extrude (0,0,1) {Surface{5}; Layers{2};Recombine;}
```

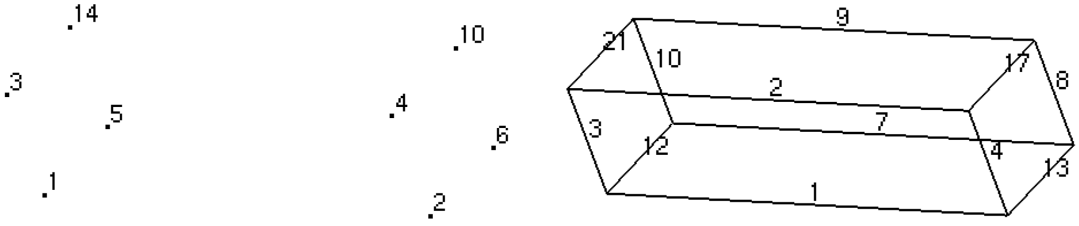
Figure 207.1 shows, the different unique identification number attached to each of the nodes, lines, surface and volume of the geometry of *cantilever beam*. Physical groups can now be created of type {nodes, lines, surface or volume} containing one or more geometrical entities of their respective type.

207.2.2.2 Physical Groups

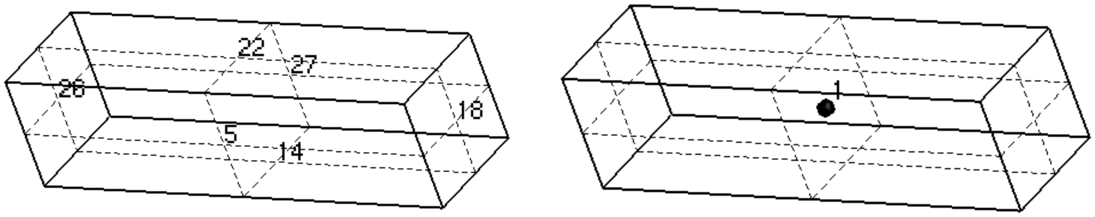
Physical groups are groups of same type {nodes, lines, surface, volume} of elementary geometrical entities. These Physical Groups cannot be modified by geometry commands. Their only purpose is to assemble elementary entities into larger groups, possibly modifying their orientation, so that they can be referred to by the mesh module as single entities. As is the case with elementary entities, each physical point, physical line, physical surface or physical volume are also assigned a unique identification number.

NOTE:- A geometrical entity has only one elementary entity number but can be a part of many physical groups by sharing their unique identification number.

Below is the continuation of Example_2.geo in Gmsh for creating physical Groups of *cantilever beam*.



(a) All Points (b) All Lines



(c) All Surface (d) All Volume

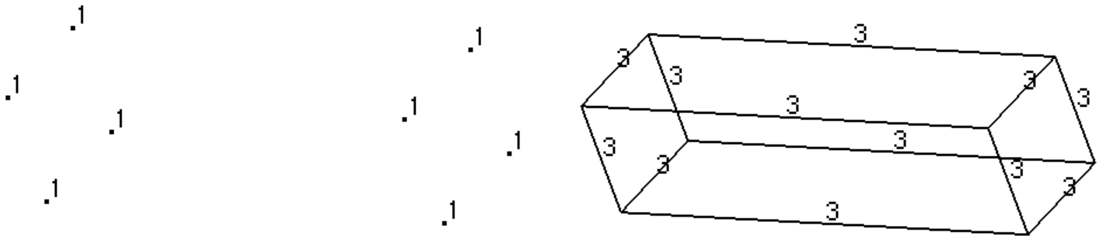
Figure 207.1: Showing Geometrical Entities. Every point, line, surface and volume has an unique identification number assigned to it.

Just for the sake of example, 4 physical groups are created which consist of all points, lines, surface and volume respectively of the *cantilever beam model*. Also physical groups of the surface where fixities and load is applied is created.

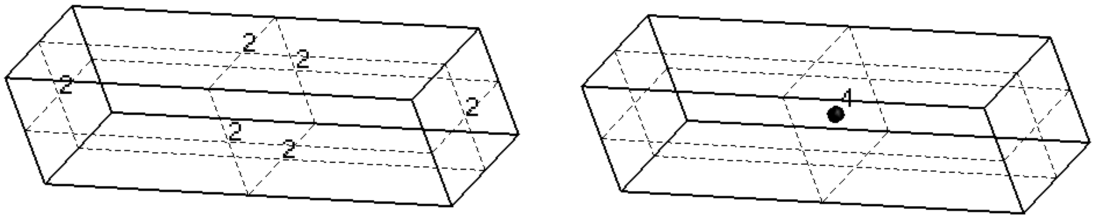
```
$ cat Example_2.geo
.....
Physical Point ("All_Points") ={1,2,3,4,5,6,10,14};
Physical Surface("All_Surfaces") = {5,14,22,27,18,26};
Physical Line("All_Lines") ={1,2,3,4,12,13,21,17,7,8,9,10};
Physical Volume("All_Volumes") ={1};
Physical Surface("ApplySurfaceLoad") ={27};
Physical Surface("SurfaceToBeFixed") ={26};
```

In generated mesh (.msh) file, all the geometrical entities have a tag list which contains the ids of the physical groups to which it belongs or is associated. In the above example shown in Figure 207.2, every point, line, surface, volume belongs to only one physical group and thus are showing only one associative number against themselves. Figure 207.3 shows geometrical entities which are part of many physical groups. For example:- the volume shown in Figure 207.3 shows physical group of volumes having id 1 and 7.

The whole idea of creating a Physical Group of points, lines, surfaces and volumes and giving it a unique string name is to allow quick identification and manipulation during gmESSI commands. In Gmsh the



(a) Physical group of Points (b) Physical group of Lines



(c) Physical group of Surface (d) Physical group of Volume

Figure 207.2: Showing all 4 Physical Groups with entities numbered by their physical group id's.

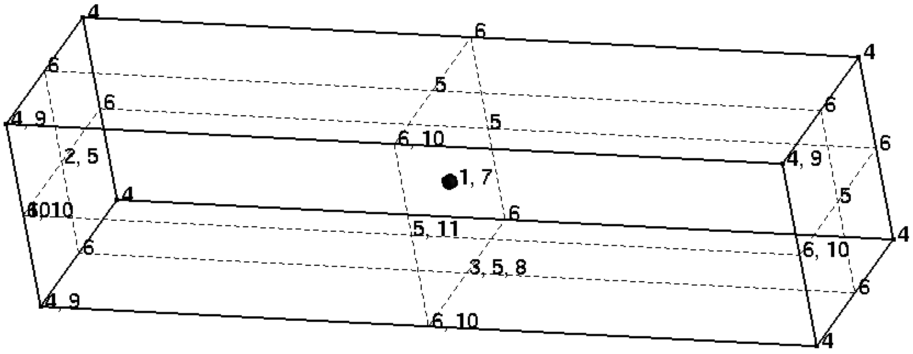


Figure 207.3: Showing geometrical entities associated with more than one physical group.

name of these Physical Group along with their corresponding elements and nodes gets transferred to the mesh .msh file as shown below. Figure 207.4 shows how Gmsh interprets these Physical groups in .msh file.

```
$cat Example_1.msh
.....
$PhysicalNames
6
0 1 "All_Points"
1 3 "All_Lines"
2 2 "All_Surfaces"
```

```
2 5 "ApplySurfaceLoad"
2 6 "SurfaceToBeFixed"
3 4 "All_Volumes"
$EndPhysicalNames
......
```

NOTE:- While creating a physical group in Gmsh, only the information (nodes and elements) of that physical group gets written in the .msh file and rest are not written. So one must be careful to create physical groups of all entities which is needed during post-processing or conversion. More information about Gmsh syntax, physical groups, commands, .msh file, save options, is available at the main online documentation web site: http://geuz.org/gmsh/doc/texinfo/gmsh.html

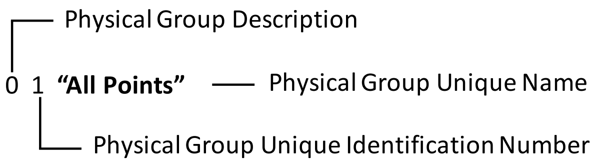

Figure 207.4: Description showing how gmsh interprets the Physical Groups.

- Physical Group Description :: Gmsh uses it to identify the type of physical group. $0, 1, 2$ *and* 3 represents the physical group of geometric points, lines, surface and volume respectively.
- Physical Group Unique Identification Number :: It is an unique identification number automatically assigned to each physical group by gmsh.
- Physical Group Unique Name :: It is also the same as *Physical Group Unique Identification Number* but the difference is that it is not automatic but defined by the user and that too in the form of string.

The gmESSI Translator utilizes the property of naming the physical group as "string" to get gmESSI commands from the user along with specific physical group on which it is operated. Below in shown [Example_2.gmessi] input file for a *Cantilever analysis*. It shows how to write gmESSI commands with physical group information on which it is operated. gmESSI utilizes the mesh (.msh) file to get the respective physical group and translated it to ESSI input (.fei) files.

```
$ cat Example_2.gmessi

gmESSI.loadGmshFile("Example_2.msh")
```

```

####### Physical Groups Available in Example_2.msh file
#0 1 "All_Points"
#1 3 "All_Lines"
#2 2 "All_Surfaces"
#2 5 "ApplySurfaceLoad"
#2 6 "SurfaceToBeFixed"
#3 4 "All_Volumes"

############ Important!! to set the file names ###################
gmESSI.setSimulationDir("./Example_2_ESSI_Simulation")
gmESSI.setMainFile(gmESSI.SimulationDir+ "main.fei")
gmESSI.setNodeFile(gmESSI.SimulationDir+ "node.fei")
gmESSI.setElementFile(gmESSI.SimulationDir+ "element.fei")
gmESSI.setLoadFile(gmESSI.SimulationDir+ "load.fei")

// My new model
! model name "Cantilever_Analysis";

[Add_All_Node{Unit:= m, NumDofs:= 3}]

// Adding Material
! add material 1 type linear_elastic_isotropic_3d mass_density = 2000*kg/m^3 ↩
    elastic_modulus = 200*MPa poisson_ratio = 0.2;

[Add_8NodeBrick{Physical_Group#All_Volumes, material_no:= 1}]
[Fix_Dofs{Physical_Group#SurfaceToBeFixed, all}]

! include "node.fei";
! include "element.fei";

! new loading stage "Stage1_Uniform_Surface_Load";

# Adding Surface Load
#[Add_8NodeBrick_SurfaceLoad{Physical_Group#All_Volumes, ↩
    Physical_Group#ApplySurfaceLoad, -10*Pa}]
[Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Fz, Mag:= ↩
    -10*kN}]

! include "load.fei";
! define algorithm With_no_convergence_check;
! define solver UMFPack;
! define load factor increment 1;
! simulate 10 steps using static algorithm;
! bye;
```

NOTE:- The first command in [.gmessi] file should be to load the mesh (.msh) file. The syntax to load the gmsh generated mesh file is

```
gmESSI.LoadGmshFile("meshfile.msh")
```

The gmESSI translator reads the command *[Add_All_Node{ Unit:= m, NumDofs:= 3}]* and adds all the nodes from mesh file to ESSI input files. Similarly it translates all the other commands as well.

207.2.3 gmESSI Command Description

gmESSI Translator as said above utilizes the naming of the physical groups to get commands from the user and then carry out the conversion by acting on the defined physical group.

207.2.3.1 gmESSI Syntax

gmESSI follows strict syntax. gmESSI parses the physical group name string in mesh (.msh) file. Let us have a quick look at the syntax of physical group name.

Physical Group Names : Physical group names are created inside gmsh geometry file. gmESSI follows special syntax as described below.

1. Physical group names used in gmsh should be unique for gmESSI to identify them during post processing.
2. Physical group names should not contain any space
3. Physical group tags can be any alphanumeric sequence but should not contain any of these [ ]$ literals in their names. Example "Physical_Group_1"

gmESSI Command Syntax : gmESSI translator commands are always enclosed between opening/closing square brackets [and] respectively. A typical gmESSI command syntax is shown in Figure 207.5

Figure 207.5: gmESSI command description.

- Command Name : Just as regular function gmESSI Commands have a name and take arguments. The names are usually self explanatory of its function like *Add_8NodeBrick*{...}, *Free_Dofs*{...} .. *etc*
- Physical Group Argument : Usually the gmESSI commands have first argument as physical group . For Example:- *Add_8NodeBrick*{*PhysicalGroup#5,...*}, *Add_8NodeBrick*{*PhysicalGroup#All_Volumes,...*}, *Free_Dofs*{*PhysicalGroup#4,...*},.. *etc*.

  Physical Group Id can be the gmsh unique string or number representing that physical group (as shown in .msh file).

- Arguments : Arguments as always are separated by comma ','.
  - Argument Tag The arguments of gmESSI commands can also have tags associated with them so that it becomes easy for the user to interpret the argument and make changes in future. The tag and the argument is separated by :=. Tag itself has no meaning but it serves as an important information center for user. An example is shown below to show how tags are applied.

    – gmESSI command having arguments without tags

    1. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, Fz, -10*kN}]

    – gmESSI command having arguments with tags

    1. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Fz, Mag:= -10*kN}]
    2. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Fz, -10*kN}]
    3. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, Force_Direction:= Fz, Strength:= -10*kN}]

It can be seen from above examples that the tags are optional and also the user can put their own tag names. The sublime plugin [*gmESSI-Tools*] comes with elaborative tags for the parameters and a lot more with syntax coloring and text-completion for gmESSI commands. It is encouraged to use the plugin and take its advantage.

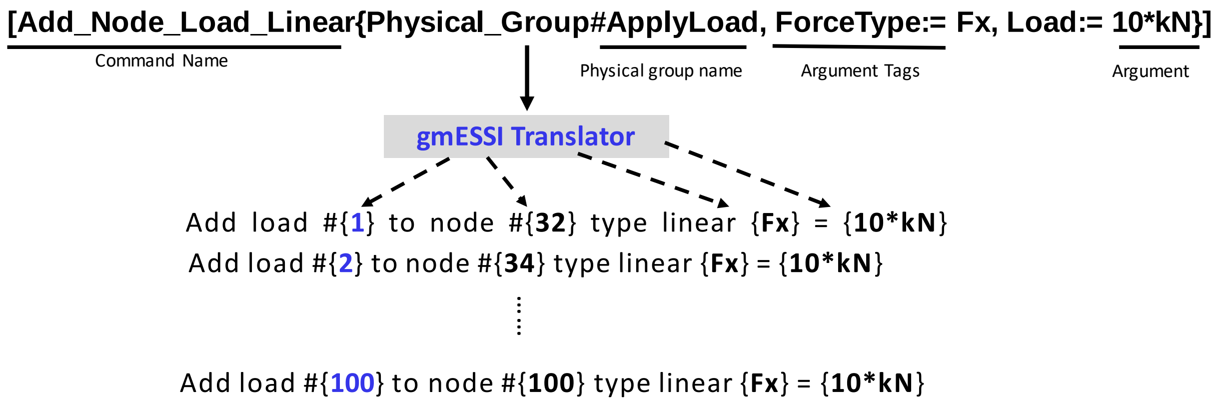

Figure 207.6: gmESSI conversion description.

Figure 207.6 shows the illustration how gmESSI works. Load gets added to all the nodes of the physical group 'ApplyLoad'. gmESSI translator automatically assigns the unique load tag sequentially. It retrieves the node tag from the physical group. Rest of the information like 'ForceType' and 'Magnitude' is obtained from the arguments.

Most of the time these arguments are dummy which means that they just get copied to their equivalent ESSI command at their respective places. These arguments thus have a "string" data-type. For example: the command Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, Fz, -10*kN} is equivalent to the Real-ESSI command add load #{} to node #{} type linear {} = {}. Fz and -10*kN goes to their respective position directly through the translator as shown in the Figure 207.6 load number 1 and node number 32 are computed by the translator and then inserted in the ESSI command.

NOTE:- The gmESSI Translator does not provide syntax checking for those dummy arguments. It means that, whatever is written gets copied at the respective position in the equivalent ESSI command, so the one must be careful with what they are writing in these arguments. For Example the command Add_Node_Load_Linear{Physical_Group#Id, ForceDirection, Magnitude} based on the arguments can get converted as

1. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Fz, Mag:= -10*kN}]
   —> add load #1 to node #32 type linear Fz = -10*kN
   —> add load #2 to node #33 type linear Fz = -10*kN
   ....
   —> add load #100 to node #100 type linear Fz = -10*kN
2. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Fz, Mag:= -10}]
   —> add load #1 to node #32 type linear Fz = -10
   —> add load #2 to node #33 type linear Fz = -10
   ....
   —> add load #100 to node #100 type linear Fz = -10
3. [Add_Node_Load_Linear{Physical_Group#ApplySurfaceLoad, ForceType:= Ft, Mag:= -10*kN}]
   —> add load #1 to node #32 type linear Ft = -10*kN
   —> add load #2 to node #33 type linear Ft = -10*kN
   ....
   —> add load #100 to node #100 type linear Ft = -10*kN

All the above conversions are correct. But only conversion (1.) is correct as an input for Real-ESSI Simulator because force direction is one of *Fx,Fy,Fz* and magnitude *10*kN* has *proper units*. So one must be very careful while writing the arguments.

Note: Some of the arguments are not string but represents numerical quantities, which are manipulated by the translator during conversion. Thus, the one must supply only numbers without any alphabets else it would lead an unexpected termination of program. These arguments corresponds to *Special Commands* such as *Connect Command* and *Variational Commands*. The manual talks about them later in Section 207.2.5.7.

207.2.3.2 gmESSI Command's Physical Group

As iterated earlier, gmESSI commands operates on physical groups. The gmESSI command usually have their first argument as physical on which it operates. The gmESSI syntax allows the users to operates it's command on specific physical groups. The user specifies the group by including an argument Physical_Group#Tag in front of the gmESSI commands describing the command. The *tag* can be either *Physical_Group_Id, Physical_Group_Name*. Let's look at some of them

- [Add_Node_Load_Linear{Physical_Group#5,Fz,-10*kN}] operates on physical group 5
- [Add_8NodeBrick{Physical_Group#All_Volumes, 1}] operates on physical group which has string_tag as All_Volumes

For example in reference to *[Example_2.gmessi]* Physical_Group#All_Volumes or Physical_Group#4 refers the same physical group.

A physical group is a group of point, line, surface or volume defined by the user which contains all the geometrical entities that falls under that domain/group. Figure 207.2 shows physical groups.

207.2.4 gmESSI Output

gmESSI Translator translates the gmESSI commands operated on mesh (.msh) file to different ESSI input (node, element, load and main) (.fei) files and put them in user-defined directory. It also updates the mesh (.msh) file and puts it in the same directory. The *log of translation, errors and warnings* are displayed on the terminal. Below is the demonstration of log messages one by one using *[Example_2.gmessi]* with mesh-file name *Example_2.msh*. The folders and Reall ESSI input (.fei) files that are created by the translator for Example_2.gmessi input file are.

207.2.4.1 Directory Example_2_ESSI_Simulation

gmESSI Translator creates simulation directory as specified by the user. The user is expected to create the necessary node (Section 207.2.4.4), element (Section 207.2.4.3) , load (Section 207.2.4.5) and main (Section 207.2.4.6) file to that directory. The user is expected to provide the directory and filenames before executing any gmESSI command. In case the directory already exists a warning messages is shown on the terminal and a new directory following the original name with '_n' (n is number) is created. A new Real-ESSI simulation directory is assigned by the following command

```
gmESSI.setSimulationDir("./Example_2_ESSI_Simulation", overwrite\_mode)
```

where, 'overwrite_mode=0' means that in case of already existing folder, a new directory following the original name with '_n' (n is number) is created. 'overwrite_mode=1' would not check for any conflicts and use the same directory as specified by user. For example:- running [Example_.gmessi] file would produce the following message.

```
$ gmessy Example_2.gmessi
Files converted to Examples/Example_2_ESSI_Simulation
```

Again, running the same example would produce the following message as shown below. In [Example_2.gmessi] overwrite is turned off and thats why it creates new-non conflicting directory by appending $_1$ to end.

```
$ gmessy Example_2.gmessi
Message:: newDirectory created as ./Example_2_ESSI_Simulation_1
```

The execution of *gmessy XYZ.gmessi* produces warnings/errors in the following situations.

- ERROR:: Please Enter the gmessi File :: It occurs if the user does not give a filename. The possible situation for getting this error is

```
$ gmessy
```

- ERROR:: The program failed to open the file XYZ.msh It occurs if the given file or one of the files in the argument does not exist or fails to open because of some reason.
- WARNING::Directory Already Present.The contents of the Folder may get changed :: It occurs when users translates the mesh file file XYZ.msh in overwrite mode and the corresponding folder XYZ_ESSI_Simulation already exists at the execution location.
- Files converted to Examples/Example_2_ESSI_Simulation :: The message refers to the location of the folder where the translations have been saved.

207.2.4.2 Translation Log Terminal

gmESSI Translator displays the log of translation of gmESSI commands to corresponding *Real-ESSI commands* on the terminal. Proper *Errors Messages* and *Warnings* are echoed to the user. The execution of the commands are sequential which means the commands written first are executed first and similarly their success and failure is also echoed first. Let us look at this aspect with Example_2.gmessi.

```
$cat Example_2.gmessi
......
! add material 1 type linear_elastic_isotropic_3d mass_density = 2000*kg/m^3 ↩
    elastic_modulus = 200*MPa poisson_ratio = 0.2;

[Add_8NodeBrick{Physical_Group#All_Volumes, material_no:= 1}]

[Fix_Dofs{Physical_Group#SurfaceToBeFixed, all}]

! include "node.fei";
! include "element.fei";
......
```

Here, the sequence of execution of commands is '! add material # 1 type linear_elastic_isotropic_3d mass_density $= 2000 * kg/m^3$ elastic_modulus $= 200 * MPa$ poisson_ratio $= 0.2$; ', [Add_8NodeBrick{ Physical_Group#All_Volumes, material_no:= 1}], [Fix_Dofs{ Physical_Group#SurfaceToBeFixed, all}] and '! include "node.fei";'. Notice that the same order gets reflected in the translation log on the terminal as shown below. Also, it must be noted that the commands followed by '!' or '//' or '#' or python commands do not have any log messages corresponding to them.

It must be noted that the lines following '!' are directly copied to the main (Section 207.2.4.6). Usually Real-ESSI domain specific language that does not operate/require any physical group should be written following exclamation '!' sign.

```
$ gmessy ./Example_2.gmessi
......
```

```

Add_8NodeBrick{Physical_Group#All_Volumes, material_no:= 1}
Found!!
Successfully Converted

Fix_Dofs{Physical_Group#SurfaceToBeFixed, all}
Found!!
Successfully Converted
```

Apart from displaying the log details on the terminal, similar log is added for each translation of gmESSI commands in their respective files in which they are translated. In these files, each successful translation is enclosed between corresponding *RespectiveGmESSICommand Begins* and *RespectiveGmESSICommand Ends*. The same is shown below through the contents of node.fei. Notice that all the translations are enclosed between Begins and Ends Tag.

```
$ cat Examples/Example_2_ESSI_Simulation/node.fei

//****************************************************************
// Add_All_Node{Unit:= m, NumDofs:= 3}Starts
//****************************************************************

add node # 1 at (0.000000*m,0.000000*m,0.000000*m) with 3 dofs;
add node # 2 at (4.000000*m,0.000000*m,0.000000*m) with 3 dofs;
add node # 3 at (0.000000*m,1.000000*m,0.000000*m) with 3 dofs;
...............................................................

//****************************************************************
// Add_All_Node{Unit:= m, NumDofs:= 3}Ends
//****************************************************************
```

```
$ cat Examples/Example_2_ESSI_Simulation/element.fei

//***********************************************************************
// Add_8NodeBrick{Physical_Group#All_Volumes, material_no:= 1}Starts
//***********************************************************************

add element #1 type 8NodeBrick with nodes (51,46,29,37,33,17,1,9) use material #1;
add element #2 type 8NodeBrick with nodes (47,28,5,19,51,46,29,37) use material ↩
   #1;
add element #3 type 8NodeBrick with nodes (42,32,46,51,13,3,17,33) use material ↩
   #1;
..............................................................

//*********************************************************************
// Add_8NodeBrick{Physical_Group#All_Volumes, material_no:= 1}Ends
//*********************************************************************
```

NOTE:- The ordering/sequence of commands in ESSI analysis file is important and so the user must make sure that the translations are made in the same order or if not the user should change it manually by (cut/copy/paste) in *node.fei, load.fei and main.fei* files before execution.

Having given a short description of the other translation log/error messages. Let us look more closely one by one and understand the messages,errors and warnings prompted on the terminal.

- Found!! : This message in front of the gmESSI command as shown above on translation log in the terminal means that, the corresponding command was found in the gmESSI Command Library.
- Successfully Converted : As the message itself describes, it occurs if the command has been successfully translated.
- Not Found!! : It occurs if the gmESSI Translator could not find the arbitrary command XYZ in the gmESSI Command library. Example:- *Loading{Fx,10*kN} NotFound!!*
- WARNING:: Execution of the command escaped. The Gmessi command XYZ could not be found : The gmESSI Translator does not terminate the translation if a command is not found, instead gives this warning message following the *Not Found!! Error*.
- Error:: The command XYZ has a syntax error in Physical_Group# tag : It occurs if there is a syntax error in Physical_Group# argument. The correct represent ion for Physical group Tags is Physical_Group#n, where n is the group id as 1,2,3.. etc. Examples of improper representation are *Phy#2, Physical#Node, ..*
- Warning:: The command XYZ failed to convert as there is no such Physical Group :: It occurs if one of the arguments in the command is Physical_Group# and the specified physical group by the user does not exists in the .msh file.
- Warning:: The command XYZ could not find any nodes/elements on which it operates : It occurs if for a specified command, the required element types for translation could not be found in the specified Physical group. For Examples:- [Add_8NodeBrick{Physical_Group#1,1}] would give this warning as the Physical_Group#1 being a Physical line group does not contain any 8-Noded Brick elements on which this command operates.
- ERROR:: Gmsh File has invalid symbols in Node Section. Unable to convert string to integer in Gmsh File : It occurs if there is perhaps a string inside the Nodes section of .msh file.
- ERROR:: The command XYZ has a syntax errors :: It occurs if the specified command by the user contain any syntax errors caught while parsing the command.

- ERROR:: Gmsh File has invalid symbols in Element Section. Unable to convert string to integer in Gmsh File : It occurs if there is perhaps a string inside the Element section of .msh file.

207.2.4.3 Element File (element.fei)

Element file *element.fei* is one of four parts of Real-ESSI input file that contains the translation of commands related to only initialization of elements of the FEM mesh. Generally, all the conversions from Elemental Command (Section 207.2.5.5) are written to element file.

A new analysis element file is assigned by the following python command

```
gmESSI.setElementFile(gmESSI.SimulationDir+ "element.fei")
```

where, 'gmESSI.SimulationDir' returns the Real-ESSI Simulation directory specified by the user (see section 207.2.4.1).

207.2.4.4 Node File (node.fei)

Node file *node.fei* is one of four parts of Real-ESSI input file that contains the translation of commands related to only initialization of nodes of the FEM mesh. All the conversions from Add Node Command (Section 207.2.5.2) are written to node file.

A new analysis node file is assigned by the following python command

```
gmESSI.setNodeFile(gmESSI.SimulationDir+ "node.fei")
```

where, 'gmESSI.SimulationDir' returns the Real-ESSI Simulation directory specified by the user (see section 207.2.4.1).

207.2.4.5 Load File (load.fei)

Load file *load.fei* contains the translation of commands related to the load and boundary conditions on the structure, for example declaration of fixities, boundary conditions, tied/connected nodes, nodal loads, surface loads etc....

A new load file is assigned by the following python command

```
gmESSI.setLoadFile(gmESSI.SimulationDir+ "load.fei")
```

where, 'gmESSI.SimulationDir' returns the Real-ESSI Simulation directory specified by the user (see section 207.2.4.1).

207.2.4.6 Analysis File (main.fei)

Analysis file *main.fei* is the main file which is run on Real-ESSI Simulator. The main file must include load, node and element file through *include 'filename.fei'* command.

A new analysis main file is assigned by the following python command

```
gmESSI.setMainFile(gmESSI.SimulationDir+ "main.fei")
```

where, 'gmESSI.SimulationDir' returns the Real-ESSI Simulation directory specified by the user (see section 207.2.4.1). A typical analysis file after conversion looks like the following.

```
$ cat Examples/Example_2_ESSI_Simulation/Example_2_analysis.fei

// My new model
 model name "Cantilever_Analysis";

// Adding Material
add material 1 type linear_elastic_isotropic_3d mass_density = 2000*kg/m^3 ↩
    elastic_modulus = 200*MPa poisson_ratio = 0.2;

include "node.fei";
include "element.fei";

new loading stage "Stage1_Uniform_Surface_Load";

include "load.fei";
 define algorithm With_no_convergence_check;
 define solver UMFPack;
 define load factor increment 1;
 simulate 10 steps using static algorithm;
bye;
```

The user can now add solver, time steps and even rearrange the file structure accordingly to Real-ESSI syntax.

NOTE: Real-ESSI Interpreter is sequential and follows certain ordering in commands like materials should be declared before assigning to elements, main-follower nodes can be assigned only when both nodes are declared .. etc.. One should be careful with the order in which conversions are made and if necessary should change it manually by (cut/copy/paste) later in the files geometry.fei, load.fei and analysis.fei or use the python module discussed later before running in ESSI.
Please refer to the Real-ESSI manual for more details on the ordering of the commands.

207.2.4.7 Mesh File (XYZ.msh)

Mesh file *XYZ.msh* is the input required by the translator. The translator updates the mesh file with users addition. For example:- if Connect-Command (Section 207.2.5.8) is used, the file contains additional physical group, nodes and 2-noded elements. The Connect Command is discussed in the more detail later in Section 207.2.5.8.

207.2.4.8 Updated ESSI Tags Terminal

Updated ESSI Tags refers to the new tag numbering reference associated with ESSI Tags. ESSI has tag numberings associated for damping, displacement, element, field, load, material, and node/nodes. For example in Real-ESSI Command *add node # 1 at (x,y,z) with 3 dofs*, node is a tag and requires a new number like 1 to be associated with that node. The translator displays the new numberings available for each ESSI Tag so that the user is made aware of new numberings for manually specifying an ESSI command after the translation.

gmESSI also provides a python command to set the ESSI Tag. The command is

```
gmESSI.setESSITag(ESSI_Tag_Name,Tag)
```

where,

- ESSI_Tag_Name : It refers to a string representing to the Real-ESSI tag such as 'node', 'element', 'field'...etc
- Tag : It refers to an integer representing the next available tag.

NOTE : If user is writing its own Real-ESSI domain specific language (DSL), it is expected that the user will update the corresponding Real-ESSI tag used in that DSL. Otherwise, gmESSI would not be able to know the updated available tags. See Example_1.gmessi for its usage.

```
$ gmessy Example_2.gmessi
.....................
******* Updated New Tag Numbering ********
Damping = 1
displacement = 1
element = 21
field = 1
load = 19
material = 2
motion = 1
node = 55
nodes = 55
Gmsh_Elements = 127
Gmsh_Nodes = 55
```

207.2.5 gmESSI Commands

Having the knowledge about the syntax, output files, errors and warnings, its time to move on to different types of commands that gmESSI offers. it provide commands operated on physical group to allow conversion for to equivalent Real-ESSI commands. There are also some special command that gmESSI supports. For simplicity, the commands are categorized on the basis of their operation on nodes/elements. As stated earlier, the commands are translated to one of the four files *node.fei, element.fei, load.fei and main.fei*. Let us look at them closely one by one along with all its supported commands.

207.2.5.1 Singular Commands

Singular Commands does not require any physical group to operate. All the text following exclamation mark '!' are copied directly to the *main.fei* (Section 207.2.4.6). For Example:- ' ! include 'load.fei'; ' is translated as 'include "load.fei" ' in main.fei analysis file. See [Example_1.gmessi] for its usage.

Note:- Real-ESSI DSL/commands must be followed by the exclamation mark '!'.

207.2.5.2 Add Node Commands

Add Node Commands have only two commands. *[Add_All_Node{unit,nof_dofs}]* adds all the nodes generated in mesh (.msh) file to 'node.fei' file. Whereas, *[Add_Node{Unit,NumDofs}]* add all the nodes of only specified physical group by the user. These commands operates on all the nodes of the physical group and generate an equivalent Real-ESSI DSL for each of them.

NOTE:- Every Add Node commands get translated into the *node.fei* (Section 207.2.4.4).

- gmESSI : [Add_Node{PhysicalGroup , Unit , NumDofs}]
  translates to series of
  Real-ESSI DSL : add node $\# < . >$ at ($< L >$,$< L >$,$< L >$) with $< . >$ dofs;
  operated over all the nodes defined in the gmsh '.msh' file.

- gmESSI : [Add_All_Node{Unit , NumDofs}]
  translates to series of
  Real-ESSI DSL : add node $\# < . >$ at ($< L >$,$< L >$,$< L >$) with $< . >$ dofs;
  operated over all the nodes of the defined physical group

207.2.5.3 Nodal Commands : Operates On All Nodes of the defined Physical Group

Nodal commands operates on all the nodes of the physical group defined by the user. For example:- [Fix_Dofs{Physical_Group#Lateral_Surface,ux}] would fix ux degree of freedom of all the nodes of physical group 'Lateral_Surface'. It will generate equivalent Real-ESSI DSL 'fix node # < . > dof < . >' and apply to all the nodes of that physical group. Figure 207.6 shows how gmESSI operated on physical groups.

As earlier stated, that the arguments of gmESSI commands are dummy and gets copied directly to the ESSI equivalent command, so one must be very much aware while writing the arguments to the commands. The arguments should be filled with values of the corresponding ESSI command along with required units if any. For more details about the values to the arguments, please refer to ESSI Manual.

NOTE:- Every Nodal command gets translated to the *load.fei* file (Section 207.2.4.5).

The different commands under this category and their corresponding Real-ESSI commands are listed below

1. gmESSI : [Add_Nodes_To_Physical_Group{PhysicalGroup , Physical_Node_Group_String}]
   translates to series of
   Real-ESSI DSL : add nodes (< . >) to [physical_node_group] "*string*";
   operated over all the nodes of the defined physical group

2. gmESSI : [Add_Self_Weight_To_Node{PhysicalGroup , field#1}]
   translates to series of
   Real-ESSI DSL : add load # < . > to node # < . > type [self_weight] use acceleration field # < . >;
   operated over all the nodes of the defined physical group

3. gmESSI : [Add_Node_Load_Linear{PhysicalGroup , Force_Type , Magnitude}]
   translates to series of
   Real-ESSI DSL : add load # < . > to node # < . > type [linear] [FORCETYPE] = < *forceormoment* >; //[FORCETYPE] = [Fx] [Fy] [Fz] [Mx] [My] [Mz] [F_fluid_x] [F_fluid_y] [F_fluid_z]
   operated over all the nodes of the defined physical group

4. gmESSI : [Add_Node_Load_Path_Time_Series{PhysicalGroup , Force_Type , Magnitude , Series_File}]
   translates to series of
   Real-ESSI DSL : add load # < . > to node # < . > type [path_time_series] [FORCETYPE] =

$< forceormoment >$ series_file = "$string$";
operated over all the nodes of the defined physical group

5. gmESSI : [Add_Node_Load_Path_Series{PhysicalGroup , Force_Type , Magnitude , Time_Step , Series_File}]
   translates to series of
   Real-ESSI DSL : add load # < . > to node # < . > type [path_series] [FORCETYPE] = $< forceormoment >$ time_step = $< T >$ series_file = "$string$";
   operated over all the nodes of the defined physical group

6. gmESSI : [Add_Node_Load_From_Reaction{PhysicalGroup}]
   translates to series of
   Real-ESSI DSL : add load # < . > to node # < . > type [from_reactions];
   operated over all the nodes of the defined physical group

7. gmESSI : [Add_Node_Load_Imposed_Motion_Time_Series{PhysicalGroup , Dof_Type , Time_Step , Disp_Scale , Disp_File , Vel_Scale , Vel_File , Acc_Scale , Acc_File}]
   translates to series of
   Real-ESSI DSL : add imposed motion # < . > to node # < . > dof $< DOFTYPE >$ time_step = $< T >$ displacement_scale_unit = $< L >$ displacement_file = "$string$" velocity_scale_unit = $< L/T >$ velocity_file = "$string$" acceleration_scale_unit = $< L/T^2 >$ acceleration_file = "$string$";
   operated over all the nodes of the defined physical group

8. gmESSI : [Add_Node_Load_Imposed_Motion_Time_Series{PhysicalGroup , Dof_Type , Time_Step , Disp_Scale , Disp_File , Vel_Scale , Vel_File , Acc_Scale , Acc_File}]
   translates to series of
   Real-ESSI DSL : add load # < . > type imposed motion to node # < . > dof $< DOFTYPE >$ time_step = $< T >$ displacement_scale_unit = $< L >$ displacement_file = "$string$" velocity_scale_unit = $< L/T >$ velocity_file = "$string$" acceleration_scale_unit = $< L/T^2 >$ acceleration_file = "$string$";
   operated over all the nodes of the defined physical group

9. gmESSI : [Add_Node_Load_Imposed_Motion_Series{PhysicalGroup , Dof_Type , Disp_Scale , Disp_File , Vel_Scale , Vel_File , Acc_Scale , Acc_File}]
   translates to series of
   Real-ESSI DSL : add imposed motion # < . > to node # < . > dof $< DOFTYPE >$ displacement_scale_unit = $< L >$ displacement_file = "$string$" velocity_scale_unit = $< L/T >$ velocity_file

= "*string*" acceleration_scale_unit = $< L/T^2 >$ acceleration_file = "*string*";
operated over all the nodes of the defined physical group

10. gmESSI : [Add_Node_Load_Imposed_Motion_Time_Series{PhysicalGroup , Dof_Type , Time_Step , Disp_Scale , Disp_File , Vel_Scale , Vel_File , Acc_Scl , Acc_File}]
translates to series of
Real-ESSI DSL : add load # < . > type imposed motion to node # < . > dof $< DOFTYPE >$ displacement_scale_unit = $< L >$ displacement_file = "*string*" velocity_scale_unit = $< L/T >$ velocity_file = "*string*" acceleration_scale_unit = $< L/T^2 >$ acceleration_file = "*string*";
operated over all the nodes of the defined physical group

11. gmESSI : [Add_Damping_To_Node{PhysicalGroup , damping#1}]
translates to series of
Real-ESSI DSL : add damping # < . > to node # < . >;
operated over all the nodes of the defined physical group

12. gmESSI : [Add_Mass_To_Node{PhysicalGroup , MassX , MassY , MassZ}]
translates to series of
Real-ESSI DSL : add mass to node # < . > mx = $< M >$ my = $< M >$ mz = $< M >$;
operated over all the nodes of the defined physical group

13. gmESSI : [Add_Beam_Mass_To_Node{PhysicalGroup , MassX , MassY , MassZ , ImassX , ImassY , ImassZ}]
translates to series of
Real-ESSI DSL : add mass to node # < . > mx = $< M >$ my = $< M >$ mz = $< M >$ Imx = $< ML^2 >$ Imy = $< ML^2 >$ Imz = $< ML^2 >$;
operated over all the nodes of the defined physical group

14. gmESSI : [Fix_Dofs{PhysicalGroup , Dof_Types}]
translates to series of
Real-ESSI DSL : fix node # < . > dofs $< DofTypes >$;
operated over all the nodes of the defined physical group

15. gmESSI : [Free_Dofs{PhysicalGroup , Dof_Types}]
translates to series of
Real-ESSI DSL : free node # < . > dofs < . >;
operated over all the nodes of the defined physical group

16. gmESSI : [Remove_Node{PhysicalGroup}]
    translates to series of
    Real-ESSI DSL : remove node # $<$. $>$;
    operated over all the nodes of the defined physical group

17. gmESSI : [Remove_Equal_Dof_Constrain{PhysicalGroup}]
    translates to series of
    Real-ESSI DSL : remove constraint [equal_dof] node # $<$. $>$;
    operated over all the nodes of the defined physical group

18. gmESSI : [Remove_Displacement_From_Node{PhysicalGroup}]
    translates to series of
    Real-ESSI DSL : remove displacement from node # $<$. $>$;
    operated over all the nodes of the defined physical group

207.2.5.4 General Elemental Commands : Operates On All Elements of the defined Physical Group

General Elemental Commands operates on all the elements of a physical group. The translations are written in *load.fei* file. For example:- [Add_SelfWeight_To_Element{Physical_Group#Soil,Field:= 1}] would add self-weight to all the elements of the physical group 'Soil' along the field#1 direction using series of equivalent Real-ESSI DSL 'add load # < . > to element # < . > type [self_weight] use acceleration field # < . >;'

The different commands under this category and their corresponding ESSI commands are listed below

1. gmESSI : [Add_Elements_To_Physical_Group{PhysicalGroup , Physical_Element_Group_String}]
   translates to series of
   Real-ESSI DSL : add elements (< . >) to [physical_element_group] "*string*";
   operated over all the nodes of the defined physical group
2. gmESSI : [Add_Self_Weight_To_Element{PhysicalGroup , field#1}]
   translates to series of
   Real-ESSI DSL : add load # < . > to element # < . > type [self_weight] use acceleration field # < . >;
   operated over all the nodes of the defined physical group
3. gmESSI : [Add_Damping_To_Element{PhysicalGroup , damping#1}]
   translates to series of
   Real-ESSI DSL : add damping # < . > to element # < . >;
   operated over all the nodes of the defined physical group
4. gmESSI : [Remove_Element{PhysicalGroup}]
   translates to series of
   Real-ESSI DSL : remove element # < . >;
   operated over all the nodes of the defined physical group
5. gmESSI : [Remove_Strain_From_Element{PhysicalGroup}]
   translates to series of
   Real-ESSI DSL : remove strain from element # < . >;
   operated over all the nodes of the defined physical group

207.2.5.5 Elemental Commands : Operates On All Elements of the defined Physical Group

Elemental Commands operates only to specific elements of a physical group. The translations are written in *element.fei* file. For example:- [Add_8NodeBrick{Physical_Group#Soil,1}] would initialize all the hexahedron elements of physical group 'Soil' to equivalent Real-ESSI commands for defining 8-noded bricks elements 'add element # $< . >$ type [8NodeBrick] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$;'. Figure 207.6 shows how gmESSI operated on physical groups. The different commands under this category and their corresponding ESSI commands are listed below

1. gmESSI : [Add_20NodeBrick{PhysicalGroup , Num_Gauss_Points , material#1}]
   translates to series of
   Real-ESSI DSL : add element # $< . >$ type [20NodeBrick] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$;
   operated over all the elements of the defined physical group

2. gmESSI : [Add_20NodeBrick_Variable_GaussPoints{PhysicalGroup , Num_Gauss_Points , material#1}]
   translates to series of
   Real-ESSI DSL : add element # $< . >$ type [20NodeBrick] using $< . >$ Gauss points each direction with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$;
   operated over all the elements of the defined physical group

3. gmESSI : [Add_20NodeBrick_upU{PhysicalGroup , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus , Fluid_Bulk_Modulus}]
   translates to series of
   Real-ESSI DSL : add element # $< . >$ type [20NodeBrick_upU] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$ and porosity = $< . >$ alpha = $< . >$ rho_s = $< M/L^3 >$ rho_f = $< M/L^3 >$ k_x = $< L^3T/M >$ k_y = $< L^3T/M >$ k_z = $< L^3T/M >$ K_s = $< stress >$ K_f = $< stress >$;
   operated over all the elements of the defined physical group

4. gmESSI : [Add_20NodeBrick_upU_Variable_GaussPoints{PhysicalGroup , Num_Gauss_Points , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus

, Fluid_Bulk_Modulus}]

translates to series of

Real-ESSI DSL : add element # $< . >$ type [20NodeBrick_upU] using $< . >$ Gauss points each direction with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$ and porosity = $< . >$ alpha = $< . >$ rho_s = $< M/L^3 >$ rho_f = $< M/L^3 >$ k_x = $< L^3T/M >$ k_y = $< L^3T/M >$ k_z = $< L^3T/M >$ K_s = $< stress >$ K_f = $< stress >$;

operated over all the elements of the defined physical group

5. gmESSI : [Add_20NodeBrick_up{PhysicalGroup , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus , Fluid_Bulk_Modulus}]

   translates to series of

   Real-ESSI DSL : add element # $< . >$ type [20NodeBrick_up] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$ and porosity = $< . >$ alpha = $< . >$ rho_s = $< M/L^3 >$ rho_f = $< M/L^3 >$ k_x = $< L^3T/M >$ k_y = $< L^3T/M >$ k_z = $< L^3T/M >$ K_s = $< stress >$ K_f = $< stress >$;

   operated over all the elements of the defined physical group

6. gmESSI : [Add_20NodeBrick_up_Variable_GaussPoints{PhysicalGroup , Num_Gauss_Points , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus , Fluid_Bulk_Modulus}]

   translates to series of

   Real-ESSI DSL : add element # $< . >$ type [20NodeBrick_up] using $< . >$ Gauss points each direction with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$ and porosity = $< . >$ alpha = $< . >$ rho_s = $< M/L^3 >$ rho_f = $< M/L^3 >$ k_x = $< L^3T/M >$ k_y = $< L^3T/M >$ k_z = $< L^3T/M >$ K_s = $< stress >$ K_f = $< stress >$;

   operated over all the elements of the defined physical group

7. gmESSI : [Add_27NodeBrick{PhysicalGroup , material#1}]

   translates to series of

   Real-ESSI DSL : add element # $< . >$ type [27NodeBrick] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material # $< . >$;

operated over all the elements of the defined physical group

8. gmESSI : [Add_27NodeBrick_upU{PhysicalGroup , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus , Fluid_Bulk_Modulus}]
   translates to series of
   Real-ESSI DSL : add element $\# < . >$ type [27NodeBrick_upU] with nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) use material $\# < . >$ and porosity $= < . >$ alpha $= < . >$ rho_s $= < M/L^3 >$ rho_f $= < M/L^3 >$ k_x $= < L^3T/M >$ k_y $= < L^3T/M >$ k_z $= < L^3T/M >$ K_s $= < stress >$ K_f $= < stress >$;
   operated over all the elements of the defined physical group

9. gmESSI : [Add_27NodeBrick_upU_Variable_GaussPoints{PhysicalGroup , NumGaussPoints , material#1 , Porosity , Alpha , Solid_Density , Fluid_Density , Perm_X , Perm_Y , Perm_Z , Solid_Bulk_Modulus , Fluid_Bulk_Modulus}]
   translates to series of

operated over all the elements of the defined physical group

207.2.5.6 Elemental Compound Commands : Operates On All Surface Elements of the defined Physical Group [Surface Loads]

Elemental Compound Commands operates on two physical groups, one for surface and another for the element on which surface is present. It is used mainly for adding surface loads, which require surface number as well as element no in Real-ESSI DSL. For example:- [Add_8NodeBrick_SurfaceLoad{Physical_Group#Volume, Physical_Group#Surface, 10*Pa}] would initialize surface load of $10Pa$ on surfaces defined by physical_group 'Surface' on elements defined by physical_group 'Volume'.

The different commands under this category and their corresponding ESSI commands are listed below

NOTE:- Every Elemental commands get translated into the *load.fei* (Section 207.2.4.5).

1. gmESSI : [Add_20NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Pressure}]
   translates to series of
   Real-ESSI DSL : add load # $< . >$ to element # $< . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) with magnitude $< Pa >$;
   operated over all the elements of the defined physical group

2. gmESSI : [Add_20NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Press1 , Press2 , Press3 , Press4 , Press5 , Press6 , Press7 , Press8}]
   translates to series of
   Real-ESSI DSL : add load # $< . >$ to element # $< . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) with magnitudes ($< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$);
   operated over all the elements of the defined physical group

3. gmESSI : [Add_27NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Pressure}]
   translates to series of
   Real-ESSI DSL : add load # $< . >$ to element # $< . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) with magnitude $< Pa >$;
   operated over all the elements of the defined physical group

4. gmESSI : [Add_27NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Press1 , Press2 , Press3 , Press4 , Press5 , Press6 , Press7 , Press8 , Press9}]
   translates to series of

Real-ESSI DSL : add load $\# < . >$ to element $\# < . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$, $< . >$) with magnitudes ($< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$);
operated over all the elements of the defined physical group

5. gmESSI : [Add_8NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Pressure}]
   translates to series of
   Real-ESSI DSL : add load $\# < . >$ to element $\# < . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$) with magnitude $< Pa >$;
   operated over all the elements of the defined physical group

6. gmESSI : [Add_8NodeBrick_SurfaceLoad{PhysicalGroup#Volume , PhysicalGroup#Surface , Press1 , Press2 , Press3 , Press4}]
   translates to series of
   Real-ESSI DSL : add load $\# < . >$ to element $\# < . >$ type [surface] at nodes ($< . >$, $< . >$, $< . >$, $< . >$) with magnitudes ($< Pa >$, $< Pa >$, $< Pa >$, $< Pa >$);
   operated over all the elements of the defined physical group

207.2.5.7 Special Commands

The translator supports some special commands to perform some special functions that are regularly required in simulations. It supports the Connect Command (Section 207.2.5.8) allows to join or create nodes between two physical groups.

207.2.5.8 Connect Command

Connect Commands creates/find layers of 2-noded elements between any two parallel geometrical physical entities like two lines, two surface or two volumes and creates a physical group of those elements and updates this information in the *XYZ.msh* file. Since gmsh does not include the feature of defining or creating 2-noded elements after the mesh creation, this command can be very useful in that case. For example;- defining contacts/interfaces, embedded piles, boundary conditions, connections etc. The command syntax for connect command is
gmESSI :: [Connect{Physical_Group#tag_From , Physical_Group#tag_To, Physical_Group#tag_Between, dir_vect, mag, no_times, $algo\_(find|create)$, tolerance,New_Physical_Group_Name}]

- Physical_Group#tag_From :: It defines the starting nodes
- Physical_Group#tag_To :: It defines the set of end nodes
- Physical_Group#tag_Between:: It defines the set of nodes where the intermediary nodes can be found, while searching. While creating nodes, it does not play any role.
- dir_vect :: It defines the direction in which the user wants to create or find the nodes. The direction vector argument is given as {x_comp \y_comp \z_comp}. Example:- {0 \0 \-1} , {1 \1 \0} .. etc.
- mag :: It defines the length of each 2-noded line elements
- no_times :: It defines number of layers of 2-noded elements, the user want to create/find
- algo_(find/create) :: It defines the algo which is either 0 or 1 meaning whether to find or create the intermediary node
- tolerance :: It defines the tolerance is required to finding the nodes. It should be less than the minimum of the distance of neighboring nodes.
- New_Physical_Group_Name :: This argument enables the user to give a name to the 2-noded new-physical group formed

Figure 207.7 graphically describes arguments of connect command.
This command updates and creates additional nodes and 2-noded elements and also assigns a physical group name "$New_Physical_Group_Name$". gmESSI automatically adds the next id available to the new physical group. The user can then manipulate this newly created physical group with any other gmESSI commands.

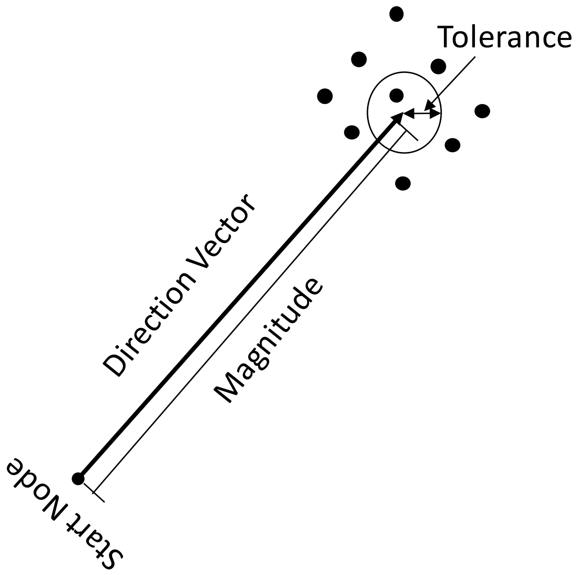

Figure 207.7: Pictorial representation of working of connect command.

The working of this command would be more clear through examples. [Example_3] can be downloaded here. [Example_4] can be downloaded here. These examples describes two situation one where new nodes are to be created and the other where already present nodes needs to be found respectively. In both the cases 2-noded line elements are always created. The examples can also be alternatively located in Examples folder of gmESSI directory

[Example_3] is a simple example where a tower of certain height above ground surface and also its base embedded in soil is modeled. It starts with a mesh file that creates a node for tower at a certain height and then using algorithm -'create' new nodes are created at certain intervals to generate the beam elements. On the other hand, the embedded beam is created by "-find" algorithm. Let us look at the [Example_3.geo] file.

```
$ cat Example_3.geo

// Size of the soil block in meter
Size = 10;

// Height of the Tower in meter
Height = 6;

// Mesh Size of the soil block
Mesh_Size = 1;

// Adding Points and extruding
Point(1)={-Size/2,-Size/2,-Size/2};
```

```
Extrude{Size,0,0}{Point{1};Layers{Size/Mesh_Size};Recombine;}
Extrude{0,Size,0}{Line{1};Layers{Size/Mesh_Size};Recombine;}
Extrude{0,0,Size}{Surface{5};Layers{Size/Mesh_Size};Recombine;}

// Make the tower located at height 6 m from the ground surface
Tower = newp;
Point (Tower) = {0,0,Size/2+Height};

//// Create Physical Groups
Physical Volume ("Soil") = {1};
Physical Surface ("Soil_Base_Surface") ={5};
Physical Surface ("Soil_Top_Surface") ={27};
Physical Point ("Tower") = {Tower};
```

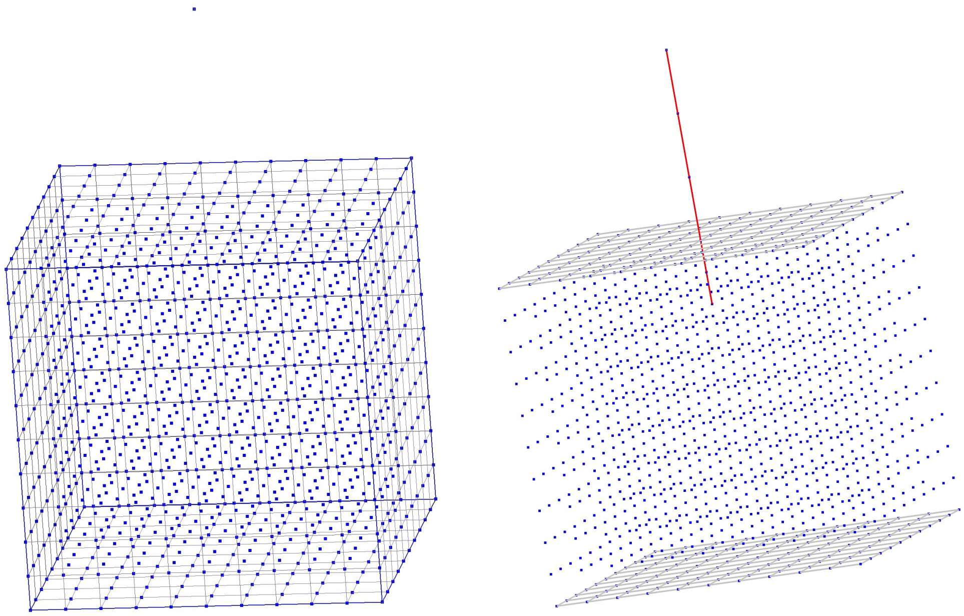
Running [Example_3.gmessi] with the .msh output of geometry file would produces additional nodes and elements as shown in Figure 207.8. An excerpt showing use of connect command with create algo in [Example_3.gmessi] is shown below. The effect of the command is shown in Figure 207.8.

```
$ cat Example_3.gmessi
..........
[Connect{Physical_Group#Tower, Physical_Group#Soil_Top_Surface, ↩
   Physical_Group#Soil_Top_Surface, dv1:= 0 \ 0 \ -1, mag:= 2, Tolerance:= 0, ↩
   algo:= create, noT:= 3, PhysicalGroupName:= Tower_Beam_Above_Ground}]
..............
```

The terminal displays the information about number of elements and nodes created and also displays the information about the new physical group information i.e id and name. The new physical group creation can be seen in the [Example_3.gmsh] in *Example_3_ESSI_Simulation* folder. The terminal message and mesh file is shown below. It also displays error message if more than one node is found in the tolerance provided.

```
$ gmessy Example_3.gmessi
New Physical Group "Tower_Beam_Above_Ground" having id 5 consisting of 4 Nodes ↩
   and 3 2-noded elements created
```

```
$ cat Example_3_ESSI_Simulation\Example_3.msh
............
$PhysicalNames
7
0 4 "Tower"
2 2 "Soil_Base_Surface"
2 3 "Soil_Top_Surface"
3 1 "Soil"
1 5 "Tower_Beam_Above_Ground"
3 6 "TowerBaseNode"
1 7 "Tower_Embedded_Beam"
$EndPhysicalNames
```



(a) Initial mesh file Example_3.msh generated by gmsh. The dir vector is in Z axis 0,0,-1

(b) Final mesh after gmESSI

Figure 207.8: Example 3 Contact Problem. (b) shows the nodes and elements generated by gmESSI Translator.

```
...........
```

[Example_4] describes a foundation on soil problem with contact/interface between them. The contact element is created with the help of comment command using algo "-find". Let us look at the [Example_4.geo] file.

```
$ cat Example_4.geo

// Size of the soil block
Size = 1;

// Thickness of Foundation
Thick = 0.1;
Foundation_Layers = 2;

//// Mesh Size of the block
Mesh_Size = 0.2;

// Adding Points an1 extruding
Point(1)={-Size/2,-Size/2,-Size/2};
Extrude{Size,0,0}{Point{1};Layers{Size/Mesh_Size};Recombine;}
```

```
Extrude{0,Size,0}{Line{1};Layers{Size/Mesh_Size};Recombine;}
Extrude{0,0,Size}{Surface{5};Layers{Size/Mesh_Size};Recombine;}

// Make sure in Tools -> Geometry -> General
// Geometry tolerance is set smaller than Epsilon
// such as Geometry tolerance = 1e-14

Epsilon = 1e-8;
Translate {0, 0, Epsilon} {Duplicata{Surface{27};}}
Transfinite Line {29,30,31,32} = Size/Mesh_Size +1;
Transfinite Surface {28};
Recombine Surface {28};

//// Extruding the surface to foundation thickness
Extrude{0,0,Thick}{Surface{28};Layers{Foundation_Layers};Recombine;}

//// Create Physical Groups
Physical Volume ("Soil") = {1};
Physical Surface ("Soil_Base_Surface") ={5};
Physical Surface ("Soil_Top_Surface") ={27};
Physical Surface ("Foundation_Base_Surface")={28};
Physical Surface ("Foundation_Top_Surface") ={54};
Physical Volume ("Foundation") = {2};

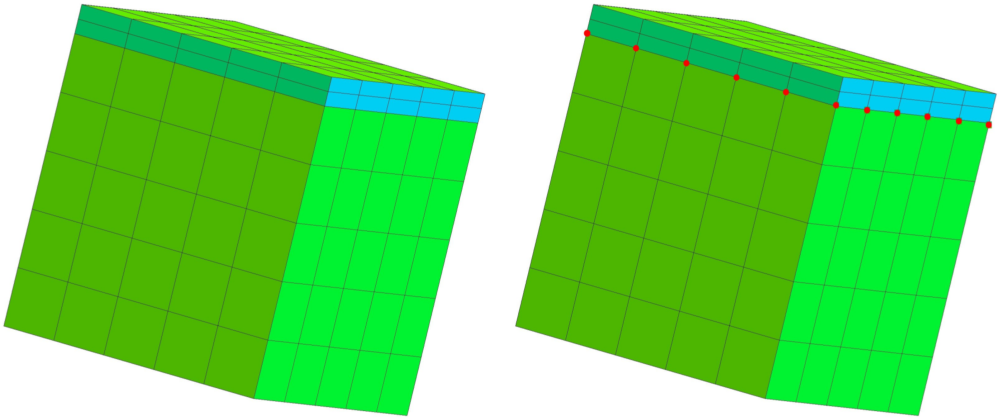
Physical Surface("Fix_X") = {26, 53, 45, 18};
Physical Surface("Fix_Y") = {22, 49, 14, 41};
Physical Volume("3_Dofs") = {1,2};
```

The above geometry file is then meshed with gmsh to get the .msh file. In this file, the connect command is applied between physical group *Foundation_Base_Surface* and *Soil_Top_Surface* to create contact/interface elements. The corresponding connect command would be as

```
$ gmessy Example_4.gmessi
..........
[Connect{Physical_Group#Soil_Top_Surface, ↩
   Physical_Group#Foundation_Base_Surface, ↩
   Physical_Group#Foundation_Base_Surface, dv1:= 0\0\1, mag:= 0, Tolerance:= ↩
   0.001, algo:= find, noT:= 1, PhysicalGroupName:= Contact_Elements}]
..............
```

Similarly the updated [Example_4.msh] contains the new physical group and terminal shows the new physical group of 2-noded elements created. Figure 207.9 shows the new nodes found and creation of 2-noded elements.

```
$ gmessy Example_3.gmessi
New Physical Group "Contact_Elements" having id 10 consisting of 72 Nodes and ↩
   36 2-noded elements created
```



(a) Initial mesh file Example4.msh generated by gmsh. The dir vector is in Z axis {0,0,1}

(b) New physical group Contact_Element

Figure 207.9: Example 4 finding nodes problem.(b) shows the nodes and elements generated by gmESSI Translator.

```
$ cat Example_4_ESSI_Simulation\Example_4.msh
10
2 2 "Soil_Base_Surface"
2 3 "Soil_Top_Surface"
2 4 "Foundation_Base_Surface"
2 5 "Foundation_Top_Surface"
2 7 "Fix_X"
2 8 "Fix_Y"
3 1 "Soil"
3 6 "Foundation"
3 9 "3_Dofs"
1 10 "Contact_Elements"
............
```

NOTE : Since the algo is to only find the nodes, so no new nodes are created, but only elements are created. The same message can be seen on the terminal.

207.2.5.9 Write Command

Write command takes filename as an argument and writes the content of a physical group in two separate files one containing all the nodes info and other containing all the elements info and places in the same XYZ_ESSI_Simulation folder. The command syntax is gmESSI:: [Write_Data{PhyEntyTag,filename}]

- Creates files *XYZ_filename_Nodes.txt* and *XYZ_filename_Elements.txt*
- XYZ_filename_Nodes.txt :: Contains data for all nodes in a physical group. Each node data is represented in one line as

  Node_no x_coord y_cord z_cord

  with meanings as usual.
- XYZ_filename_Elements.txt :: Contains data for all elements in a physical group.Each element data is represented in one line as

  Element_no Element_type node1 node2 node3 ..

  with meanings as usual. Element_type refers to the same as in Gmsh Manual.

[Example_4.gmessi] shows the usage of write command.

207.2.5.10 Write DRM HDF5 Command

Domain reduction method (DRM) is a very useful method to input 3D seismic excitations into earthquake soil structure interacting system. With a defined physical group as DRM layer, a HDF5 file containing geometric information of the DRM layer, can be generated with the following commands for 1D, 2D and 3D mesh, respectively:

- gmESSI::[Generate_DRM_HDF5_1D{Physical_Group#<PhyEnty Name or Tag>, Surface_Normal:= <X | Y | Z>, Node_Coordinate_Tol:=<tolerance>, FileName:=<HDF5 file name>}]
- gmESSI::[Generate_DRM_HDF5_2D{Physical_Group#<PhyEnty Name or Tag>, Surface_Plane:=<XY|XZ|YZ>, Surface_Normal:= <X | Y | Z>, Node_Coordinate_Tol:=<tolerance>, FileName:=<HDF5 file name>}]
- gmESSI::[Generate_DRM_HDF5_3D{Physical_Group#<PhyEnty Name or Tag>, Surface_Normal:= <X | Y | Z>, Node_Coordinate_Tol:=<tolerance>, FileName:=<HDF5 file name>}]

Where:

- Physical_Group# defines the physical group name or tag for the DRM layer.
- Surface_Normal:= defines the surface normal direction of the DRM layer. It can be X or Y or Z.
- Surface_Plane:= defines the surface plane of the 2D DRM layer. It can be XY or YZ or XZ.

- Node_Coordinate_Tol:= defines the tolerance to distinguish two different DRM nodes. The tolerance should be much smaller than the FEM mesh size!
- FileName:= defines the file name of the HDF5 file to be generated.

207.2.6 Steps For Using gmESSI tool

Using gmESSI it is very easy to convert a .msh file to ESSI (.fei) file. This section guides the user through a simple [Example_1.geo], to show the steps necessary for generating Real-ESSI files directly from .msh file through gmESSI. Lets define a problem as shown in Figure 207.10. The [Example_1.geo] can be located in the gmESSI ''Examples' directory. Alternatively, it can be downloaded here.

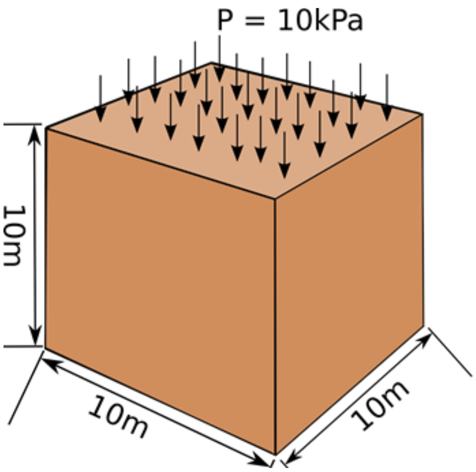


Figure 207.10: Example_1 description of a block of soil with surface load.

It is a block of dimension $10m \times 10m \times 10m$ of soil mass whose all 4 lateral faces are fixed in ux, uy dofs. The bottom face is fixed in ux, uy, uz dofs. A uniform pressure surface load of $10Pa$ is applied. The density and elastic modulus of the soil increases from $2000 * kg/m^3$ and Young's modulus is taken as $200MPa$ as shown in Figure 207.10.

207.2.6.1 Building geometry (.geo) file in Gmsh

The first step is to make the geometry file in *Gmsh*. While creating the geometry the user should also define all the physical groups on which they intend to either apply boundary condition, define elements, loads etc. In [Example_1.geo], 3 physical groups are needed : one for applying surface load, one for fixities, and one for defining the soil volume and assigning material. The content of [Example_1.geo] file is shown below

```
$cat Example_1.geo

// Size of the block
Size = 10;

//// Mesh Size of the block
Mesh_Size = 2;
```

```

// Adding Points and extruding
Point(1)={-Size/2,-Size/2,-Size/2};
Extrude{Size,0,0}{Point{1};Layers{Size/Mesh_Size};Recombine;}
Extrude{0,Size,0}{Line{1};Layers{Size/Mesh_Size};Recombine;}
Extrude{0,0,Size}{Surface{5};Layers{Size/Mesh_Size};Recombine;}

//// Create Physical Groups
Physical Volume ("Soil") = {1};
Physical Surface ("Base_Surface") = {5};
Physical Surface ("Lateral_Surface") = {18,22,14,26};
Physical Surface ("Top_Surface") ={27};
```

207.2.6.2 Generate mesh (.msh) file in Gmsh

Once .geo file is ready with all the physical groups, next step is to mesh the model. The mesh operation will generate the mesh file (.msh) that contains all the mesh information.

The model can be meshed from the terminal directly by running:

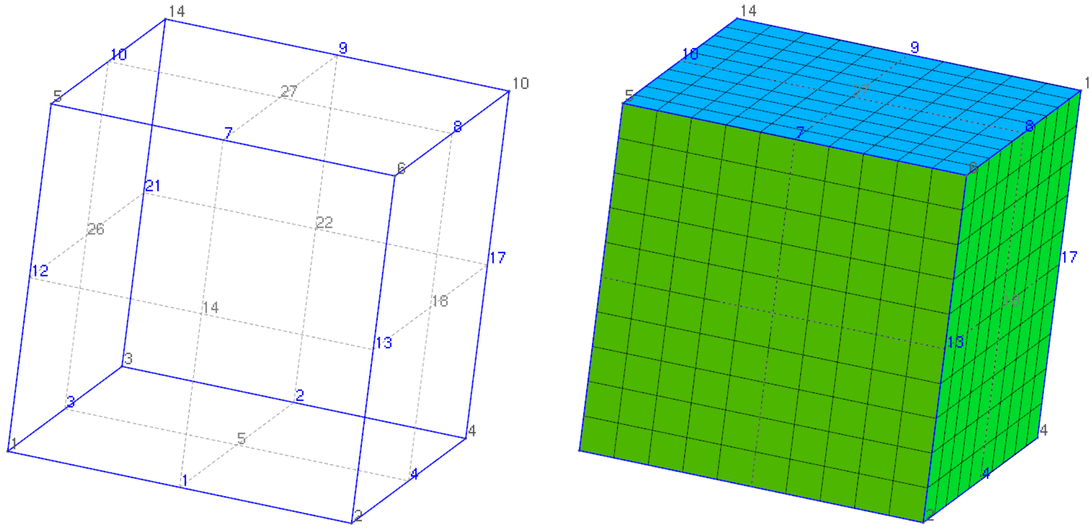
```
gmsh Example_1.geo -3
```

Here -3 means we are meshing a 3D object, which will automatically mesh all the 3D volumes, 2D surfaces and 1D lines object defined in the geometry model. If there are only 2D surfaces and/or 1D lines object defined in the geometry (.geo) file, use -2 instead. If there are only 1D lines object defined in the geometry (.geo) file, use -1 instead.

A quick look at the generated [Example_1.msh] file containing physical groups is shown below:

```
$cat Example_5.geo
..............
$PhysicalNames
4
2 2 "Base_Surface"
2 3 "Lateral_Surface"
2 4 "Top_Surface"
3 1 "Soil"
$EndPhysicalNames
................
```

Figure 207.11 shows the geometry and mesh visualization in Gmsh. It is noted that Gmsh performs meshing for linear interpolation elements by default. In other words, the above cubic block geometry object is meshed into eight-node bricks, that have linear isoparametric interpolation, `8NodeBrick`. For higher order interpolation meshing options, that is for meshing twenty-seven node brick elements mesh, `27NodeBrick` for example, additional -order int should be used. int here is the integer specifying the



(a) Geometry File

(b) Mesh File

Figure 207.11: Gmsh geometry and mesh file for Example_1

order of meshing. For example, the following terminal command with -order 2, i.e., 2^{nd} order meshing, generates twenty-seven node brick meshes (`27NodeBrick`):

```
gmsh Example_1.geo -3 -order 2
```

207.2.6.3 Writing all gmESSI Commands for the model

Using gmESSI for mesh conversion is very easy. To achieve this, a [Example_1.gmessi] file is created containing all the required gmESSI commands to be executed sequentially. Let us look at each of them

Since physical group names and ids are required for referring the gmESSI commands, its always best to copy all the physical group data from the .msh file (in this case *[Example_1.msh]* file) in the header of .gmessi file, so that its easier for th user to refer to the physical groups while writing commands in .gmessi file. The contents of the .gmessi file are shown below.

```
$cat Example_1.gmessi

### Physical Groups defined in the msh file.
#2 2 "Base_Surface"
#2 3 "Lateral_Surface"
#2 4 "Top_Surface"
#3 1 "Soil"

### loading the gmsh file
```

```
gmESSI.loadGmshFile("Example_1.msh")

### Defining the Simulation Directory and node, element, load and main file
### Its important to define the directory and these files at the beginning of ↩
    any gmESSI command conversion
### 1 refers as overwrite mode ( will overwrite the directory if present) --- 0 ↩
    would not overwrite
gmESSI.setSimulationDir("./Example_1_ESSI_Simulation",1)
gmESSI.setMainFile(gmESSI.SimulationDir+ "main.fei")
gmESSI.setNodeFile(gmESSI.SimulationDir+ "node.fei")
gmESSI.setElementFile(gmESSI.SimulationDir+ "element.fei")
gmESSI.setLoadFile(gmESSI.SimulationDir+ "load.fei")

#### // is used to provide commands and gets translated in the main.fei file
#### Also, the commands followed by exclamation '!' get directly copied to the ↩
    main.fei file
#### Usually, the user would write Real-ESSI DSL against the exclamation mark.

// My new model
! model name "Soil_Block";

[Add_All_Node{ unit:= m, nof_dofs:= 3}]

// Adding Material also assigning it to elements
! add material #1 type linear_elastic_isotropic_3d_LT mass_density = ↩
    2000*kg/m^3 elastic_modulus = 200*MPa poisson_ratio = 0.3;
[Add_8NodeBrick{Physical_Group#Soil, MaterialNo:= 1}]

! include "node.fei";
! include "element.fei";
! new loading stage "Stage1_Self_Weight";

# Applying Fixities
[Fix_Dofs{Physical_Group#Base_Surface, all}]
[Fix_Dofs{Physical_Group#Lateral_Surface, ux uy}]

#### For applying Self-Weight Load to the soil elements
! add acceleration field # 1 ax = 0*g ay = 0*g az = -1*g ;
! add load #1 to all elements type self_weight use acceleration field # 1;

 #Updating the tag inside gmESSI as user entered by himself load tag
gmESSI.setESSITag("load",2)

! include "load.fei";
! NumStep = 10;
!
! define algorithm With_no_convergence_check;
! define solver UMFPack;
! define load factor increment 1/NumStep;
! simulate NumStep steps using static algorithm;
```

```

#### updating the new load file before new loading stage
gmESSI.setLoadFile(gmESSI.SimulationDir+ "Surface_Load.fei")
! new loading stage "Stage2_Surface_Loading";

### For applying Surface load on the Top Surface of the Soil Block
[Add_8NodeBrick_SurfaceLoad{Physical_Group#Soil,Physical_Group#Top_Surface,10*Pa}]

##### For applying Nodal loads to all the nodes of the top surface
#[Add_Node_Load_Linear{Physical_Group#Top_Surface, ForceType:= Fx, Mag:= 10*kN}]

! include "Surface_Load.fei";
! NumStep = 10;
!
! define algorithm With_no_convergence_check;
! define solver UMFPack;
! define load factor increment 1/NumStep;
! simulate NumStep steps using static algorithm;

! bye;
```

NOTE: The gmESSI commands are executed and written to the file sequentially, so the user should be careful with the order of translation.

207.2.6.4 Executing gmESSI on Example_1.gmessi input file

Once .gmessi input file is ready, the next task is to run it using the ‘gmessy’ command in terminal. Running would carryout the translation to all and produce the log of translation, displayed on the terminal

```
$ gmessy Example_1.gmessi

Message:: newDirectory created as ./Example_1_ESSI_Simulation

Add_All_Node{ unit:= m, nof_dofs:= 3}
   Found!!
   Successfully Converted

Add_8NodeBrick{Physical_Group#Soil, MaterialNo:= 1}
   Found!!
   Successfully Converted

Fix_Dofs{Physical_Group#Base_Surface, all}
   Found!!
   Successfully Converted
```

```

Fix_Dofs{Physical_Group#Lateral_Surface, ux uy}
   Found!!
   Successfully Converted

Add_8NodeBrick_SurfaceLoad{Physical_Group#Soil,Physical_Group#Top_Surface,10*Pa}
   Found!!
   Successfully Converted

************************ Updated New Tag Numbering **********************
damping = 1
displacement = 1
element = 126
field = 1
load = 27
material = 1
motion = 126
node = 217
nodes = 217
Gmsh_Elements = 276
Gmsh_Nodes = 217
```

It would create a folder [Example_1_ESSI_Simulation] and places load.fei, node.fei, element.fei and main.fei files. The user at this point do not need to write anything in the Example_5_analysis.fei file as every command was sequentially written down in .gmessi file and is converted. The content of the main.fei is shown below.

```
$cat Example_5_analysis.fei
// My new model
 model name "Soil_Block";

// Adding Material also assigning it to elements
 add material #1 type linear_elastic_isotropic_3d_LT mass_density = 2000*kg/m^3 elastic_modulus = 200*MPa poisson_ratio = 0.3;

 include "node.fei";
 include "element.fei";
 new loading stage "Stage1_Self_Weight";

 add acceleration field # 1 ax = 0*g ay = 0*g az = -1*g ;
 add load #1 to all elements type self_weight use acceleration field # 1;
 include "load.fei";
 NumStep = 10;

  define algorithm With_no_convergence_check;
  define solver UMFPack;
  define load factor increment 1/NumStep;
  simulate NumStep steps using static algorithm;
```

```
new loading stage "Stage2_Surface_Loading";

include "Surface_Load.fei";
NumStep = 10;

 define algorithm With_no_convergence_check;
 define solver UMFPack;
 define load factor increment 1/NumStep;
 simulate NumStep steps using static algorithm;
bye;
```

207.2.6.5 Running Real-ESSI and visualization in paraview

With all files ready in their place, the next step is to run the main.fei file directly in ESSI.

```
$essi -f main.fei
```

Running ESSI creates .feioutput file which can be visualized in paraview using PVESSIReader plugin. Figure 207.12 shows the visualization of hdf5 output produced in paraview.

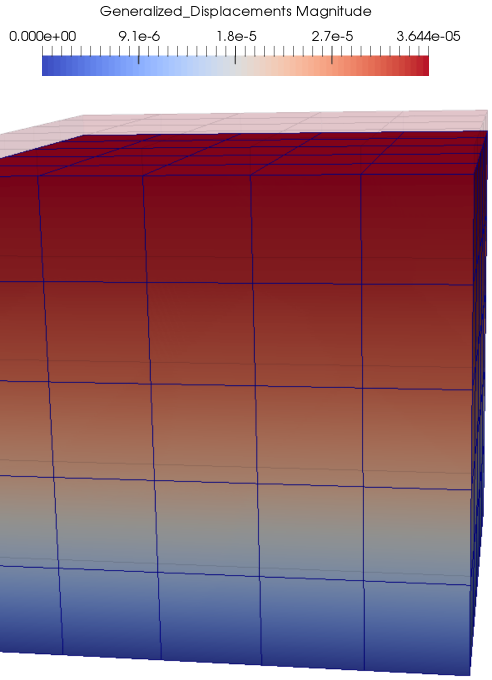


Figure 207.12: Visualizing output in Paraview.

207.2.7 Illustrative Examples

The *Examples* directory of gmESSI folder contains five examples as Example_1,Example_2.... and Example_5. They are summarized as

1. [Example_1] : Modeling of Surface load on block of Soil. The geometry (.geo), mesh (.msh) and .gmessi input files can be downloaded HERE.
2. [Example_2] : Modeling of Cantilever Beam. The geometry (.geo), mesh (.msh) and .gmessi input files can be downloaded HERE.
3. [Example_3] : Modeling of Tower (beam) located above the ground and embedded in soil using contact/interface elements. The geometry (.geo), mesh (.msh) and .gmessi input files can be downloaded HERE.
4. [Example_4] : Modeling of a concrete foundation on Soil connected by contact elements. The geometry (.geo), mesh (.msh) and .gmessi input files can be downloaded HERE.
5. [Example_5] : Modeling of a embedded shells and beam in Solids. The geometry (.geo), mesh (.msh) and .gmessi input files can be downloaded HERE.

[Example_1] was discussed in the previous section. Examples 1 to 4 are discussed and refereed in the manual at several instances. The user is encouraged to over these examples and learn to create geometry '.geo' and .gmessi input files. Here, two examples Example_2 about cantilever beam analysis and Example_5 about beams and shell is discussed.

207.2.7.1 Modeling of Cantilever Beam With Surface Load [Example_2]

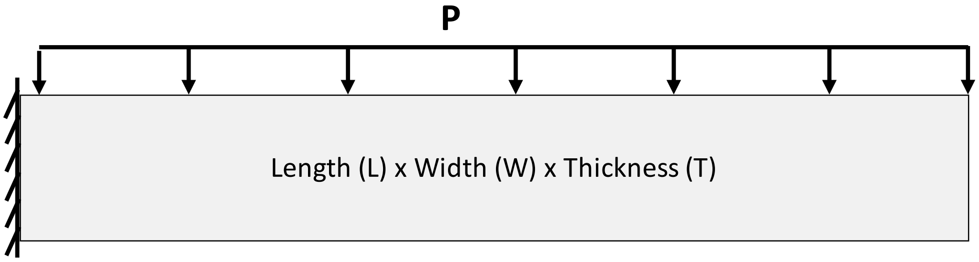

Figure 207.13: Illustration of the cantilever problem.

The problem consist of a cantilever beam with its left end fixed. A uniform surface load of P is applied. The geometry (.geo) and the gmessi input file for this problem can be downloaded here. Figure 207.14 shows visualization of output after running the model in Real-ESSI.

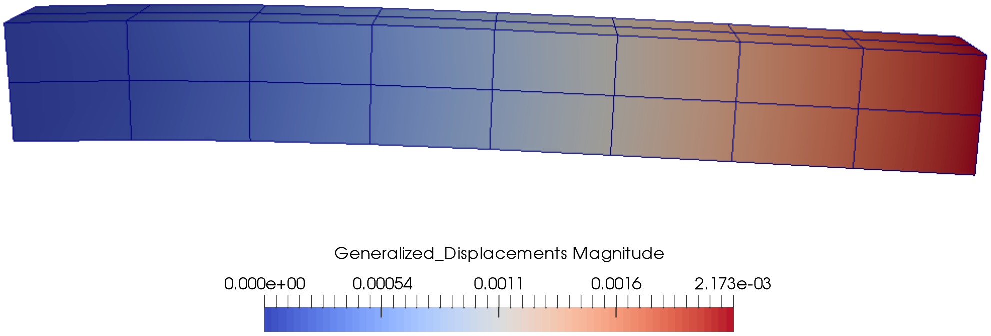

Figure 207.14: Illustration of the cantilever problem.

207.2.7.2 Modeling of a embedded shells and beam in Solids [Example_5]

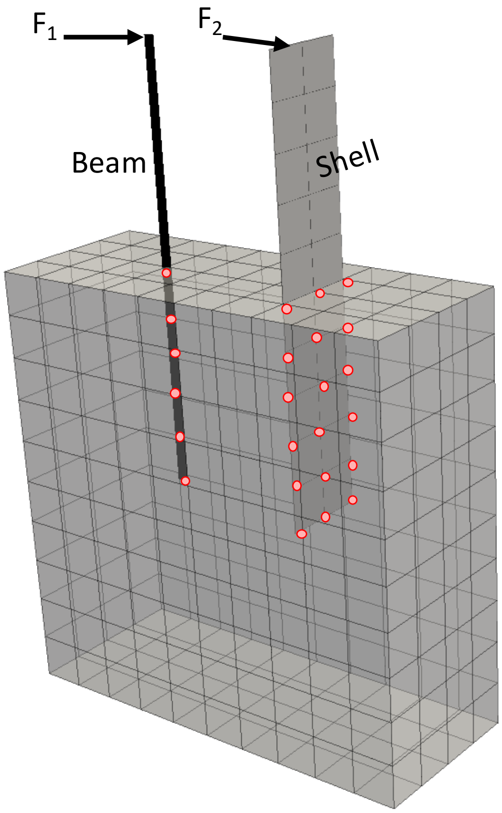

Figure 207.15: Illustration of the cantilever problem.

The problem consist of solid of 3 dofs in which beams and shells of 6dofs are embedded. The embedded beams and shell elements are connected by contact/interface elements. A nodal load to the top of the beam and shell is applied. The geometry (.geo) and the gmessi input file for this problem can be downloaded here. Figure 207.16 shows visualization of output after running the model in Real-ESSI.

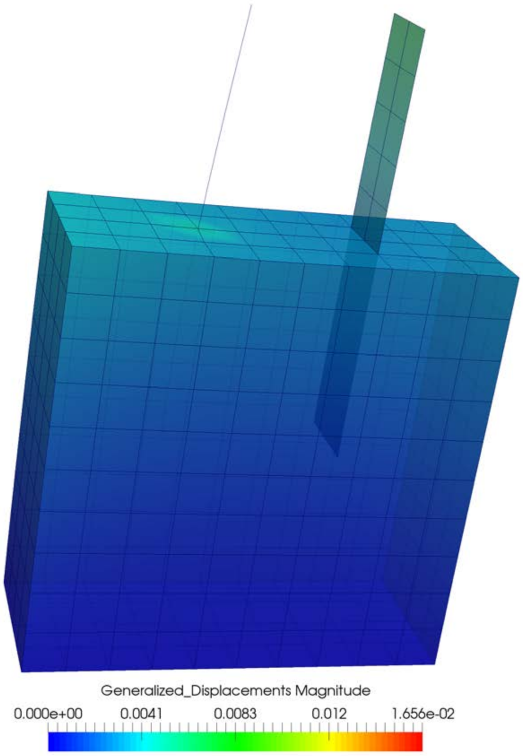

Figure 207.16: Visualizing displacement field in Paraview.

207.2.8 Realistic Models Developed Using gmESSI

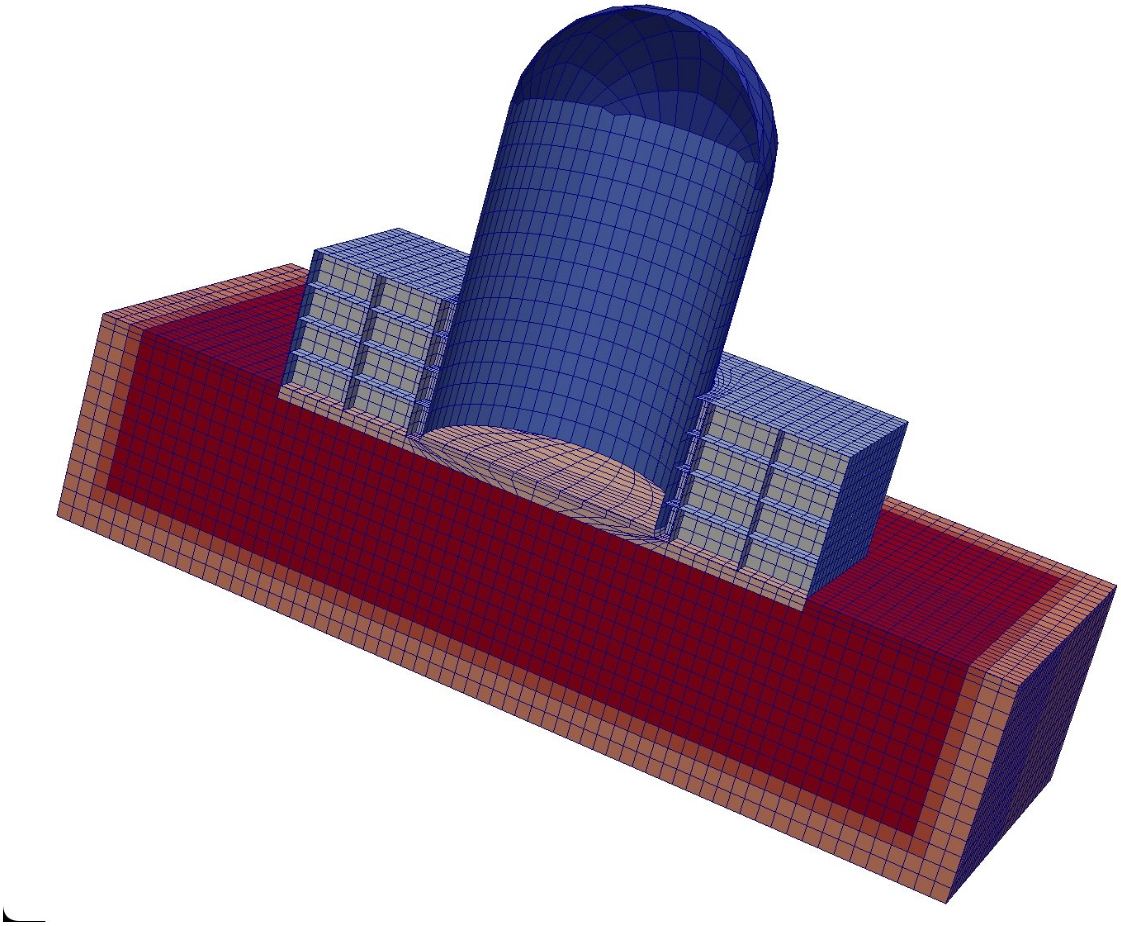

Figure 207.17: Nuclear Power Plant model 1, half model shown, with vertical plane cut.

207.3 Introduction to SASSI-ESSI Translator

This section will cover a simple mesh translator that translates mesh from SASSI format into ESSI format.

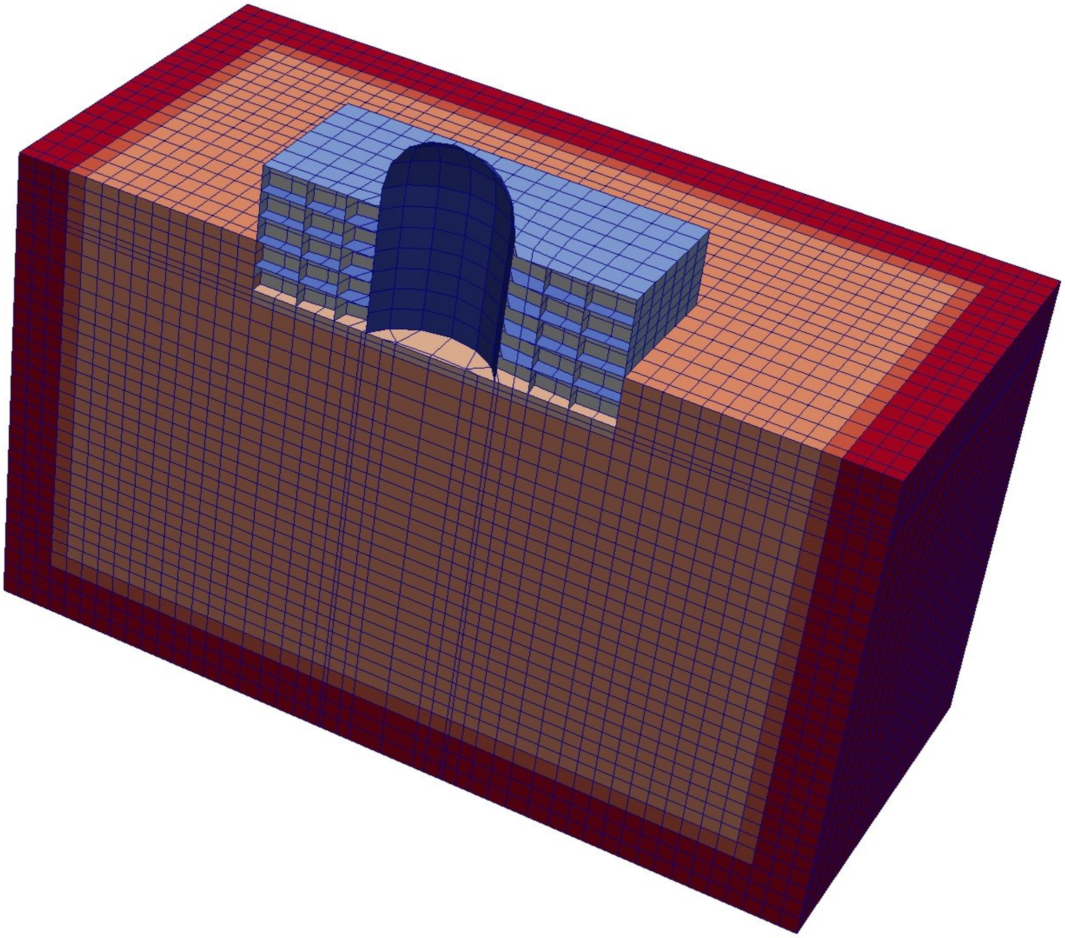

Figure 207.18: Nuclear Power Plant model 2, half model shown, with vertical plane cut.

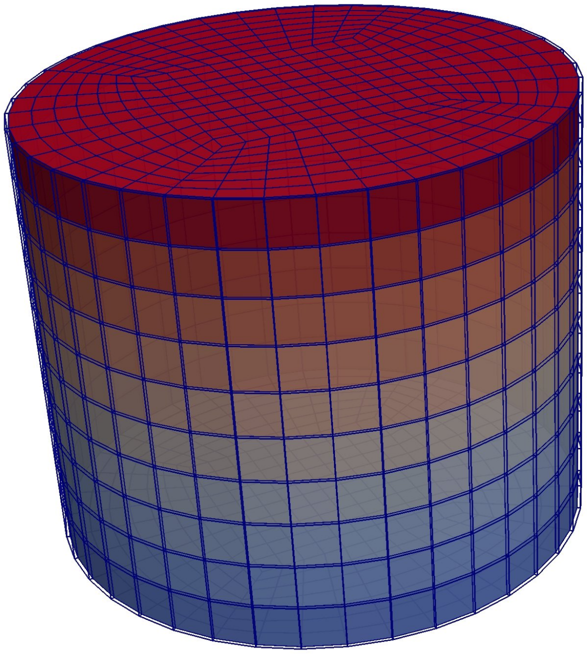

Figure 207.19: Shear Box.

Chapter 208

Real-ESSI Post Processing Methods

(2010-2014-2016-2017-2018-2019-2020-2021-)

(In collaboration with Prof. Sumeet Kumar Sinha, Dr. Yuan Feng, Prof. Han Yang, and Dr. Hexiang Wang)

208.1 Introduction

208.2 Model Results Post-Processing

This chapter describes methodology for post processing simulation results from the Real-ESSI Simulator. Two main approaches are used:

- Plotting time histories of scalar results (described in section 208.3 on page 1290), using Python and/or Matlab for:
  - components of displacements, velocities, accelerations, pore fluid pressures, for finite element nodes,
  - components of stress and/or strain at integration (Gauss) points within each finite element,
  - components of section forces for structural finite elements
  - energy input and dissipation for parts or whole of the volume/model, in incremental and/or cumulative form
- Visualization of a part or a complete model for displacements, velocities, accelerations, stress and strain components, sectional forces, energy dissipation through visualization system ParaView, as described in section 208.4 on page 1291.

208.3 Time Histories Plotting

Time histories of various scalar results (as listed above) can be extracted from output files, saved in HDF5 (Group, 2020), in a format described in chapter 206, on page 1180 in Jeremić et al. (1989-2025).

An excellent set of Python postprocessing tools was developed by Dr, Konstantinos Kanellopoulos, from ETH Zürich! You can find these tools at his github:
`https://github.com/ConstantinosKanellopoulos/Real-ESSI_postprocessing_tools`.

208.4 Post Processing and Visualization using ParaView

ParaView package http://www.paraview.org/ (Ayachit, 2015) is a very powerful multi-platform data analysis and visualization program available as an Open Source. Paraview can be run on supercomputers to analyze datasets of peta-scale size as well as on laptops for smaller data, and has become an integral tool in many national laboratories, universities and industry, and has won several awards related to high performance computation.

PVESSIReader is a plugin for paraview that integrates Real-ESSI Simulator output to Paraview for visualization. PVESSIReader reads Real-ESSI output file, in HDF5 format, files with extension .feioutput. The plugin works for sequential, parallel as well as remote visualization mode. It has a number of visualization features to visualize stresses, eigen modes, relative displacement, physical groups, energy dissipation, etc.

The installation of both Paraview and PVESSIReader is described in some detail in section 209.8.2 on page 1345 of the main document (Jeremić et al., 1989-2025).

208.4.1 Visualization in ParaView : Features

PVESSIReader has been consistently developed and added with lot of visualization options which are built on ParaView Visualization Toolkit (VTK) framework. This section shows all the visualization options that PVESSIReader offers other than what is available in ParaView. The features are illustrated in subsections below with help of examples in *Examples* folder of PVESSIReader source directory.

Before, looking at the features, it's important to know how PVESSIReader works. PVESSIReader takes Real-ESSI HDF5 output (.feioutput) file format as input and creates a *PVESSIReader* folder inside the HDF5 file. PVESSIReader does this to ensure the visualization to be optimized. The contents inside this folder are not important for any regular user. The contents of "PVESSIReader" folder is shown in Figure 208.1, although it is not important to regular users. User must know that, the plug-ins first creates this folder and then uses the content of this folder for visualization in ParaView. So creation/reading of this folder is the essence to visualization in ParaView.

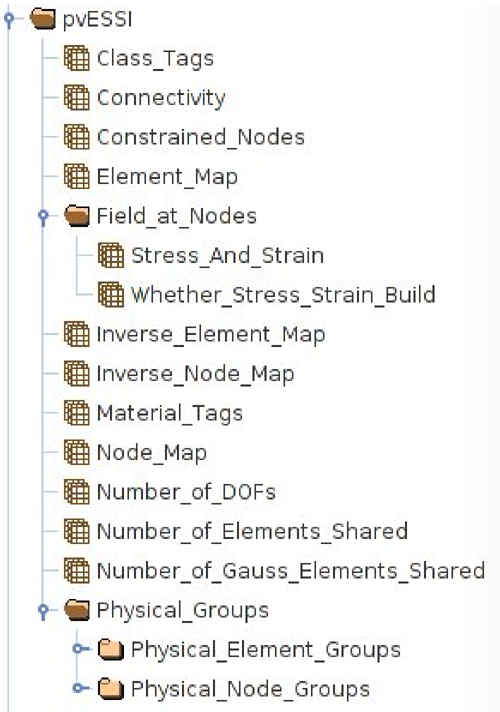

Figure 208.1: Contents of PVESSIReader folder.

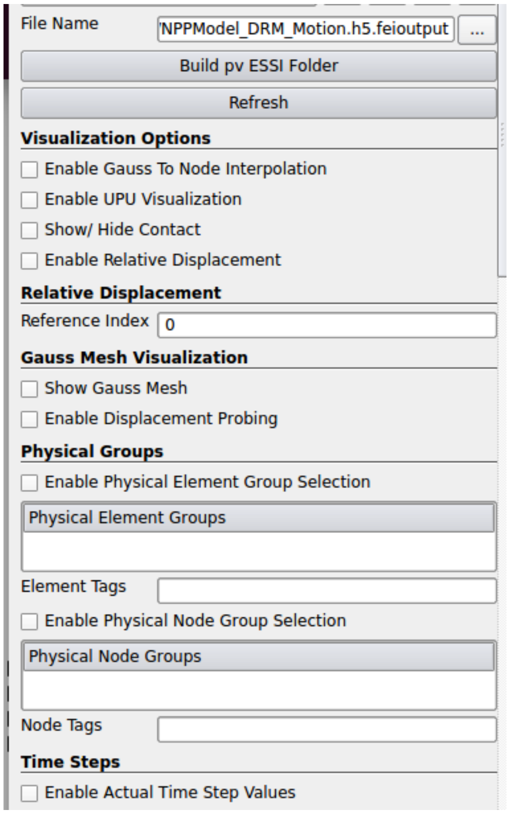
208.4.1.1 PVESSIReader Visualization Options

By default PVESSIReader builds a node mesh. Figure 208.2 shows the various visualization options that is available for PVESSIReader. The Gauss to node interpolation is turned off and other options shown in Figure 208.2 is turned off. As stated in previous Section 208.4.1, the plugin creates the *PVESSIReader* *folder* inside the output HDF5 file only once and uses it for rest of visualization (even after you close and reopen it). The ‘Build PVESSIReader folder’ button shown in Figure 208.2 on clicking rebuilds the ‘PVESSIReader folder’. If in case the loading of ‘.feioutput’ file fails in ParaView, the user should clicks the ‘Build PVESSIReader Folder’ before hitting ‘Apply’ button.



File Name: NPPModel_DRM_Motion.h5.feioutput

Time Steps

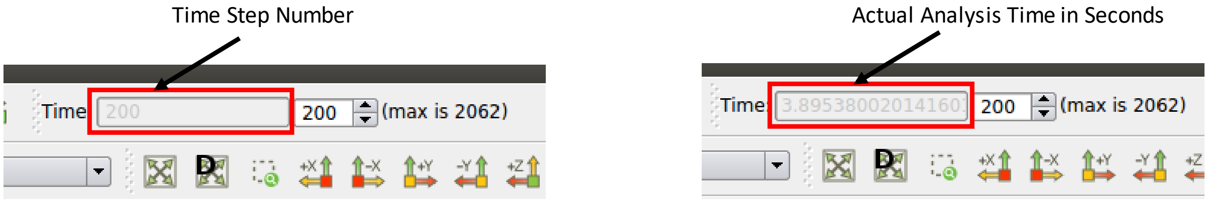
☐ Enable Actual Time Step Values

Figure 208.2: PVESSIReader build options.

Description of various PVESSIReader visualization options in the order shown in Figure 208.2 is listed below.

- Build PVESSIReader Folder - Rebuild the content of PVESSIReader folder inside output file
- Refresh - It reloads the current visualization view.
- Enable Gauss to Node Interpolation - Enables the interpolation from Gauss points to node using shape functions. It works only for 8 node and 27 node brick with 8 and 27 Gauss points respectively. See Section 208.4.1.9.
- Enable uPU Visualization - Enables the visualization of fluid displacements (U) and pore-pressure (P) at nodes. See Section 208.4.1.10.

- Enable Relative Displacement - When this is enabled, the displacement of any time step can be visualized with respect to any other reference time step. See Section 208.4.1.6.
- Reference Time Step No -This option is used to set the reference time step number about which the relative displacements would be visualized. See Section 208.4.1.6.
- Show Gauss Mesh - This option can be enabled to visualize the Gauss points (mesh) of the entire model. See Section 208.4.1.8.
- Enable Displacement Probing - This option only works if Gauss mesh option is enabled. With this option, displacements are calculated at Gauss points using ParaView interpolation functions for each elements containing those Gauss points. See Section 208.4.1.8.
- Physical Groups - This option is enabled to visualize pre-defined physical groups in Real-ESSI input or manually defined selected nodes or elements. See Section 208.4.1.12.
- Enable Actual Time Step Values - By default instead of actual simulation time (in seconds), time step number of analysis is provided to ParaView VCR. Figure 208.3 shows the result of enable/disable of this option.



(a) Actual Time Step Values Disabled

(b) Actual Time Step Values Enabled

Figure 208.3: Illustration of difference between enable and disable of `actual time step values`.

In the Figure 208.3, the enabled option gives the exact simulation time of $3.895s$. Whereas, disabling the option shows time step number of 200.

The visualization gets automatically updated on enable/disable of options. When one hit's apply, the corresponding changed result gets updated i.e. the mesh would get real time updated with enable/disable of these options.

208.4.1.2 Sequential Visualization

Sequential visualization means visualizing the Real-ESSI output on a single core of laptop/desktop. This is used for single output files that Real-ESSI produces for sequential runs. Figure 208.4 shows the visualization of output file produced by sequential Real-ESSI simulation.

```
cd pvESSI/Examples
ParaView ShearBox_Sequential.h5.feioutput
```

The parallel output files of ESSI can also be visualized sequentially. Each individual (core) file can be sequentially visualized showing only a part of the model results. Also all the parallel files at once can be opened as well in ParaView as shown in Figure 208.5. All PVESSIReader examples can be obtained at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_pvESSI/Examples`.

1. To open one core output in sequential

```
cd pvESSI/Examples
ParaView ShearBox_Parallel.h5.1.feioutput
```

2. To open all cores output in parallel

```
cd pvESSI/Examples
ParaView ShearBox_Parallel.h5.feioutput
```

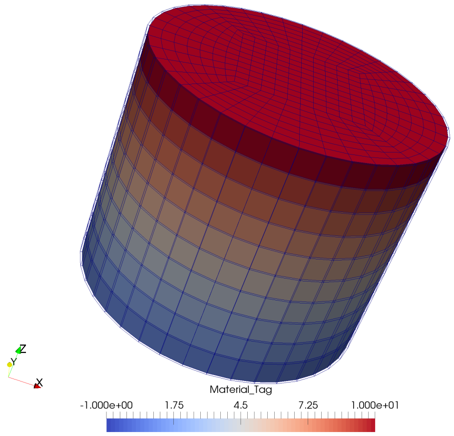


Figure 208.4: Sequential Visualization of output produced by sequential Real-ESSI simulation.

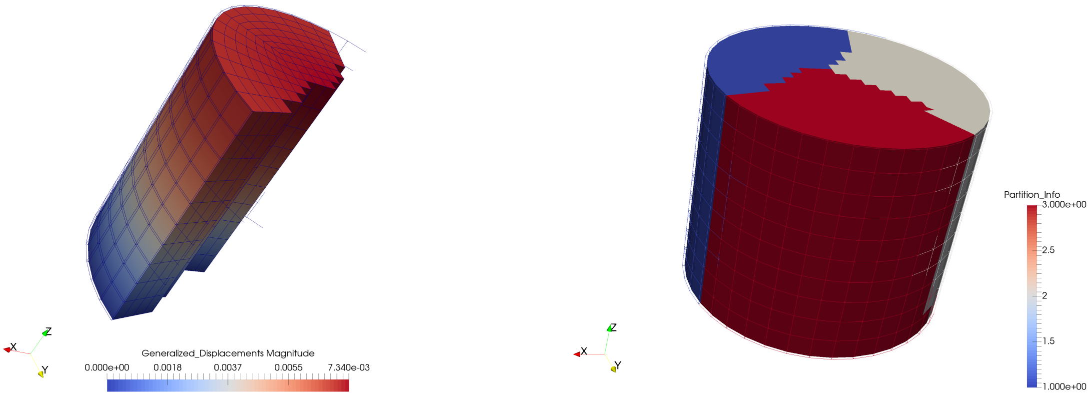


(a) Visualizing only one slave output file

(b) Visualizing all slave output files at once

Figure 208.5: Sequential Visualization of output produced by parallel Real-ESSI simulation.

208.4.1.3 Remote Visualization

Remote visualization is an important feature that ParaView offers. This is an important feature in need, when simulations are run on super computers with thousands of cores. The steps for remote visualization are shown below with an example on local desktop.

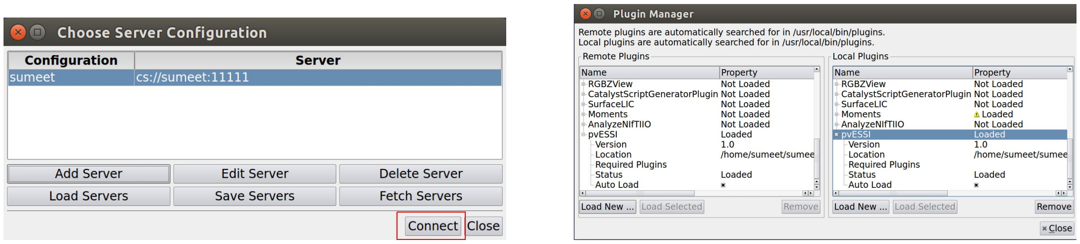
1. Run pvserver on server

```
$pvserver
Waiting for client...
%Connection URL: cs://sumeet:11111
%Accepting connection(s): sumeet:11111
Connection URL: cs://jeremic:11111
Accepting connection(s): jeremic:11111
```

2. Open ParaView on client side and click on connect button located on top left window.

Figure 208.6: Connect Server.

3. Select and connect to the server and then load the plugins on both client and server side as shown in Figure 208.7



Configuration	Server
sumeet	cs://sumeet:11111

(a) Connect to Server

Remote plugins are automatically searched for in /usr/local/bin/plugins.
Local plugins are automatically searched for in /usr/local/bin/plugins.

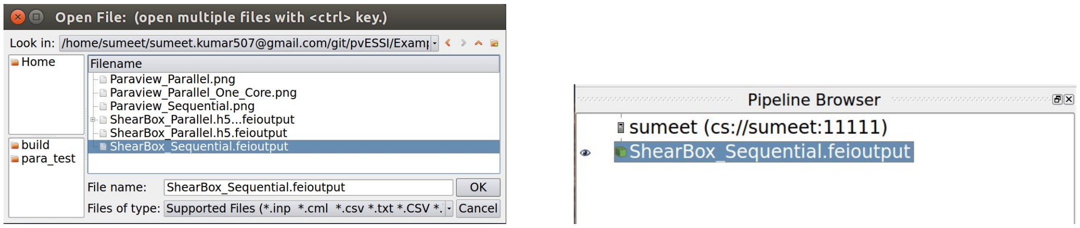
Figure 208.7: Connect to the server and load plugins.

4. Navigate to *pvESSI/Examples/ShearBox_Parallel.h5.1.feioutput* and hit apply

208.4.1.4 Parallel Visualization

Parallel visualization is similar to remote visualization. The only difference is to start the pvserver in parallel on multiple cores. It is recommended to have the same number of cores that was used in Real-ESSI parallel simulation. Below shows steps on how to do parallel visualization in ParaView.



Look in: /home/sumeet/sumeet.kumar507@gmail.com/git/pvESSI/Examp

(b) Client Side Pipeline

Figure 208.8: ParaView Remote Visualization.

```
$ mpirun -np $(nop) pvserver
# $(nop) is replaced by number of cores on which parallel visualization is to be run.
```

The next following steps are same to that of Remote visualization as shown in Section 208.4.1.3. Thus, parallel visualization can be performed remotely as well as locally.

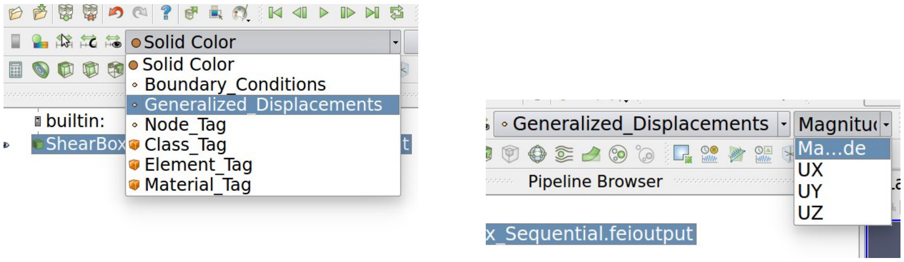
208.4.1.5 General Field Visualization

Below is the list of general visualization variables available for any model in ParaView using PVESSIReader plugin. The following subsections describes each option through an example. The examples can be found in pvESSI/Examples directory. The example file ‘`ShearBox_Sequential.h5.feioutput`’ can be downloaded here.

```
cd pvESSI/Examples
ParaView ShearBox_Sequential.h5.feioutput
```

Displacement Field : The displacement field represents the total displacement from the start of the Real-ESSI simulation. There are two modes of displacement field visualization available in ParaView. NOTE: Please remember to change step number from 0 to any other step number, as all output, including displacements, is 0.0 at step 0.

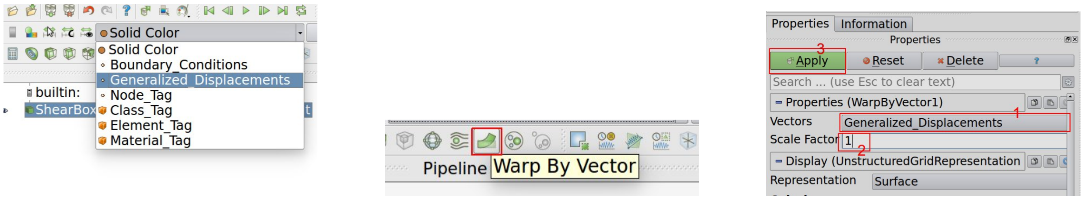
1. Scalar field visualization : The options available are each individual displacement vector components u_x, u_y and u_z in x,y,z directions respectively. It also shows the displacement magnitude $|u| = \sqrt{u_x^2 + u_y^2 + u_z^2}$. The units of displacements field in $[m]$.



(a) Select Displacement Field (b) Select scalar field

Figure 208.9: Displacement Scalar Field Visualization.

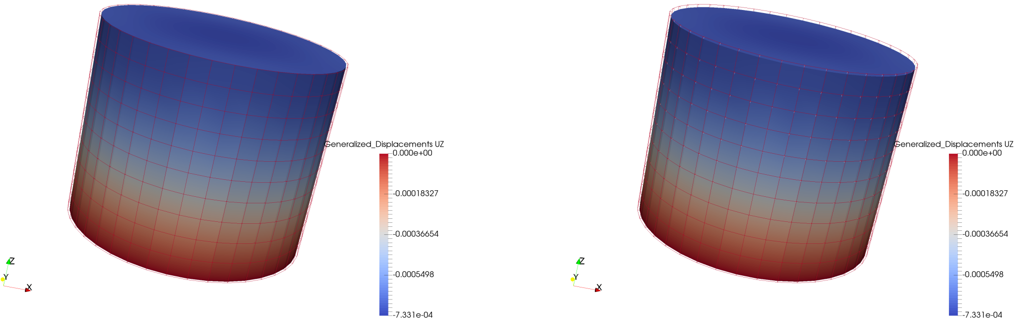
2. Vector Field visualization : This is achieved using ‘`Wrap by Vector`’ plugin available in ParaView. Figure 208.10 and Figure 208.11 shows steps to visualize deformed mesh.



Vectors Generalized_Displacements
Scale Factor 1
Representation Surface

(a) Select Displacement Field (b) Select plugin (c) Plugin properties

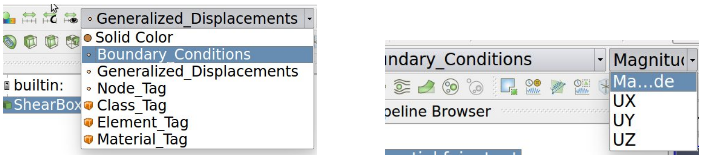
Figure 208.10: Deformation Visualization.



(a) Displacement Field Visualization in Uz (b) Deformation Visualization

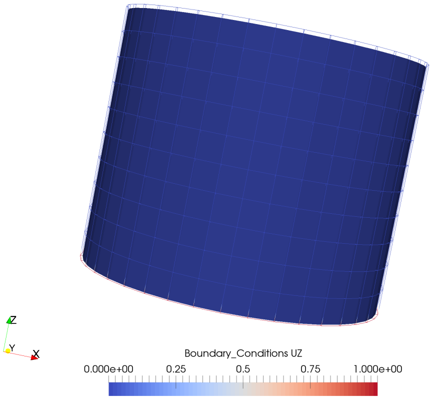
Figure 208.11: Displacement field visualization in ParaView.

Boundary Conditions: Again this a vector field which contains information about boundary conditions i.e fixities applied in u_x, u_y and u_z directions. A value of 1 means the node is fixed while 0 means it is free. Figure 208.12 shows steps to visualize boundary conditions.



(a) Select Boundary Conditions

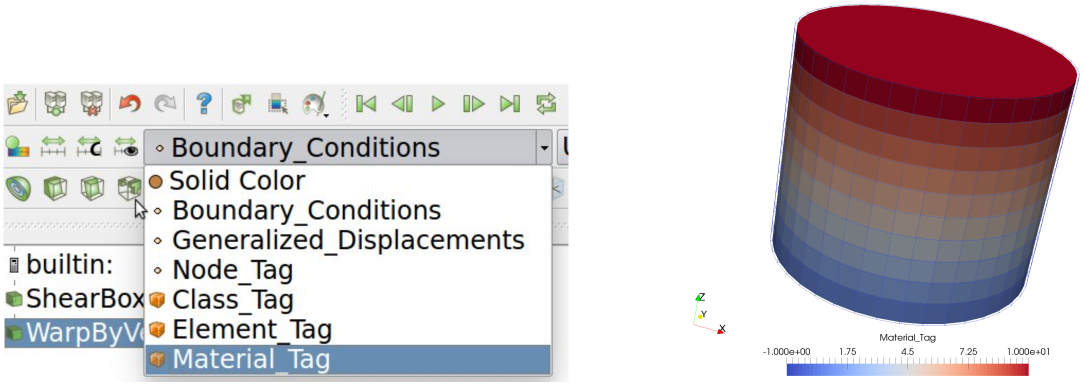
(b) Select Fixities Type



(c) Boundary Conditions in Uz

Figure 208.12: Boundary Conditions Visualization.

Material Tag Visualization : This is a scalar field visualization that shows the *material tag no* associated with the elements in Real-ESSI simulation. Figure 208.13 shows steps to visualize element's material tag.

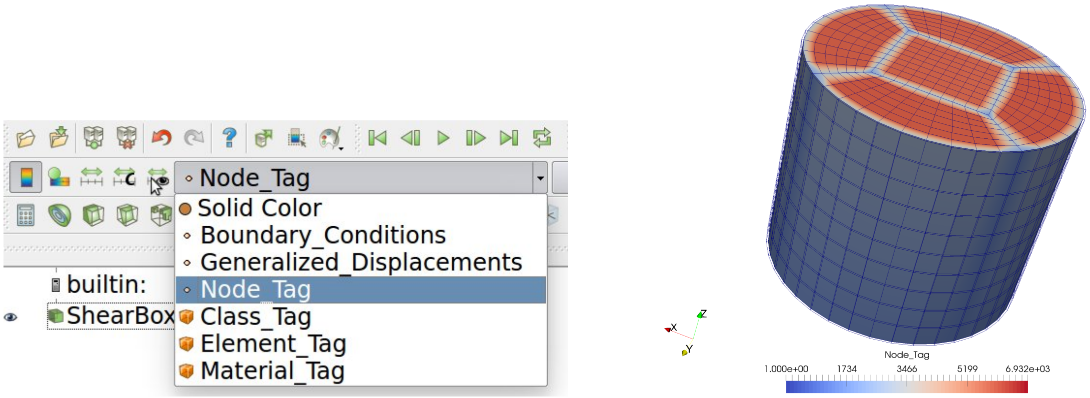


(a) Select Material Tag

(b) Material Tag Field

Figure 208.13: Material Tag Visualization.

Node Tag Visualization : This is a scalar field visualization that shows the `node no` associated with the nodes in Real-ESSI simulation. Figure 208.14 shows steps to visualize node's tag.

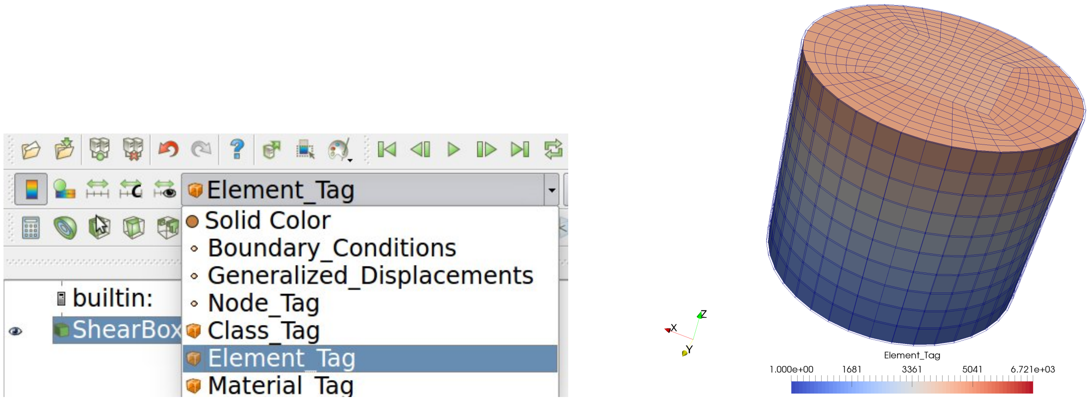


(a) Select Node Tag

(b) Node Tag Field

Figure 208.14: Node Tag Visualization.

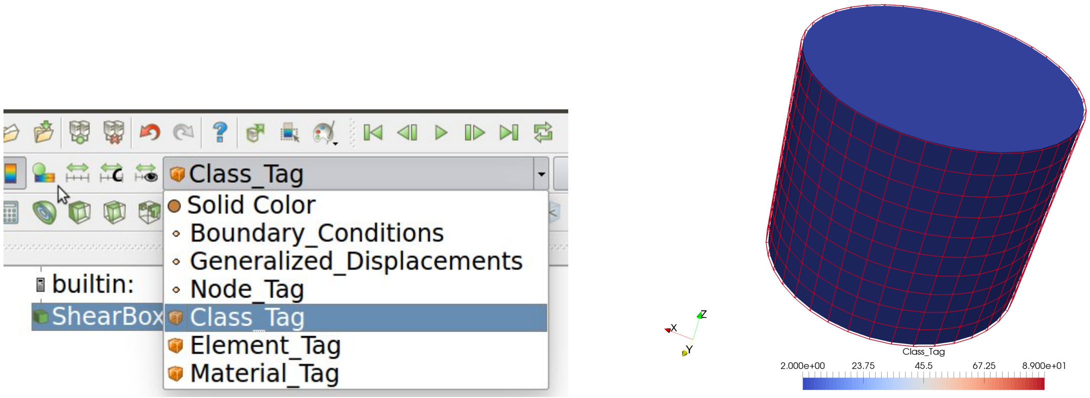
Element Tag Visualization : This is a scalar field visualization that shows the `element no` associated with the elements in Real-ESSI simulation. Figure 208.15 shows steps to visualize element's tag.



(a) Select Element Tag (b) Element Tag Field

Figure 208.15: Element Tag Visualization.

Element Class Tag Visualization : This is a scalar field visualization that shows the Element's Class Tag number associated with the each *element type* in Real-ESSI simulation. Figure 208.15 shows steps to visualize element's tag. Section 206.5.4.4 shows the class tag for various element types available in Real-ESSI.

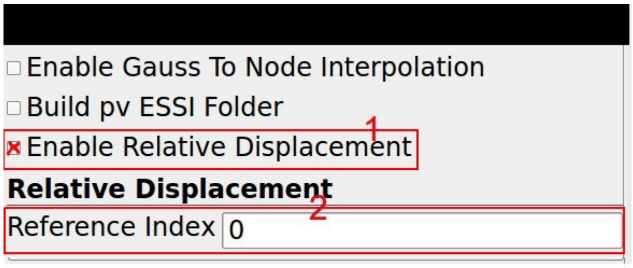


(a) Select Class Tag (b) Class Tag Field

Figure 208.16: Class Tag Visualization.

208.4.1.6 Relative Displacement Visualization

When the '`Enable Relative Displacement`' is checked, the relative displacement visualization option becomes active. BY default, the relative displacement time step number is set to '0' as shown in Figure 208.17. Time step number '0' corresponds to initial conditions of the loading stage output file.



☐ Enable Gauss To Node Interpolation

☐ Build pv ESSI Folder

☒ Enable Relative Displacement

Relative Displacement

Reference Index 0

Figure 208.17: Enable Relative Displacement.

Reference Time Step Number - It defines the relative time step index number for relative displacement visualization. By default it is set to 0 i.e. to the initial conditions. Its very useful, when one wants to visualize deformation coming from the stage itself. For example:- Separating self-weight from Static Pushover Analysis in the Shear Box simulation. The steps to do the same is shown below. The example file `ShearBox_PushOver.h5.feioutput` can be downloaded here.

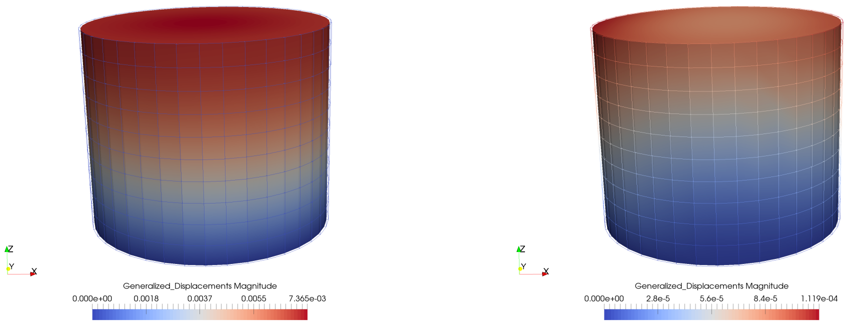
1. Open an example in ParaView

```
cd pvESSI/Examples
ParaView ShearBox_PushOver.h5.feioutput
```

2. Check on `Enable Relative Displacement` under visualization options

3. Apply `warp by vector` plugin and follow the steps as shown in Figure 208.10

Figure 208.18 shows the visualization with and without relative displacement.



(a) Without Relative Displacement

(b) With Relative Displacement

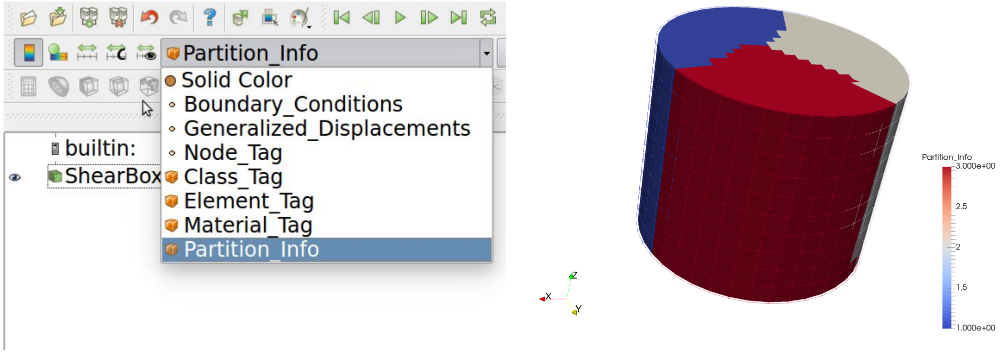
Figure 208.18: Pushover analysis of Shear Box after self-weight load application.

208.4.1.7 Visualizing Element's Partition

If the ESSI simulation was run in parallel mode, it becomes important to visualize the elements distribution between different cores. In ParaView, one can see the element distribution by selecting "`Partition Info`". Following is shown in Figure 208.19 an example to visualize mesh partitioning. All the example files can be obtained here.

```
cd pvESSI/Examples
ParaView ShearBox_Parallel.h5.feioutput
```

and then select Partition_Info as shown below in Figure 208.19



(a) Select Partition Info

(b) Mesh Partitioning

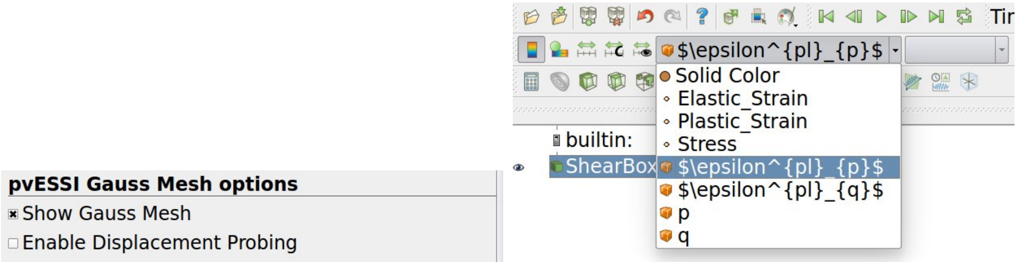
Figure 208.19: Visualizing mesh partitioning.

208.4.1.8 Gauss Mesh Visualization Options

Often, it is required to visualize stress and strain fields. Since stress or strains are evaluated at Gauss points in 3-D elements, Gauss mesh is needed to visualize them. PVESSIReader offers option to visualize Gauss mesh and it's fields.

- Show Gauss Mesh - Shows only Gauss mesh with Gauss attributes.
- Enable Displacement Probing - When this option is enabled, displacements are probed to the Gauss location. Its useful in the situation, when one wants to visualize the change in stress with deformation. With this as active, one can apply '`warp by vector`' filter.

It must be noted that the `Enable Displacement Probing` options only works when `Show Gauss Mesh` mode is enabled. Figure 208.20 shows the steps to visualize Gauss mesh.



pvESSI Gauss Mesh options

☒ Show Gauss Mesh

☐ Enable Displacement Probing

(a) Gauss Mesh Options (b) Gauss Mesh Fields

Figure 208.20: Visualizing Gauss mesh and it's fields.

The various fields that can be visualized in Gauss mesh mode as shown in Figure 208.20 are shown below.

- Total Strain ϵ : It defines the total strain from the start of the simulation. It has six independent component $\epsilon_{xx}, \epsilon_{xy}, \epsilon_{xz}, \epsilon_{yy}, \epsilon_{yz}$ and ϵ_{zz}. The magnitude of the total stress in ParaView is defined as $\sqrt{\epsilon_{ij} : \epsilon_{ij}}$.
- Total Plastic Strain ϵ^{pl} : It defines the total plastic strain from the start of the simulation. It has six independent component $\epsilon^{pl}_{xx}, \epsilon^{pl}_{xy}, \epsilon^{pl}_{xz}, \epsilon^{pl}_{yy}, \epsilon^{pl}_{yz}$ and ϵ^{pl}_{zz}. The magnitude of the total plastic strain in ParaView is defined as $\sqrt{\epsilon^{pl}_{ij} : \epsilon^{pl}_{ij}}$.
- Total Effective Stress $\sigma\prime$: It defines the total effective stress from the start of the simulation. It has six independent component $\sigma'_{xx}, \sigma'_{xy}, \sigma'_{xz}, \sigma'_{yy}, \sigma'_{yz}$ and σ'_{zz}. The magnitude of the total effective stress in ParaView is defined as $\sqrt{\sigma'_{ij} : \sigma'_{ij}}$. The unit of visualization is in $[Pa]$.

- Total Mean Effective Stress p : It defines the total mean of the effective stress σ' from the start of the simulation. It is defined as $p = -\sigma'_{ii}/3$ as described in Equation ??. The unit of Visualization is in $[Pa]$.

- Total Deviatoric Effective Stress q : It defines the deviatoric invariant of the total effective stress σ' from the start of the simulation. It is defined as $q = \sqrt{3J_2}$ as described in Equation ??. Where, J_2 is the second invariant of the deviatoric stress tensor $s_{ij} = \sigma'_{ij} - \sigma'_{kk}/3\delta_{ij}$. The unit of visualization is in $[Pa]$.

- Total Mean Plastic Strain ϵ_p^{pl} : It defines the mean total plastic strain ϵ^{pl} invariant from the start of the simulation. It is defined as $\epsilon_p^{pl} = -\epsilon_{ii}^{pl}/3$. This visualization parameter is unit-less.

- Total Deviatoric Plastic Strain ϵ_p^{pl} : It defines the deviatoric invariant of the total plastic strain ϵ^{pl} from the start of the simulation. It is defined as $\epsilon_p^{pl} = \sqrt{3J'_2}$. Where, J'_2 is the second invariant of the deviatoric plastic strain tensor $e_{ij}^{pl} = \epsilon_{ij}^{pl} - \epsilon_{kk}^{pl}/3\delta_{ij}$. This visualization parameter is unit-less.

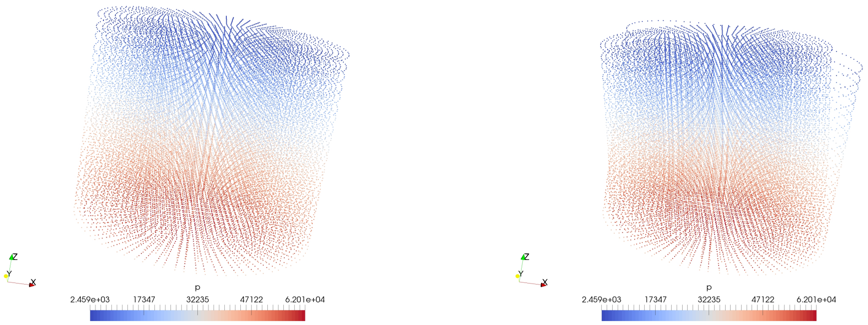
1. Open an example in ParaView. All the example files can be obtained at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_pvESSI/Examples`.

```
cd pvESSI/Examples
ParaView ShearBox_PushOver.h5.feioutput
```

2. Check on *Enable Relative Displacement* under PVESSIReader build options

3. Enable Gauss mesh as shown in Figure 208.20(a). Select `Mean Effective Stress` p `[Pa]`. The resulting visualization is shown in Figure 208.21(a).

4. Enable `displacement probing` as shown in Figure 208.20(a). Apply a `warp by vector` filter and select the vector `displacement` as shown in Figure 208.10. Now select again the `Mean Effective Stress` p `[Pa]` field option to visualize. The resulting visualization is shown in Figure 208.21(b).



(a) Gauss Mesh (b) Gauss Mesh with displacement probing

Figure 208.21: Visualization of mean effective stress p invariant in Gauss mesh.

208.4.1.9 Gauss To Node Interpolation Mode Visualization

This visualization mode can be enabled by checking the '`Gauss To Node Interpolation`' option as shown in Figure 208.22(a). In this mode, the total effective stress σ'_{ij}, total strain ϵ_{ij}, total plastic strain ϵ^{pl}_{ij}, total mean effective stress p, total deviatoric effective stress q, total mean plastic strain ϵ^{pl}_{p} and total deviatoric plastic strain ϵ^{pl}_{q} are interpolated from the Gauss points to the nodes of individual element. Individual shape functions of the element (with full Gauss integration) are used to obtain the stress or strain field at nodes. To smooth out the jumps in stress or strain field at the node by adjacent elements, unweighted averaging is performed. For the elements (usually structural) with no Gauss points, the stress or strain contribution at nodes are considered as zero. While taking the averaging, their contributions are not taken, as Real-ESSI does not output stress/strain for them.

In this mode, visualization of all the parameters listed and described in Section 208.4.1.8 is available. Figure 208.22 show the steps to enable and use `Gauss to Node Interpolation` option.

1. Open an example in ParaView. All the example files can be obtained at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_pvESSI/Examples`.

```
cd pvESSI/Examples
ParaView ShearBox_Sequential.feioutput
```

2. Follow the steps as shown in Figure 208.22

Note : The option `Gauss to node interpolation` is provides only an approximate estimate for stress and strains at nodes. The values obtained at nodes is not accurate and thus `Gauss Mesh Visualization` option described in Section 208.4.1.8 must be performed to get the accurate stress and strains at Gauss points. Also, it must be noted that this option works only for 8 node brick with 8 Gauss points and 27 node brick with 27 node points. For elements which have less number of nodes that Gauss points, the total number of equations (unknowns) is not equal to constraints (knowns). In this case, only the shape function defined at the nodes are used to get the stress or strain back to the node.

Figure 208.22: Steps to visualize stress and strain interpolated from Gauss points to nodes.

208.4.1.10 upU Visualization

This mode is to visualize the upU elements used in Real-ESSI simulation. Enabling this mode, produces additional outputs of '`Pore Pressure` $p[Pa]$' and '`Fluid Displacement` $U_x[m]$`,` $U_y[m]$ `and` $U_z[m]$' at nodes. These additional outputs are described below.

- Pore Pressure $p[Pa]$: It defines the pore-fluid pressure in the upU element at the nodes. The magnitude of the pore pressure is $[Pa]$.
- Fluid Displacement $U[m]$: It defines the displacement by the fluid particles of upU at nodes. The units is in meters $[m]$. The solid displacement is termed as u and refers to the '`Displacement` u' variable in visualization as described in Section 208.4.1.5.

Since general dry elements does not have any fluid, enabling this option would produce '`zero`' pore fluid pressure and fluid displacements at nodes. Below is shown an example that shows how to use the upU visualization feature. Figure 208.23 shows the steps.

1. Open an example in ParaView. All the example files can be obtained at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_pvESSI/Examples`.

```
cd pvESSI/Examples
ParaView upU_Visualization_Example.feioutput
```

2. Follow the steps as shown in Figure 208.23

208.4.1.12 Visualizing Physical Node and Element groups

In Real-ESSI it is possible to define different physical groups, for nodes and for elements. If one has defined physical groups in Real-ESSI, you can visualize the same in ParaView. There are two sections here that shows all the physical groups (nodes and elements) defined in the model as shown in Figure 208.26. Section 205.3.4.36 and Section 205.3.4.43 shows how to define and add physical group of nodes and elements respectively in Real-ESSI. All the example files can be obtained at `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_pvESSI/Examples`.

```
cd pvESSI/Examples
ParaView Model_With_Physical_Groups.h5.feioutput
```

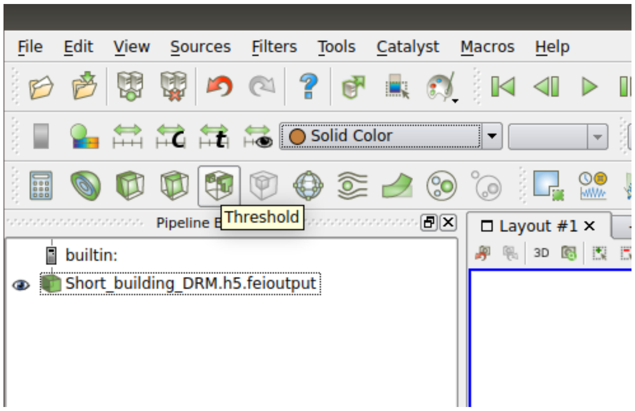
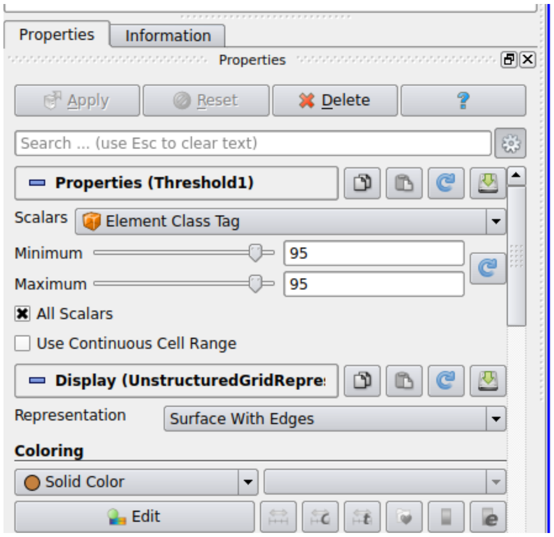
208.4.1.13 Using Threshold to Visualize Certain Elements

ParaView allows user to choose specific element types and only visualize selected elements. This function is achieved using Threshold. As shown in Figure 208.32, first click on the Threshold button in toolbar. Then, choose Element Class Tag in the drop-down list of Scalars, which can be found in Properties. A certain range of Element Class Tag can be chosen by setting the minimum and maximum values. If the minimum and maximum values are the same, only one element type will be selected and visualized.



(a) Click on Threshold



Scalars: Element Class Tag

Minimum: 95

Maximum: 95

☒ All Scalars

☐ Use Continuous Cell Range

Representation: Surface With Edges

Coloring: Solid Color

(b) Choose Element Class Tag

Figure 208.32: Using Threshold to Visualize Certain Elements.

A list of available element class tags in Real-ESSI is provided in Table 208.1.

Table 208.1: Available element class tags in Real-ESSI.

Finite Element Name	Element Class Tag
Truss Element	88
Shear Beam Element	93
Elastic Beam–Column Element	89
Timoshenko Elastic Beam–Column Element	129
Elastic Beam-Column Element with Lumped Mass	90
3D Displacement Based Fiber Beam-Column Element	95
4 Node ANDES Shell with Drilling DOFs	92
3 Node ANDES Shell with Drilling DOFs	91
Super Element Linear Elastic Import	9904
8 Node Brick Element (Order One, Two, Three, Four, Five, Six)	2 (14, 26, 38, 50, 62, 74)
8 Node Brick u-p Element (Order One, Two, Three, Four, Five, Six)	3 (15, 27, 39, 51, 63, 75)
8 Node Brick u-p-U Element (Order One, Two, Three, Four, Five, Six)	4 (16, 28, 40, 52, 64, 76)
20 Node Brick Element (Order One, Two, Three, Four, Five, Six)	5 (17, 29, 41, 53, 65, 77)
20 Node Brick u-p Element (Order One, Two, Three, Four, Five, Six)	6 (18, 30, 42, 54, 66, 78)
20 Node Brick u-p-U Element (Order One, Two, Three, Four, Five, Six)	7 (19, 31, 43, 55, 67, 79)
27 Node Brick Element (Order One, Two, Three, Four, Five, Six)	8 (20, 32, 44, 56, 68, 80)
27 Node Brick u-p Element (Order One, Two, Three, Four, Five, Six)	9 (21, 33, 45, 57, 69, 81)
27 Node Brick u-p-U Element (Order One, Two, Three, Four, Five, Six)	10 (22, 34, 46, 58, 70, 82)
Variable Node Brick Element (Order One, Two, Three, Four, Five, Six)	11 (23, 35, 47, 59, 71, 83)
Variable Node Brick u-p Element (Order One, Two, Three, Four, Five, Six)	12 (24, 36, 48, 60, 72, 84)
Variable Node Brick u-p-U Element (Order One, Two, Three, Four, Five, Six)	13 (25, 37, 49, 61, 73, 85)
8 Node Cosserat Brick Element	96
Bonded Contact/Interface/Joint Element	102
Force Based Dry Hard Contact/Interface/Joint Element	86
Force Based Dry Soft Contact/Interface/Joint Element	87
Force Based Coupled Hard Contact/Interface/Joint Element	97
Force Based Coupled Soft Contact/Interface/Joint Element	98
Stress Based Dry Hard Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior	99
Stress Based Dry Hard Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior	100
Stress Based Dry Hard Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior	101
Stress Based Dry Soft Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior	107
Stress Based Dry Soft Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior	108
Stress Based Dry Soft Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior	109
Stress Based Coupled Hard Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior	104
Stress Based Coupled Hard Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior	105
Stress Based Coupled Hard Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior	106
Stress Based Coupled Soft Contact/Interface/Joint Element with Elastic Perfectly Plastic Shear Behavior	110
Stress Based Coupled Soft Contact/Interface/Joint Element with Nonlinear Hardening Shear Behavior	111
Stress Based Coupled Soft Contact/Interface/Joint Element with Nonlinear Hardening and Softening Shear Behavior	112

Chapter 209

Software Platform Build Process

(1993-1994-1996-1999-2003-2005-2007-2008-2009-2010-2011-2015-2017-2018-2019-2020-2021-)

(In collaboration with Prof. José Abell, Dr. Yuan Feng, Dr. Hexiang Wang, and Prof. Han Yang)

209.1 Chapter Summary and Highlights

This Chapter gives a brief description of build and installation procedures for the Real-ESSI Simulator. It is noted that current installation procedures rely on Real-ESSI Simulator program Debian package distribution, with pre and post processing modules that are installed separately. Both sequential and parallel version of the Real-ESSI Simulator program Debian packages are distributed, for Linux/Ubuntu operating system.

209.2 Introduction to the Real-ESSI Simulator Program

The Real-ESSI Simulator systems consists of the Real-ESSI Program, Real-ESSI Computer and Real-ESSI Notes. Alternative name for the Real-ESSI Simulator system is Real-ESSI Simulator system. The name Real-ESSI, is explained in section 201.2.6 on page 710.

209.3 Real-ESSI Simulator System Install

In adition to the Real-ESSI Program, Real-ESSI Simulator system consists of a pre-processing modules and post-processing modules. Installation of pre-processing modules is described in Chapter 207, on page 1221 of the main document, lecture notes (Jeremić et al., 1989-2025). Installation of post-processing modules is described in Chapter 208, on page 1287 of the main document, lecture notes (Jeremić et al., 1989-2025).

Both pre and post processing manuals are also available through the main Real-ESSI Simulator web site: `http://real-essi.info/`.

209.4 Build Procedures for the Real-ESSI Program and Modules

Note: This section describes build procedure for the Global Release 25.04 version of Real-ESSI. The very same procedures will apply to future version...

These build procedures are meant for users that have access to Real-ESSI Program source code. Required operating system is Ubuntu 24.04 LTS, unless otherwise specified. Building Real-ESSI on older versions of Ubuntu is no longer supported. Users that do not have source code can install Real-ESSI form Debian package, that is also available.

209.4.1 System Libraries Update/Upgrade

```
sudo apt update
sudo apt upgrade
sudo apt dist-upgrade
sudo apt autoremove
```

209.4.2 Install Build Dependencies

```
sudo apt install -y bison
sudo apt install -y build-essential
sudo apt install -y cmake
sudo apt install -y flex
sudo apt install -y git
sudo apt install -y mpich
sudo apt install -y ssh
sudo apt install -y valgrind
sudo apt install -y wget
sudo apt install -y zlib1g-dev
sudo apt install -y libboost-all-dev
sudo apt install -y libgmp3-dev
sudo apt install -y libhdf5-serial-dev
sudo apt install -y liblapack-dev
sudo apt install -y libmpfr-dev
sudo apt install -y libopenblas-dev
sudo apt install -y libopenmpi-dev
sudo apt install -y libpthread-workqueue-dev
sudo apt install -y libssl-dev
sudo apt install -y libtbb-dev
```

You may need to manually link the HDF5 libs to their proper names so that the compiler can find them. The HDF5 maybe in different versions. NOTE: what is needed is a latest version of libhdf5 for serial execution, the one "cpp" and the one without "cpp", so search for it by doing:

```
cd /usr/lib/x86_64-linux-gnu
dir `find . -name "*hdf5*serial*cpp*"`
```

and

```
dir `find . -name "*hdf5*serial*"` | grep -v cpp
```

Then the linking has to be for both versions, for example:

```
cd /usr/lib/x86_64-linux-gnu
sudo ln -s libhdf5_serial.so.103.3.0 libhdf5.so
sudo ln -s libhdf5_serial_cpp.so.103.3.0 libhdf5_cpp.so
```

If the libs `libhdf5.so` and `libhdf5_cpp.so` are already there, just move on.

209.4.3 Download Real-ESSI Source

It is important to note that Real-ESSI sources are not available for public download. This is so that we can control and guarantee Real-ESSI quality. Only developer collaborators are contributing sources, and those sources are quality checked and quality assured. In addition, there are a number of unique solutions, unique formulations, unique implementation details within Real-ESSI sources that are not available in any other research of commercial program. If you happen to obtain Real-ESSI sources from Prof. Jeremić, you can proceed with the installation procedure below.

Please make sure that you are in the main directory where your Real-ESSI global release is placed ((`GLOBAL_RELEASE`). Make a directory where all the sources will reside and go there:

```
cd
mkdir Real-ESSI
cd Real-ESSI
```

Obtain Real-ESSI sources from the github:

```
git clone git@github.com:BorisJeremic/Real-ESSI.git
```

Go to the Real-ESSI source directory:

```
cd Real-ESSI
```

Remember to 'git checkout' to the proper branch.

209.4.4 Download and Compile Real-ESSI Dependencies

Make directories for the dependencies:

```
mkdir -p ../RealESSI_Dependencies
mkdir -p ../RealESSI_Dependencies/include
mkdir -p ../RealESSI_Dependencies/lib
mkdir -p ../RealESSI_Dependencies/bin
mkdir -p ../RealESSI_Dependencies/SRC
```

Go to the directory, download and extract the sources of the dependencies:

```
cd ../RealESSI_Dependencies
wget http://sokocalo.engr.ucdavis.edu/~jeremic/RealESSI/Dependencies_SRC.tar.gz
tar -xzvf ./Dependencies_SRC.tar.gz -C ./SRC --strip-components 1
```

Go to the Real-ESSI directory and compile the dependencies:

```
cd ../Real-ESSI
./build_libraries suitesparse
./build_libraries arpack
```

```
./build_libraries lapack
./build_libraries parmetis
./build_libraries petsc_itself
```

209.4.5 Configure, Build, and Install the Real-ESSI Program

Configure and build the sequential version of Real-ESSI:

```
mkdir build
cd build
cmake ..
make -j 8
cd ..
```

Configure and build the parallel version of Real-ESSI:

```
mkdir pbuild
cd pbuild
cmake -DCMAKE_CXX_COMPILER=/usr/bin/mpic++ -DPROGRAMMING_MODE=PARALLEL ..
make -j 16
cd ..
```

Copy the Real-ESSI executables to system directory:

```
sudo cp build/essi /usr/local/bin/essi-sequential
sudo cp pbuild/essi /usr/local/bin/essi-parallel
```

209.4.6 Install Sublime Text and Real-ESSI Packages

Sublime Text (`https://www.sublimetext.com/`) is the recommended editor for Real-ESSI input files and pre-processing files. Install Sublime Text following the official installation steps, or using the following command:

```
wget -qO - https://download.sublimetext.com/sublimehq-pub.gpg | gpg --dearmor | ↩
   sudo tee /etc/apt/trusted.gpg.d/sublimehq-archive.gpg
echo "deb https://download.sublimetext.com/ apt/stable/" | sudo tee ↩
   /etc/apt/sources.list.d/sublime-text.list
sudo apt-get update
sudo apt-get install sublime-text
```

Open Sublime Text. Open the ‘Tools’ menu and select ‘Install Package Control...’. Open the ‘Preferences’ menu, select ‘Package Control’, then select ‘Package Control: Install Package’.

In the opened search bar, type the package name and click on the package to install it. Three packages should be installed:

FEI Syntax-n-Snippets, Real-ESSI syntax and auto completion plugin for [].fei files (input files for Real-ESSI program).

gmsh-Tools, syntax and autotext completion for Gmsh model development tools for Real-ESSI.

gmESSI-Tools, syntax and autotext completion for gmESSI model development tools for Real-ESSI.

209.4.7 Install HDFView

`HDFView` can be used to open Real-ESSI output files, which are in HDF5 format. Download the latest version of `HDFView` from `https://support.hdfgroup.org/ftp/HDF5/releases/HDF-JAVA/`. Click on the latest version, which is `hdfview-3.2.0` as of June 2022. Go to `bin/`, click `HDFView-3.2.0-ubuntu2004_64.tar.gz` and save the file in your `./Downloads/` directory. Then extract and install HDFView:

```
cd
tar -xvf ./Downloads/HDFView-3.2.0-ubuntu2004_64.tar.gz -C ./Downloads
sudo apt install -y ./Downloads/hdfview_3.2.0-1_amd64.deb
sudo ln -s /opt/hdfview/bin/HDFView /usr/local/bin/hdfview
```

Now you can use `HDFView` from a terminal. To be able to use `HDFView` when you click on a Real-ESSI output file, do the following additional steps. First open the file using the following command:

```
sudo gedit /usr/share/applications/hdfview-HDFView.desktop
```

Find the line:

```
Exec=/opt/hdfview/bin/HDFView
```

Replace it with:

```
Exec=/opt/hdfview/bin/HDFView %F
```

Save the file and close it.

Go to a Real-ESSI output file, which should have the suffix ‘h5.feioutput’. Right click on the file and select ‘Open with Other Application’. Click ‘View All Applications’ and choose `HDFView` from the list. Note that you only need to do this once. Next time when you click on a Real-ESSI output file, it will be opened automatically using `HDFView`.

209.4.8 Compile ParaView and PVESSIReader for Post-Processing

Install the build dependencies for ParaView:

```
sudo apt install -y libgl1-mesa-dev
sudo apt install -y libxt-dev
```

```
sudo apt install -y libqt5x11extras5-dev
sudo apt install -y libqt5help5
sudo apt install -y qttools5-dev
sudo apt install -y qtxmlpatterns5-dev-tools
sudo apt install -y libqt5svg5-dev
sudo apt install -y libtbb-dev
sudo apt install -y python3-dev
sudo apt install -y python3-numpy
sudo apt install -y ninja-build
```

Go to the directory where you want to install ParaView. Suggested location is the parent directory of the Real-ESSI source. If you are continuing from the previous subsection, do the following:

```
cd ..
```

Download the ParaView source from GitHub:

```
git clone --recursive https://gitlab.kitware.com/paraview/paraview.git
```

Make the build directory:

```
cd paraview
mkdir paraview_build
```

Modify the cmake file to include PVESSIReader plugin in the building process. Open the file `CMakeLists.txt` in the ParaView source directory. Find "set(paraview_default_plugins" and add "PVESSIReader" to the end of the list of plugins. Download the PVESSIReader source from GitHub:

```
cd Plugins
git clone git@github.com:BorisJeremic/Real-ESSI-pvESSI.git
mv Real-ESSI-pvESSI PVESSIReader
```

Go to the build directory and compile ParaView:

```
cmake -GNinja -DPARAVIEW_USE_PYTHON=ON -DPARAVIEW_USE_MPI=ON ↩
   -DVTK_SMP_IMPLEMENTATION_TYPE=TBB -DCMAKE_BUILD_TYPE=Release ..
ninja
```

Copy the ParaView executable to system directory:

```
sudo cp bin/paraview /usr/local/bin/paraview
```

Start `ParaView` and click 'Tools' → 'Manage Plugins...'. Click 'Load New...' and find the plugin named 'PVESSIReader.so' under directory `paraview/lib/paraview-5.10/plugins/PVESSIReader/`. Also check the box 'Auto Load' then close `ParaView`.

The procedures described in this subsection are based on the official build instruction of ParaView (https://gitlab.kitware.com/paraview/paraview/blob/master/Documentation/dev/build.md).

209.5 Build Real-ESSI Debian Package

Note: This section describes Debian package build procedure for the Global Release 22.07 and later versions of Real-ESSI. As noted before, the very same procedures will apply to future Ubuntu versions ...

Starting from the Global Release 22.07 version, the Real-ESSI Simulator system is distributed as a Debian package for Linux users. This section documents the build procedure of a Real-ESSI Debian package. Note that the steps described here are for building a "basic" or "quick" stand-alone Debian package containing the already-compiled Real-ESSI program, pre-processor gmsh/gmESSI and results viewer Paraview/pvESSI modules. This is different from building a Debian package containing the program sources. For more information see:

- https://wiki.debian.org/Packaging
- https://www.internalpointers.com/post/build-binary-deb-package-practical-guide
- https://ubuntuforums.org/showthread.php?t=910717

209.5.1 Build the Real-ESSI Program and Modules

Before starting to build the Debian package, you should have finalized building the Real-ESSI program and modules from source. To build Real-ESSI from source, please follow the build procedure described in section 209.4.

209.5.2 Build the Debian Package

209.5.2.1 Package Name

Standard Debian notation is all lowercase in the following format:

```
<project>_<major version>.<minor version>-<package revision>
```

The current Real-ESSI Debian package has the name:

```
real-essi_25.04_amd64
```

Note that the version names will change and be consistent with the version of Real-ESSI program, as decribed at http://real-essi.info/, so that users will have to change the above name to reflect the actual Real-ESSI version and the Debian package.

209.5.2.2 Create Directory

Create a directory to make your package in. The name should be the same as the package name.

```
mkdir real-essi_25.04_amd64
```

209.5.2.3 Create Internal Structure

Good idea is to put packaging directory in the root of Real-ESSI system. So go to where all of this happening, for example:

```
cd /home/jeremic/oofep/Rad_na_Sokocalu/GLOBAL_RELEASE/Real-ESSI
```

Make space for files of your program where they would be installed on a linux system.

```
mkdir real-essi_25.04_amd64/usr
mkdir real-essi_25.04_amd64/usr/local
mkdir real-essi_25.04_amd64/usr/local/bin
mkdir real-essi_25.04_amd64/usr/lib
mkdir real-essi_25.04_amd64/usr/lib/x86_64-linux-gnu
mkdir real-essi_25.04_amd64/opt
mkdir real-essi_25.04_amd64/opt/gmESSI
mkdir real-essi_25.04_amd64/opt/paraview
```

209.5.2.4 Copy Files

Copy the files to the packaging directory. Note that you should use your own directory paths....

For example:

```
cp bin/essi.sequential real-essi_25.04_amd64/usr/local/bin/essi.sequential
cp bin/essi.parallel real-essi_25.04_amd64/usr/local/bin/essi.parallel
```

209.5.2.5 Create the `control` File

Create a special metadata file that is used by the package manager to install program. The control file lives inside the `DEBIAN` directory. Mind the uppercase: a similar directory named `debian` (lowecase) is used to store source code for the so-called source packages. This tutorial is about binary packages,so we don't need source code. Create the empty `control` file:

```
mkdir real-essi_25.04_amd64/DEBIAN
touch real-essi_25.04_amd64/DEBIAN/control
```
