    python3-pygments, liboctave-dev, python2.7-dev
Section: misc
Priority: optional
Provides: real-essi
Description: The Real-ESSI Simulator.
 The Real-ESSI Simulator (Realistic Modeling and Simulation
 of Earthquakes, and/or Soils, and/or Structures and their
 Interaction) is a software, hardware and documentation
 system for high performance, sequential or parallel, time
 domain, linear or nonlinear, elastic and inelastic,
 deterministic or probabilistic, finite element modeling and
 simulation of
  - statics and dynamics of soil,
  - statics and dynamics of rock,
  - statics and dynamics of structures,
  - statics of and dynamics of soil-structure systems,
  - dynamics of earthquakes, and
  - dynamic earthquake-soil-structure interaction.
Homepage: http://real-essi.info
```

209.5.2.6 Create the Post-Installation and Post-Remove Files

```
touch real-essi_25.04_amd64/DEBIAN/postinst
touch real-essi_25.04_amd64/DEBIAN/postrm
```

Both of these files have to have the following permissions::

```
chmod u+rwx real-essi_25.04_amd64/DEBIAN/postinst
chmod u+rwx real-essi_25.04_amd64/DEBIAN/postrm

chmod og=rx real-essi_25.04_amd64/DEBIAN/postinst
chmod og=rx real-essi_25.04_amd64/DEBIAN/postrm
```

The `postinst` file/script is executed after a successful installation of the Debian package. This script looks like this:

```
#!/bin/sh
# postinst script for real-essi

set -e

case "$1" in
    configure)
# not used
# ln -s /opt/gmESSI/build/bin/gmessy /usr/local/bin/
# ln -s /opt/paraview/bin/paraview /usr/local/bin/

update-alternatives --install /usr/bin/python python /usr/bin/python2.7 1
pip install h5py
    ;;

    abort-upgrade|abort-remove|abort-deconfigure)
    ;;

    *)
        echo "postinst called with unknown argument \`$1'" >&2
        exit 1
    ;;
esac

exit 0
```

The postrm file/script is executed after a successful removal of the Debian package. This script looks like this:

```
#!/bin/sh
# postrm script for real-essi

set -e

case "$1" in
    purge|remove|upgrade|failed-upgrade|abort-install|abort-upgrade|disappear)
# not used
# rm /usr/local/bin/gmessy
# rm /usr/local/bin/paraview
    ;;

    *)
        echo "postrm called with unknown argument \`$1'" >&2
        exit 1
    ;;
esac

exit 0
```

209.5.2.7 Build the Package

Build the package:

```
dpkg-deb --build --root-owner-group real-essi_25.04_amd64
```

The `--root-owner-group` flag makes all deb package content owned by the root user, which is the standard way to go. Without such flag, all files and folders would be owned by your user, which might not exist in the system the deb package would be installed to.

The command above will generate a nice `.deb` file alongside the working directory or print an error if something is wrong or missing inside the package. If the operation is successful you have created debian package ready for distribution.

209.6 Real-ESSI and OpenFOAM, Connecting

Note: This section describes build procedure for old versions of Real-ESSI and/or its modules.

OpenFOAM is a free, open source computational fluid dynamics (CFD) software developed primarily by OpenCFD Ltd since 2004 (https://www.openfoam.com/). Real-ESSI supports numerical interface with OpenFOAM and can perform solid/structure fluid interaction analysis through Real-ESSI – OpenFOAM connection.

209.6.1 Installation of Customized OpenFOAM

We have made in-house modifications and developments to the InterFOAM application (Deshpande et al., 2012) of OpenFOAM-v1612+ for solid fluid interaction. This section presents the installation of the Customized OpenFOAM:

Install the dependencies:

```
sudo apt-get update
sudo apt-get install build-essential
sudo apt-get install flex
sudo apt-get install bison
sudo apt-get install cmake
sudo apt-get install zlib1g-dev
sudo apt-get install libboost-system-dev
sudo apt-get install libboost-thread-dev
sudo apt-get install libopenmpi-dev
sudo apt-get install openmpi-bin
sudo apt-get install gnuplot
sudo apt-get install libreadline-dev
sudo apt-get install libncurses-dev
sudo apt-get install libxt-dev
```

```
sudo apt-get install qt4-dev-tools
sudo apt-get install libqt4-dev
sudo apt-get install libqt4-opengl-dev
sudo apt-get install freeglut3-dev
sudo apt-get install libqtwebkit-dev
sudo apt-get install libscotch-dev
sudo apt-get install libcgal-dev
```

Also, make sure gcc and cmake meet the following minimum version requirements:

- gcc: version 4.8.5 or above
- cmake: version 3.3 or above

Check the version of gcc and cmake by running the following commands on terminal. If you are installing on Ubuntu 16.04 and above, the system version of gcc and cmake should already meet the requirements.

```
gcc --version
cmake --version
```

Downloaded the source code of Customized OpenFOAM:

```
wget http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/
_Chapter_SoftwareHardware_Build_Process/OpenFOAM/sources/OpenFOAM.tar.gz
```

Choose a directory and extract the downloaded compressed file to the target directory.

```
tar -xzvf OpenFOAM.tar.gz -C /target/directory
```

For example, hereafter we choose $HOME as target directory. Replace $HOME with your chosen directory accordingly.

```
tar -xzvf OpenFOAM.tar.gz -C $HOME
```

Go to the extracted folder and source OpenFOAM environment configurations:

```
cd $HOME/OpenFOAM
source $HOME/OpenFOAM/OpenFOAM-v1612+/etc/bashrc
```

Setup CGAL and Boost version for compilation:

```
cgal_version=CGAL-4.9.1
boost_version=boost-system
```

Check the system readiness

```
foamSystemCheck
```

Change to the main OpenFOAM directory:

```
foam
```

Note: if running *foam* cannot change to the main OpenFOAM directory, in this case the directory is *$HOME/OpenFOAM*, source the environment configuration again by running the following terminal command.

```
source $HOME/OpenFOAM/OpenFOAM-v1612+/etc/bashrc
```

Compile OpenFOAM:

```
./Allwmake
```

Since OpenFOAM is shipped with ParaView for post-processing OpenFOAM field results using developed plug-in paraFoam (https://cfd.direct/openfoam/user-guide/v6-paraview/). We also need to compile customized ParaView with paraFoam plug-in:

```
cd $WM_THIRD_PARTY_DIR
./makeParaView
```

209.6.2 Check the Customized OpenFOAM Installation

Open a new terminal and source the OpenFOAM environment:

```
source $HOME/OpenFOAM/OpenFOAM-v1612+/etc/bashrc
```

Validate the build by running:

```
foamInstallationTest
```

Create a user run directory:

```
mkdir -p $FOAM_RUN
```

go to the user run directory:

```
run
```

Copy a simulation case from OpenFOAM tutorial to the user run directory:

```
cp -r $FOAM_TUTORIALS/incompressible/simpleFoam/pitzDaily ./
```

go to the copies case directory:

```
cd pitzDaily
```

Generate the mesh:

```
blockMesh
```

Perform the analysis with the application simpleFoam:

```
simpleFoam
```

Visualize the simulation results:

```
paraFoam
```

209.6.3 Compile Real-ESSI with Link to OpenFOAM

Go to Real-ESSI source directory under directory RealESSI_ROOT and clean any previous old compilation of Real-ESSI:

```
cd RealESSI_ROOT/Real-ESSI
rm -rf bin
rm -rf lib
rm -rf build_sequential
mkdir bin
mkdir lib
mkdir build_sequential
cd build_sequential
```

Build and install the executable, using 16 CPUs in this case. Of course, if you have more CPUs available, you can use most of them. Please make sure to specify your OpenFOAM installation directory with CMake argument -DOPENFOAM_DIR. For example, in this case, we specify the installation directory as *$HOME/OpenFOAM*.

```
time cmake -DUSE_OPENFOAM=TRUE -DOPENFOAM_DIR=$HOME/OpenFOAM ..
time make -j 16
make install
```

Rename essi to essi.sequential just so to distinguish it from the parallel executable:

```
cd ../bin
cp essi essi.sequential
```

Finally, install essi.sequential in system binary directory so that others can use it:

```
sudo rm /usr/bin/essi /usr/bin/essi.sequential
sudo cp essi.sequential /usr/bin/essi.sequential
sudo chmod a+x /usr/bin/essi.sequential
```

209.7 Code Verification After the Build Process

After build process, test cases to verify that installation is successful should be run. There are four groups of verification cases. The first two groups are designed for users. The last two groups are designed for developers.

1. The first group of test cases compares the sequential essi results to the analytic solutions.
2. The second group of test cases compares the parallel essi results to the analytic solutions.
3. The third group of test cases tests the version stability between two essi executables.
4. The fourth group of test cases tests the memory management of Real-ESSI with valgrind.

209.7.1 Run all verification test cases

In order to run all test cases to verify the installation, users can run

```
cd $RealESSI_PATH/
bash run_all_verification.sh
```

Please make sure that sequential essi is available as 'essi' in the PATH, and parallel essi is available as 'essi_parallel' in the PATH before running all the verification test cases.

In addition, if users want to clean the test results, users can run

```
cd $RealESSI_PATH/
bash clean_all_verification.sh
```

Finally, users can also run a single group of test cases as follows.

209.7.2 Test Sequential Real-ESSI

In order to test whether the installation of sequential essi is successful, open the sequential example folder and run the bash script.

```
cd $RealESSI_PATH/CompGeoMechUCD_Miscellaneous/examples/analytic_solution
bash make_comparison.sh
```

This bash script will run all the examples automatically and compare the results to the analytic solutions. The comparison results are not only printed in the Terminal but also saved as a .log file in the same folder. Before you run the examples, make sure *essi* is in your PATH.

209.7.3 Test Parallel Real-ESSI

In order to test whether the installation of parallel essi is successful, open the parallel example folder and run the bash script.

```
cd $RealESSI_PATH/CompGeoMechUCD_Miscellaneous/examples/parallel
bash make_comparison.sh
```

This bash script will run all the examples automatically and compare the results to the analytic solutions. The comparison results are not only printed in the Terminal but also saved as a .log file in the same folder. Before you run the examples, make sure *essi_parallel* is in your PATH.

209.7.4 Version Stability Test

Since new features are continuously updated and improved in Real-ESSI, the version stability test helps the developers to guarantee their modification will not affect the correct operation of other code.

In order to test version stability,

```
cd $RealESSI_PATH/CompGeoMechUCD_Miscellaneous/examples/version_stability
bash generate_original.sh
```

This bash script will run all the examples automatically and save the results for reference later. This bash script above should run with the previous stable essi.

Then, to test the new essi and compare the results

```
cd $RealESSI_PATH/CompGeoMechUCD_Miscellaneous/examples/version_stability
bash make_comparison.sh
```

This bash script will run all the examples again and compare the results to the previous saved results. This bash script should run with the new essi. The comparison results are not only printed in the Terminal but also saved as a .log file in the same folder.

209.7.5 Memory Management Test

Memory management is important in C/C++ programming. This group of test cases helps the developers to track the memory leak in Real-ESSI. For the details about the code stability verification, please refer to the Section 303.2 on Page 1459.

Before you run the test cases, make sure Valgrind is installed. You can install Valgrind by this command.

```
sudo apt-get install valgrind
```

You can also download the source of Valgrind and compile it from scratch.

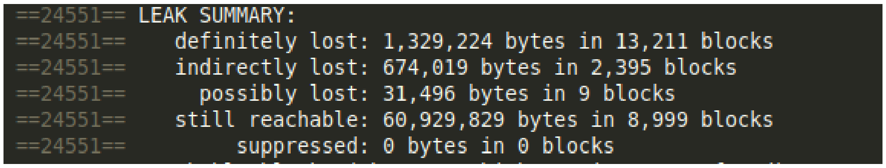
It is important to test memory leak in parallel simulations.

```
mpirun -np 3 valgrind --log-file='log_%p.valgrind' --leak-check=yes ↩
   essi-parallel-debug -f main.fei
```

A few important things to mention here:

- To test memory leak in parallel simulation, you obviously need a parallel version of Real-ESSI.
- Real-ESSI needs to be compiled in debug mode. This is important for Valgrind to capture and location the source of memory leaks.
- Running Real-ESSI in debug mode and in Valgrind means the simulation will be very slow. So it's not practical to run memory leak test using a large model. You should have a model with only a few elements/nodes (but more than 1 element so that it runs in parallel) that includes the specific functions you want to test.
- Valgrind log files will be saved in the location where you run the model. There will be multiple log files named as `log_processID.valgrind`. Each process will have its own Valgrind log file. There might be a few empty Valgrind log files generated, you can just ignore those. The number of Valgrind log files that actually contain memory leak information should be the same as the number of cores you use in your simulation.
- Valgrind is a powerful tool with many options. The command shown above is rather basic but serves as a good starting point. Memory leaks can be very tricky to track and fix. You should learn and experiment with Valgrind options for different issues you want to fix.

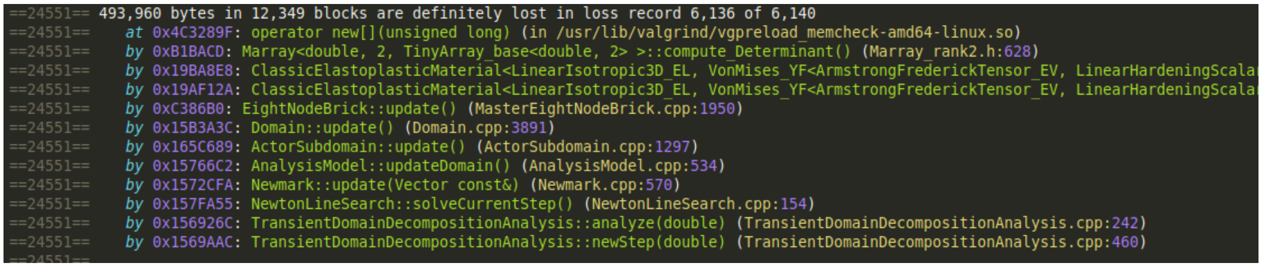
Valgrind log file can be very long and hard to read. At the bottom, there is a leak summary that looks like this: You should primarily focus on the 'definitely lost' result. 'Indirectly lost' and 'possibly lost' can also be problematic but should go away once you fix the source of 'definitely lost'. 'Still reachable' is usually not considered as actual memory leak but is something that can be optimized. Refer to the Valgrind User Manual for more information.



```
==24551== LEAK SUMMARY:
==24551==    definitely lost: 1,329,224 bytes in 13,211 blocks
==24551==    indirectly lost: 674,019 bytes in 2,395 blocks
==24551==      possibly lost: 31,496 bytes in 9 blocks
==24551==    still reachable: 60,929,829 bytes in 8,999 blocks
==24551==         suppressed: 0 bytes in 0 blocks
```

Figure 209.1: Valgrind log file: Memory leak summary.

Valgrind log file contains detailed information on each memory leak. A typical leak detail looks like this. Following the trail, you should be able to locate the source of a specific leak and then fix it properly.



```
==24551== 493,960 bytes in 12,349 blocks are definitely lost in loss record 6,136 of 6,140
==24551==    at 0x4C3289F: operator new[](unsigned long) (in /usr/lib/valgrind/vgpreload_memcheck-amd64-linux.so)
==24551==    by 0xB1BACD: Marray<double, 2, TinyArray_base<double, 2> >::compute_Determinant() (Marray_rank2.h:628)
==24551==    by 0x19BA8E8: ClassicElastoplasticMaterial<LinearIsotropic3D_EL, VonMises_YF<ArmstrongFrederickTensor_EV, LinearHardeningScala
==24551==    by 0x19AF12A: ClassicElastoplasticMaterial<LinearIsotropic3D_EL, VonMises_YF<ArmstrongFrederickTensor_EV, LinearHardeningScala
==24551==    by 0xC386B0: EightNodeBrick::update() (MasterEightNodeBrick.cpp:1950)

==24551==    by 0x165C689: ActorSubdomain::update() (ActorSubdomain.cpp:1297)
==24551==    by 0x15766C2: AnalysisModel::updateDomain() (AnalysisModel.cpp:534)
==24551==    by 0x1572CFA: Newmark::update(Vector const&) (Newmark.cpp:570)
==24551==    by 0x157FA55: NewtonLineSearch::solveCurrentStep() (NewtonLineSearch.cpp:154)
==24551==    by 0x156926C: TransientDomainDecompositionAnalysis::analyze(double) (TransientDomainDecompositionAnalysis.cpp:242)
==24551==    by 0x1569AAC: TransientDomainDecompositionAnalysis::newStep(double) (TransientDomainDecompositionAnalysis.cpp:460)
==24551==
```

Figure 209.2: Valgrind log file: Memory leak detail.

A serious memory leak issue caused by external solvers used by PETSc was found. As shown in Figure 209.3, when the `mumps` option was used in parallel solver, a significant amount of memory leak was detected by Valgrind. More importantly, such memory leak was observed to increase with the number of time steps. This means large-scale, long-duration simulation could be interrupted due to not enough memory in the operating system. Note that this issue was also reported in other occasions where the `mumps` package is used within PETSc, as recent as June 2020.

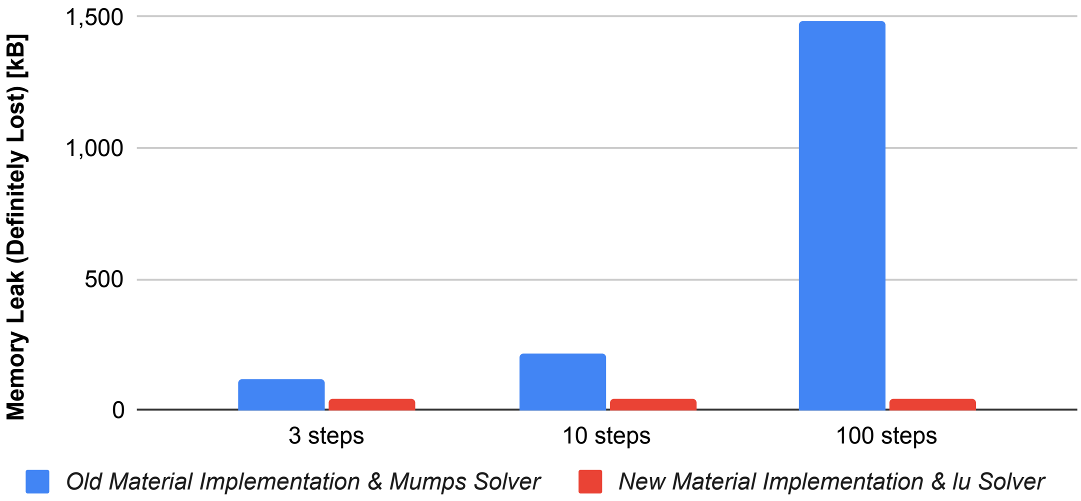

Figure 209.3: Comparison of memory leak between different PETSc solver options.

After extensive tests, it has been found out that other options/packages in PETSc don't have the memory leak issue mentioned above. Therefore it is recommended to use options other than `mumps` for large-scale, long-duration simulations. For example, the following command calls the default direct solver of PETSc:

```
define solver parallel petsc "-ksp_type preonly -pc_type lu" ;
```

209.8 Compiling Real-ESSI Utilities

Note: This section describes build procedure for old versions of Real-ESSI and/or its modules.

Real-ESSI comes with a lot of utilities to help the users speed up the simulation process. It provides mesh building, auto-input generation and visualization features which makes it quite nice.

Real-ESSI source code contains build_utilities script which can be used to build all the avialble utilities. We will go through the following subsection to introduce each utility and how to compile them.

The first step is to download all the sources of utilities that needs to be build. To do this, one has to run

```
cd Real-ESSI
./build_utilities download
```

This would download all the utilities sources in tar.gz format and would place them in "/SRC" of RealESSI_Utilities directory. The script is very powerfull and accepts targets that can be used to build a particular utility or all utilities at once. The available options to the scripts can be found by running the target help as shown below. A snippet is shown below

```
./build_utilities help

#usage: make [target]
#
#Utilities:
# gmessi Builds gmessi
# paraview Builds paraview
# pvessi Builds pvessi
# gmsh Builds gmsh
# visit Builds visit
# visitessi Builds visitessi
#
#Sequential:
# clean_utilities Cleans all utilities
#
#Default:
# all Builds all the necessary utilities for REAL-ESSI
# all_utils Builds all the necessary utilities for REAL-ESSI
# clean_all Cleans everything
# clean Cleans everything
#
#Check:
# check_utilities Checks if all utilities libraries are build
#
```

```
#Miscellaneous:
# list_utilities Lists all the available utilities version from SRC folder
# list_build_utilities Lists all the utilities library allready build in lib folder
# help Show this help.
# download Downloads the Utilities Sources
#
#Update:
# update_gmessi update gmessi utility
# update_pvessi update pvessi utility
# update_visitessi update visitessi utility
#
#Clean:
# clean_gmessi Clean gmessi utility
# clean_paraview Clean paraview utility
# clean_pvessi Clean pvessi utility
# clean_gmsh Cleans gmsh utility
# clean_visit Cleans visit
# clean_visitessi Cleans visitessi utility
```

The user can compile individual utilities by running just running

```
./build_utilities <utilitu_name>
```

Note: All the binaries of the utilities after build gets linked/copied to the RealESSI_Utilities/bin directory inside RealESSI_ROOT.

209.8.1 Installation of gmsh and gmESSI

gmsh is a 3-D finite element mesh generator for academic problems with parametric input and advanced visualization capabilities. It can be downloaded and installed from http://geuz.org/gmsh/. Additionally, the user can also install gmsh from terminal:

```
sudo apt-get install gmsh
```

gmESSI is effective pre-processor for generating Real-ESSI input files directly for the mesh file provided by gmsh. More information about gmESSI and how it works is given in Chapter 207 of the main document, lecture notes (Jeremić et al., 1989-2025). The gmESSI package is available from the main repository site: http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Pre_Processing/Real-ESSI_gmESSI.tgz. Before installing gmESSI, please install required libraries, as explained in Section ?? on Page ??. To install gmESSI, go to the Real-ESSI directory and then run

```
./build_utilities gmessi
```

To update the utility at the user just needs to run

```
./build_utilities update_gmessi
```

Refer to section 209.9 on page 1351 for instructions on what and how to install autocompletion and syntax coloring for gmESSI and Real-ESSI syntax on sublime text editor.

209.8.2 Installation of `ParaView` and `PVESSIReader`

ParaView package `http://www.paraview.org/` is a powerfull multi-platform data analysis and visualization application avialable in Open Source. It can be run on supercomputers to analyze datasets of petascale size as well as on laptops for small datasets. ParaView can be used to visualize results of Real-ESSI simulations. A plug-in was developed for ParaView so that all the simulations results from Real-ESSI finite elements, material models and analysis types can be directly visualized, animated, etc.

209.8.2.1 Building ParaView and PVESSIReader Plugin from Source on Linux System

Note that ParaView, as well as its building procedure, has recently (during 2020) gone through some major changes. The building procedures shown in this section are mostly based on the information available at: `https://gitlab.kitware.com/paraview/paraview/blob/master/Documentation/dev/build.md`.

1. Install Dependencies

```
sudo apt-get install libgl1-mesa-dev libxt-dev qt5-default ↩
   libqt5x11extras5-dev libqt5help5 qttools5-dev qtxmlpatterns5-dev-tools ↩
   libqt5svg5-dev python3-dev python3-numpy ninja-build
```

2. Obtain the source of ParaView

```
git clone --recursive https://gitlab.kitware.com/paraview/paraview.git
cd paraview
git checkout v5.8.1
git submodule update --init --recursive
mkdir paraview_build
```

3. Obtain the source of PVESSIReader plugin

   - The source of PVESSIReader plugin can be downloaded from `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Post_Processing/_Real_ESSI_PVESSIReader_.zip`

  - Extract the files and move the `PVESSIReader` folder to `./Plugins/`

4. Modify the cmake file to include PVESSIReader plugin in the building process. Open the file `paraview/CMakeLists.txt` using your choice of text editor. Find "`set(paraview_default_plugins`" and add "`PVESSIReader`" to the end of the list of plugins.

5. Build

```
cd paraview_build
cmake -GNinja -DPARAVIEW_USE_PYTHON=ON -DPARAVIEW_USE_MPI=ON ↩
    -DVTK_SMP_IMPLEMENTATION_TYPE=TBB -DCMAKE_BUILD_TYPE=Release ..
ninja
```

6. Load PVESSIReader plugin into ParaView

  - Run the ParaView executable and click on Tools → Manage Plugins → Load New ...
  - Find `PVESSIReader.so` at `paraview/paraview_build/lib/paraview-5.9/plugins/PVESSIReader` and click OK to load it.
  - Now you should see PVESSIReader loaded in the list of plugins. Double click on it to expand advanced options and check Auto Load.
  - Close the ParaView application and reopen it. Now the PVESSIReader plugin should be automatically loaded and ready to use.

209.8.2.2 Building ParaView and PVESSIReader Plugin from Source on Windows System

Note that ParaView, as well as its building procedure, has recently (during 2020) gone through some major changes. The building procedures shown in this section are mostly based on the information available at: `https://gitlab.kitware.com/paraview/paraview/blob/master/Documentation/dev/build.md`. It is noted that user should be prepared to spend some time (perhaps hours) on installing procedure...

1. Install Dependencies

  - Download and install git bash for windows. Use the latest release version.
  - Download and install cmake. Use the lastest release version.
  - Download and install Visual Studio 2017 Community Edition. Please make sure that you tick the packages related to "Desktop Development with C++" and "Universal Windows Platform development".

- Download ninja-build and drop `ninja.exe` in `C:\Windows\`. Use the latest release version.
- Download and install both `msmpisetup.exe` and `msmpisdk.msi` from Microsoft MPI. Use the latest release version from Microsoft.
- Download and install Python for Windows. Latest release version should work fine. To avoid potential compatibility issues, install the same Python version that is used for the latest release of ParaView. (Currently, 01May2023, use Python 3.8.10 for Windows, as this version is the same as version used by Paraview 5.9.1.)
- Download and install Qt 5.12.3 for Windows, make sure to check the MSVC 2015 64-bit component during installation, make sure to add `C:\Qt\Qt5.12.3\5.12.3\msvc2017_64\bin` to your `PATH` environnement variable. Note that Qt for Windows is x86 but it works for x64 machine as well.

2. Obtain the source of ParaView, (Currently, 01May2023, version is Paraview 5.9.1.)

   - Open your preferred Windows command prompt. Windows PowerShell is a nice tool for people usually work with Linux system. Git Bash application also works nice.
   - To build ParaView developement version 5.9.1 (usually refered as "master"), run the following commands:

   ```
   cd C:
   mkdir pv
   cd pv
   git clone --recursive https://gitlab.kitware.com/paraview/paraview.git
   mv paraview pv
   mkdir pvb
   cd pv
   git checkout v5.9.1
   git submodule update --init --recursive
   ```

   - To build a specific ParaView version, please refer to `https://gitlab.kitware.com/paraview/paraview/blob/master/Documentation/dev/build.md`.

3. Obtain the source of PVESSIReader plugin

   - The source of PVESSIReader plugin can be downloaded from `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Post_Processing/_Real_ESSI_PVESSIReader_.zip`
   - Extract the files and move the `PVESSIReader` folder to `C:\pv\Plugins\`

4. Modify the cmake file to include PVESSIReader plugin in the building process. Open the file `C:\pv\CMakeLists.txt` using your choice of text editor. Find "`set(paraview_default_plugins`" and add "`PVESSIReader`" to the end of the list of plugins.

5. Build

   - Open VS2017 x64 Native Tools Command Prompt and run the following commands

   ```
   cd C:\pv\pvb
   cmake -GNinja -DPARAVIEW_USE_PYTHON=ON -DPARAVIEW_USE_MPI=ON ↩
       -DCMAKE_BUILD_TYPE=Release ..\pv
   ninja
   ```

   - This step could be take a few hours. If no configuration or compilation error is encountered, you should have the ParaView executable at `C:\pv\pvb\bin\`.
   - Download and install Python 3.9.11 for Windows, as needed to run ParaView executable.

6. Load PVESSIReader plugin into ParaView

   - Run the ParaView executable and click on Tools → Manage Plugins → Load New ...
   - Find `PVESSIReader.dll` at `C:\pv\pvb\bin\paraview-5.9\plugins\PVESSIReader\` and click OK to load it.
   - Now you should see PVESSIReader loaded in the list of plugins. Double click on it to expand advanced options and check Auto Load.
   - Close the ParaView application and reopen it. Now the PVESSIReader plugin should be automatically loaded and ready to use.

209.8.2.3 Building ParaView and PVESSIReader Plugin from Source on AWS

Currently, the AWS image has Ubuntu 18.04. This may change in the future. Because AWS is a remote server, properly running ParaView needs more steps in compilation. Note that most information here are based on this discussion.

1. Install Dependencies

```
sudo apt-get install libgl1-mesa-dev libxt-dev qt5-default ↩
    libqt5x11extras5-dev libqt5help5 qttools5-dev qtxmlpatterns5-dev-tools ↩
    libqt5svg5-dev python3-dev python3-numpy ninja-build gettext python-mako
```

2. Download, Build and Install LLVM

```
wget http://releases.llvm.org/7.0.1/llvm-7.0.1.src.tar.xz
mkdir llvm
cd llvm
tar -xvf /path/to/llvm-7.0.1.src.tar.xz
mkdir llvm_build
mkdir llvm_install
cd llvm_build
cmake \
  -DCMAKE_BUILD_TYPE=Release \
  -DBUILD_SHARED_LIBS=ON \
  -DCMAKE_INSTALL_PREFIX=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/llvm/llvm_install ↩
      \
  -DLLVM_ENABLE_RTTI=ON \
  -DLLVM_INSTALL_UTILS=ON \
  -DLLVM_TARGETS_TO_BUILD:STRING=X86 \
  ../llvm-7.0.1.src
make -j8 install
```

3. Download, Build and Install Mesa

```
wget ↩
    https://gitlab.freedesktop.org/mesa/mesa/-/archive/mesa-18.3.3/mesa-mesa-18.3.3.tar.bz2
mkdir mesa
cd mesa
tar -xvf /path/to/mesa-mesa-18.3.3.tar.bz2
cd mesa-mesa-18.3.3
autoreconf --force --verbose --install
cd ../
mkdir mesa_build
mkdir mesa_install
cd mesa_build
../mesa-mesa-18.3.3/configure ↩
    --prefix=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/mesa/mesa_install ↩
    \
--enable-opengl --disable-osmesa --disable-gallium-osmesa \
--enable-glx --with-platforms=x11 --disable-gles1 --disable-gles2 \
--disable-va --disable-gbm --disable-xvmc --disable-vdpau \
--disable-shared-glapi --disable-dri --with-dri-drivers= \
--enable-llvm ↩
    --with-llvm-prefix=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/llvm/llvm_install ↩
    \
--with-gallium-drivers=swrast,swr --with-swr-archs=avx,avx2 --disable-egl
make -j8 install
```

4. Obtain the source of ParaView

```
git clone --recursive https://gitlab.kitware.com/paraview/paraview.git
cd paraview
git checkout v5.8.1
```

```
git submodule update --init --recursive
```

5. Obtain the source of PVESSIReader plugin

   - The source of PVESSIReader plugin can be downloaded from http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/_Chapter_SoftwareHardware_Post_Processing/_Real_ESSI_PVESSIReader_.zip
   - Extract the files and move the `PVESSIReader` folder to `./Plugins/`

6. Modify the cmake file to include PVESSIReader plugin in the building process. Open the file `paraview/CMakeLists.txt` using your choice of text editor. Find "`set(paraview_default_plugins`" and add "`PVESSIReader`" to the end of the list of plugins.

7. Build ParaView with Mesa

```
mkdir paraview_build
cd paraview_build
cmake -GNinja ↩
    -DOPENGL_gl_LIBRARY=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/mesa/mesa_install/lib
    \
-DOPENGL_INCLUDE_DIR=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/mesa/mesa_install/inclu
    \
-DOPENGL_EGL_INCLUDE_DIR= -DOPENGL_GLES2_INCLUDE_DIR= \
-DOPENGL_GLES3_INCLUDE_DIR= -DOPENGL_GLX_INCLUDE_DIR= \
-DOPENGL_egl_LIBRARY= -DOPENGL_gles2_LIBRARY= \
-DOPENGL_gles3_LIBRARY= -DOPENGL_glu_LIBRARY= \
-DOPENGL_glx_LIBRARY= -DOPENGL_opengl_LIBRARY= ../paraview \
-DPARAVIEW_USE_PYTHON=ON -DPARAVIEW_USE_MPI=ON \
-DVTK_SMP_IMPLEMENTATION_TYPE=TBB -DCMAKE_BUILD_TYPE=Release ../paraview
LD_LIBRARY_PATH=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/llvm/llvm_install/lib ↩
    ninja
```

   Note: There are many warnings showed up when I was doing this step, but it doesn't seem to terminate the build process.

8. Run ParaView with Mesa

```
LD_LIBRARY_PATH=/home/ubuntu/RealESSI_ROOT/RealESSI_Utilities/llvm/llvm_install/lib:/home/
    paraview
```

9. Load PVESSIReader plugin into ParaView

   - Run the ParaView executable and click on Tools → Manage Plugins → Load New ...

- Find `PVESSIReader.so` at `paraview/paraview_build/lib/paraview-5.9/plugins/PVESSIReader` and click OK to load it.
- Now you should see PVESSIReader loaded in the list of plugins. Double click on it to expand advanced options and check Auto Load.
- Close the ParaView application and reopen it. Now the PVESSIReader plugin should be automatically loaded and ready to use.

209.9 Sublime Text Editor

Note: This section describes build procedure for old versions of Real-ESSI and/or its modules.

Install `sublime` text editor from `http://www.sublimetext.com/`. Then install package control to sublime in order to install plugins. (go to preferences, package control, install package.) Then install two packages:

> FEI Syntax-n-Snippets, Real-ESSI syntax and auto completion plugin for [].fei files (input files for Real-ESSI program).
>
> gmsh-Tools, syntax and autotext completion for gmsh model development tools for Real-ESSI.
>
> gmESSI-Tools, syntax and autotext completion for gmESSI model development tools for Real-ESSI.

209.10 Model Conversion/Translation using `FeConv`

FeConv allows conversion/translation of input files (models) between Real-ESSI and SASSI, Sofistik, Ansys, OpenSees and Strudyn. FeConv was developed and is maintained by Mr. Viktor Vlaski.

209.11 Build Procedures on Amazon Web Service

This section shows the steps to install a new Real-ESSI image on Amazon Web Service (AWS). This document is only intended for Real-ESSI developers, not for general users. For using Real-ESSI on AWS, please refer to Chapter 211, on page 1373 in Jeremić et al. (1989-2025).

Noted that when creating a new image, the instance type should be consistent with future usage. For example, if the user intend to launch a Real-ESSI instance using the instance type "General Purpose", such as the T2 series, the image should also be created with the same instance type. If the image is created with a different instance type, Real-ESSI will not be able to run, and the following error message will be observed:

```
Illegal instruction (core dumped)
```

209.11.1 Sign In to AWS

Here is the link to the AWS sign in page. Click "Sign In to the Console" button on the upper right corner of the page. No need to register a new account. You should already have the account ID, IAM user name, and password for AWS sign in. If not, please contact an administrator to add you to the developers' group.

After sign in, go to the "EC2" tab under "Service". Here you can view all your instances and AMIs. This is where you can start new simulations or install new images.

Note that you probably also need to choose the correct region. On the upper right corner of the page, you can see your current region and switch to another one if necessary.

209.11.2 Copy an Existing Image

Since we already have a few images for Real-ESSI, the most efficient way to create a new image is to simply copy an existing one. To do this, go to the "AMIs" tab under "IMAGES" on the left part of the page. Now you should be able to view all existing images.

Select the image that you want to copy. Click the "Actions" button and choose "Copy AMI". On the pop-up window, enter the informations of this new image that you want to create. Then just click the "Copy AMI" button.

Now you should have a new image that has been installed with all the Real-ESSI components. To make any change inside this image, you need to launch it as a new instance and access it using X2GO. Procedures to install and use X2GO can be found in Chapter 211. For cloud server, on AWS or similar, the build procedures are the same as those for local installation, which can be found in previous sections of this chapter.

209.11.3 Create a New Image

If you need to create a new Real-ESSI image from scratch, this section shows the steps to do so. First sign in to AWS and go to "EC2". Choose the correct region. Click the "Instance" tab under "INSTANCES" on the left part of the page. Choose "Launch Instance" to start a new instance that later will be saved as your new image.

Then, follow these steps:

1. Choose AMI: Ubuntu Server 16.04 LTS (HVM), SSD Volume Type.

2. Choose Instance Type: Family = Compute optimized, Type = c5.4xlarge, vCPUs = 16, Memory (GiB) = 32.

3. Keep other options as default, and click "Review and Launch".

4. Review the information of the new instance, and click "Launch".

Next, you are asked to choose a key pair for your instance. It's recommended to create a new key pair for the first time, then use it in the future. First, choose "Create a new key pair", and enter a name. Click the "Download Key Pair" button. Save the key in a secure directory in your local computer for future use, for example in .ssh directory.

Now, you can select "Choose an existing key pair", and select your key pair that should be visible. Check the box for acknowledging the use of a private key. Finally, your new instance is launched. Note that this new instance is a brand new Ubuntu server, which means that you need to install everything.

At this point, the new Ubuntu server on AWS does not have X2GO for remote access or a GUI desktop to operate. We will now install these necessary softwares. First, run the following command to access the remote Ubuntu server on AWS using ssh. Note that you need to change the name of your ssh key to the one you just created. The public IP address can be found on the AWS webpage where you launched your new instance. Go the description of your instance to find the "IPv4 Public IP".

```
chmod 400 your_ssh_key.pem
ssh -i your_ssh_key.pem ubuntu@your_AWS_public_IP_address
```

Run the following command to install X2GO server on Ubuntu Linux.

```
sudo apt-get install software-properties-common
sudo add-apt-repository ppa:x2go/stable
sudo apt-get update
sudo apt-get install x2goserver x2goserver-xsession
```

Xfce is a lightweight desktop and ideal for usage on a remote server. Run the following command to install xfce on Ubuntu.

```
sudo apt-get install xfce4 xfce4-goodies
```

Now you can access your new instance (the remote Ubuntu server) using X2GO. Steps to do this can be found in Chapter 211. After you established remote control of the Ubuntu server on AWS, the build procedures are the same as those for local installation, which can be found in previous sections of this chapter.

The last step is to create a new image from this instance so that you can launch it in the future. Go the "Instances", and choose the correct instance. Click "Actions", and select "Create Image" under

"Image". You can change the size of the instance volume, but it's not necessary at this moment. Give your image a name and a description, and click "Create Image". Now you have sucessfully created a new image for Real-ESSI. If you go to "AMIs", you should be able to see this new image you just created.

209.11.4 Build AWS ESSI Image from Scratch

This section is a developer guide, which presents the procedures to build AWS ESSI Image from scratch. ESSI AWS users do not need to know the technical details in this section.

1. Launch EC2 instance from an AWS blank image: Ubuntu 16.04 Server.

   EC2 Dashboard → Instances → Instance → Launch Instance.

   Choose

   ```
   Ubuntu Server 16.04 (HVM), SSD Volume Type.
   ```

   Since there is no Desktop version available, so we have to launch the server version and install desktop by ourself.

   You will need to download a .pem key to launch the instance.

2. Login to the Remote Instance using Terminal.

   Copy the external IP address of the remote instance from the Browser.

   Use the downloaded .pem key to login to the remote instance.

   ```
   chmod 400 your_key.pem
   ssh -i your_key.pem ubuntu@your_remote_instance_IP
   ```

3. Install Desktop and git on AWS Remote Instance

   ```
   sudo apt update
   sudo apt install -y ubuntu-desktop git
   ```

4. Install remote-desktop-server (x2goserver) on AWS Remote Instance

   ```
   sudo add-apt-repository ppa:x2go/stable
   sudo apt update
   sudo apt install -y x2goserver x2goserver-xsession xfce4
   ```

5. Set up the automatic launch of remote desktop server

   ```
   sudo systemctl enable x2goserver.service
   sudo systemctl start x2goserver.service
   ```

6. Install ESSI

```
# Install prerequisite
sudo apt install -y cmake
sudo apt install -y build-essential
sudo apt install -y zlib1g-dev
sudo apt install -y libtbb-dev
sudo apt install -y bison flex
sudo apt install -y libboost-dev
sudo apt install -y python
sudo apt install -y gfortran
sudo apt install -y libopenblas-dev
sudo apt install -y liblapack-dev
sudo apt install -y python-scipy
sudo apt install -y libhdf5-dev libhdf5-cpp-11
sudo apt install -y python-h5py
sudo apt install -y python-matplotlib
sudo apt install -y libssl-dev

# Download ESSI
#
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
git clone {https://github.com/BorisJeremic/Real-ESSI.git} # Need ↩
   permission from Boris Jeremic for Real-ESSI on github
cd Real-ESSI

# Build ESSI Dependencies
./build_libraries download
./build_libraries sequential
./build_libraries hdf5_sequential
./build_libraries suitesparse
./build_libraries arpack
./build_libraries parmetis
./build_libraries petsc

# Build Sequential ESSI
mkdir build
cd build
cmake ..
make -j $(nproc)
cd ..

# Build Parallel ESSI
mkdir build_parallel
cd build_parallel
cmake -DCMAKE_CXX_COMPILER=/usr/bin/mpic++ -DPETSC_HAS_MUMPS=TRUE ↩
   -DPROGRAMMING_MODE=PARALLEL ..
make -j $(nproc)
cd ..
```

7. Install gmsh

```
sudo apt install -y gmsh
```

8. Install gmESSI

```
# Install the prerequisite
sudo apt install -y libboost-all-dev
sudo apt install -y build-essential
sudo apt install -y python-dev
sudo apt install -y liboctave-dev

# Install gmESSI
## download the package from the main Real-ESSI repository
#
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
wget ↩
   {http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/gmESSI/_all_files_gmESSI
mkdir Real-ESSI-gmESSI
mv _all_files_gmESSI_.tgz Real-ESSI-gmESSI
cd Real-ESSI-gmESSI

make -j $(nproc)

# Add binary PATH to ~/.bashrc
cd ./build/bin/
part1="export PATH=\""
part2=$PWD
part3=":\$PATH\""
newline=$part1$part2$part3
echo $newline >> ~/.bashrc
```

9. Install ParaView with PVESSIReader plugin

```
# Install the prerequisite
sudo apt install -y libavformat-dev
sudo apt install -y libswscale-dev
sudo apt install -y ffmpeg
sudo apt install -y libphonon-dev libphonon4 qt4-dev-tools
sudo apt install -y libqt4-core libqt4-gui qt4-qmake libxt-dev
sudo apt install -y g++ gcc cmake-curses-gui libqt4-opengl-dev
sudo apt install -y mesa-common-dev python-dev
sudo apt install -y libvtk6.2
sudo apt install -y mpich libopenmpi-dev
sudo apt install -y libxmu-dev libxi-dev

# Download the ParaView
#
```

```
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
git clone {https://github.com/Kitware/ParaView.git}
cd ParaView
git checkout v5.1.2
git submodule update --init

# Download the Plugin
cd Plugins
#
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
wget ↩
   {http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/pvESSI/_pvESSI_all_files
tar -xvzf _pvESSI_all_files_.tgz
cd ..

# Compile ParaView along with PVESSIReader
mkdir build && cd build
cmake -DPARAVIEW_USE_MPI=true -DPARAVIEW_ENABLE_PYTHON=true ↩
   -DPARAVIEW_ENABLE_FFMPEG=true ..
make -j $(nproc) # require Internet during ParaView compilation.

# Add binary PATH to ~/.bashrc
cd bin
part1="export PATH=\""
part2=$PWD
part3=":\$PATH\""
newline=$part1$part2$part3
echo $newline >> ~/.bashrc
```

10. Install Sublime Text 3 and ESSI plugin. Following this link.

```
#
# using curly brackets to help in checking scripts, that rely on these
# brackets being available around URL
#
wget -qO - {https://download.sublimetext.com/sublimehq-pub.gpg} | sudo ↩
   apt-key add -
sudo apt-get install apt-transport-https
echo "deb {https://download.sublimetext.com/ apt/stable/}" | sudo tee ↩
   /etc/apt/sources.list.d/sublime-text.list
sudo apt-get update
sudo apt-get install sublime-text
```

11. Install Sublime Text Plugin:

```
# Inside Sublime Text Window
```

```
# Ctrl+Shift+P, then Type
install package control

# Ctrl+Shift+P, then Type
install package # press ENTER, then type
fei syntax-n-snippets

# Ctrl+Shift+P, then Type
install package # press ENTER, then type
gmESSI-Tools

# Ctrl+Shift+P, then Type
install package # press ENTER, then type
gmsh-Tools
```

12. Create Image inside Browser.

    Select the launched Image with the above software installed.

    Choose Actions → Image → Create Image.

    Type your Image Name and descriptions.

    You will then see your image in EC2 Dashboard → Images → AMIs

209.11.5 Update an Existing Image

For updating an existing image, for example for a new version or release follow instruction below. First sign in to AWS and go to "EC2". Choose the correct region. Click the "Instance" tab under "INSTANCES" on the left part of the page. Choose "Launch Instance" to start a new instance that later will be saved as your new image.

Then, follow these steps:

1. Choose an existing AMI, for example GlobalRelease...
2. Choose Instance Type, for example: Family = Compute optimized, Type = c5.4xlarge, vCPUs = 16, Memory (GiB) = 32.
3. Keep other options as default, and click "Review and Launch".
4. Review the information of the new instance, and click "Launch".

Next, you are asked to choose a key pair for your instance. It's recommended to create a new key pair for the first time, then use it in the future. That is the keypair that is saved, for example in .ssh.

Now, you can select "Choose an existing key pair", and select your key pair that should be visible. Check the box for acknowledging the use of a private key. Finally, your new instance is launched. Note that this new instance is an already existing Ubuntu server/image. This image is the one we will update.

Now you can access your new instance (the remote Ubuntu server) using X2GO. Steps to do this can be found in Chapter 211. After you established remote control of the Ubuntu server on AWS, the build procedures are the same as those for local installation, which can be found in previous sections of this chapter.

The last step is to create a new image from this instance so that you can launch it in the future. Go the "Instances", and choose the correct instance. Click "Actions", and select "Create Image" under "Image". You can change the size of the instance volume, but it's not necessary at this moment. Give your image a (new) name and a description, and click "Create Image". Now you have sucessfully created a new image for Real-ESSI. If you go to "AMIs", you should be able to see this new image you just created.

Now you can go to `Software` directory and follow install procedures from section ?? on page ??.

After compiling and linking both sequential and parallel Real-ESSI, and install them on /usr/bin (follow procedures for build), and delete source code (!), one can make this instance into a new image. Create new image inside AWS EC2 Management Console Browser window. Select the launched Image with the above software installed. Choose Actions → Image → Create Image. Type your Image Name and descriptions. Click Create Image. This might take some time. You will then see your image in EC2 Dashboard → Images → AMIs (on the left side bar).

Make sure that you terminate all the running instances so that you do not get charged. Find: Action, Instance State, Terminate.

209.11.6 Upload an Existing Real-ESSI Simulator Image to AWS MarketPlace

- Copy to private image for region North Virginia
- Go to the AWS market place https://aws.amazon.com/marketplace,
- Choose sell in AWS marketplace,
- Choose AMIs selection the new private in Region North Virginia to publish.
- Proceed until finalizing the AWS Marketplace Image.

Chapter 210

Software Platform Procurement, Distribution

(2019-2020-2021-)

(In collaboration with Prof. Han Yang and Dr. Hexiang Wang)

210.1 Chapter Summary and Highlights

210.2 Introduction

The Real-ESSI Simulator program (Jeremić et al., 1988-2025) can be installed on user's computers in a number of different ways:

- The most efficient executables are created when Real-ESSI sources are compiled on user computer. Compilation is performed using batch scripts that execute all the necessary operations. This process takes approximately 40 minutes, for both sequential and parallel versions of the Real-ESSI. It is assumed that all the necessary libraries are installed prior to this. More details about this mode of installation are given in section 209, on page 1324 of the main document (Jeremić et al., 1989-2025). For this mode of installation, sources for the Real-ESSI need to be made available. Sources for the Real-ESSI program are usually not distributed, except to collaborators and in some other special circumstances.

- The Real-ESSI program can also be downloaded and installed as a Debian package, starting from version 22.07, built for Ubuntu 22.04 LTS. The Debian package contains the sequential and parallel Real-ESSI executables, The gmESSI tool for pre-processing using Gmsh, and pvESSI tool for post-processing using ParaView and other useful external programs, like Gmsh and ParaView, will NOT be automatically installed when installing the Real-ESSI Debian package. This change was made since those other packages should be installed using their own installation procedures, that have gone though some recent changes. Therefor installation of those packages is best done directly using downloaded version from their own web site, and then connecting them to the Real-ESSI Simulator systems using Gmsh and pvESSI tools. Installation of Gmsh and pvESSI tools is described in:

  - Installation of pre-processing modules is described in Chapter 207, on page 1221 in Jeremić et al. (1989-2025).
  - Installation of post-processing modules is described in Chapter 208, on page 1287 in Jeremić et al. (1989-2025).

  It is noted that old installations of Real-ESSI main program and gmsh and ParaView should be removed before the Real-ESSI Simulator systems is installed from Debian package.

- The Real-ESSI program can also be installed through direct download of program executables, as noted in section 210.4. These executable were build without use of any special optimization options, so they are not very efficient, and do not use special, high performance features of most modern CPUs. On the other hand these generic executables will run, execute on most computers.

- Docker support is discontinued since Windows users can now use Windows Subsystem for Linux (WSL), and install Real-ESSI Simulator Debian package. The Real-ESSI program can also be installed through a docker container, as described in section 210.5. Similar to the previous case, these executable were developed without special optimization options, so they are not very efficient. However, Real-ESSI program will these generic executables will run, within docker container, on all computers.

210.3 Real-ESSI Program Debian Package Download and Install

210.3.1 System Libraries Update/Upgrade

```
sudo apt-get update
sudo apt-get upgrade
sudo apt-get dist-upgrade
sudo apt-get autoremove
```

`sudo apt-get update`

`sudo apt-get upgrade`

`sudo apt-get dist-upgrade`

`sudo apt-get autoremove`

210.3.2 Real-ESSI Debian Package Download

The Real-ESSI program Debian package can be downloaded from Real-ESSI Simulator website: `http://real-essi.info/`. Alternatively, contact Prof. Jeremić to arrange for customized Real-ESSI Debian package.

210.3.3 Real-ESSI Debian Package Install

Start the Real-ESSI Simulator Debian package install by removing the old installations of Real-ESSI program, pre-processor gmsh/gmESSI and post-processor ParaView/pvESSI. Then, go to the directory where you have downloaded the Real-ESSI Debian package. Install the Debian package, for example use the following command:

```
sudo apt install ./real-essi_22.07-1_amd64.deb
```

Note that some warning messages might appear but they don't affect the installation.

After a successful installation, the sequential and parallel Real-ESSI executables. are installed and ready to use.

210.3.4 Load pvESSI Plugin in ParaView

Install ParaView system using installation procedure described on their web site. Then install pvESSI plugin. Start `ParaView` and click 'Tools' → 'Manage Plugins...'. Click 'Load New...' and find the plugin named 'PVESSIReader.so' under directory `/opt/paraview/lib/paraview-5.10/plugins/PVESSIReader/`. Also check the box 'Auto Load' then close `ParaView`. Next time when ParaView is started, Real-ESSI output files can be visualized and post-processed.

210.3.5 Install Other Useful Programs

210.3.5.1 HDFView

`HDFView` can be used to open Real-ESSI output files, which are in HDF5 format. Download the latest version of `HDFView` from `https://support.hdfgroup.org/ftp/HDF5/releases/HDF-JAVA/`. Click on the latest version, which is `hdfview-3.2.0` as of June 2022. Go to `bin/`, click `HDFView-3.2.0-ubuntu2004_64.tar.gz` and save the file in your `./Downloads/` directory. Then extract and install HDFView:

```
cd
tar -xvf ./Downloads/HDFView-3.2.0-ubuntu2004_64.tar.gz -C ./Downloads
sudo apt install -y ./Downloads/hdfview_3.2.0-1_amd64.deb
sudo ln -s /opt/hdfview/bin/HDFView /usr/local/bin/hdfview
```

Now you can use `HDFView` from a terminal. To be able to use `HDFView` when you click on a Real-ESSI output file, do the following additional steps. First open the file using the following command:

```
sudo gedit /usr/share/applications/hdfview-HDFView.desktop
```

Find the line:

```
Exec=/opt/hdfview/bin/HDFView
```

Replace it with:

```
Exec=/opt/hdfview/bin/HDFView %F
```

Save the file and close it.

Go to a Real-ESSI output file, which should have the suffix 'h5.feioutput'. Right click on the file and select 'Open with Other Application'. Click 'View All Applications' and choose `HDFView` from the list.

Note that you only need to do this once. Next time when you click on a Real-ESSI output file, it will be opened automatically using `HDFView`.

210.3.5.2 Sublime Text

Sublime Text (https://www.sublimetext.com/) is the recommended editor for Real-ESSI input files and pre-processing files. Install Sublime Text using the following command:

```
wget -qO - https://download.sublimetext.com/sublimehq-pub.gpg | gpg --dearmor | ↩
   sudo tee /etc/apt/trusted.gpg.d/sublimehq-archive.gpg
echo "deb https://download.sublimetext.com/ apt/stable/" | sudo tee ↩
   /etc/apt/sources.list.d/sublime-text.list
sudo apt-get update
sudo apt-get install sublime-text
```

Open Sublime Text. Open the 'Tools' menu and select 'Install Package Control...'. Open the 'Preferences' menu, select 'Package Control', then select 'Package Control: Install Package'.

In the opened search bar, type the package name and click on the package to install it. Three packages should be installed: `FEI Syntax-n-Snippets`, `gmsh-Tools`, and `gmESSI-Tools`.

210.4 Real-ESSI Program Executables Download and Install

Executables for the Real-ESSI Simulator program (Jeremić et al., 1988-2025) are available online. Prebuilt executables are available for Linux, Ubuntu 18.04, and can be downloaded and installed by analyst.

In order for prebuild executables to be able to run on a user/analyst computer, system libraries have to be brought up to date and additional libraries installed. System libraries update/upgrade:

```
sudo apt-get update
sudo apt-get upgrade
sudo apt-get dist-upgrade
sudo apt-get autoremove
```

For sequential and/or parallel version of Real-ESSI, additional libraries are needed, as described below.

210.4.1 Sequential Version of Real-ESSI Program.

Libraries required to be installed for using sequential version of the Real ESSI program:

```
sudo apt-get install libboost-all-dev
sudo apt-get install libhdf5-dev
sudo apt-get install libtbb-dev
sudo apt-get install libssl1.0.0
```

210.4.2 Parallel Version of Real-ESSI Program.

Libraries required to be installed for executing parallel version of the Real ESSI program:

```
sudo apt-get install libboost-all-dev
sudo apt-get install libhdf5-dev
sudo apt-get install libtbb-dev
sudo apt-get install mpich
sudo apt-get install libopenmpi-dev
sudo apt-get install libssl1.0.0
```

210.4.3 Real-ESSI Executable Downloads.

The Real-ESSI program executables can be downloaded from Real-ESSI Simulator website: `http://real-essi.info/`. Alternatively, contact Prof. Jeremić to arrange for customized Real-ESSI executables.

210.5 DISCONTINUED, use WSL! Real-ESSI Simulator Install as Container through Docker

Docker support is discontinued since Windows users can now use Windows Subsystem for Linux (WSL), and install Real-ESSI Simulator Debian package.

Recent developments in virtualization of operating systems (OS) has created an opportunity to deploy programs and software systems as container images. Container images are used by the host OS (Linux, Windows, MacOS) to create a container. A container is a running instance of a container image, and is represented by a Linux/Windows/MacOS process that can be used to run programs that are installed within container. Programs that are installed within a container have all the necessary libraries available within container and are fully self sufficient, irrespective of what container host OS is used, be it Linux or Windows or MacOS.

More information used virtualization, containers, docker, etc. can be found at:

- `https://en.wikipedia.org/wiki/OS-level_virtualization`
- `https://en.wikipedia.org/wiki/Docker_(software)`
- `https://developers.redhat.com/blog/2018/02/22/container-terminology-practical-introduction`

Starting from Real-ESSI version 20.07, Real-ESSI Simulator is now available as a Docker Container Image, and can be installed and used on Linux, Windows and MacOS.

210.5.1 DISCONTINUED, use WSL! Real-ESSI Docker Image Development

This section is intended for Real-ESSI developers, users can skip this section. The development of Real-ESSI Docker image follows typical steps to 'dockerize' any application. Here are some very helpful sources:

- Official documentation: `https://docs.docker.com/`
- A Docker Tutorial for Beginners:
  `https://docker-curriculum.com/#our-first-image`
- How to dockerize any application:
  `https://hackernoon.com/how-to-dockerize-any-application-b60ad00e76da`
- Slimming Down Your Docker Images:
  `https://towardsdatascience.com/slimming-down-your-docker-images-275f0ca9337e`

It should be mentioned that there are many different ways and styles that can be employed to create Docker image. Here, multistage build is used to save build/debug time and, more importantly, reduce size of the final image.

Provided below are steps used to create the Real-ESSI Docker image.

- Obtain the source code of Real-ESSI.
- The following 'Dockerfile' is created to build the Real-ESSI Docker image.

```
FROM ubuntu:18.04 AS basesystem

MAINTAINER Han Yang <hhhyang@ucdavis.edu>

WORKDIR /usr/src

COPY . .

RUN useradd -m ubuntu && \
       apt-get update && apt-get install -y \
       bison \
       build-essential \
       cmake \
       flex \
       libboost-all-dev \
       libhdf5-serial-dev \
       liblapack-dev \
       libopenblas-dev \
       libopenmpi-dev \
       libpthread-workqueue-dev \
```

```
        libssl-dev \
        libtbb-dev \
        mpich \
        ssh \
        valgrind \
        wget \
        zlib1g-dev

        cd pbuild && \
        cmake -DCMAKE_CXX_COMPILER=/usr/bin/mpic++ ↩
            -DPROGRAMMING_MODE=PARALLEL .. && \
        make -j 16 && \
        cp essi essi_parallel
```

```
FROM ubuntu:18.04

MAINTAINER Han Yang <hhhyang@ucdavis.edu>

RUN useradd -m ubuntu && \
       apt-get update && apt-get install -y \
       libboost-all-dev \
       libhdf5-dev \
       libopenmpi-dev \
       libtbb-dev \
       mpich \
       ssh

COPY --from=builder /usr/src/Real-ESSI/build/essi_sequential ↩
   /usr/src/Real-ESSI/pbuild/essi_parallel /usr/bin/

USER ubuntu

WORKDIR /workspace

VOLUME ["/workspace"]
```

- Put the 'Dockerfile' in the same directory with the source code of Real-ESSI.
- Build the Real-ESSI Docker image. This step usually takes a long time, especially for the first time.

```
docker build -t realessilocal:test .
```

- Correctly tag your image. This is not only necessary for later push but also just a good practice to organize your Docker images.

```
docker tag realessilocal:test realessi/real-essi-repo:<tag>
```

  Replace <tag> with the tag you want to use. It's usually a version name.

- Push your build to Docker Hub. Make sure you have the proper permission to do so.

```
docker push realessi/real-essi-repo:<tag>
```

210.5.2 DISCONTINUED, use WSL! Running Real-ESSI Container through Docker

Provided below are steps needed to install and run Real-ESSI within a Docker Container. The following steps work for both Linux and Windows systems. In a Linux system, run the following commands in a terminal. In a Windows system, run these commands in PowerShell. It should also work for Mac OS but hasn't been tested yet.

- Install Docker on the local computer, desktop, laptop. Documentation on how to install Docker on user OS can be found here:
  - Linux: https://docs.docker.com/engine/install/#server
  - Windows: https://docs.docker.com/docker-for-windows/install/
  - MacOS: https://docs.docker.com/docker-for-mac/install/
- Manage Docker as a non-root user on Linux hosts

  If you are using a Linux host, by default you need to run Docker using `sudo`. If you don't want to preface the docker command with `sudo`, create a group called `docker` and add users to it.

  To create the `docker` group and add your user:

  1. Create the `docker` group.

     ```
     sudo groupadd docker
     ```

     Sometimes the `docker` group might already exist after the installation of Docker. This is okay, just move on to the next step.
  2. Add your user to the `docker` group.

     ```
     sudo usermod -aG docker $USER
     ```

     Replace `$USER` with your user name.
  3. Log out and log back in so that your group membership is re-evaluated. On Linux, you can also run the following command to activate the changes to groups:

     ```
     newgrp docker
     ```

  4. Verify that you can run `docker` commands without `sudo`.

     ```
     docker run hello-world
     ```

     This command downloads a test image and runs it in a container. When the container runs, it prints an informational message and exits.

  More information on managing Docker as a non-root user can be found here: https://docs.docker.com/engine/install/linux-postinstall/

- Pull the Real-ESSI image

```
docker pull realessi/real-essi-repo:tag
```

  Replace `tag` with the latest version of Real-ESSI. For example, if the latest version is 23.01, then the pull command is `docker pull realessi/real-essi-repo:23.01`.

  Current Real-ESSI Simulator version is kept up to date at the Real-ESSI web site HERE. In adition, you can find tags of Real-ESSI at `https://hub.docker.com/repository/docker/realessi/real-essi-repo/tags`.

- Run the Real-ESSI image:

```
docker run -it --rm -v your_working_directory:/workspace ↩
   realessi/real-essi-repo:tag
```

  Again, replace `tag` with the version of Real-ESSI you pulled. Once you start running the Real-ESSI Docker image, you are working inside the container. The container is Ubuntu 18.04 with Real-ESSI installed. Note that you should replace `your_working_directory` with the absolute path of your working directory.

- Run Real-ESSI:

```
essi_sequential -f main.fei
```

Note that the current directory on your local machine is shared with the container, so it can work with any files there. The files need to have the correct permissions to be run by a non-administrator user. You can move files after the container started and they will be recognized by the container.

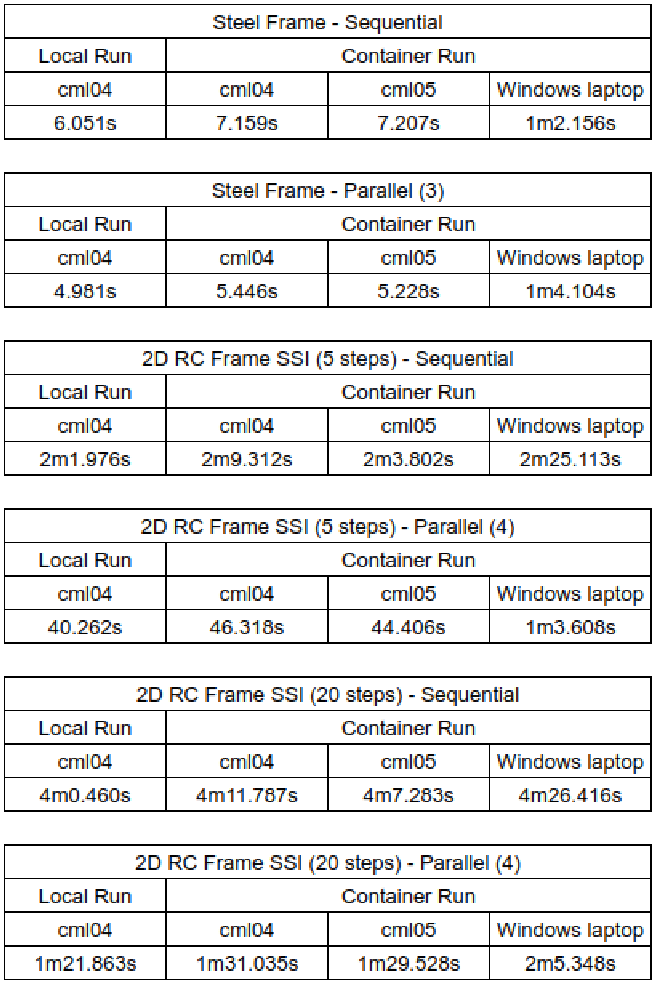
After the simulation is finished, simply exit the container. You will see the output files and log file in your current directory. They will not be erased when you exit the container.

210.5.3 DISCONTINUED, use WSL! Performance of Real-ESSI Container

To test the performance of Real-ESSI container, a series of sequential and parallel simulations are conducted. The results and comparison are summarized in Figure 210.1.

210.6 Real-ESSI Simulator System Install

In adition to the Real-ESSI Program, Real-ESSI Simulator system consists of a pre-processing modules and post-processing modules. Installation of pre-processing modules is described in Chapter 207, on



Steel Frame - Sequential			
Local Run	Container Run

Figure 210.1: Comparison of Real-ESSI performance on local Linux machine and Linux/Windows containers.

page 1221 in Jeremić et al. (1989-2025). Installation of post-processing modules is described in Chapter 208, on page 1287 in Jeremić et al. (1989-2025).

Both pre and post processing manuals are also available through the main Real-ESSI Simulator web site: `http://real-essi.info/`.

210.6.1 Student Manual for Real-ESSI Simulator System Install

Students at ETH, Mr. Max Sieber and Mr. Antonio Felipe Salazar created a manual for installation of the Real-ESSI Simulator system on virtual machine computers. The manual is available HERE.

Chapter 211

Cloud Computing

(2017-2018-2019-2021-2023)

(In collaboration with Dr. Yuan Feng, Prof. Han Yang, and Dr. Hexiang Wang)

211.1 Chapter Summary and Highlights

Described in this chapter are details of accessing and using Real-ESSI Simulator using remote computers, the so called "cloud" computational resources. Current focus is on using Amazon Web Services (AWS) computers.

211.2 Real-ESSI Cloud Computing Overview

Cloud computing refers to the accessing and computing over the Internet rather than on local computers. Cloud computing is a model for enabling on-demand access to a shared pool of configurable computing resources, which can be setup and released rapidly.[1]

Using Real-ESSI Cloud Service, users can get computing instances on demand without requiring a lot of maintenance and financial resources a common, local parallel computer, cluster would require. In addition, users do not need to go through the installation of the dependent libraries, source-code compilation and the installation of other related software, for example preprocessing and post-processing environment. The complete Real-ESSI Simulator system is pre-configured and built within the image such that Real-ESSI Simulator system is portable over the cloud. A stable, release version of Real-ESSI is built and can be used anywhere and anytime.

There are two ways to obtain a Real-ESSI image on Amazon Web Services (AWS):

- Obtain a Real-ESSI private image from Prof. Boris Jeremić, see Section 211.3.1 on page 1376.
- Use a public image of Real-ESSI on AWS marketplace, as described in Section 211.3.2 on page 1388.

After a Real-ESSI image is launched, a Real-ESSI EC2 instance is generated on AWS. The instance can be accessed through a X2GO client. The procedures are written in Section 211.4 on page 1388.

When the simulation on the Real-ESSi instance is finished and all the output result files are fetched, remember to terminate the running instance so that AWS would not keep charging you. Section 211.5 on page 1391 describes how to terminate a running Real-ESSI instance. See Section 211.8 on page 1394 for more information about the cost of AWS cloud computing services.

211.2.1 Real-ESSI Cloud Service Content

One image is built for a single-machine setup, which contains

---

[1] This is an excerpt from Jeremić et al. (1989-2025)

- Ubuntu 16.04 LTS Desktop and X2GO Server
- Real-ESSI sequential program
- Real-ESSI parallel program
- Real-ESSI 3C seismic motion developments (SW4)
- Real-ESSI pre-processing (gmESSI)
- Real-ESSI post-processing (PVESSIReader)
- Real-ESSI Editor, Sublime plug-ins
- Real-ESSI Documentation
- Real-ESSI Examples

211.3 Launch Real-ESSI Instance on AWS

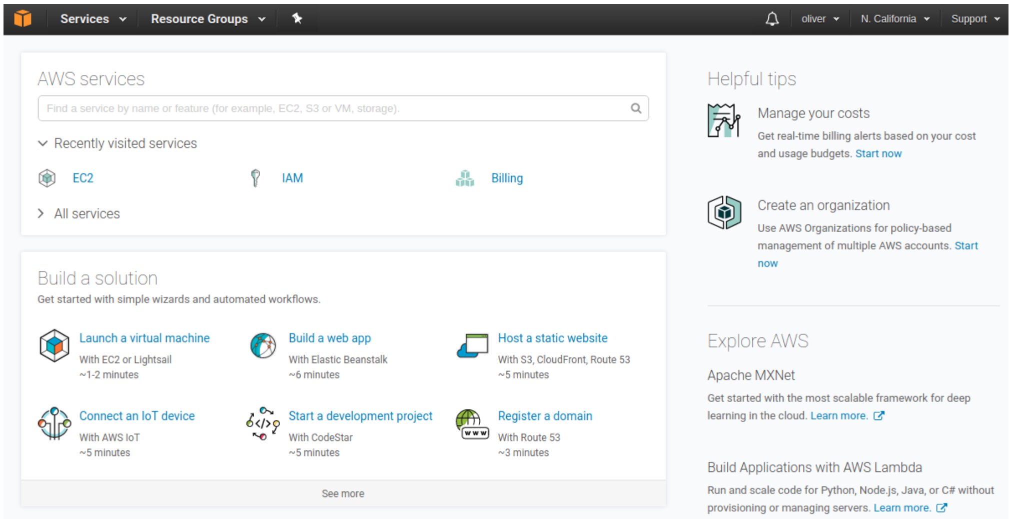
A Real-ESSI instance can be launched either from the private image with authorization of Prof. Boris Jeremić or from the public image on AWS market place.

211.3.1 Launch Real-ESSI Instance from AWS Private Images

Follow the steps below to launch instances from Real-ESSI Private Image.

1. Create an AWS account.

   AWS is the most widely used cloud service provider. If you do not have one, creating an AWS account is easy. You can create an AWS account through their website https://aws.amazon.com/. After you login, you can see the services on AWS `Console Home` as follows.



AWS services

Figure 211.1: AWS Console Home.

2. Request the Real-ESSI image.

   Real-ESSI image is currently a private Amazon Machine Images (AMI). After you get the 12-digit AWS account ID, email the AWS account ID to Prof. Boris Jeremić to obtain the Real-ESSI image. From AWS Console Home, go to `Services` → `EC2`

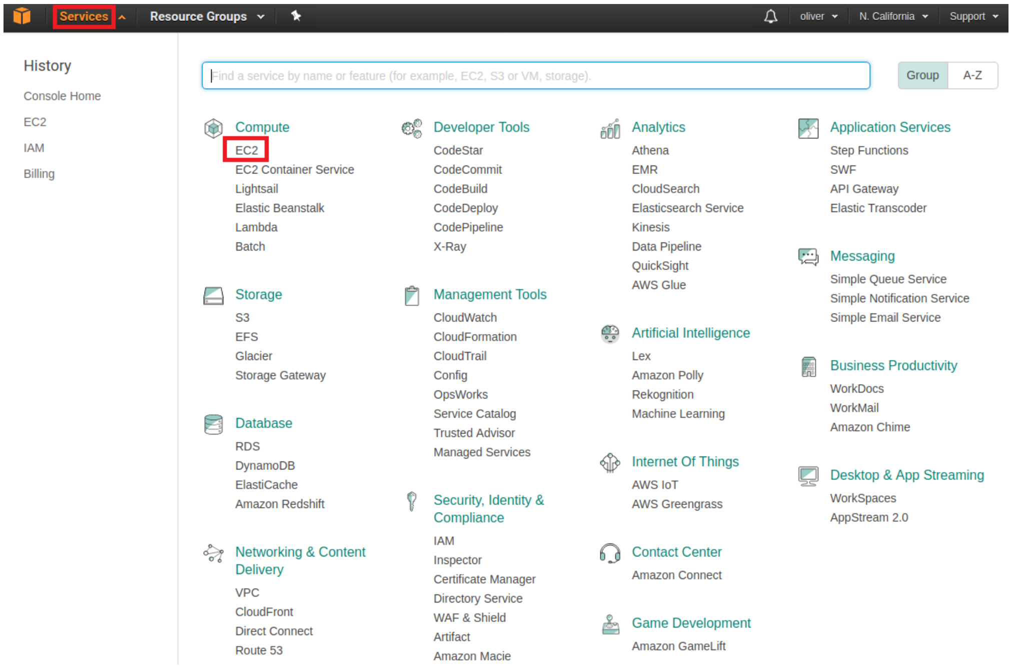

Figure 211.2: AWS Services.

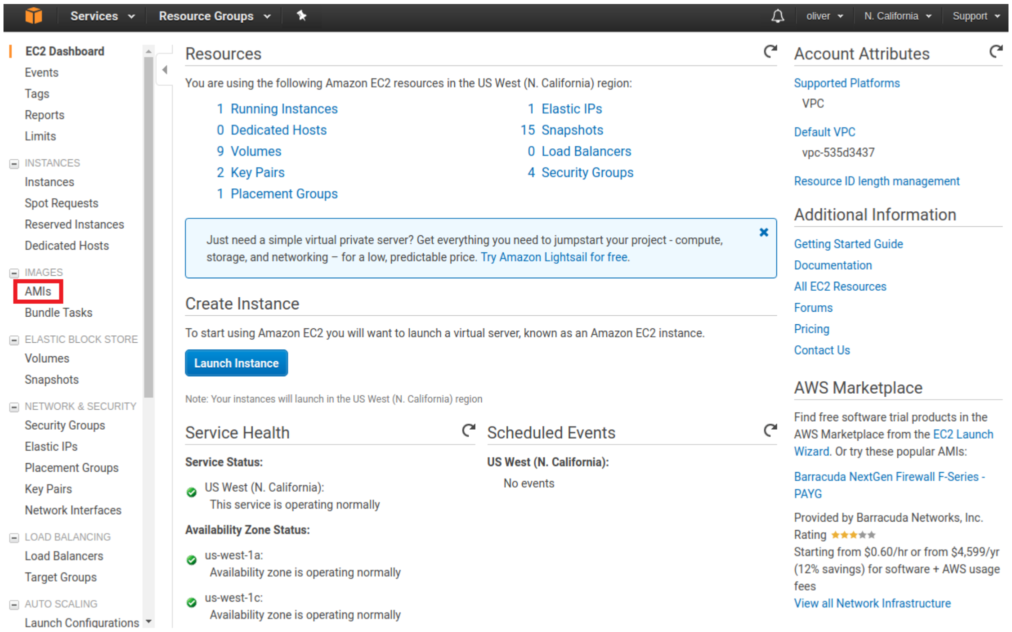
From EC2 Dashboard, go to AMIs to check the Real-ESSI image.



Resources

You are using the following Amazon EC2 resources in the US West (N. California) region:

1 Running Instances
0 Dedicated Hosts
9 Volumes
2 Key Pairs
1 Placement Groups
1 Elastic IPs
15 Snapshots
0 Load Balancers
4 Security Groups

Just need a simple virtual private server? Get everything you need to jumpstart your project - compute, storage, and networking – for a low, predictable price. Try Amazon Lightsail for free.

Create Instance

To start using Amazon EC2 you will want to launch a virtual server, known as an Amazon EC2 instance.

Note: Your instances will launch in the US West (N. California) region

AWS Marketplace

Find free software trial products in the AWS Marketplace from the EC2 Launch Wizard. Or try these popular AMIs:

Barracuda NextGen Firewall F-Series - PAYG

Provided by Barracuda Networks, Inc.
Rating ★★★★★
Starting from $0.60/hr or from $4,599/yr (12% savings) for software + AWS usage fees
View all Network Infrastructure

Figure 211.3: AWS EC2 Dashboard AMIs.

If users cannot find the Real-ESSI image, please make sure you are in the same AWS region with Prof. Boris Jeremić, the `region` is shown in the top-right corner on EC2 dashboard. The current Real-ESSI AMIs region are in both `North California` and `Oregon`.

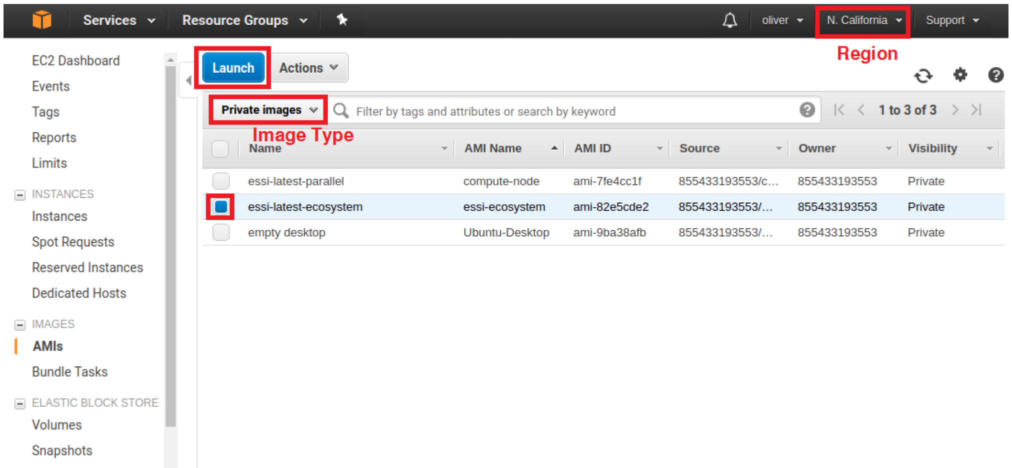
3. Launch the Real-ESSI image.

		AMI Name	AMI ID	Source	Owner	Visibility
☐	el	compute-node	ami-7fe4cc1f	855433193553/c...	855433193553	Private
☐	essi-latest-ecosystem	essi-ecosystem	ami-82e5cde2	855433193553/...	855433193553	Private
☐	empty desktop	Ubuntu-Desktop	ami-9ba38afb	855433193553/...	855433193553	Private

Figure 211.4: AWS EC2 Private AMIs.

Follow the steps below to launch instances from the Real-ESSI image.

(a) Choose AMI.

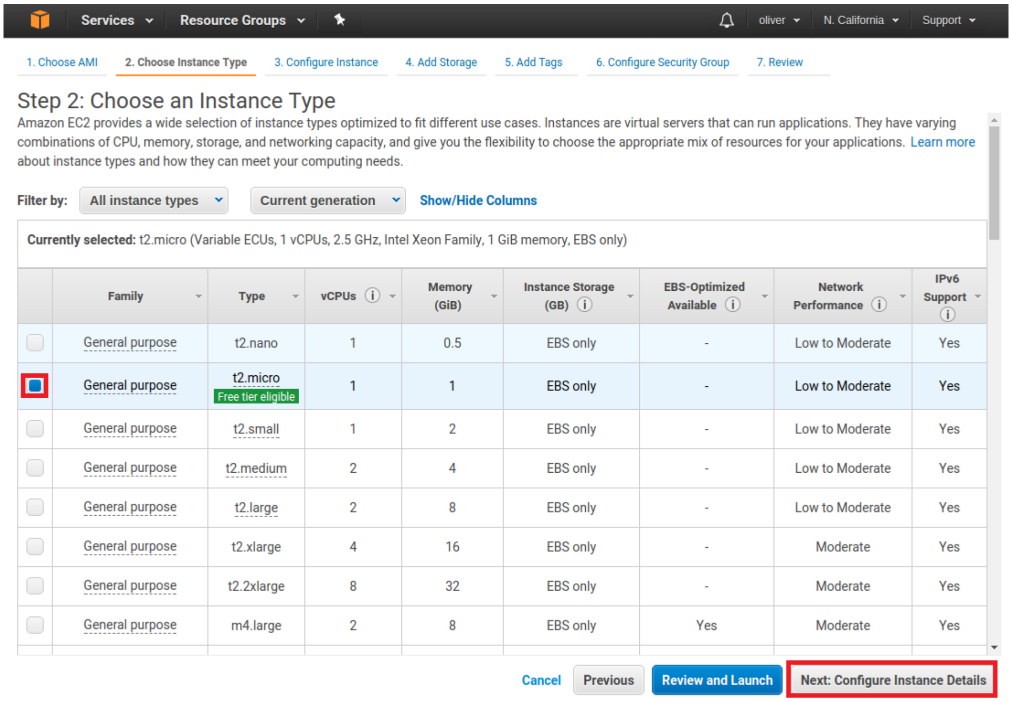


☐	Name	AMI Name	AMI ID	Source	Owner	Visibility
☐	essi-latest-parallel	compute-node	ami-7fe4cc1f	855433193553/c...	855433193553	Private
☑	essi-latest-ecosystem	essi-ecosystem	ami-82e5cde2	855433193553/...	855433193553	Private
☐	empty desktop	Ubuntu-Desktop	ami-9ba38afb	855433193553/...	855433193553	Private

Figure 211.5: EC2 Launch Steps: Choose AMI.

(b) Choose Instance Type

From AMIs, users can launch any number and type of instances and choose the desired EC2 configurations. In order to have the best experiences, the compute-optimized instances (C4, C5 as the latest one, as of early 2019) are recommended.



Step 2: Choose an Instance Type

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instances are virtual servers that can run applications. They have varying combinations of CPU, memory, storage, and networking capacity, and give you the flexibility to choose the appropriate mix of resources for your applications. Learn more about instance types and how they can meet your computing needs.

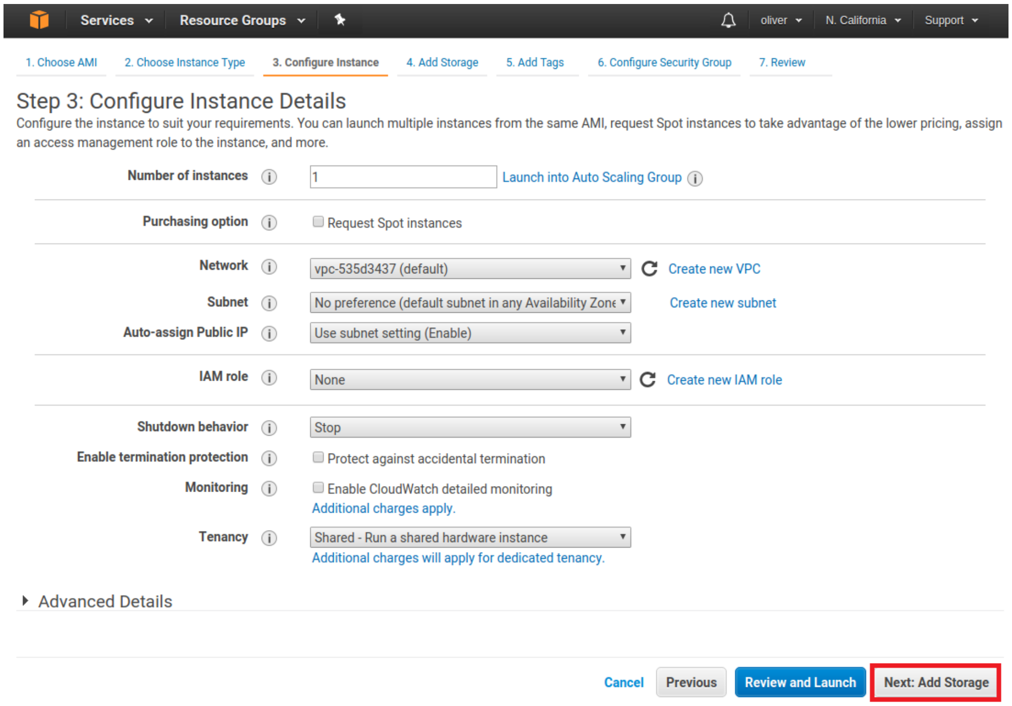
Filter by: All instance types Current generation Show/Hide Columns

Currently selected: t2.micro (Variable ECUs, 1 vCPUs, 2.5 GHz, Intel Xeon Family, 1 GiB memory, EBS only)

	Family	Type	vCPUs	Memory (GiB)	Instance Storage (GB)	EBS-Optimized Available	Network Performance	IPv6 Support
☐	General purpose	t2.nano	1	0.5	EBS only	-	Low to Moderate	Yes
■	General purpose	t2.micro Free tier eligible	1	1	EBS only	-	Low to Moderate	Yes
☐	General purpose	t2.small	1	2	EBS only	-	Low to Moderate	Yes
☐	General purpose	t2.medium	2	4	EBS only	-	Low to Moderate	Yes
☐	General purpose	t2.large	2	8	EBS only	-	Low to Moderate	Yes
☐	General purpose	t2.xlarge	4	16	EBS only	-	Moderate	Yes
☐	General purpose	t2.2xlarge	8	32	EBS only	-	Moderate	Yes
☐	General purpose	m4.large	2	8	EBS only	Yes	Moderate	Yes

Figure 211.6: EC2 Launch Steps: Choose Instance Type.

(c) Configure Instance



Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of instances: 1 — Launch into Auto Scaling Group

Purchasing option: ☐ Request Spot instances

Network: vpc-535d3437 (default) — Create new VPC

Subnet: No preference (default subnet in any Availability Zone — Create new subnet

Auto-assign Public IP: Use subnet setting (Enable)

IAM role: None — Create new IAM role

Shutdown behavior: Stop

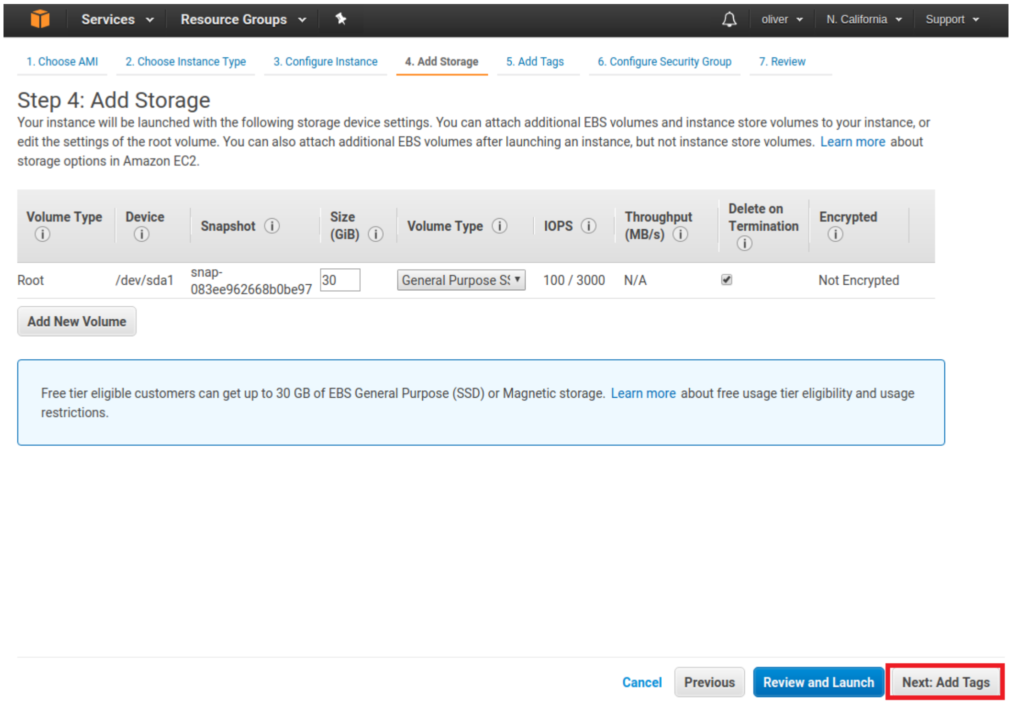
Enable termination protection: ☐ Protect against accidental termination

Monitoring: ☐ Enable CloudWatch detailed monitoring
Additional charges apply.

Tenancy: Shared - Run a shared hardware instance
Additional charges will apply for dedicated tenancy.

Figure 211.7: EC2 Launch Steps: Configure Instance.

(d) Add Storage



Step 4: Add Storage

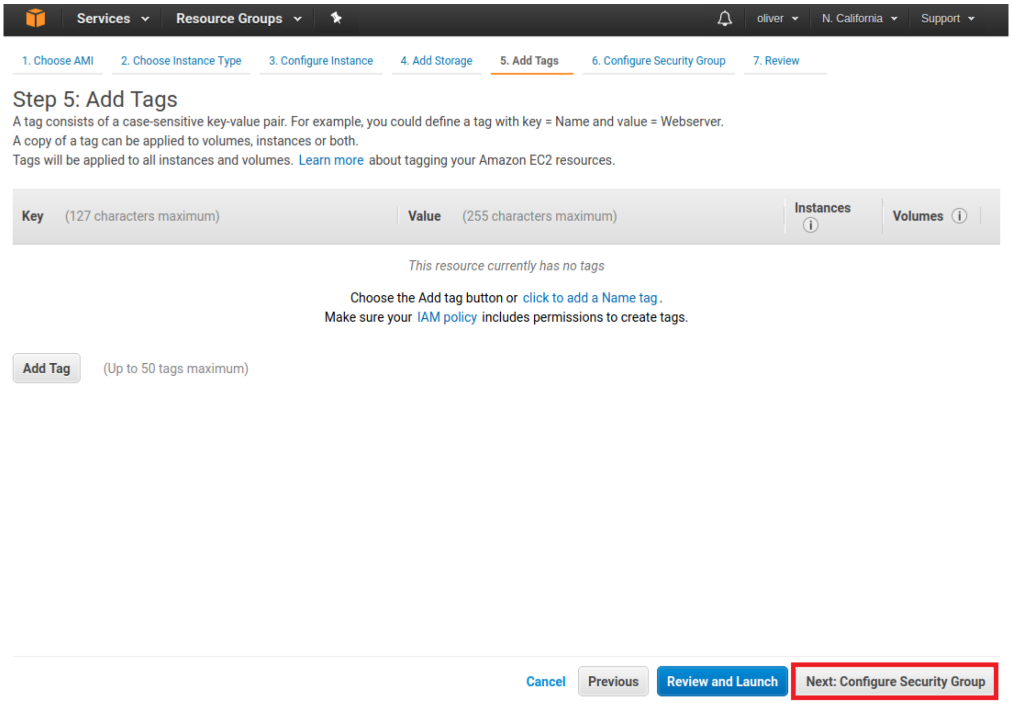
Your instance will be launched with the following storage device settings. You can attach additional EBS volumes and instance store volumes to your instance, or edit the settings of the root volume. You can also attach additional EBS volumes after launching an instance, but not instance store volumes. Learn more about storage options in Amazon EC2.

Volume Type	Device	Snapshot	Size (GiB)	Volume Type	IOPS	Throughput (MB/s)	Delete on Termination	Encrypted
Root	/dev/sda1	snap-083ee962668b0be97	30	General Purpose S!	100 / 3000	N/A	☑	Not Encrypted

Free tier eligible customers can get up to 30 GB of EBS General Purpose (SSD) or Magnetic storage. Learn more about free usage tier eligibility and usage restrictions.

Figure 211.8: EC2 Launch Steps: Add Storage.

(e) Add Tags



Step 5: Add Tags

A tag consists of a case-sensitive key-value pair. For example, you could define a tag with key = Name and value = Webserver.
A copy of a tag can be applied to volumes, instances or both.
Tags will be applied to all instances and volumes. Learn more about tagging your Amazon EC2 resources.

Key (127 characters maximum)	Value (255 characters maximum)	Instances	Volumes

This resource currently has no tags

Choose the Add tag button or click to add a Name tag.
Make sure your IAM policy includes permissions to create tags.

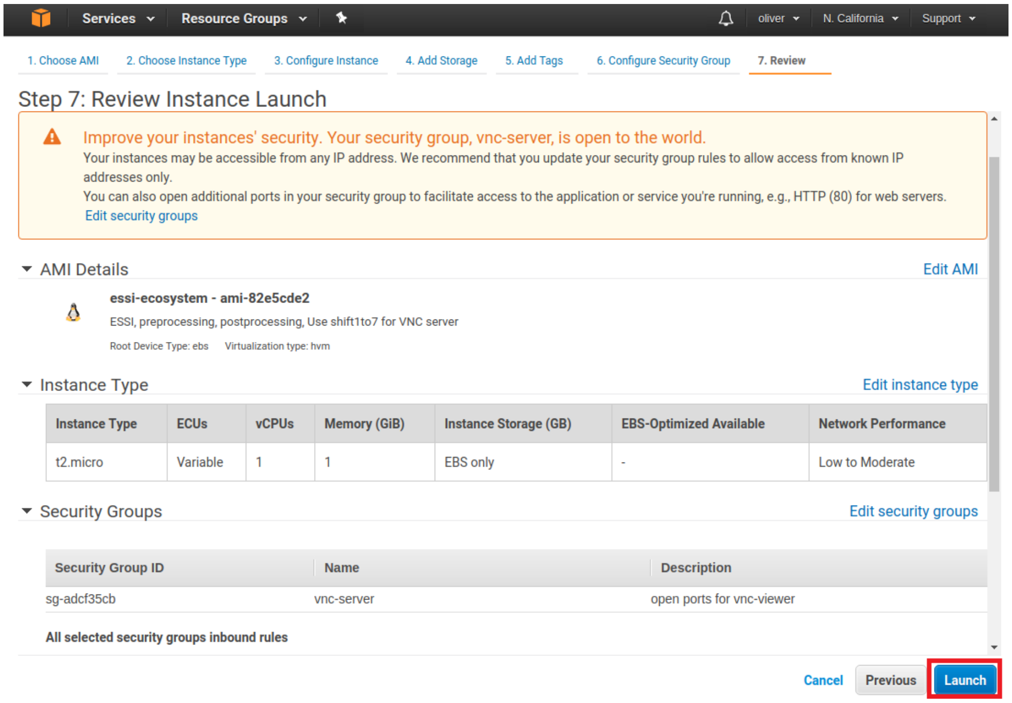
Figure 211.9: EC2 Launch Steps: Add Tags.

(f) Configure Security Group.

Please keep the default Security Group setting.

(g) Review

You may be asked to create a key-pair for later access of the instance you created. The key-pair can be reused later if you created other instances. Besides, the key-pair is portable across other machines. Last but not least, the key-pair cannot be recreated after you launch the instance, so please make sure you save the key-pair in a safe place.



Step 7: Review Instance Launch

Improve your instances' security. Your security group, vnc-server, is open to the world.

Your instances may be accessible from any IP address. We recommend that you update your security group rules to allow access from known IP addresses only.

You can also open additional ports in your security group to facilitate access to the application or service you're running, e.g., HTTP (80) for web servers.

Edit security groups

AMI Details — Edit AMI

essi-ecosystem - ami-82e5cde2

ESSI, preprocessing, postprocessing, Use shift1to7 for VNC server

Root Device Type: ebs Virtualization type: hvm

Instance Type — Edit instance type

Instance Type	ECUs	vCPUs	Memory (GiB)	Instance Storage (GB)	EBS-Optimized Available	Network Performance
t2.micro	Variable	1	1	EBS only	-	Low to Moderate

Instance: i-051f8df1f5a8b8819 Elastic IP: 50.18.192.135

Instance ID i-051f8df1f5a8b8819
Instance state running
Instance type t2.micro
Elastic IPs 50.18.192.135*
Public DNS (IPv4) ec2-50-18-192-135.us-west-1.compute.amazonaws.com
IPv4 Public IP 50.18.192.135
IPv6 IPs -
Private DNS ip-172-31-11-121.us-west-1.compute.internal

Figure 211.11: EC2 Running Instances.

You can login to your instances either by `ssh` or by using X2GO client 211.4. Please note that every time when you restart the instances, the public IP address will change.

5. Fix Public IP Address (Optional)

   The public IP address of Real-ESSI instances change for each reboot. If users want to have a fixed public IP address for every login, users can allocate one elastic IP address and associate the IP address to a Real-ESSI instance such that users can have a fixed public IP address for each login.

6. Attach more Storage (Optional)

   The Real-ESSI Image holds 30GB Hard disk and already uses 15GB. In the case of a real large simulations, this size hard drive might not be enough for the full output. Users can attach more storage through elastic block store.

211.3.2 Launch Real-ESSI Instance from AWS Market Place

This section gives a quick start guide for using Real-ESSI on AWS market place.

Real-ESSI Simulator system (pre processing, main Real-ESSI program, post processing) is available on Amazon Web Services MarketPlace. Point your web browser to the Amazon Web Services Market Place, and search for "Real ESSI", "Real-ESSI" or "MS ESSI".

In summary, a quick guide to launching an instance from AWS Market Place is:

- Go to the ESSI Cloud Product Page.
- Click Continue to go to Launch ESSI from the Cloud.
- Click Manual Launch (use 1-Click Launch, if comfortable with settings).
- Click Launch from the EC2 Console for your preferred region.
- Select your preferred instance from the table, e.g. t2.micro.
- Click Review and Launch.

211.4 Connect to Real-ESSI Instance on AWS

211.4.1 Install X2GO Client

Before connecting to the Real-ESSI cloud, users should install the client-side of X2GO. X2Go is a remote desktop software that can visualize the launched Real-ESSI instance. Installation of X2GO for different operating systems is fairly straightforward, and users can find installation instructions on their own or follow installation instructions below.

211.4.1.1 Installing X2GO client on Ubuntu Linux

User can directly install X2GO client by using debian install utility, to install x2goclient.

211.4.1.2 Installing X2GO client on Apple Mac

Users can download the package through this link: `http://code.x2go.org/releases/X2GoClient_latest_macosx_10_9.dmg`.

211.4.1.3 Installing X2GO client on Windows

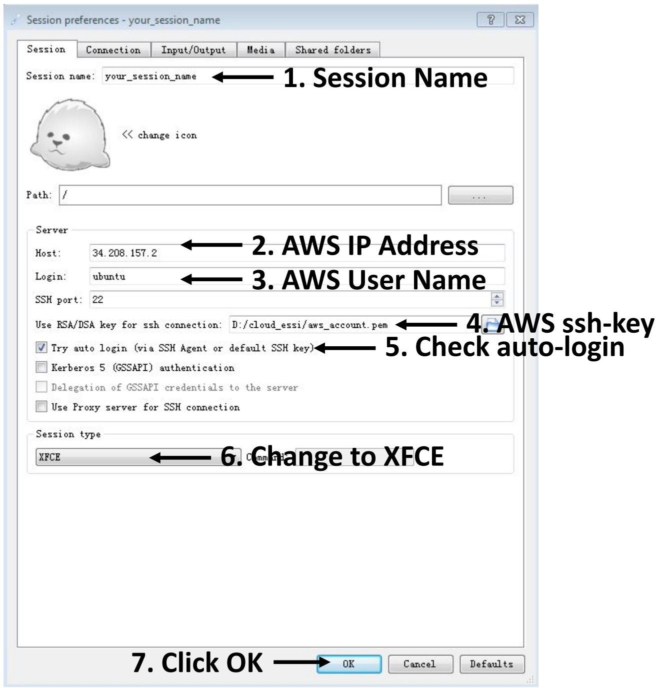
Users can download the package through this link: `http://code.x2go.org/releases/X2GoClient_latest_mswin32-setup.exe`.

211.4.1.4 Installing X2GO client on other operating systems

If you are using a different operating system, please refer to X2GO website for the installation. The X2GO website for client installation is `https://wiki.x2go.org/doku.php/download:start`

211.4.2 Configure the Client-Side of X2GO

For all operating systems, users will see the same session when they open the x2goclient new-session, as shown in Fig. 211.12.



Session name: your_session_name

1. Session Name

Path: /

Server

Host: 34.208.157.2

2. AWS IP Address

Login: ubuntu

3. AWS User Name

SSH port: 22

Use RSA/DSA key for ssh connection: D:/cloud_essi/aws_account.pem

4. AWS ssh-key

☑ Try auto login (via SSH Agent or default SSH key)

5. Check auto-login

☐ Kerberos 5 (GSSAPI) authentication

☐ Delegation of GSSAPI credentials to the server

☐ Use Proxy server for SSH connection

Session type

XFCE

6. Change to XFCE

7. Click OK

Figure 211.12: Configuration of X2GO client.

1. Users can name their own session.
2. AWS IP address is to be copied from EC2 management console, from the description TAB of launched instance, at the bottom of the page. This is IPv4 Public IP... it goes into Host: ...
3. AWS User Name is "ubuntu".
4. AWS ssh-key is the one saved from before, in .ssh directory
5. Please check the auto-login.
6. Please change the session type to XFCE.
7. Click OK to finish the configuration.

In addition to the Desktop login, users can also use `ssh` to login the Real-ESSI Terminal.

```
chmod 400 your_ssh_key.pem
ssh -i your_ssh_key.pem ubuntu@your_AWS_public_IP_address
```

211.4.3 Connect to the Launched Instance

Click the configured session to connect to the ESSI instance. You should see a virtual desktop pop up on your local machine, as shown in Fig. 211.13. Now you have successfully connected to the Real-ESSI Simulator instance on AWS. You can now use Real-ESSI Simulator within the virtual desktop.

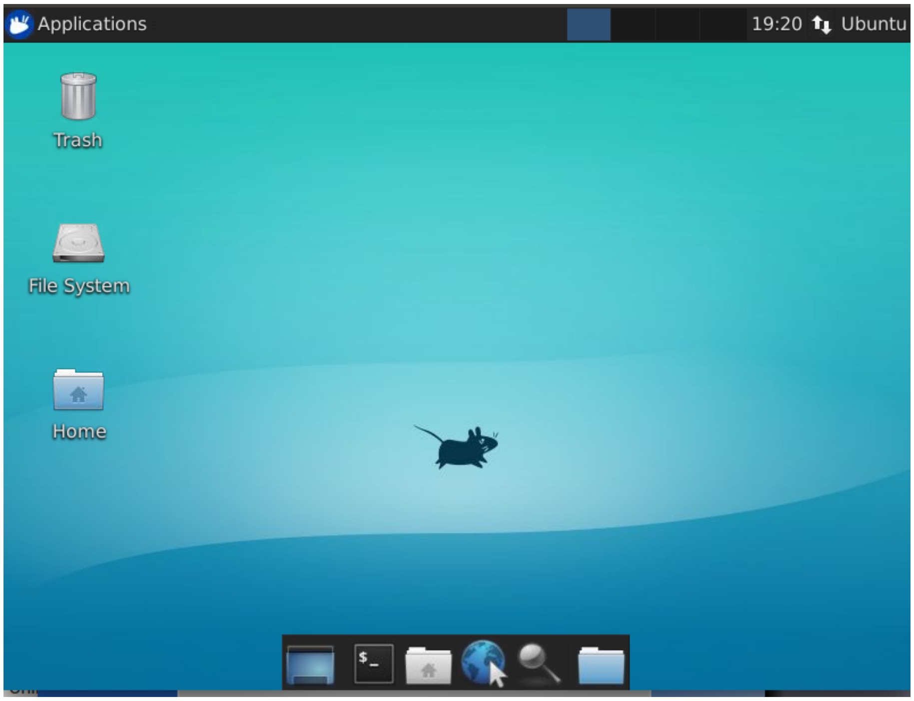


Figure 211.13: Connected to the already launched Real-ESSI instance.

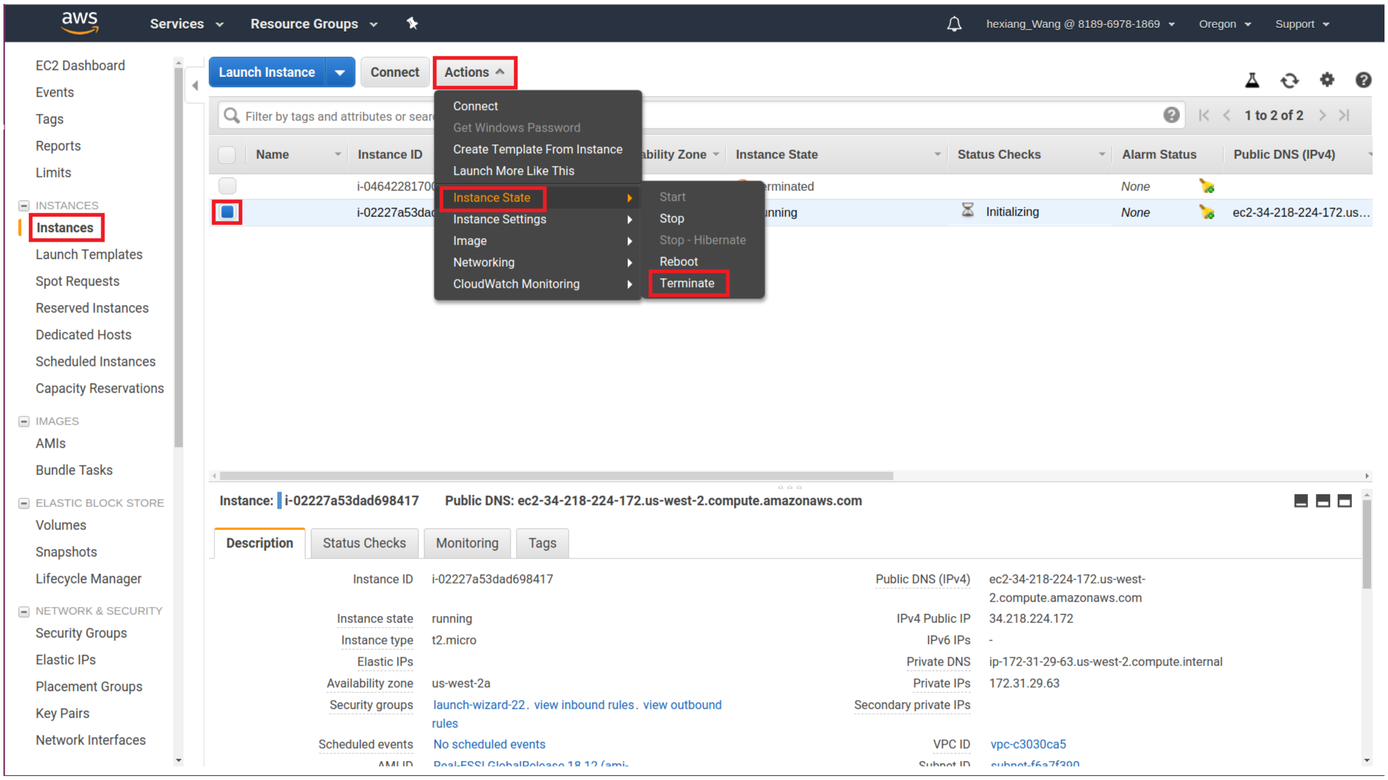
211.5 Terminate Real-ESSI Instance on AWS

Once the Real-ESSI simulation on AWS is finished, the user can transfer output files to the local local computer, or leave them on AWS, preferably on cheap S3 storage Section 211.8 on page 1394 provides detailed description of storage and transfer options and costs. NOTE: Users need to terminate the running Real -ESSI instance on AWS to avoid additional charges. The terminate operation is done on AWS console that is the same place where you launch the Real-ESSI instance. As shown Fig. 211.14, following steps are required:

1. Click 'Instances' from the sidebar to see all your running instances on AWS.
2. Choose the instance you want to terminate.
3. Click 'Actions'.

4. Click 'Instance State'

5. Click 'Terminate'



Instance ID	Instance State	Status Checks	Alarm Status	Public DNS (IPv4)
i-04642281700	rminated		None	
i-02227a53da	nning	Initializing	None	ec2-34-218-224-172.us...

Instance: i-02227a53dad698417 Public DNS: ec2-34-218-224-172.us-west-2.compute.amazonaws.com

Instance ID	i-02227a53dad698417	Public DNS (IPv4)	ec2-34-218-224-172.us-west-2.compute.amazonaws.com
Instance state	running	IPv4 Public IP	34.218.224.172
Instance type	t2.micro	IPv6 IPs	-
Elastic IPs		Private DNS	ip-172-31-29-63.us-west-2.compute.internal
Availability zone	us-west-2a	Private IPs	172.31.29.63
Security groups	launch-wizard-22. view inbound rules. view outbound rules	Secondary private IPs	
Scheduled events	No scheduled events	VPC ID	vpc-c3030ca5

Figure 211.14: Terminate a Real-ESSI Simulator instance.

211.6 Adding Permission for Private Real-ESSI Image to User AWS Accounts

login to AWS

sign in to console

go to image in a region, say N, California

then go to EC2

go to AMIs on left side

select image to be shared

go to Actions

go to Modify Image Permissons and put user account number then click Add Permission and then Save...

211.7 Real-ESSI Instructional Videos Cloud Computing

This section presents few short instructional videos about how to use Real ESSI on Amazon Web Services (AWS) computers.

211.7.1 Installing X2GO for Windows

Youtube instructional video.

211.7.2 Installing X2GO for Macintosh

Youtube instructional video.

211.7.3 Installing X2GO for Linux

Youtube instructional video.

211.7.4 Launch AWS Marketplace

Youtube instructional video.

211.7.5 Access Running Instance on AWS

Youtube instructional video.

211.7.6 Start Real-ESSI Program on AWS

Youtube instructional video.

211.7.7 Run Real-ESSI Example Model on AWS

Youtube instructional video.

211.7.8 Visualize Real-ESSI Example Model on AWS

Youtube instructional video.

211.7.9 Post-Process, Visualize Real-ESSI Results on AWS

Youtube instructional video.

211.8 Cost of AWS EC2

The cost breakdown for using Real-ESSI on AWS (EC2) is:

- AWS computer cost

  There are 3 ways to pay for AWS computer cost (EC2 instances)

  - On-Demand instance, offers a real, instant pay-per-use model. On-Demand instance is sold at a fixed price, and AWS computer availability is guaranteed (within the limits of the service-level agreement). Running Real-ESSI On-Demand Instance: User prepares simulation runs, and then can simulate problems at hand immediately.
  - Spot instance, uses spare AWS computers that users can bid for. Prices for those spot instances fluctuate based on the supply and demand of available AWS computers. When a user makes a bid for a Spot instance, a spot instance is launched when the bid exceeds the current Spot market price, and continues until terminated by the user. The user is charged the Spot market price, not the bid price while the instance runs. Spot instances can offer substantial savings over On-Demand instances, as shown in the AWS Spot Bid Advisor. Running Real-ESSI using Spot instance: User can prepare simulation runs, and then bid on computer hardware and run simulations at later time, when cost is acceptable.
  - Reserved instance, uses spare AWS computers during scheduled, later time as determined by AWS and reserved by the user. Running Real-ESSI using Reserved Instance: User prepares simulation runs, and then reserves AWS computer to simulate problem at hand at predetermined/reserved time.

- AWS data storage cost

  Input data/files and output data/files are stored using:

  - Amazon Elastic Block Store (EBS), attached to a AWS computer (EC2 instance) during simulation run. Storage cost is charged by the size of storage in GB per month, pro-rated to the hour, until the storage is released. The cost of EBS is typically $\$0.10$ per GB per month. When running Real-ESSI program on AWS computer, the storage is used during simulation, while the data (input and output) is transferred out of the AWS computer, to other type of storage that is less expensive (the so called S3 storage, see below), or to user's desktop computer, before AWS computer/instance is terminated and storage released.

  - Amazon Simple Storage Service (S3), offers better value for longer term data storage. S3 pricing varies by region and frequency of access. Cost of S3 storage is typically between $\$0.0125$ are $\$0.03$ per GB per month.
  - Amazon Glacier, provides storage at an even lower cost of $\$0.007$ per GB per month for data archiving.

- AWS data transfer cost

  Data transfer charges are listed as part of the On-Demand EC2 pricing. Transfer is typically charged at $\$0.09$ per GB beyond the first 1GB of data and up to the first 1TB of a given month. After the first TB, price drops down.

- Real-ESSI program cost

  Use of Real-ESSI for educational purposes is free. For commercial use of Real-ESSI, please contact Prof. Jeremić or one of the commercial companies that offer access to Real-ESSI on AWS.

211.8.1 Cost of Running Real-ESSI on AWS

211.8.1.1 Small Size Real-ESSI Example

Imposed Motion Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 5,000
- Number of Time Step: 210
- Running Time: 30 Second
- Disk Space: 25 MB.
- Recommended Machine: Free Instance Amazon EC2 t2.micro

The Real-ESSI input files for this example are available HERE. The compressed package of input files is HERE.

The Modeling parameters are listed below

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

The thickness of the shell structure is 2 meters. The simulation model is shown below.

The simulation results:

The time series of simulation results is shown in Fig. 410.22.

The response spectrum of motion is shown in Fig. 410.23.

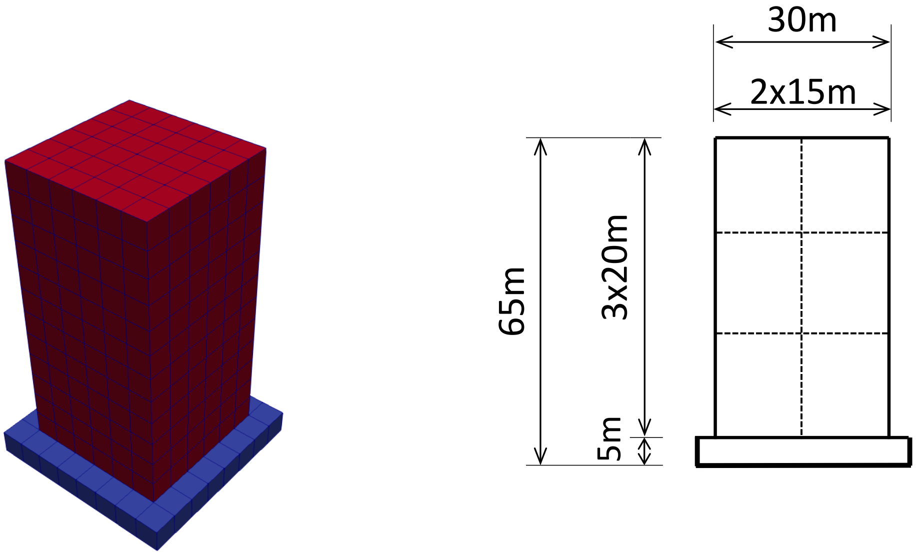


Figure 211.15: Simulation Model.

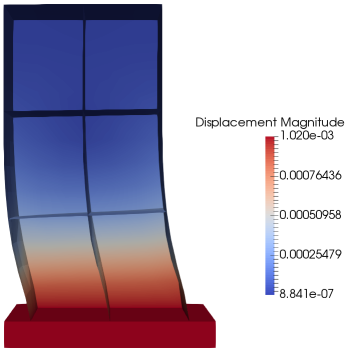

Figure 211.16: Simulation Results.

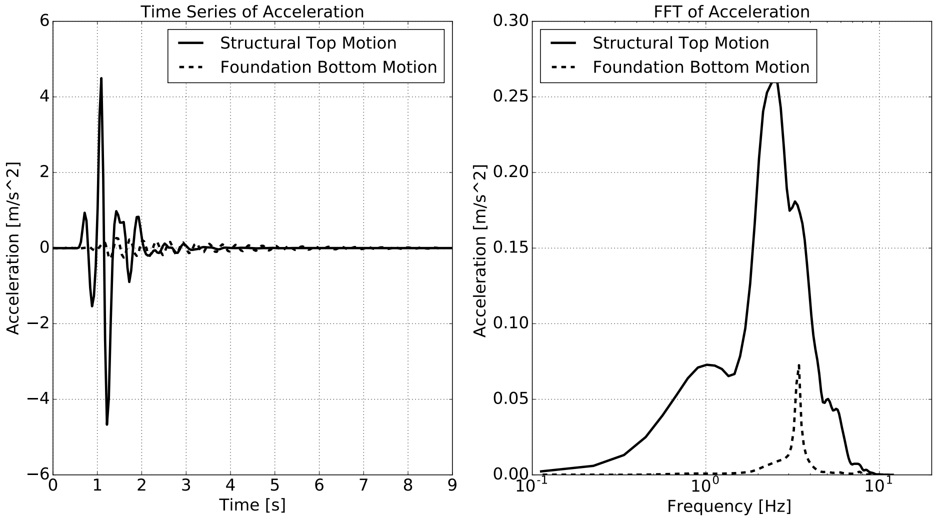

Figure 211.17: Simulation Results: Acceleration Time Series with 1C imposed motion.

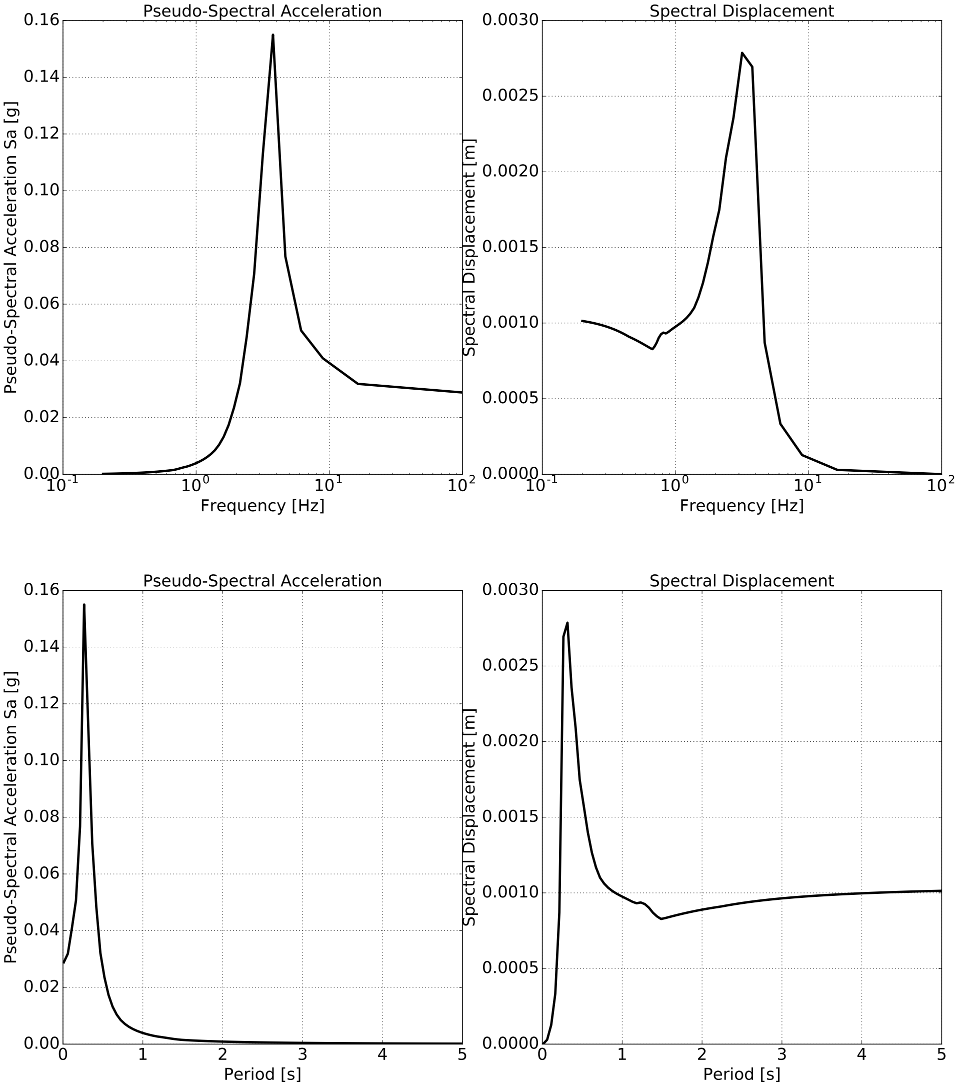

Figure 211.18: Simulation Results: Response Spectrum of Structure Top with 1C imposed motion.

Eigen Analysis Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 5,000
- Number of Eigenmodes: 10
- Running Time: 3 Second
- Disk Space: 25 MB.
- Recommended Machine: Free Instance Amazon EC2 t2.micro

The Real-ESSI input files for this example are available HERE. The compressed package of input files is HERE.

The thickness of the shell structure is 2 meters. The simulation model is shown below.

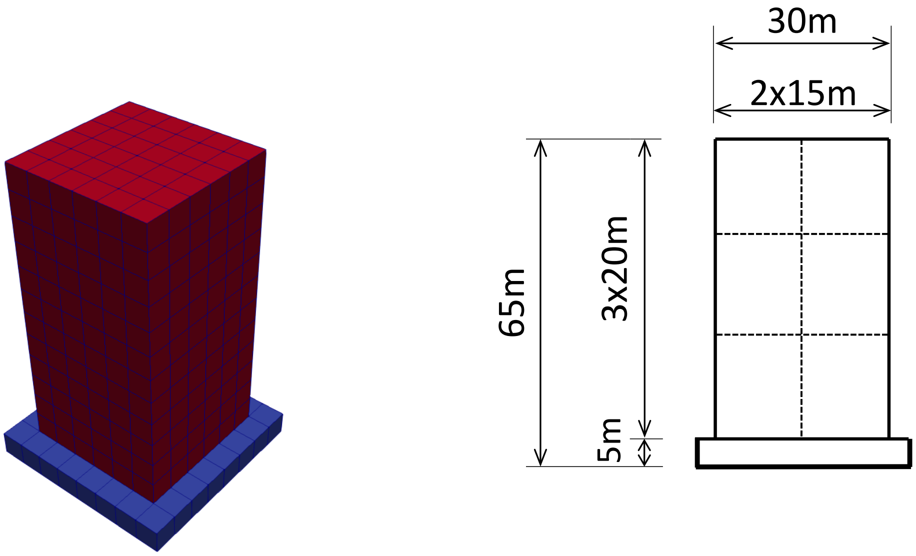

Figure 211.19: Simulation Model.

The eigen results:

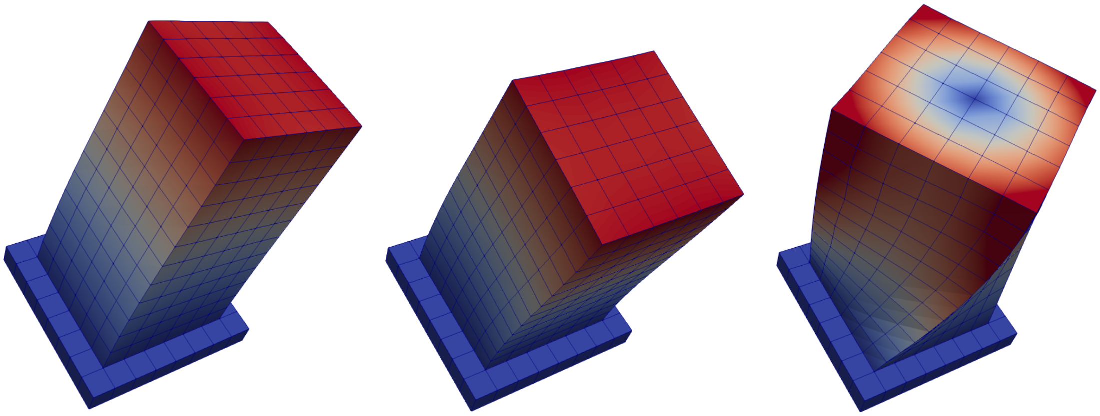

Figure 211.20: Eigen Results (Eigen Mode 1 to 3 from left to right).

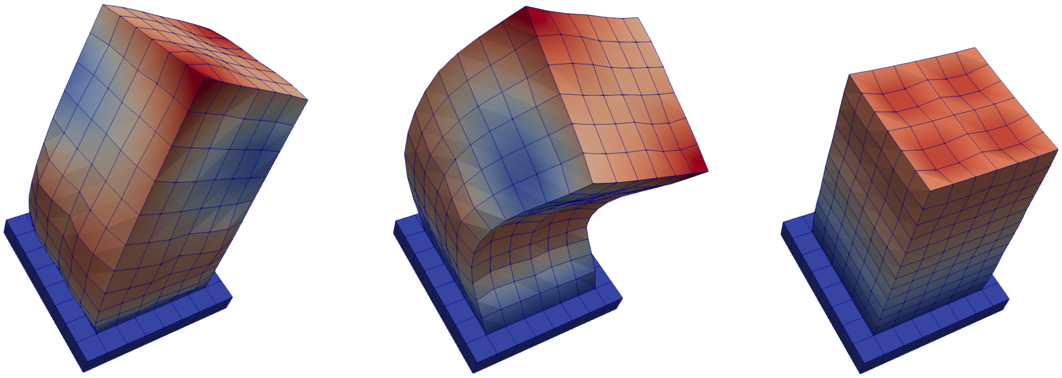

Figure 211.21: Eigen Results (Eigen Mode 4 to 6 from left to right).

211.8.1.2 Medium Size Real-ESSI Example

Elastic Material The compressed package of input files is available HERE.

Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 132,000
- Number of Time Steps: 210
- Running Time: 10 minutes
- Disk Space: 3GB
- Recommended Machine: Amazon EC2 c4.2xlarge instance 8 cores.
- Estimated Bill in AWS Region Oregon/Ohio/Northern Virginia:
  - For simulation time: $\$0.398 * 10/60 = \$0.07$
  - For General Purpose (SSD) Storage: $\$0.1 * 3 = \$0.3$ (monthly)
  - For S3 Storage: $\$0.023 * 3 = \$0.069$ (monthly)

The Modeling parameters are listed below

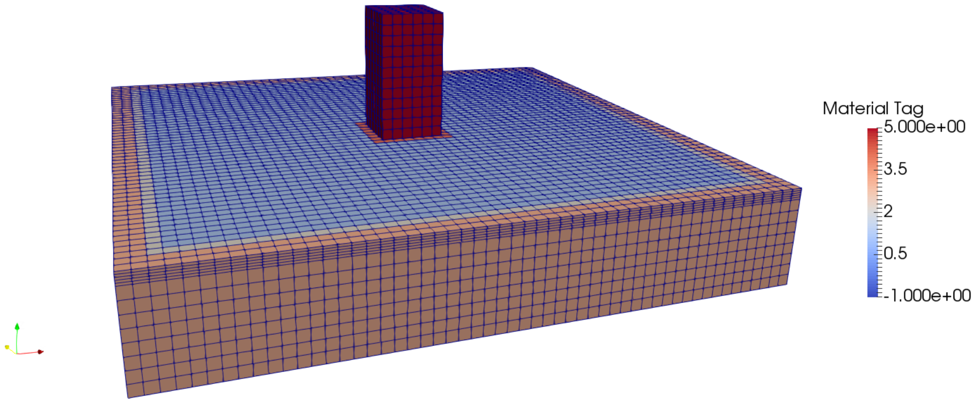
- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

The illustration results of the simulation is shown in Fig. 410.12. It is noted that outside the DRM layer, there are no outgoing waves.

von-Mises Armstrong-Frederick Material The compressed package of input files is available HERE.

Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 132,000
- Number of Time Steps: 210
- Running Time: 46 minutes



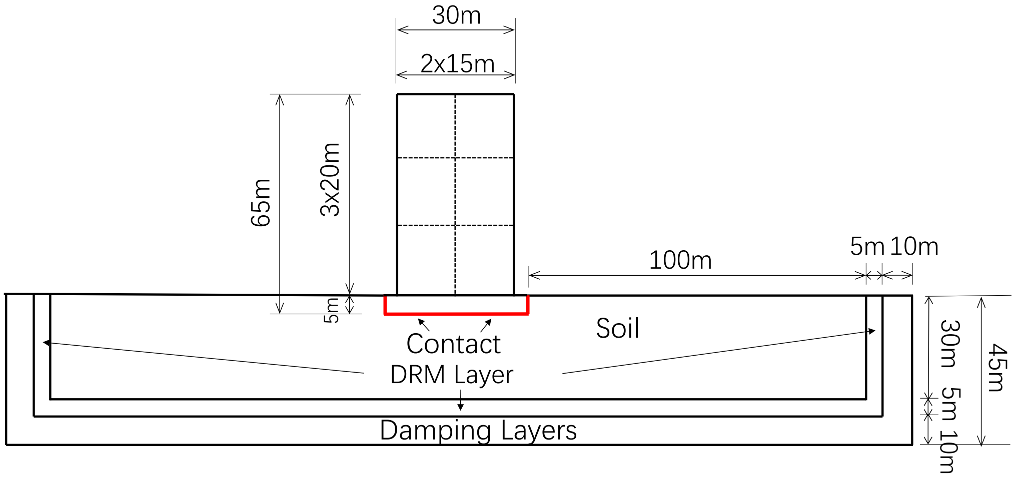


Figure 211.22: Simulation Model.

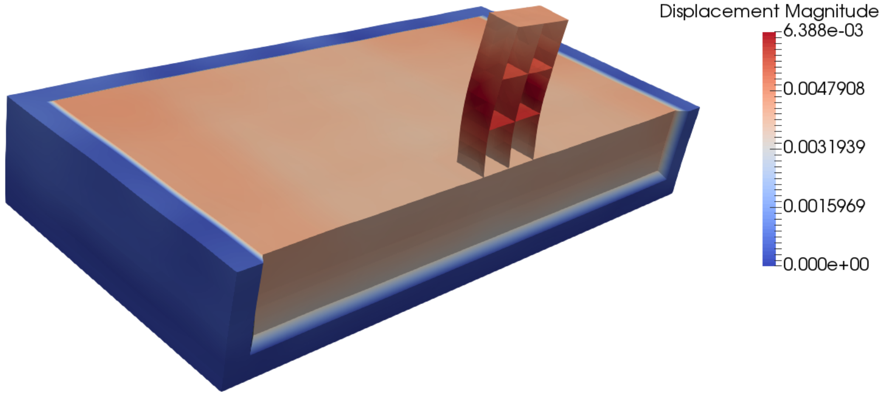

Figure 211.23: Simulation Model.

- Disk Space: 3GB
- Recommended Machine: Amazon EC2 c4.2xlarge instance 8 cores.
- Estimated Bill in AWS Region Oregon/Ohio/Northern Virginia:
  - For simulation time: $\$0.398 * 46/60 = \$0.31$
  - For General Purpose (SSD) Storage: $\$0.1 * 3 = \$0.3$ (monthly)
  - For S3 Storage: $\$0.023 * 3 = \$0.069$ (monthly)

The Modeling parameters are listed below

- von-Mises nonlinear hardening material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - von Mises radius, k, 60 kPa
  - Nonlinear kinematic hardening, H_a, 30 MPa
  - Nonlinear kinematic hardening, C_r, 60
  - Shear strength ($\approx \sqrt{2/3}\; H_a/C_r$), S_u, 408 kPa
  - Isotropic hardening rate, K_{iso}, 0 Pa

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 46 minutes.

211.8.1.3 Large Example

Elastic Simulation The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 210,000
- Number of Time Steps: 2065
- Running Time: 17 hours
- Disk Space: 45GB
- Recommended Machine: Amazon EC2 c4.8xlarge instance 36 cores.
- Estimated Bill in AWS Region Oregon/Ohio/Northern Virginia:
  - For simulation time: $\$1.591 * 17 = \$27.05$
  - For General Purpose (SSD) Storage: $\$0.1 * 45 = \$4.5$ (monthly)
  - For S3 Storage: $\$0.023 * 45 = \$1.035$ (monthly)
  - For Network Bandwidth if transfer: $\$0.09 * 45 = \$4.05$

SIMULATION TIME: With 32 cores on AWS EC2 c4.8xlarge instance, the running time for this example is 17 hours.

The Modeling parameters are listed below

- Soil
  - Unit weight, γ, 21.4 kPa
  - Shear velocity, Vs, 500 m/s
  - Young's modulus, E, 1.3 GPa
  - Poisson's ratio, ν, 0.25
  - Shear strength, S_u, 650 kPa
  - von Mises radius, k, 60 kPa
  - kinematic hardening, H_a, 30 MPa
  - kinematic hardening, C_r, 25
- Structure

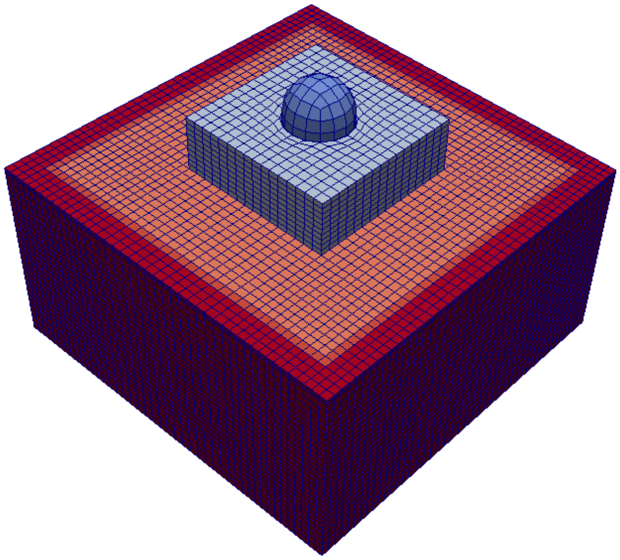

Figure 211.24: Simulation Model.

- Unit weight, γ, 24 kPa
- Young's modulus, E, 20 GPa
- Poisson's ratio, ν, 0.21

The input motion is a 3C wave from SW4.

Inelastic Simulation The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

Real-ESSI modeling and simulation on AWS summary:

- DOFs in the Model: 210,000
- Number of Time Steps: 2065
- Running Time: 30 hours
- Disk Space: 45GB
- Recommended Machine: Amazon EC2 c4.8xlarge instance 36 cores.
- Estimated Bill in AWS Region Oregon/Ohio/Northern Virginia:
  - For simulation time: $\$1.591 * 30 = \$47.73$
  - For General Purpose (SSD) Storage: $\$0.1 * 45 = \$4.5$ (monthly)
  - For S3 Storage: $\$0.023 * 45 = \$1.035$ (monthly)
  - For Network Bandwidth if transfer: $\$0.09 * 45 = \$4.05$

SIMULATION TIME: With 32 cores on AWS EC2 c4.8xlarge instance, the running time for this example is 30 hours.

The Modeling parameters are listed below

- Soil
  - Unit weight, γ, 21.4 kPa
  - Shear velocity, Vs, 500 m/s
  - Young's modulus, E, 1.3 GPa
  - Poisson's ratio, ν, 0.25
  - Shear strength, S_u, 650 kPa
  - von Mises radius, k, 60 kPa
  - kinematic hardening, H_a, 30 MPa
  - kinematic hardening, C_r, 25
- Structure

  - Unit weight, γ, 24 kPa
  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.21
- Contact
  - Initial axial stiffness, k_n^{init}, 1e9 N/m
  - Stiffening rate, S_r, 1000 /m
  - Maximum axial stiffness, k_n^{max}, 1e12 N/m
  - Shear stiffness, k_t, 1e7 N/m
  - Axial viscous damping, C_n, 100 $N \cdot s/m$
  - Shear viscous damping, C_t, 100 $N \cdot s/m$
  - Friction ratio, μ, 0.25

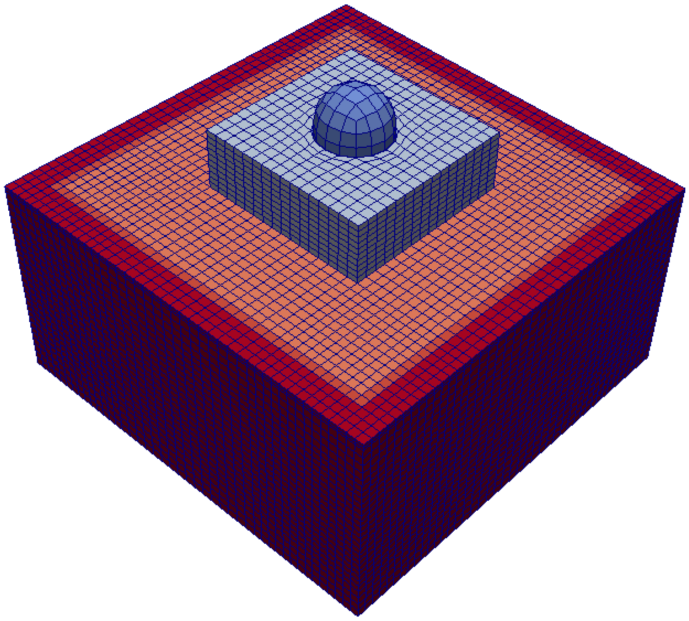

Figure 211.25: Simulation Model.

211.8.2 Real-ESSI AWS Manual, April 2023

Real-ESSI AWS manual developed for the Real-ESSI Short Course, in March, April 2023, is provided below.

1. Summary and Highlights

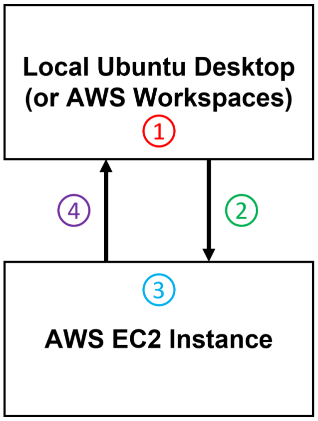
This chapter describes details of accessing and using Real-ESSI Simulator using remote computers, the so-called "cloud" computational resources. The current focus is on using Amazon Web Services (AWS) computers.

Note: If you have a local Ubuntu desktop, you may download and install the Debian package for Real-ESSI. The procedures are documented in Real-ESSI Simulator System Procurement Procedures.

2. Real-ESSI Cloud Computing Overview

Cloud computing refers to the accessing and computing over the Internet rather than on local computers. Cloud computing is a model for enabling on-demand access to a shared pool of configurable computing resources, which can be setup and released rapidly.[1]

Using Real-ESSI Cloud Service, users can get computing instances on demand without requiring a lot of maintenance and financial resources a common, local parallel computer cluster would require. In addition, users do not need to go through the installation of the dependent libraries, source-code compilation and the installation of other related software, for example preprocessing and post-processing environments. The complete Real-ESSI Simulator system is pre-configured and built within the image such that the Real-ESSI Simulator system is portable over the cloud. A stable, release version of Real-ESSI is built and can be used anywhere and anytime.



① Prepare input files on local desktop

② Transfer input files to AWS instance

③ Run the simulation on AWS instance

④ Transfer output files to local desktop

The suggested workflow for Real-ESSI cloud computing using AWS is shown above. The recommended workflow is a client-server style workflow, the most efficient and economical way to perform cloud computing. First, a local Ubuntu desktop (*AWS Workspaces is a good*

---

[1] This is an excerpt from Jeremic et al. (1989-2023)

substitute if you don't have a local Ubuntu desktop) is used to prepare input files, receive output files, and post-processing simulation results. Then, an AWS EC2 instance is used to conduct high-performance parallel computation from the Real-ESSI simulation. We will introduce detailed procedures in the following chapters.

3. Create AWS Account

3.1 AWS account types

There are two types of accounts on AWS, the Root user and the IAM user, each with unique credentials.

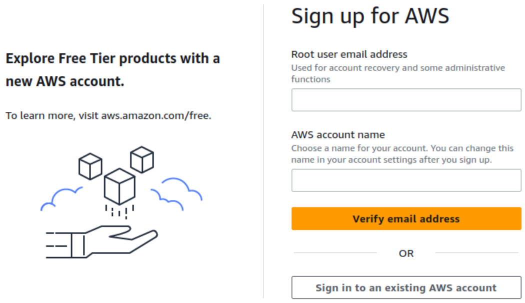
- The root user in Amazon Web Services (AWS) is the initial administrative user created when creating an AWS account. The root user has full access to all AWS services, financials, and resources in the account and can perform any action on them. **It is highly recommended to avoid using the root user account for regular day-to-day operations in AWS due to security reasons.**
- On the other hand, an IAM (Identity and Access Management) user is a user account that is created within your AWS account, separate from the root account. IAM users have a set of permissions that are defined by an AWS administrator (or yourself) to limit what actions they can perform in AWS. This allows you to grant specific permissions to users or groups of users without giving them full access to the AWS account.

IAM users can be created with unique usernames and credentials, and their permissions can be managed separately from the root user. This provides better security and allows you to grant different levels of access to different users or groups, based on their roles and responsibilities.

If you're a first-time user of AWS, your first step is to sign up for a Root user AWS account. When you sign up, AWS creates an AWS account with the details you provide and assigns the account to you. We also suggest activating multi-factor authentication (MFA) for the root user and assigning administrative access to a user. You can find complete documentation on AWS Account Management here.

3.2 Create a root user account

- To create your AWS account, open the AWS home page in your browser and choose **Create an AWS account**.
- Supply your email, then the code sent to your email address.



Explore Free Tier products with a new AWS account.

To learn more, visit aws.amazon.com/free.

Sign up for AWS

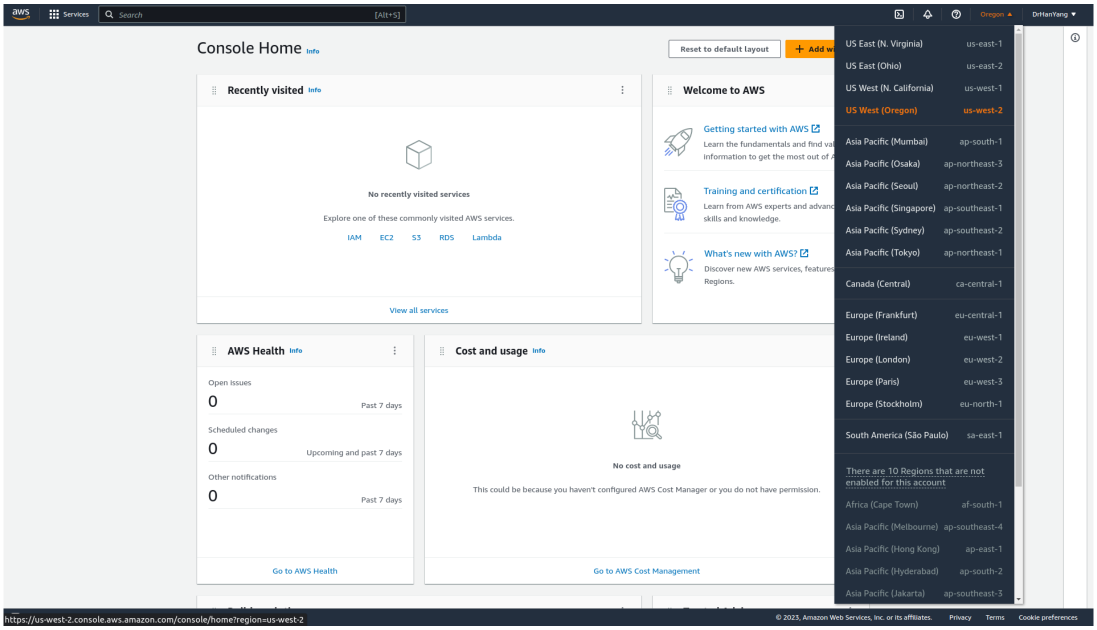
Root user email address
Used for account recovery and some administrative functions

AWS account name
Choose a name for your account. You can change this name in your account settings after you sign up.

- Create a root user password.
- Provide contact information.
- Provide billing information.
- Confirm your identity.
- Select a support plan. The **Basic support - Free** option is enough for using Real-ESSI.
- Select **Complete sign up**

3.3 Initial setups for your new AWS account

- Sign **into** your root account.
- Switch your region to **US West (Oregon)**. Your region is located near the top right corner of your webpage.



No recently visited services

Explore one of these commonly visited AWS services.

Learn the fundamentals and find val information to get the most out of A

Convert existing Amazon WorkSpaces to the WorkSpaces Streaming Protocol without a rebuild
By: Andrew Morgan | Date: January 18, 2023

Amazon WorkSpaces Introduces Ubuntu Desktops
By: Sébastien Stormacq | Date: September 29, 2022

Learn the fundamentals and find valuable information to get the most out of AWS.

Learn from AWS experts and advance your skills and knowledge.

Discover new AWS services, features, and Regions.

The services we need are **Workspaces** and **EC2**.

4. Amazon Workspaces

If you already have and want to use your own local Ubuntu desktop, skip this chapter.

Summary: This chapter presents setting up, launching, and connecting to your Amazon Workspace. Note that Amazon Workspace is used as a substitute for local Ubuntu desktops.

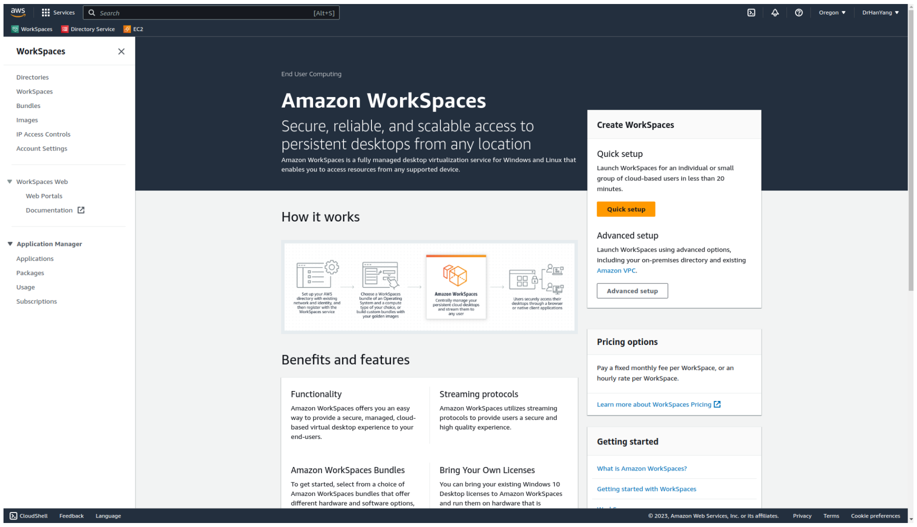
Amazon WorkSpaces enables you to provision virtual, cloud-based Microsoft Windows, Amazon Linux, or Ubuntu Linux desktops, known as *WorkSpaces*. WorkSpaces eliminates the need to purchase and set up your own Ubuntu desktop. Instead, users can access their virtual desktops from multiple devices or web browsers. Complete documentation regarding Amazon Workspaces can be found here.

4.1 WorkSpaces quick setup

This tutorial uses the **Quick Setup** option to launch your WorkSpace. This option is available only if you have never launched a WorkSpace. Alternatively, for the full documentation see here.

Step 1: Launch the WorkSpace

- Open the WorkSpaces console at https://console.aws.amazon.com/workspaces/.
- Choose **Quick setup**. If you don't see this button, either you have already launched a WorkSpace in this Region, or you aren't using one of the Regions that support Quick Setup. In this case, see Launch a virtual desktop using WorkSpaces.



End User Computing

Amazon WorkSpaces

Secure, reliable, and scalable access to persistent desktops from any location

Amazon WorkSpaces is a fully managed desktop virtualization service for Windows and Linux that enables you to access resources from any supported device.

How it works

Benefits and features

Functionality

Amazon WorkSpaces offers you an easy way to provide a secure, managed, cloud-based virtual desktop experience to your end-users.

Streaming protocols

Amazon WorkSpaces utilizes streaming protocols to provide users a secure and high quality experience.

Amazon WorkSpaces Bundles

To get started, select from a choice of Amazon WorkSpaces bundles that offer different hardware and software options,

Bring Your Own Licenses

You can bring your existing Windows 10 Desktop licenses to Amazon WorkSpaces and run them on hardware that is

Create WorkSpaces

Quick setup

Launch WorkSpaces for an individual or small group of cloud-based users in less than 20 minutes.

Advanced setup

Launch WorkSpaces using advanced options, including your on-premises directory and existing Amazon VPC.

Pricing options

Pay a fixed monthly fee per WorkSpace, or an hourly rate per WorkSpace.

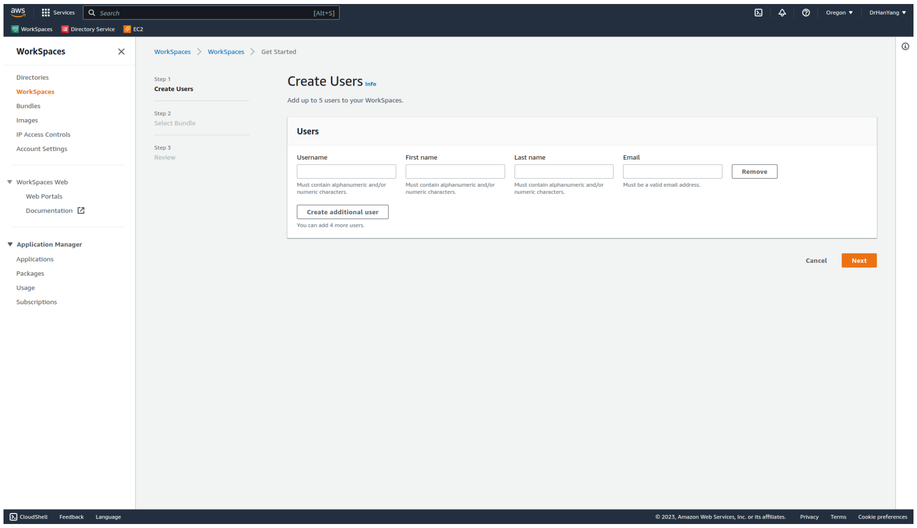
Learn more about WorkSpaces Pricing

Getting started

What is Amazon WorkSpaces?

Getting started with WorkSpaces

- For **Create Users**, enter the **Username**, **First Name**, **Last Name**, and **Email**. Then choose **Next**. Note that you can enter multiple users here, but this doesn't mean they can use the same Workspace. Instead, multiple Workspaces will be created, one for each user.



Step 1
Create Users

Review

Create Users Info

Add up to 5 users to your WorkSpaces.

Users

Username	First name	Last name	Email	
				Remove
Must contain alphanumeric and/or numeric characters.	Must contain alphanumeric and/or numeric characters.	Must contain alphanumeric and/or numeric characters.	Must be a valid email address.	

You can add 4 more users.

- For **Bundles**, select a bundle (hardware and software) for the user with the appropriate protocol (PCoIP or WSP). For Real-ESSI cloud computing, choose PowerPro with Ubuntu 22.04 with the WSP protocol. You can find this bundle by its ID wsb-8w32qplfk.

	Name	ID	Langua...	Client proto...	Bundle type	Bundle state	Updated date
○	PowerPro with Ubuntu 22.04	wsb-8w32qplfk	English	WSP	Regular	✓ Available	Wednesday, September 21, 2022

- Review your **information**. Then choose **Create WorkSpace**.

- It takes approximately 20 minutes, up to 40 minutes, for your WorkSpace to be created. When the launch is complete, the status is AVAILABLE and an invitation is sent to the email address that you specified for each user. If the users don't receive their invitation emails, see [Send an invitation email](#).

Step 2: Connect to the WorkSpace

After you receive the invitation email, you can connect to the WorkSpace using the client of your choice. After you sign in, the client displays the WorkSpace desktop.

- If you haven't set up credentials for the user already, open the link in the invitation email and follow the directions. Remember the password that you specify as you will need it to connect to your WorkSpace.

- When prompted, download one of the client applications or launch **Web Access**. If you aren't prompted and you haven't installed a client application already, open https://clients.amazonworkspaces.com/ and download one of the client applications or launch **Web Access**.

- Start the client, enter the registration code from the invitation email, and choose **Register**.

- When prompted to sign in, enter the sign-in credentials, and then choose **Sign In**.

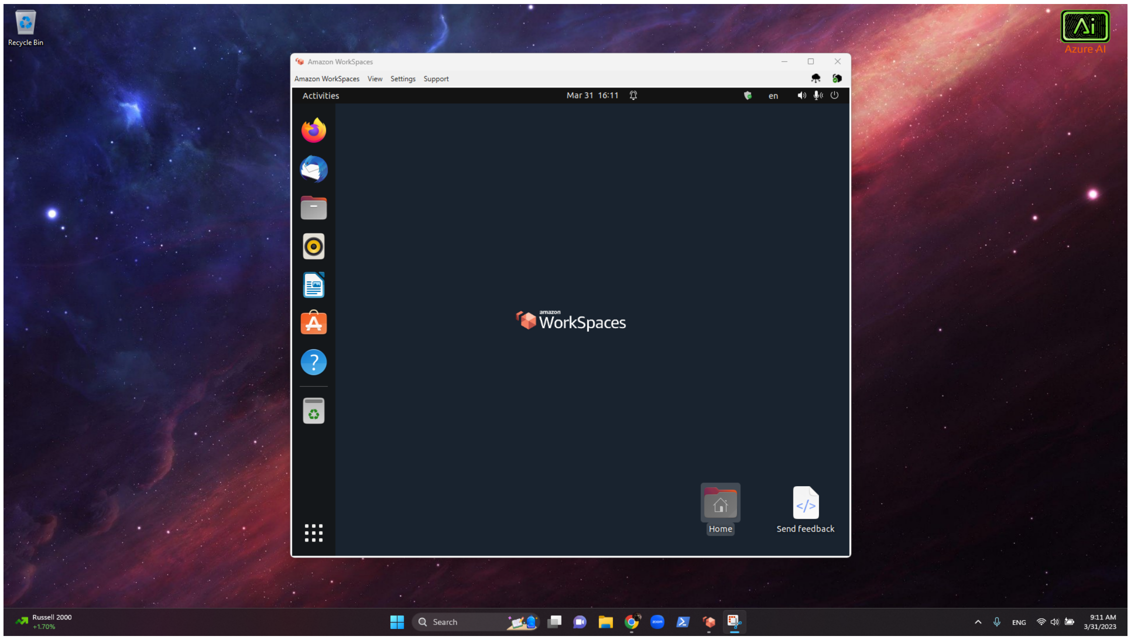
- (Optional) When prompted to save your credentials, choose Yes.

Step 3: Clean up (Optional)

If you are finished with the WorkSpace that you created for this tutorial, you can delete it. For more information, see Delete a WorkSpace.

4.2 Install Real-ESSI Debian package on your Workspace

Once you successfully connect to your Workspace, it will be the same as if you are working with a local Ubuntu desktop.



The next step is to install Real-ESSI on your Workspace. Full documentation can be found in Section 1.3 of the Real-ESSI Simulator Procurement Manual. Quick setup steps are summarized below.

Step 1: System libraries update/upgrade

Open a terminal and use the following commands.

```
sudo apt update
sudo apt upgrade
sudo apt autoremove
```

You will be asked to provide a password. The password is the same one you used to connect to your Workspace.

Step 2: Real-ESSI Debian package download

The Real-ESSI program Debian package can be downloaded here. Alternatively, contact Prof. Jeremic to arrange for a customized Real-ESSI Debian package.

Step 3: Real-ESSI Debian package install

Start the Real-ESSI Simulator Debian package install by removing the old installations of Real-ESSI. Then, go to the directory where you have downloaded the Real-ESSI Debian package. Install the Debian package, for example use the following command.

```
sudo apt install ./real-essi_23.01-1_amd64.deb
```

Note that some warning messages might appear but they don't affect the installation. After a successful installation, the sequential and parallel Real-ESSI executables, gmsh/gmESSI preprocessor, paraview/pvESSI post-processor/visualizer, Gmsh, and ParaView are all installed and ready to use.

Step 4: Load pvESSI plugin in ParaView

Start ParaView. Click **Tools**, then **Manage Plugins**. Click **Load New** and find the plugin **PVESSIReader.so** under directory /opt/paraview/lib/paraview-5.10/plugins/PVESSIReader/. Also, check the box **Auto Load** then close ParaView. Next time when ParaView is started, Real-ESSI output files can be visualized and post-processed.

Step 5: Install other useful programs

- **HDFView** can be used to open Real-ESSI output files, which are in HDF5 format.
- **Sublime Text** is the recommended editor for Real-ESSI input files and pre-processing files.

Documentation on how to install these programs can be found in Section 1.3.5 of the Real-ESSI Simulator Procurement Manual.

4.3 Build your model and prepare the input files

Once you have installed Real-ESSI on your Workspace, you are ready to start building your Real-ESSI model. You should finish preparing all the input files on your Workspace before moving on to the next Chapter. Full documentation on Real-ESSI pre-processing and input file formats is available.

Note that if the model is sufficiently small, you can simply run the simulation on your Workspace, without using the AWS Real-ESSI instance which is designed to be used in cases with large models.

5. Launch Real-ESSI Instance on AWS

A Real-ESSI instance can be launched either from the private image with authorization of Prof. Boris Jeremic or from the public image on AWS Marketplace (coming soon). Full documentation regarding launching an instance on AWS can be found here.

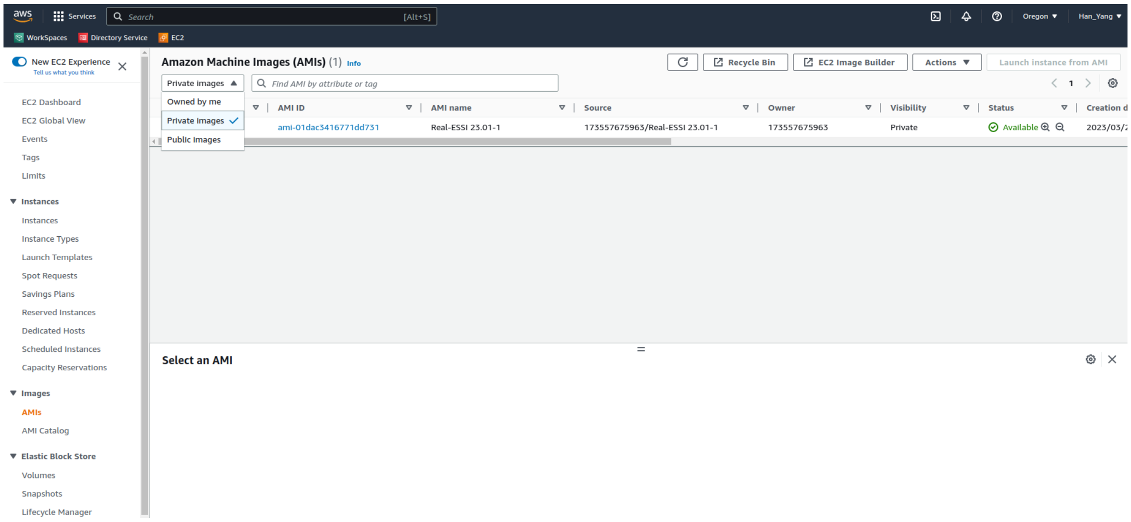
5.1 Launch Real-ESSI instance from AWS private images

Follow the steps below to launch instances from Real-ESSI Private Image.

Step 1: Request the Real-ESSI image

Real-ESSI image is currently a private Amazon Machine Images (AMI). After you get the 12-digit AWS account ID, email the AWS account ID to Prof. Boris Jeremic to obtain the Real-ESSI image.

To check if you have access to the Real-ESSI image, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. Go to **AMIs** and choose **Private images** to see the Real-ESSI image. Currently, the Real-ESSI AMIs are available in the **Oregon** region. The region is shown in the top-right corner on the EC2 dashboard.

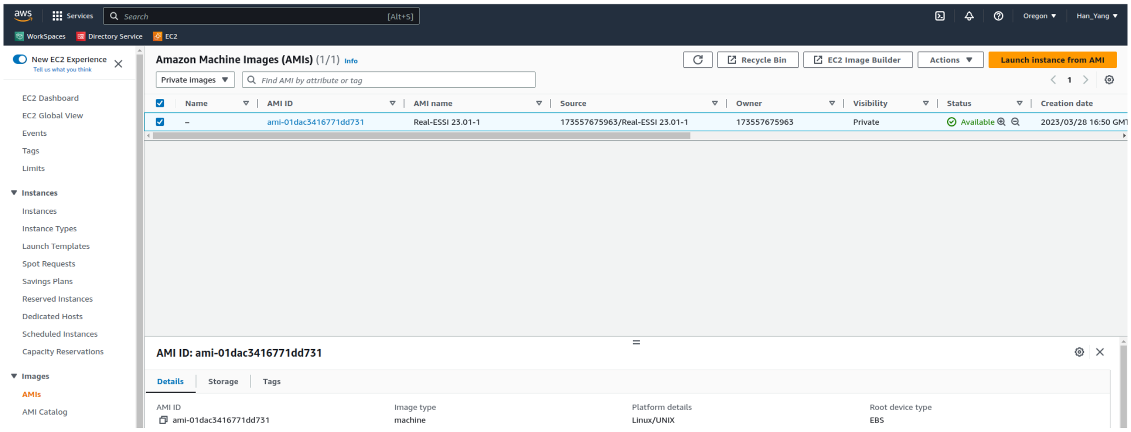


AMI ID	AMI name	Source	Owner	Visibility	Status	Creation d
ami-01dac3416771dd731	Real-ESSI 23.01-1	173557675963/Real-ESSI 23.01-1	173557675963	Private	Available	2023/03/

Step 2: Launch the Real-ESSI instance

You can launch the Real-ESSI instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you quickly launch your first instance, so it doesn't cover all possible options. For information about advanced options, see [Launch an instance using the new launch instance wizard](). For information about other ways to launch your instance, see [Launch your instance]().

- Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
- From the EC2 console dashboard, Go to **AMIs** and choose **Private images** to see the Real-ESSI image. Choose the image and choose **Launch instance from AMI**.



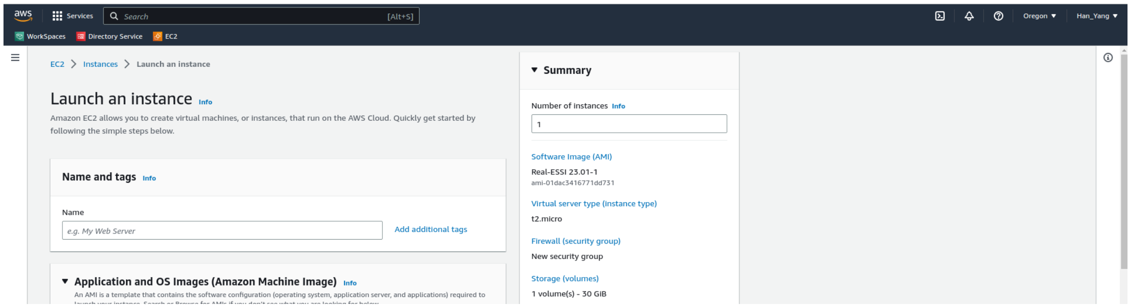
Amazon Machine Images (AMIs) (1/1) Info

☑	Name	AMI ID	AMI name	Source	Owner	Visibility	Status	Creation date
☑	–	ami-01dac3416771dd731	Real-ESSI 23.01-1	173557675963/Real-ESSI 23.01-1	173557675963	Private	Available	2023/03/28 16:50 GMT

AMI ID: ami-01dac3416771dd731

AMI ID: ami-01dac3416771dd731
Image type: machine
Platform details: Linux/UNIX
Root device type: EBS

- Under **Name and tags**, for **Name**, enter a descriptive name for your instance.



Launch an instance

Amazon EC2 allows you to create virtual machines, or instances, that run on the AWS Cloud. Quickly get started by following the simple steps below.

Name and tags

Name: e.g. My Web Server

▼ Application and OS Images (Amazon Machine Image)

An AMI is a template that contains the software configuration (operating system, application server, and applications) required to

▼ Summary

Number of instances: 1

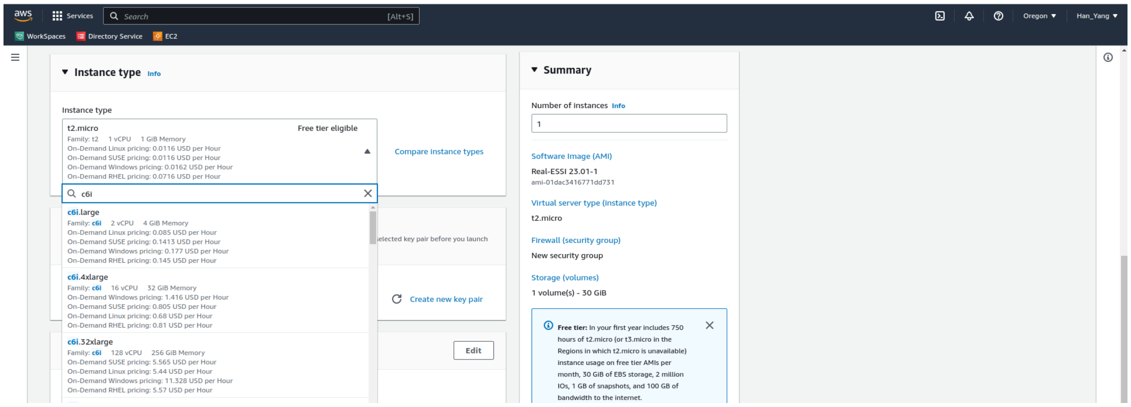
Software Image (AMI): Real-ESSI 23.01-1, ami-01dac3416771dd731

Virtual server type (instance type): t2.micro

Firewall (security group): New security group

Storage (volumes): 1 volume(s) - 30 GiB

- Under **Instance type**, you can select the hardware configuration for your instance. For Real-ESSI instances, the compute-optimized **c6i** series is recommended. Click the drop-down list under **instance type** and type **c6i** in the search bar. Depending on the size of your model, you can choose an instance type with appropriate computing power.



▼ Instance type

Instance type

t2.micro Free tier eligible
Family: t2 1 vCPU 1 GiB Memory
On-Demand Linux pricing: 0.0116 USD per Hour
On-Demand SUSE pricing: 0.0116 USD per Hour
On-Demand Windows pricing: 0.0162 USD per Hour
On-Demand RHEL pricing: 0.0716 USD per Hour

c6i

c6i.large
Family: c6i 2 vCPU 4 GiB Memory

On-Demand SUSE pricing: 0.805 USD per Hour
On-Demand Linux pricing: 0.68 USD per Hour
On-Demand RHEL pricing: 0.81 USD per Hour

c6i.32xlarge
Family: c6i 128 vCPU 256 GiB Memory
On-Demand SUSE pricing: 5.565 USD per Hour
On-Demand Linux pricing: 5.44 USD per Hour
On-Demand Windows pricing: 11.328 USD per Hour
On-Demand RHEL pricing: 5.57 USD per Hour

elected key pair before you launch

▼ Summary

Number of instances: 1

Software Image (AMI): Real-ESSI 23.01-1, ami-01dac3416771dd731

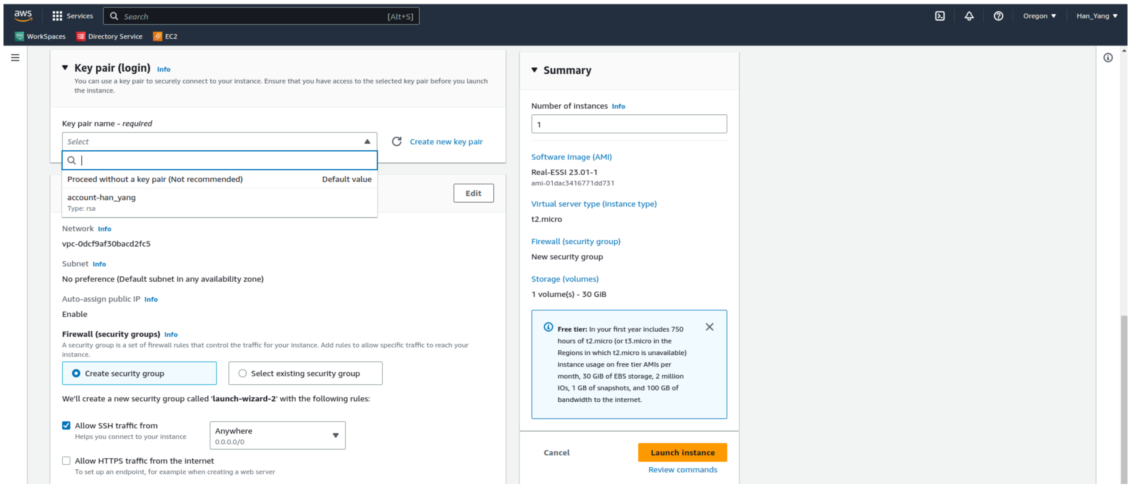
Virtual server type (instance type): t2.micro

Firewall (security group): New security group

Storage (volumes): 1 volume(s) - 30 GiB

Free tier: In your first year includes 750 hours of t2.micro (or t3.micro in the Regions in which t2.micro is unavailable) instance usage on free tier AMIs per month, 30 GiB of EBS storage, 2 million IOs, 1 GB of snapshots, and 100 GB of bandwidth to the internet.

- Under **Key pair (login)**, select the key pair for your instance.



Key pair (login) Info

You can use a key pair to securely connect to your instance. Ensure that you have access to the selected key pair before you launch the instance.

Key pair name - *required*

Select

Proceed without a key pair (Not recommended) Default value

account-han_yang
Type: rsa

Network Info
vpc-0dcf9af30bacd2fc5

Subnet Info
No preference (Default subnet in any availability zone)

Auto-assign public IP Info
Enable

Firewall (security groups) Info

A security group is a set of firewall rules that control the traffic for your instance. Add rules to allow specific traffic to reach your instance.

● Create security group ○ Select existing security group

We'll create a new security group called '**launch-wizard-2**' with the following rules:

☑ Allow SSH traffic from — Anywhere 0.0.0.0/0
Helps you connect to your instance

☐ Allow HTTPS traffic from the internet
To set up an endpoint, for example when creating a web server

Summary

Number of instances Info: 1

Software Image (AMI)
Real-ESSI 23.01-1
ami-01dac3416771dd731

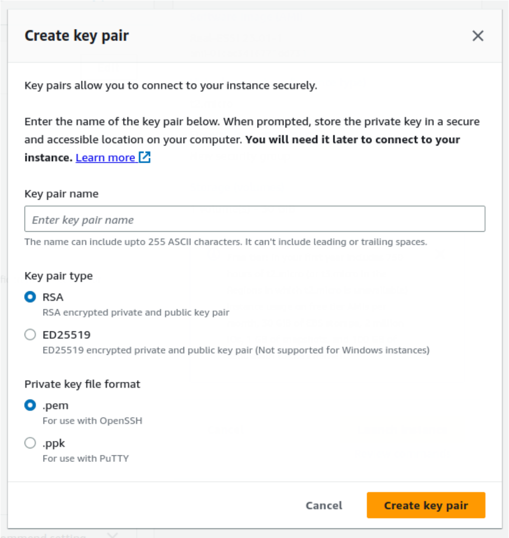
Virtual server type (instance type)
t2.micro

Firewall (security group)
New security group

Storage (volumes)
1 volume(s) - 30 GiB

Free tier: In your first year includes 750 hours of t2.micro (or t3.micro in the Regions in which t2.micro is unavailable) instance usage on free tier AMIs per month, 30 GiB of EBS storage, 2 million IOs, 1 GB of snapshots, and 100 GB of bandwidth to the internet.

If you have not created a key pair before, choose **Create new key pair**.



Create key pair

Key pairs allow you to connect to your instance securely.

Enter the name of the key pair below. When prompted, store the private key in a secure and accessible location on your computer. **You will need it later to connect to your instance.** Learn more

Key pair name

Enter key pair name

The name can include upto 255 ASCII characters. It can't include leading or trailing spaces.

Key pair type

● RSA
RSA encrypted private and public key pair

○ ED25519
ED25519 encrypted private and public key pair (Not supported for Windows instances)

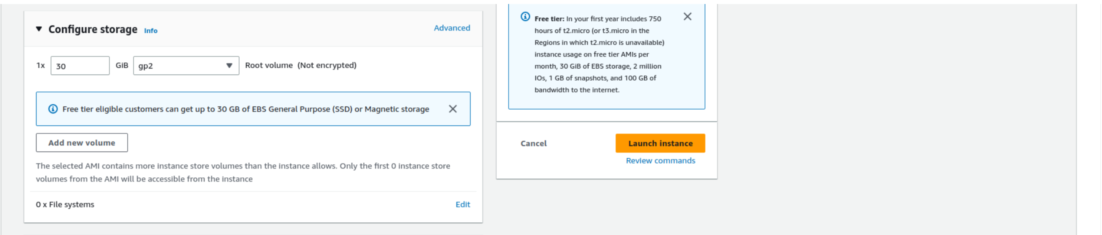
Private key file format

● .pem
For use with OpenSSH

○ .ppk
For use with PuTTY

Enter a descriptive name for your key pair. Leave everything else the same. Then click **Create key pair**. You will be prompted to save the key pair. Note that the key pair cannot be recreated after you launch the instance, so please make sure you save it in a safe place. The key pair can be reused later when you launch other instances.

- Under **Configure storage**, change the Root volume depending on the size of your model and simulation options.



1x 30 GiB gp2 Root volume (Not encrypted)

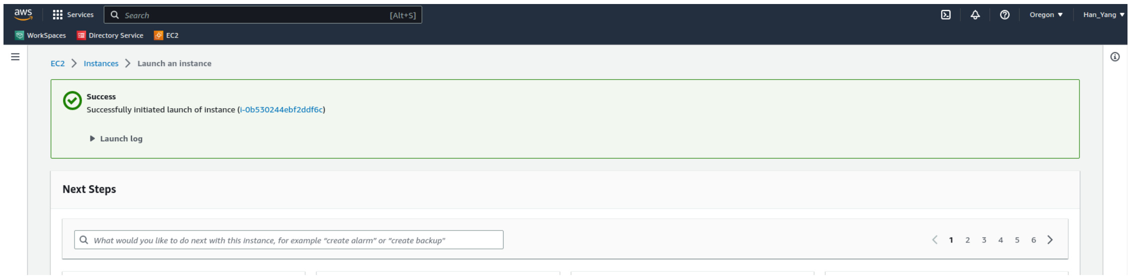
Free tier eligible customers can get up to 30 GB of EBS General Purpose (SSD) or Magnetic storage

The selected AMI contains more instance store volumes than the instance allows. Only the first 0 instance store volumes from the AMI will be accessible from the instance

0 x File systems

Free tier: In your first year includes 750 hours of t2.micro (or t3.micro in the Regions in which t2.micro is unavailable) instance usage on free tier AMIs per month, 30 GiB of EBS storage, 2 million IOs, 1 GB of snapshots, and 100 GB of bandwidth to the internet.

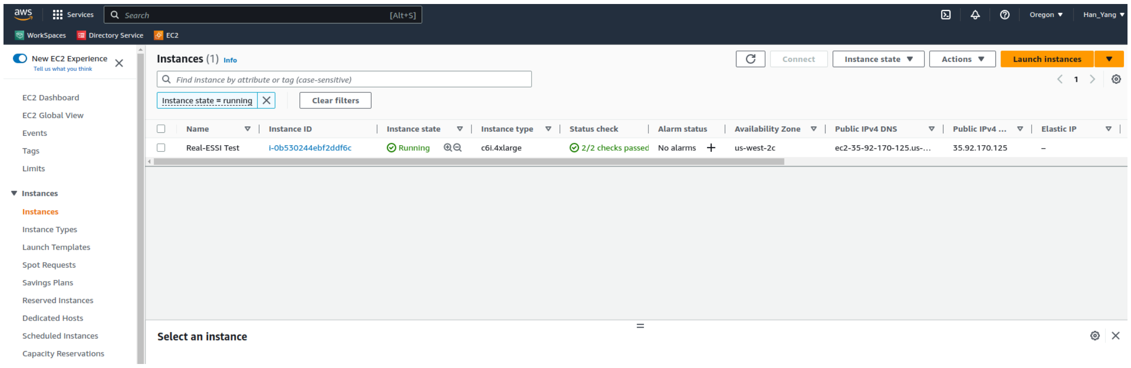
- Click **Launch instance**. You should see the message below if the launch is successful.



Success
Successfully initiated launch of instance (i-0b530244ebf2ddf6c)

What would you like to do next with this instance, for example "create alarm" or "create backup"

- You can view your running instances by clicking **Instances** on the left side list of your screen.



Name	Instance ID	Instance state	Instance type	Status check	Alarm status	Availability Zone	Public IPv4 DNS	Public IPv4 ...	Elastic IP
Real-ESSI Test	i-0b530244ebf2ddf6c	Running	c6i.4xlarge	2/2 checks passed	No alarms	us-west-2c	ec2-35-92-170-125.us-...	35.92.170.125	–

5.2 Launch Real-ESSI instance from AWS Marketplace

Coming soon…

6. Connect to Real-ESSI Instance

This chapter provides information about how to connect to a Real-ESSI instance after you have launched it, and how to transfer files between your local computer and your instance. For more information, please refer to the AWS documentation here. To troubleshoot connecting to your instance, see Troubleshoot connecting to your instance.

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you. The following instructions explain how to connect to your instance using an SSH client. For more connection options, see Connect to your Linux instance.

6.1 Prerequisites

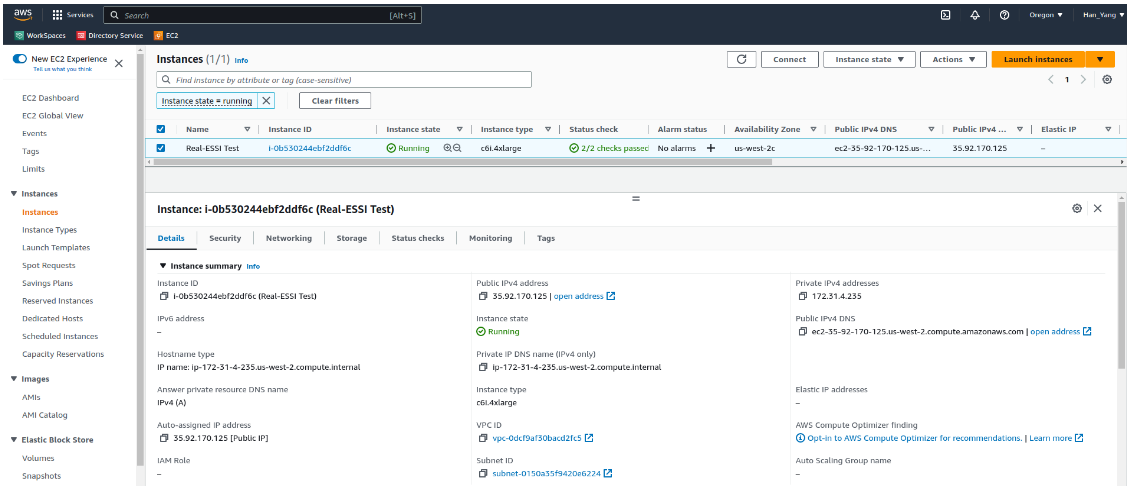
Before you connect to your Linux instance, complete the following prerequisites.

Check your instance status

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the **Instances** page.

Get the public IP address to connect to your instance

Click on your instance to show more information about it. You can find the public IPv4 address from either the summary or details. For example, the public IPv4 address is 35.92.170.125 for the instance shown below.



☑	Name	Instance ID	Instance state	Instance type	Status check	Alarm status	Availability Zone	Public IPv4 DNS	Public IPv4 ...	Elastic IP
☑	Real-ESSI Test	i-0b530244ebf2ddf6c	Running	c6i.4xlarge	2/2 checks passed	No alarms	us-west-2c	ec2-35-92-170-125.us-...	35.92.170.125	–

Instance: i-0b530244ebf2ddf6c (Real-ESSI Test)

Instance summary

Instance ID i-0b530244ebf2ddf6c (Real-ESSI Test)	Public IPv4 address 35.92.170.125 | open address	Private IPv4 addresses 172.31.4.235
IPv6 address –	Instance state Running	Public IPv4 DNS ec2-35-92-170-125.us-west-2.compute.amazonaws.com | open address
Hostname type IP name: ip-172-31-4-235.us-west-2.compute.internal	Private IP DNS name (IPv4 only) ip-172-31-4-235.us-west-2.compute.internal	
Answer private resource DNS name IPv4 (A)	Instance type c6i.4xlarge	Elastic IP addresses –

IAM Role –	Subnet ID subnet-0150a35f9420e6224	Auto Scaling Group name –

Locate the private key and set the permissions

You must know the location of your private key file to connect to your instance. For SSH connections, you must set the permissions so that only you can read the file.

Get the fully-qualified path to the location on your computer of the `.pem` file for the key pair that you specified when you launched the instance.

Use the following command to set the permissions of your private key file so that only you can read it. Replace `key-pair-name` with the actual name of your key pair.

```
chmod 400 key-pair-name.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

6.2 Connect to your Real-ESSI instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot connecting to your instance.

- In a terminal window, use the **ssh** command to connect to the instance. You specify the path and file name of the private key (.pem) and the IPv4 address for your instance. To connect to your instance, use the following command.

```
ssh -i /path/key-name.pem ubuntu@IPv4-address
```

Replace /path/ with the full absolute path to your key pair. Replace key-name with the actual name of your key pair. Replace IPv4-address with the public IPv4 address of your instance.

You will see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com
   (198-51-100-1)' can't be established.
   ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.
   Are you sure you want to continue connecting (yes/no)?
```

- (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.

- Enter `yes`.

You will see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com'
   (ECDSA) to the list of known hosts.
```

- (Optional) Create a directory to organize your Real-ESSI simulation files. Replace test_folder with your folder name.

```
mkdir test_folder
```

6.3 Transfer Input Files to Real-ESSI Instance

This section describes how to transfer files with the secure copy protocol (SCP). The procedure is similar to the procedure for connecting to an instance with SSH.

- Open a terminal on your local Ubuntu desktop (or Amazon Workspace).

- Determine the file location on your local Ubuntu desktop (or Amazon Workspace) and the destination path on the instance. In the following example, the name of the private key file is key-name.pem, the file to transfer is main.fei, and the IPv4 address of the instance is IPv4-address. Enter the following command in your terminal.

```
scp -i /path1/key-name.pem /path2/main.fei ubuntu@IPv4-address:/path3/
```

  There are three paths in this command.
  ➢ Replace /path1/ with the full absolute path to your key pair on your local desktop.
  ➢ Replace /path2/ with the full absolute path to the file to transfer on your local desktop.
  ➢ Replace /path3/ with the full absolute path to the destination on the Real-ESSI instance.

  For example, your **scp** command may be:

```
scp -i /home/han/Documents/han-key.pem /home/han/My_Model/main.fei
ubuntu@52.26.2.245:/home/ubuntu/Test/
```

- If you haven't already connected to the instance using SSH, you will see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com
(10.254.142.33)' can't be established.
RSA key fingerprint is
1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.
Are you sure you want to continue connecting (yes/no)?
```

  (Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see (Optional) Get the instance fingerprint.

  Enter `yes`.

- If the transfer is successful, the response is similar to the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)
to the list of known hosts.
main.fei                                100%   164KB     1.3MB/s   00:00
```

- It's also possible to transfer entire folders using the **scp** command. In the following example, the name of the private key file is key-name.pem, the folder to transfer is folder, and the IPv4 address of the instance is IPv4-address. Enter the following command in your terminal.

```
scp -i /path1/key-name.pem -r /path2/folder ubuntu@IPv4-address:/path3/
```

  There are three paths in this command.

- ➢ Replace /path1/ with the full absolute path to your key pair on your local desktop.
- ➢ Replace /path2/ with the full absolute path to the folder to transfer on your local desktop.
- ➢ Replace /path3/ with the full absolute path to the destination on the Real-ESSI instance.

For example, your **scp** command may be:

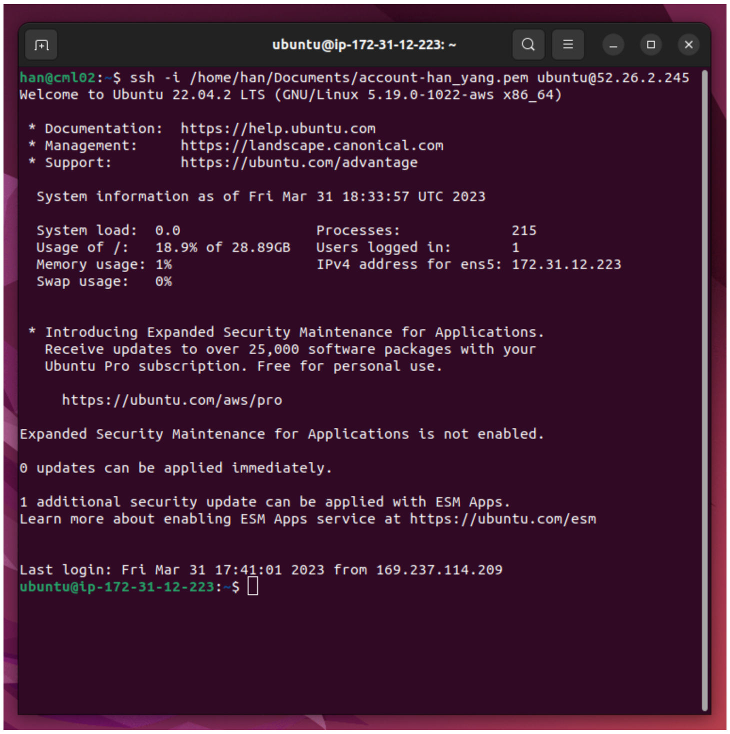
```
scp -i /home/han/Documents/han-key.pem -r /home/han/My_Model_Folder
ubuntu@52.26.2.245:/home/ubuntu/Test/
```

8. Run Simulations on Real-ESSI Instance

This chapter provides information about running your simulations on a launched Real-ESSI instance. Note that you should only attempt to do this after you have done the following:

- Create an AWS account
- Have access to a local Ubuntu desktop (or Amazon Workspace)
- Launch a Real-ESSI instance on AWS
- Connect to the Real-ESSI instance you have launched

Once you have successfully transferred your input files, open a new terminal and connect to the Real-ESSI instance. Your terminal should look like the following:



```
han@cml02:~$ ssh -i /home/han/Documents/account-han_yang.pem ubuntu@52.26.2.245
Welcome to Ubuntu 22.04.2 LTS (GNU/Linux 5.19.0-1022-aws x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:     https://landscape.canonical.com
 * Support:        https://ubuntu.com/advantage

  System information as of Fri Mar 31 18:33:57 UTC 2023

  System load:  0.0               Processes:             215
  Usage of /:   18.9% of 28.89GB   Users logged in:       1
  Memory usage: 1%                IPv4 address for ens5: 172.31.12.223
  Swap usage:   0%

Last login: Fri Mar 31 17:41:01 2023 from 169.237.114.209
ubuntu@ip-172-31-12-223:~$ 
```

- Go to the directory where you transferred your input files. Use the following command:

```
cd /path/
```

  Replace /path/ with the full absolute path to your input files on the Real-ESSI instance.

- Change the permission of your file so that it can be read and executed. Use the following command:

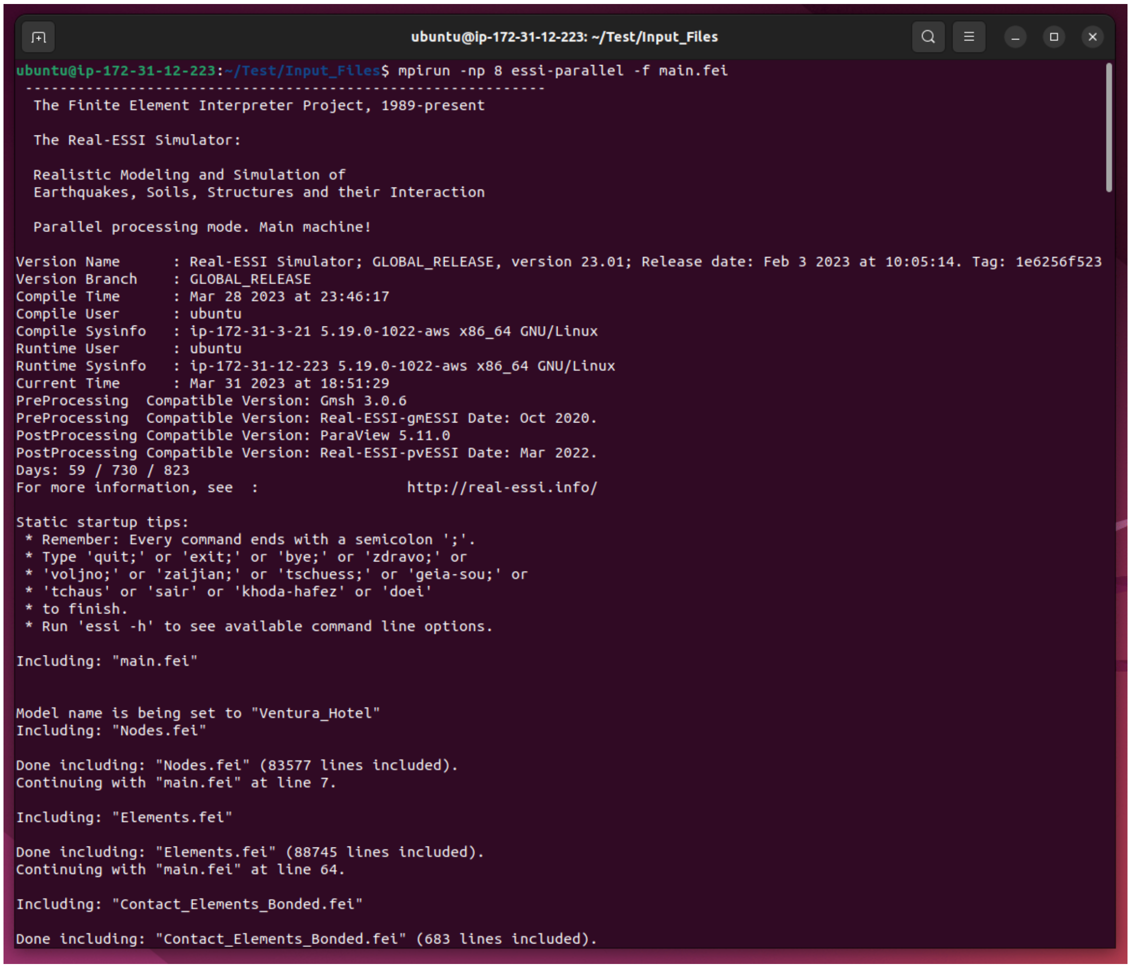
```
chmod a+rx main.fei
```

- Enter the following command to start your simulation:

```
mpirun -np num_pro essi-parallel -f main.fei
```

  Replace num_pro with the number of processes you want to use to run the simulation. Note that this number must be smaller than the number of available processes on your Real-ESSI instance. Consider using a different instance type with more available processes if your current set up is not enough for your model.

- Once the simulation has successfully started, you should see something like the following:



```
ubuntu@ip-172-31-12-223:~/Test/Input_Files$ mpirun -np 8 essi-parallel -f main.fei
 ------------------------------------------------------------
  The Finite Element Interpreter Project, 1989-present

  The Real-ESSI Simulator:

  Realistic Modeling and Simulation of
  Earthquakes, Soils, Structures and their Interaction

  Parallel processing mode. Main machine!

Version Name      : Real-ESSI Simulator; GLOBAL_RELEASE, version 23.01; Release date: Feb 3 2023 at 10:05:14. Tag: 1e6256f523
Version Branch    : GLOBAL_RELEASE
Compile Time      : Mar 28 2023 at 23:46:17
Compile User      : ubuntu
Compile Sysinfo   : ip-172-31-3-21 5.19.0-1022-aws x86_64 GNU/Linux
Runtime User      : ubuntu
Runtime Sysinfo   : ip-172-31-12-223 5.19.0-1022-aws x86_64 GNU/Linux
Current Time      : Mar 31 2023 at 18:51:29
PreProcessing  Compatible Version: Gmsh 3.0.6
PreProcessing  Compatible Version: Real-ESSI-gmESSI Date: Oct 2020.
PostProcessing Compatible Version: ParaView 5.11.0
PostProcessing Compatible Version: Real-ESSI-pvESSI Date: Mar 2022.
Days: 59 / 730 / 823
For more information, see  :                http://real-essi.info/

Static startup tips:
 * Remember: Every command ends with a semicolon ';'.
 * Type 'quit;' or 'exit;' or 'bye;' or 'zdravo;' or
 * 'voljno;' or 'zaijian;' or 'tschuess;' or 'geia-sou;' or
 * 'tchaus' or 'sair' or 'khoda-hafez' or 'doei'
 * to finish.
 * Run 'essi -h' to see available command line options.

Including: "main.fei"

Model name is being set to "Ventura_Hotel"
Including: "Nodes.fei"

Done including: "Nodes.fei" (83577 lines included).
Continuing with "main.fei" at line 7.

Including: "Elements.fei"

Done including: "Elements.fei" (88745 lines included).
Continuing with "main.fei" at line 64.

Including: "Contact_Elements_Bonded.fei"

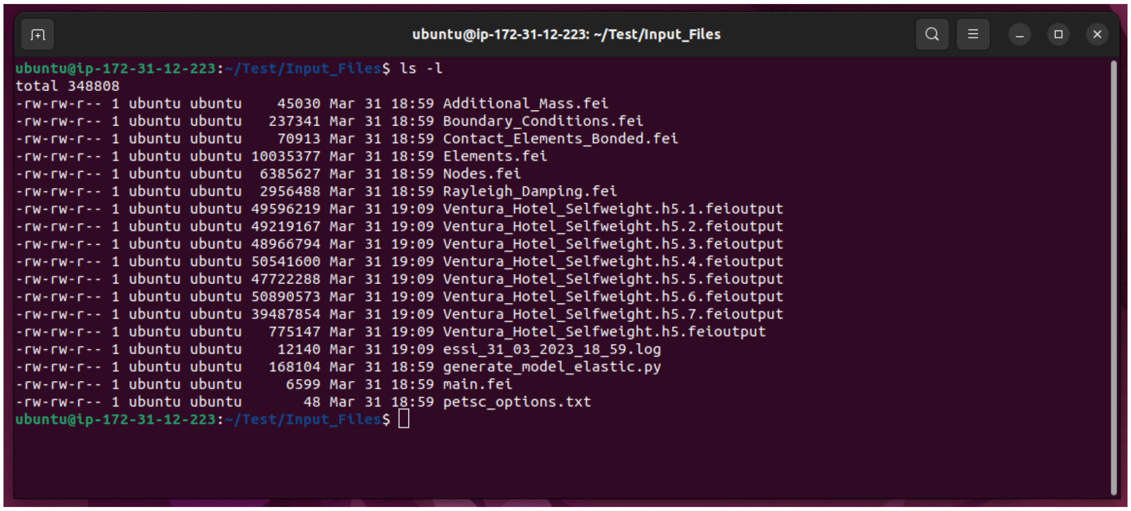
Done including: "Contact_Elements_Bonded.fei" (683 lines included).
```

Now you just need to wait for the simulation to finish.

- Once the simulation is finished, you can use the following command to list all the files in your current directory:

```
ls -l
```

You should see something like the following:



```
ubuntu@ip-172-31-12-223:~/Test/Input_Files$ ls -l
total 348808
-rw-rw-r-- 1 ubuntu ubuntu    45030 Mar 31 18:59 Additional_Mass.fei

ubuntu@ip-172-31-12-223:~/Test/Input_Files$ 
```

Notice that all the output files and a log file are now present in your working directory. Note that all Real-ESSI output files have the suffix .feioutput. For more information, refer to the Real-ESSI Simulator Output Format Manual.

9. Transfer Output Files to Local Desktop (or Amazon Workspace)

This chapter provides information about how to transfer the output files of your Real-ESSI simulation back to your local desktop (or Amazon Workspace). Note that you should only attempt to do this after your simulation has finished.

The **scp** command is used to transfer the output files from the launched Real-ESSI instance to your local Ubuntu desktop (or Amazon Workspace).

- Open a terminal on your local Ubuntu desktop (or Amazon Workspace).
- In the following example, the name of the private key file is key-name.pem and the IPv4 address of the instance is IPv4-address. Enter the following command in your terminal.

```
scp -i /path1/key-name.pem ubuntu@IPv4-address:/path2/*.feioutput /path3/
```

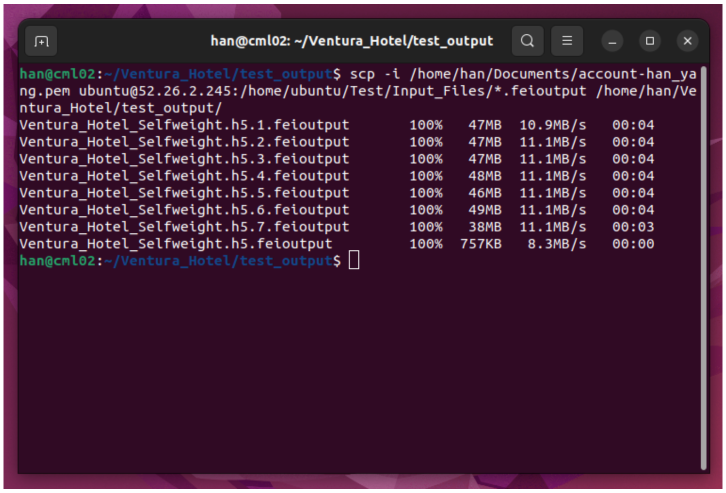
There are three paths in this command.
➢ Replace /path1/ with the full absolute path to your key pair on your local desktop.
➢ Replace /path2/ with the full absolute path to the location on the Real-ESSI instance.
➢ Replace /path3/ with the full absolute path to the location on your local desktop.

Note that the format *.feioutput means that the scp command will be executed for all the files with the suffix .feioutput. This is useful since you will have multiple output files that need to be transferred.

For example, your **scp** command may be:

```
scp -i /home/han/Documents/han-key.pem
ubuntu@52.26.2.245:/home/ubuntu/Test/*.feioutput /home/han/output/
```

- If the transfer is successful, you should see something like the following:



```
han@cml02:~/Ventura_Hotel/test_output$ scp -i /home/han/Documents/account-han_ya
ng.pem ubuntu@52.26.2.245:/home/ubuntu/Test/Input_Files/*.feioutput /home/han/Ve
ntura_Hotel/test_output/
Ventura_Hotel_Selfweight.h5.1.feioutput       100%   47MB  10.9MB/s   00:04
Ventura_Hotel_Selfweight.h5.2.feioutput       100%   47MB  11.1MB/s   00:04
Ventura_Hotel_Selfweight.h5.3.feioutput       100%   47MB  11.1MB/s   00:04
Ventura_Hotel_Selfweight.h5.4.feioutput       100%   48MB  11.1MB/s   00:04
Ventura_Hotel_Selfweight.h5.5.feioutput       100%   46MB  11.1MB/s   00:04
Ventura_Hotel_Selfweight.h5.6.feioutput       100%   49MB  11.1MB/s   00:04
Ventura_Hotel_Selfweight.h5.7.feioutput       100%   38MB  11.1MB/s   00:03
Ventura_Hotel_Selfweight.h5.feioutput         100%  757KB   8.3MB/s   00:00
han@cml02:~/Ventura_Hotel/test_output$ 
```

- Now that you have all the output files on your local Ubuntu desktop (or Amazon Workspace), you can proceed to work with them as you wish, e.g. post-processing. For more information on what you can do with your output files, refer to the Real-ESSI Simulator Post-Processing Manual.

211.8.3 AWS for Education

Amazon Web Services provides grants for educators and students from member institution[2] through AWS Educate program. AWS Educate offers cloud content, training, collaboration tools and AWS technology at no cost. Some of the AWS Educate program benefits:

- For Educators
  - $200 in AWS credits per educator - at member institutions.
  - $75 in AWS credits per educator - at non-member institutions.
  - Free AWS Technical Essentials eLearning course.
  - Free access to AWS content for classes.
- For Students
  - $100 in AWS credits per student - at member institutions.
  - $40 in AWS credits per student - at non-member institutions.
  - Access to AWS Technical Essentials Training Course (a $600 value).

If you have an email address from an educational institutions, you can use Real-ESSI on AWS for free through AWS Educate.

---

[2] List of member institution is available at this LINK.

211.8.4 AWS for Government

211.8.4.1 AWS GovCloud

211.8.4.2 AWS Secret Region

Chapter 212

Hardware Platform Design and Development

(1996-1999-2009-2011-)

212.1 Chapter Summary and Highlights

212.2 Introduction

Parallel computer used for simulations is based on a Beowulf concept (Sterling et al., 1995; Reschke et al., 1996; Sterling et al., 1998, 1999; Warren et al., 1998; Ridge et al., 1997). Hardware for a specific application to parallel computing for elastic-plastic finite elements has gone through a number of iterations (Jeremić et al., 1998, 1999) and is still evolving as the hardware components change in time and as our algorithms change/improve.

The choice of hardware platform is for a cost effective, off the shelf PC components, with about 2GB of memory per CPU/core and plenty of disk space (about 4TB for large dynamic runs). Linux is chosen as an operating system as it offers the best performance, is available in open source, which ensures that significant number of developers can contribute their expertise and can be customized to suite the needs of a parallel hardware and software. Microsoft Windows or Apple IOS operating systems are not best suited for parallel computing as their main development goal is user friendliness and not efficiency.

212.3 The NRC ESSI Computer

212.3.1 Version: December 2010

Operating System: Linux Fedora Core 14.

Kernel: `2.6.35.10-74.fc14.x86_64`

Compute Nodes (two):

- CPU: 2 × Intel Xeon E5620 Westmere 2.4 GHz Quad Core (8 threads) 32nm CPU with 256 KB Cache/core and 12MB Shared L3, DDR3-1066, 5.86GT/sec QPI, 80W
- RAM: 6 × 4GB DDR3 1333 MHz ECC/Registered Memory (24GB Total Memory 1066MHz)
- Disk: 8 × 500 GB Seagate Constellation ES 3.5" SATA/300 ST3500514NS 32MB Cache, 3Gb/s, NCQ, 7200RPM, 1.2 million hours MTBF Maximum Sustained Transfer Rate: 140 MB/sec (Linux Software RAID10)

Network: single GigaBit

212.3.2 Version: April 2012

In addition to the previous version.

Operating System:

Kernel:

Controller Node 1 (one):

- CPU: 2 x Opteron 6234 (2.4GHz, 12-Core, G34, 16MB L3 Cache) 115W TDP, 32nm
- RAM: 32GB (8 x 4GB) Operating at 1333MHz Max (DDR3-1333 ECC Registered DIMMs)
- NICs: Integrated Intel 82576 Dual-Port Gigabit Ethernet Controller
- Disk: 8 × 2TB Toshiba MK2002TSKB (3Gb/s, 7.2K RPM, 64MB Cache) 3.5" SATA

Compute Nodes, 8 (eight):

- CPU: 2 × Opteron 6234 (2.4GHz, 12-Core, G34, 16MB L3 Cache) 115W TDP, 32nm
- RAM: 32GB (8 x 4GB) Operating at 1333MHz Max (DDR3-1333 ECC Registered DIMMs)
- NICs:
  - Intel 82576 Dual-Port Gigabit Ethernet Controller
  - InfiniBand: ConnectX-2 QDR IB 40Gb/s Controller with QSFP Connector
- Disk: 1TB Toshiba MK1002TSKB (3Gb/s, 7.2K RPM, 64MB Cache) 3.5" SATA

Network (dual):

- HP ProCurve Switch 1810-48G 48 Port 10/100/1000 ports Web Managed Switch
- IB Switch: Mellanox MIS5030Q-1SFCA 36-port QDR switch; Cables: 9 x 3mtr QSFP-QSFP - Rating: QDR

Part 300

Verification and Validation

Chapter 301

Verification and Validation Introduction

(2003-2007-2009-2017-)

301.1 Chapter Summary and Highlights

301.2 Important Literature

301.3 Verification and Validation

301.3.1 Definitions

Some definitions, as seen in ASME-VV-10 (2019).

Code is a computer implementation of the algorithm developed to facilitate formulation and approximations, approximate solutions a physical problem.

Model is a representation of a system, in our case a soil and/or structure with all the loads. physical conditions. Representation includes conceptual mathematical and computational models can also include physical

Verification and validation terms revision have been used interchangeably. However, it's important to follow precise definitions:

verification has to do with mathematics

validation has to do with physics

Objectives The objective of the verification and validation are

- demonstrate credibility of simulation results
- assess reliability of computer software and numerical methods used in simulation, and to
- assess the accuracy of simulations, with respect to available experimental observations.

- How do we use experimental simulations to develop and improve models
- How much can (should) we trust model implementations (verification)
- How much can (should) we trust numerical simulations (validation)

301.3.2 Trusting Simulation Tools

- Verification: The process of determining that a model implementation accurately represents the developer's conceptual description and specification. Mathematics issue. *Verification provides evidence that the model is solved correctly.*
- Validation: The process of determining the degree to which a model is accurate representation of the real world from the perspective of the intended uses of the model. Physics issue. *Validation provides evidence that the correct model is solved.*

301.3.3 Importance of V & V

- V & V procedures are the primary means of assessing accuracy in modeling and computational simulations
- V & V procedures are the tools with which we build confidence and credibility in modeling and computational simulations

301.3.4 Maturity of Computational Simulations

NRC committee (1986) identified stages of maturity in CFD

- Stage 1: Developing enabling technologies (scientific papers published)
- Stage 2: Demonstration of and Confidence in technologies and tools (capabilities and limitations of technology understood)
- Stage 3: Compilation of technologies and tools (capabilities and limitations of technology understood)
- Stage 4: Spreading of the effective use (changes the engineering process, value exceeds expectations)
- Stage 5: Mature capabilities (fully dependable, cost effective design applications)

301.3.5 Role of Verification and Validation

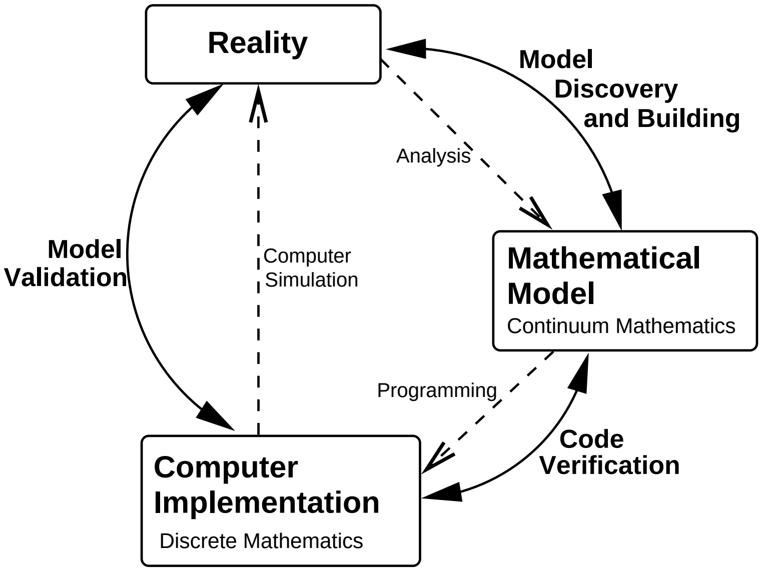

Figure 301.1: Role of Verification and Validation per Oberkampf et al. (2002).

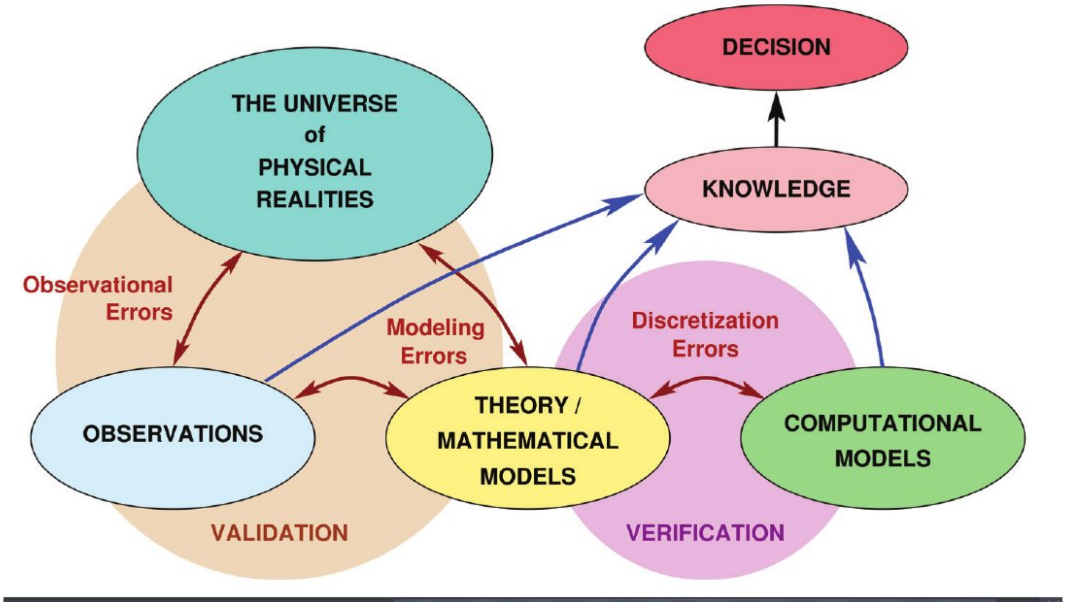

Figure 301.2: Role of Verification and Validation per Oden et al. (2010a).

301.3.5.1 Alternative V & V Definitions

IEEE V & V definitions (1984):

- Verification: The process of determining whether the products of a given phase of the software development cycle fulfill the requirements established during the previous phase
- Validation: The process of evaluating software at the end of the software development process to ensure compliance with software requirements.
- Other organization have similar definitions:
    - Software quality assurance community
    - American Nuclear Society (safety analysis of commercial nuclear reactors)
    - International Organization for Standardization (ISO)

301.3.5.2 Certification and Accreditation

- Certification: A written guarantee that a system or component complies with its specified requirements and is acceptable for operational use (IEEE (1990)).
    - Written guarantee can be issued by anyone (code developer, code user, independent code evaluator)
    - Code certification is more formal than verification and validation documentation
- Accreditation: The official certification that a model or simulation is acceptable for use for a specific purpose (DOD/DMSO (1994))
    - Only officially designated entities can accredit
    - Normally appointed by the customers/users of the code or legal authority
    - Appropriate for major liability or public safety applications

301.3.5.3 Independence of Computational Confidence Assessment

1. V&V conducted by the computational tool developer; *No Independence*
2. V&V conducted by a user from same organization
3. V&V conducted by a computational tool evaluator contracted by developer's organization
4. V&V conducted by a computational tool evaluator contracted by the customer

5. V&V conducted by a computational tool evaluator contracted by the a legal authority; *High Independence*

301.3.6 Simulation-Informed Decision Making

Based on Oberkampf and Pilch (2017)...

301.3.6.1 Purpose of Modeling and Simulation

Decision process:

- Low risk decisions: Simulation-based
- High risk decisions: computer simulations together with testing, Simulation-informed decisions process when simulation is integrated

Computer simulation is an Information Product:

- Supports a decision-making process
- Provides an improved understanding of the uncertainties and risk sustained by the use of the simulation results, a Simulation Customer.

Computer simulations are used to explore the

- design space
- use-misuse space

of a systems where physical testing is impractical and unaffordable...
What if studies over operating environment.
Operating environment:

- Normal
- Accident
- Misuse

301.3.7 Decision Making by Industry and by Regulatory Authorities

Based on NAFEMS short course on Credibility and Decision Making, June 2021, online...

Oberkampf...

Industry decision process to achieve decision result:

- return of investment, profit margin
- organizational goals
- competition
- personal goals
- organizational/personal value system
- experience with available options
- risk tolerance vs potential reward
- familiarity with information sources
- reliability of information sources

Regulatory Authority decision making:

- Risk to public
- Risk to environmental safety
- loss of political support for your regulatory function
- very risk averse value system

Information sources for decision support

- Previous experience with
  - Similar system of process, for example operating and reliability history
  - Modeling and simulation information, for example good and bad experiences
- Experimental data from testing prototype systems and subsystems
  - testing over portion of the operating envelope (application domain)

  - limited testing in adverse/abnormal environments, hazard loads...
  - limited testing of failure modes

- Credibility of modeling and simulation information depends on THREE elements:
  1. Suitable Training and Experienced personnel (example Sandia NL Fracture challenge (Boyce et al., 2014)), is a necessary element but not sufficient
  2. Quality Control of Modeling and Simulation Process, to achieve SIMUALTION CREDIBILITY
     - Physics modeling fidelity (geometric fidelity, spatial scales, temporal scales, initial conditions, boundary conditions, matgerial characteristics)
     - Verification activities (software quality assurance, static testing, dynamic testing, traditional analytic solutions, manufactured solutions, order of accuracy assessment)
     - Validation activities (validation experiments, hierarchical experiments, validation simulations, validation metrics, spatial discretization error, temporal discretization)
     - Uncertainty quantification (parametric uncertainty, model-form (modeling/epistemic) uncertainty, normal environments, abnormal environments, hostile environments, sensitivity analysis, extrapolation uncertainty)
  3. Assessment of Maturity of Modeling and Simulation (M&S) Results
     - Improved clarity of credibility in M&S results
       - Explicit statement of assumptions
       - Explicit statement of approximations
       - Explicit statement of limitations of simulation
       - Explicit statement of restrictions of simulation
       - Use of blind prediction of experimental tests
       - Use of uncertainty quantification of results
     - Use of M&S maturity assessment techniques
       - Predictive Capability Maturity Model (PCMM)
       - NASA standard for M&S (NASA, 2008, 2016)
       - ASME VVUQ techniques (ASME-VV-10, 2019; ASME-VV-40, 2018)

Responsibility for VVUQ

- Software Developer

  - Software quality assurance, bug fixes
  - Testing on different hardware and OS platforms
  - Code verification (determination of observed order of convergence)
  - Solution verification tools to estimate numerical solution errors
  - Model validation
  - Documentation of all components, models, algorithms, API, V&V, examples
  - Reproducibility of the simulation

- Simulation Producer, Analyst
  - Solution verification
  - Model parameter calibration using experimental data
  - Model validation, together with experimentalistis
  - Probabilistic simulation and uncertainty quantification
  - Software quality assurance
  - Code verification, in particular coverafe of features used
  - Documentation of simulation
  - Reproducibility of the simulation

- Simulation, Analysis Manager
  - Specifying how will simulation be used
  - Specifying what is the purpose of simulation to be used
  - Developing quality requirements for simulation
  - Developing review requirements for simulation
  - Assure, allocate adequate resources for the simulation
  - Assure, allocate adequate time for the simulation
  - Define documentation requirements for simulations
  - Define documentation requirements for experiments
  - Document in detail assumption, approximations and limitations of the simulation
  - Ensure training for analysis, modeling and simulation, personnel
  - Ensure expertise level of analysis, modeling and simulation, personnel

- Simulation Customer
  - Specifying what is the purpose of simulation to be used
  - Developing quality requirements for simulation
  - Developing review requirements for simulation
  - Allocate adequate resources for analyzing simulation results
  - Define documentation requirements for simulations
  - Ensure understanding of assumption, approximations and limitations of the simulation
  - Ensure expertise level of analysis users

Simulation Credibility Versus Risk, a Trade

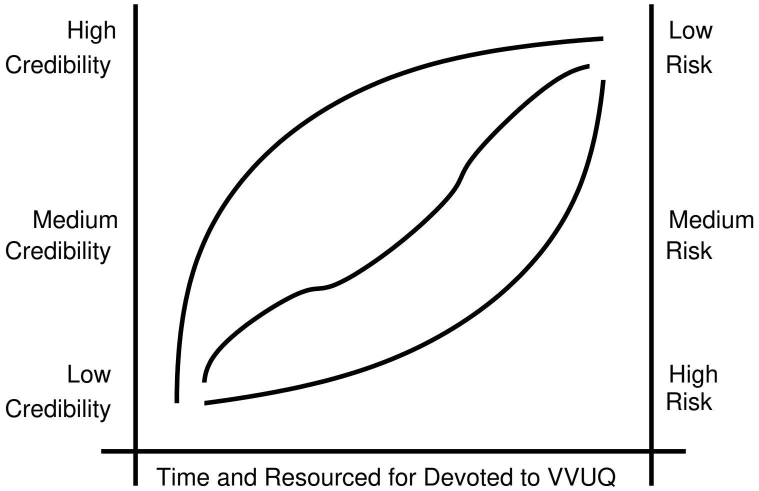

Figure 301.3: Simulation credibility versus risk, a trade that must be observed (Oberkampf...)

What one can find Under the Simulation Hood can be Surprising.

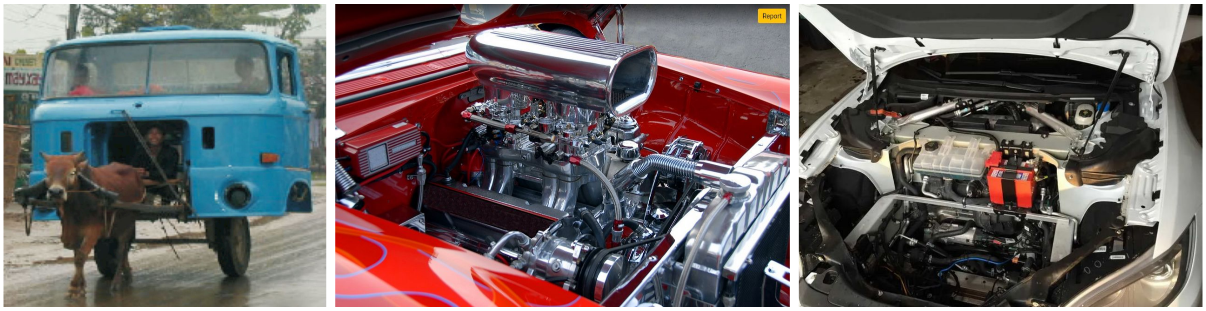

Figure 301.4: Under the Simulation Hood...

Simulation is not a magic bullet!

Simulation is Fragile!

301.3.8 Simulation Governance

Based on Szabó and Actis (2011, 2012)

Simulation Governance (SG) is needed to address prediction challenges in engineering practice. SG is a process to rank analysis models and to improve them over time with new experimental data. Control of numerical and modeling error is essential! Performance, relative and absolute, of analysis models is objectively evaluated.

301.3.8.1 Modeling, Experimental, Analytic and Numerical

Based on Szabó and Actis (2011, 2012)

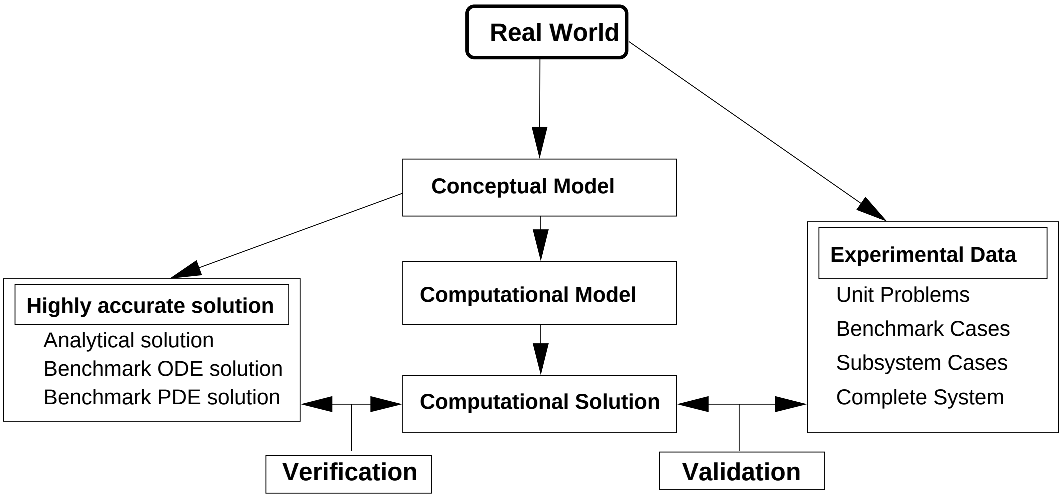
- Model is a transformation of data D that describes physical reality, into the data of interest F, results
- Data D includes all geometrical information, material information, calibration data and loading information...
- Data D features many uncertainties
- These uncertainties are transferred into corresponding uncertainties in F

- Transformation, D → F consists of operations that include modeling and simulation of mathematical problems, mechanics problems, statistical problems,
- Epistemic, parametric and aleatory, modeling uncertainties are mixed
- Simulation governance is set to minimize, control epistemic, modeling uncertainties,

Choice of mathematical model.

- Choice of mathematical model involves simplifying assumptions that restrict the scope of applicability of the model
- Are these simplifying assumptions justified for a particular application?
- This question can be addressed by performing virtual experiments
- Virtual experiments, sensitivity studies to determine if simplifying, restrictive modeling assumptions affect the date of interest to a significant degree
- Using virtual experiments Analyst, engineer can make informed decisions regarding the choice of modeling level of sophistication
- Software for virtual experiments should be able to analyze mathematical problem independent of choice of discretization
- For fixed discretization, one should be able to choose alternative mathematical model and investigate modeling change on the data of interest, results
- Similarly, for fixed mathematical problems, one should be able to develop a sequence of models that data of interest, results converge to their exact values...

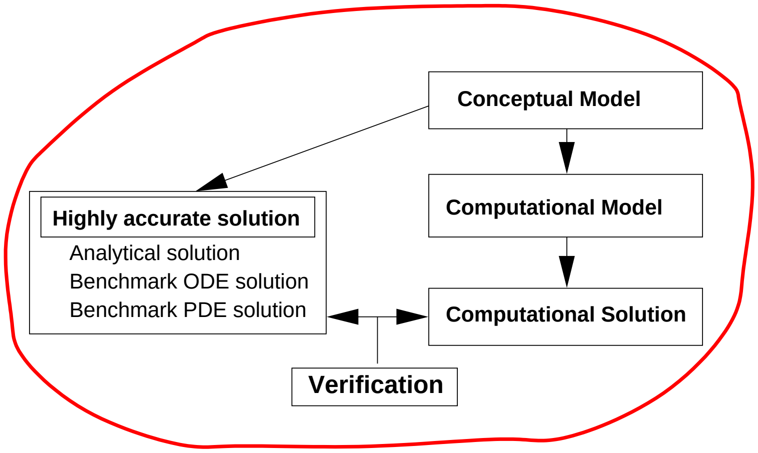
301.3.9 Detailed Look at Verification and Validation



301.3.9.1 On Verification

Verification: The process of determining that a model implementation accurately represents the developer's conceptual description and specification.

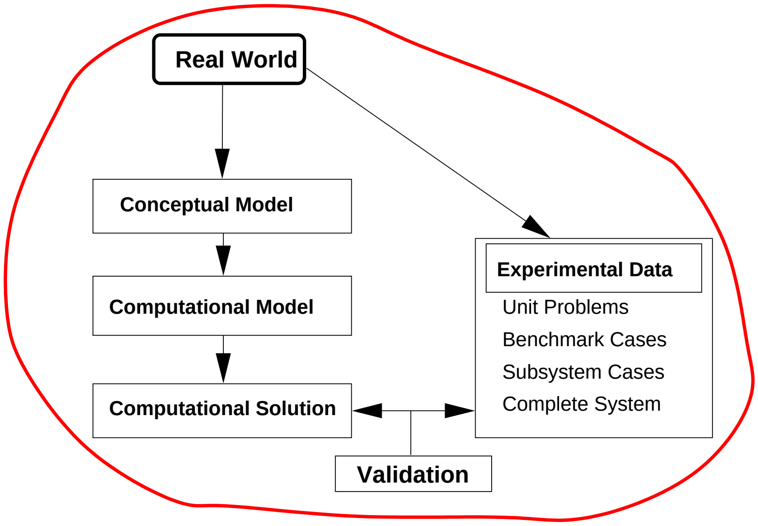
- Identify and remove errors in computer coding
  - Numerical algorithm verification
  - Software quality assurance practice
- Quantification of the numerical errors in computed solution



301.3.9.2 On Validation

Validation: The process of determining the degree to which a model is accurate representation of the real world from the perspective of the intended uses of the model.

- Tactical goal: Identification and minimization of uncertainties and errors in the computational model
- Strategic goal: Increase confidence in the quantitative predictive capability of the computational model



Goals of Validation Quantification of uncertainties and errors in the computational model and the experimental measurements

- Goals on validation
  - Tactical goal: Identification and minimization of uncertainties and errors in the computational model
  - Strategic goal: Increase confidence in the quantitative predictive capability of the computational model
- Strategy is to reduce as much as possible the following:
  - Computational model uncertainties and errors
  - Random (precision) errors and bias (systematic) errors in the experiments
  - Incomplete physical characterization of the experiment

Validation Procedure Uncertainty

- Aleatory uncertainty → inherent variation associated with the physical system of the environment (variation in external excitation, material properties...). Also know known as irreducible uncertainty, variability and stochastic uncertainty.
- Epistemic uncertainty → potential deficiency in any phase of the modeling process that is due to lack of knowledge (poor understanding of mechanics...). Also known as reducible uncertainty, model form uncertainty and subjective uncertainty

Types of Physical Experiments

- Traditional Experiments
  - Improve the fundamental understanding of physics involved
  - Improve the mathematical models for physical phenomena
  - Assess component performance
- Validation Experiments
  - Model validation experiments
  - Designed and executed to quantitatively estimate mathematical model's ability to simulate well defined physical behavior
  - The simulation tool (SimTool) (conceptual model, computational model, computational solution) is the customer

Validation Experiments

- A validation experiment should be jointly designed and executed by experimentalist and computationalist
  - Need for close working relationship from inception to documentation
  - Elimination of typical competition between each
  - Complete honesty concerning strengths and weaknesses of both experimental and computational simulations
- A validation Experiment should be designed to capture the relevant physics
  - Measure all important modeling data in the experiment

  - Characteristics and imperfections of the experimental facility should be included in the model

- A validation experiment should use any possible synergism between experiment and computational approaches
  - Offset strength and weaknesses of computations and experiments
  - Use high confidence simulations for simple physics to calibrate of improve the characterization of the experimental facility
  - Conduct experiments with a hierarchy of physics complexity to determine where the computational simulation breaks (remember, SimTool is the customer!)

- Maintain independence between computational and experimental results
  - Blind comparison, the computational simulations should be predictions
  - Neither side is allowed to use fudge factors, parameters

- Validate experiments on unit level problems, hierarchy of experimental measurements should be made which present an increasing range of computational difficulty
  - Use of qualitative data (e.g. visualization) and quantitative data
  - Computational data should be processed to match the experimental measurement techniques

- Experimental uncertainty analysis should be developed and employed
  - Distinguish and quantify random and correlated bias errors
  - Use symmetry arguments and statistical methods to identify correlated bias errors
  - Make uncertainty estimates on input quantities needed by the SimTool

301.4 Prediction

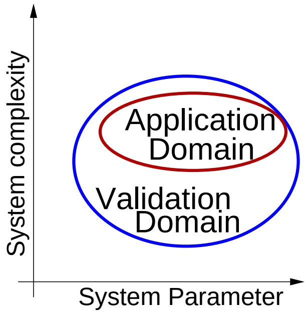
- Prediction: use of computational model to foretell the state of a physical system under consideration under conditions for which the computational model has not been validated
- Validation does not directly make a claim about the accuracy of a prediction
  - Computational models are easily misused (unintentionally or intentionally)
  - How closely related are the conditions of the prediction and specific cases in validation database
  - How well is physics of the problem understood

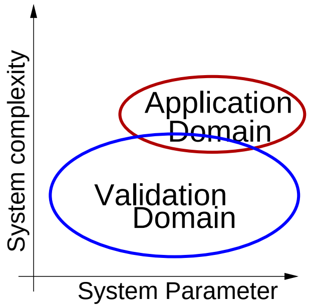
301.4.1 Relation Between Validation and Prediction

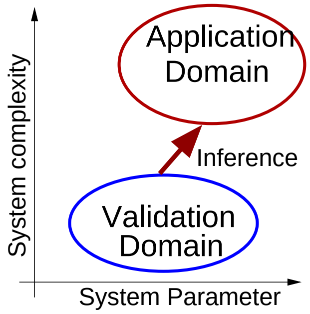
Quantification of confidence in a prediction:

- How do I quantify validation and its inference value in a predictions?
- How do I quantify verification and its inference value in a prediction?
- How far are individual experiments in my validation database from my physical system of interest?

301.5 Application Domain







- Rarely applicable to engineering systems (certainly not for infrastructure objects like bridges, buildings, port facilities, dams...)
- Even if the engineering system is small, environmental influences (generalized loads, conditions, wear and tare) are hard to predict
- Human factors (take Mars rover example with a memory overflow, operator forgot to flush the memory...)
- Inference ⇒ Based on physics or statistics
- Validation domain is actually an aggregation of tests and thus might not be convex (bifurcation of behavior)
- Experimental facilities provide validation domain that is (for the most part) exclusively non–overlapping with the application domain.

301.5.1 Importance of Models and Numerical Simulations

- Verified and Validated models can be used for assessing behavior of
  - components or
  - complete systems,
- with the understanding that the environmental influences cannot all be taken into the account prior to operation
- but with a good model, their influence on system behavior can be assessed as need be (before or after the event)

301.5.2 Prediction under Uncertainty

- Ever present uncertainty needs to be estimated for predictions
- Identify all relevant sources of uncertainty
- Create mathematical representation of individual sources
- Propagate representation of sources through modeling and simulation process (Probabilistic Elastic Plastic Theory)

301.6 Intended use of Model

(ASME-VV-10, 2019), from Executive Summary, section 1

Verification assess the numerical accuracy of a computational model regardless of the physics being modeled.

- Code verification, addressing errors in the software and numerical algorithms
- Calculation verification, estimating numerical error due to under-resolved discrete representation of the mathematical model

Validation assess the degree to which the computational model is an accurate representation of the physics being modeled.

301.6.1 System Being Modeled

Relevant Physics

Modeling and experimental activities are guided by response quantities of interest.

301.6.2 Simulation Governance

Chapter 303

Code Stability Verification

(2002-2016-2017-2019-2021-)

(In collaboration with Dr. Yuan Feng and Prof. Han Yang)

303.1 Chapter Summary and Highlights

303.2 Introduction to Code Stability

This activity addresses source code stability. Source code verification is addressed elsewhere.

303.3 Motivation

In the software development process, Real-ESSI program is a framework and new features are continuously added. From time to time, some revisions for one feature may affect the normal operation of other existing components, like a specific element or material. To guarantee the stability and correctness of Real-ESSI program for each update. A group of test cases are collected in an automatic test suite. Then, after each revision, the developers are required to successfully pass all the test cases before the revisions are finally accepted to the trunk branch.

The features of the automatic Real-ESSI test is listed below:

- Automatic comparison of the maximum displacement output between the original and the new ESSI results.
- Automatic comparison of all the displacement and stress/strain output between the original and the new ESSI results.
- Automatic comparison of the terminal output/log between the original and the new ESSI results.
- Relative difference between the original and the new ESSI results.
- Colorful diagnostic information in the terminal.
- Support for the report in HTML format.
- Version information of both the original and the new ESSI.
- Number of passed cases and the statistics.

303.4 The framework of the automatic test

In practice, all the test cases are collected in one main folder and each test case has an independent subdirectory. In addition, *Bash* and *Python* are employed go over each leaf directory of the test cases folder to execute essi and compare the results. A verification report is generated automatically after all the test cases are executed.

Regarding the test cases for the version stability, it is not necessary to choose the great model with lots of elements. The goal of version stability is to guarantee that the revision for one feature should not affect the normal operation of other commands. So the selection rule of test cases is to cover as much Real-ESSI DSL (domain specific language) commands as possible.

303.5 Installation and Tutorial

303.5.1 Installation

Makefile, *Bash* and *Python* are used to run all the test cases. So the automatic test is portable over various Linux platform as long as *Makefile*, *Bash* and *Python* are available. Besides, *git* is also required to download the test suite. In addition, if the user wants an additional report in HTML format, another package called *aha* is required. Install *aha* package on Ubuntu by using this command.

The automatic test suite is distributed within Real-ESSI source code.

```
${Real-ESSI}/CompGeoMechUCD_Miscellaneous/examples/
```

Notes: the automatic test will call the executable *essi* in the system/user PATH. So please make sure you have compiled or installed Real-ESSI first and then run this automatic test suite.

303.5.2 Tutorial

303.5.2.1 Run all verification test cases

In order to run all test cases to verify the installation, users can run

```
cd $RealESSI_PATH/
bash run_all_verification_sequential.sh $EXECUTABLE_PATH
bash run_all_verification_parallel.sh $EXECUTABLE_PATH
```

In addition to the conventional "-DDEBUG_MODE=DEBUG or OPTIMIZED", Users are required to do the test for executables compiled using the compiler options "-DDEBUG_MODE=O1 or O2" to fully verify the code. The verification will list all the results and errors. The errors may be big when the mesh is too coarse, or when Poisson's ratio is too high.

Furthermore, if developers want to verify against a previous version, developers can run

```
cd $RealESSI_PATH/
```

```
bash run_code_stability.sh $GitTAG
```

to test the verification results against one previous git version. The script will automatically checkout to the previous git-tag in detached mode and compile the old essi. After running test cases, developers can checkout to the original testing branch by running

```
cd $RealESSI_PATH/
git checkout $TestingBranch
```

In addition, if users want to clean the test results, users can run

```
cd $RealESSI_PATH/
bash clean_all_verification.sh
```

303.5.2.2 Run a single type of verification test cases

The usage of automatic test is written after the build process of source-code in Section 209.7.

For a single type of verification, for instance, in the folder

```
cd $RealESSI_PATH/CompGeoMechUCD_Miscellaneous/examples/analytic_solution
```

there are two clean options available in the main folder.

- The first one is *make clean*. This will only clean the new essi output results, including HDF5 files, terminal logs, and comparison logs.
- The second one is *make cleanall*. This will clean both the new and old essi output results for version stability test.

303.6 The underlying implementation of the automatic test

In most cases, the developers are not required to read and modify the underlying implementation of the automatic test. However, a basic introduction to the underlying implementation will help the future developers to customize the automatic test suite when necessary.

303.6.1 Generate the original results

When the command below is called,

```
bash generate_original.sh
```

Three things will be done. First, *make cleanall* will be called. This means that all the new and original output will be removed. Second, *essi* will be called to run each test cases and to generate the original HDF5 and original terminal output logs. Third, a bash command is employed to rename the HDF5 file and terminal log by adding *original* at the end of the filename.

303.6.2 Run essi and make comparison

When the command below is called,

```
bash make_comparison.sh
```

Four things will be done.

- First, *essi* will be called again to re-run each test cases. Please note that this *essi* should be the newly compiled *essi* in the development and debug stages.
- Second, a python-based comparison function will be called to compare the maximum displacement in the HDF5 output for each test case.
- Third, another python-based comparison function will be called to compare all the displacement and stress/strain results in the HDF5 output for each test case.
- Fourth, the terminal output log will be compared.

303.6.2.1 The terminal output/log comparison

The motivation to compare the terminal output is to avoid the unnecessary debug-purpose messages in the terminal output. During the debug stages, developers usually print out the variable values in the terminal. However, in the production stages, the debug-purpose messages should be disabled.

During the terminal output/log comparison, some lines are always different for each *essi* execution. These lines should be removed from comparison to avoid the false mismatch.

- The first type of different lines are the version information. The *essi* version information includes the *essi* compile time and execution time. They are always different for each execution. Therefore, these lines are extracted and the version information is printed out at the end of the comparison report.
- The second type of different lines are the *ETA* information. *ETA* stands for estimated time of arrival, which is a prediction for the *essi* execution time. However, the *ETA* information is inaccurate and they are different for each execution. Therefore, the *ETA* information is not compared either.

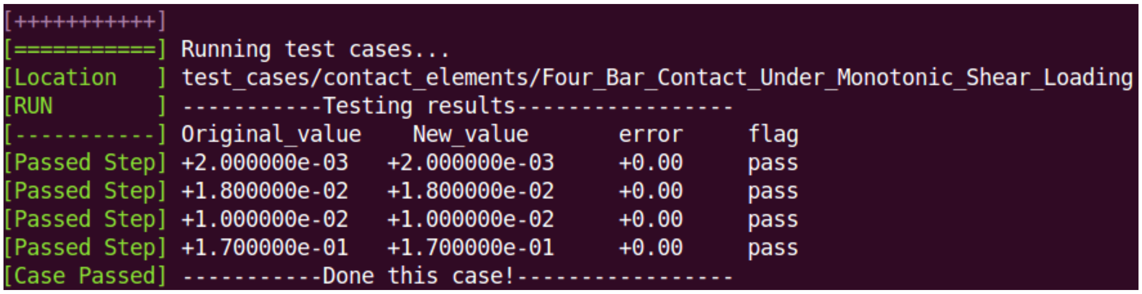
303.6.2.2 Reduce the comparison items and comparison time

During the debug stages, the developers might only want to compare the HDF5 output and the developers want to keep the verbose terminal messages so developers do not want to compare the terminal output log. Besides, during the debug stages, the developers may not want the time-consuming HDF5 output comparison. Therefore, to reduce the comparison items and comparision time, the developers can comment out the last two lines in *make_comparison.sh*.

303.7 Report Sample

For the sake of convenience, automatic test provides colorful diagnostic information. The green color is for the passed (matched) test case, while the red color is for the failed (mismatched) test case. The illustrative results are shown below. In addition, the automatic test also reports the relative path (location) of the test case. So if one of the test cases failed, developers can locate the subdirectory easily and check the mismatched model.

303.7.1 Passed test case



```
[+++++++++++]
[===========] Running test cases...

303.8 Future contribution

The automatic test is a test framework. It is easy to contribute your new test cases to the framework. The newly added test case must meet the following two requirements.

- The test case should be added as an independent leaf subdirectory within the *test_cases* folder.
- The test case should have a *main.fei* as the main model file.

(In collaboration with Dr. Yuan Feng and Prof. Han Yang)

305.1 Chapter Summary and Highlights

305.2 Verification of Constitutive Integration

In this section, the accuracy analysis of the implicit algorithm is assessed. Examples of simple models (von Mises and Drucker-Prager) for accuracy analysis are demonstrated to verify general implicit algorithm. Convergence performance analysis is conducted. More details on accuracy analysis and consistent tangent stiffness are explained. Numerical simulation examples are demonstrated using the implemented framework. Special concerns are on the comparison of experimental data and numerical results of Dafalias-Manzari model.

305.2.1 Error Assessment

There are various error measures for the integration algorithms. Simo and Hughes (1998), Manzari and Prachathananukit (2001) used the relative stress norm by Equation 305.1,

$$\delta^r = \frac{\sqrt{(\sigma_{ij} - \sigma^*_{ij})(\sigma_{ij} - \sigma^*_{ij})}}{\sqrt{\sigma^*_{pq}\sigma^*_{pq}}} \tag{305.1}$$

where σ^*_{ij} is the 'exact' stress solution, and σ_{ij} the calculated stress solution. Alternatively, Jeremić and Sture (1997) used the normalized energy norm by Equation 305.2,

$$\delta^n = \frac{\left\| \sigma_{ij} - \sigma^*_{ij} \right\|}{\left\| p^{unit} \right\|} \tag{305.2}$$

where $\left\|\sigma_{ij}\right\|^2 = \sigma_{ij} D_{ijkl} \sigma_{kl}$, and D_{ijkl} is the elastic compliance fourth-order tensor, p^{unit} is the 'unit' energy norm for normalization.

The relative stress norm by Equation 305.1 is more reasonable since two points having the same $\left\|\sigma_{ij} - \sigma^*_{ij}\right\|$ but different $\sigma^*_{pq}\sigma^*_{pq}$ should have different error measures. However, this norm becomes singular and possible meaningless when $\sigma^*_{pq}\sigma^*_{pq}$ close to zero. The normalized energy norm by Equation 305.2 have no such singularity problem but it may give the same error index for two points having the same $\left\|\sigma_{ij} - \sigma^*_{ij}\right\|$ but different $\sigma^*_{pq}\sigma^*_{pq}$. In this work, we use these two error measure methods, but for simplicity, Equation 305.2 is modified into

$$\delta^r = \frac{\sqrt{(\sigma_{ij} - \sigma^*_{ij})(\sigma_{ij} - \sigma^*_{ij})}}{\sqrt{\sigma^0_{pq}\sigma^0_{pq}}} \tag{305.3}$$

where $\sigma^0_{pq}\sigma^0_{pq}$ is evaluated at some non-zero initial isotropic stress state. That is, the normalized error is evaluated by Equation 305.3, and the relative error is evaluated by Equation 305.1.

In our examples, the initial stress state point is set $p^0 = 100$ kPa, $q^0 = 0$ kPa, $\theta^0 = 0$, which is the σ^0_{pq} in Equation 305.3. The one-step predicted stress state point for the implicit algorithm is within the range of $0.1 \leq p \leq 100$ kPa, $0 \leq q \leq 100$ kPa, $0 \leq \theta \leq \pi/3$. The 'exact' solution is actually unknown for most elastoplastic problems. Here the 'exact' solution is simply replaced by 50 substep solution of the explicit algorithm in the same one-step prediction incremental. All these error evaluations are within the material constitutive level.

The first test examples are von Mises models with the uniaxial yield strength $k = 50$ kPa, with linear elasticity parameters are Young's modulus $E = 1\times10^5$ kPa, and Poisson's ratio $\nu = 0.25$.

Figures 305.1 and 305.2 show the iso-error maps for the von Mises model with linear isotropic hardening. The linear hardening modulus $H = 2\times10^4$ kPa. The blue lines represents the yield surface boundary. It can be seen that the error magnitudes are as small as 10^{-10} to 10^{-9}, which implies that the solutions by implicit algorithm for this linear isotropic hardening von Mises model are numerically accurate.

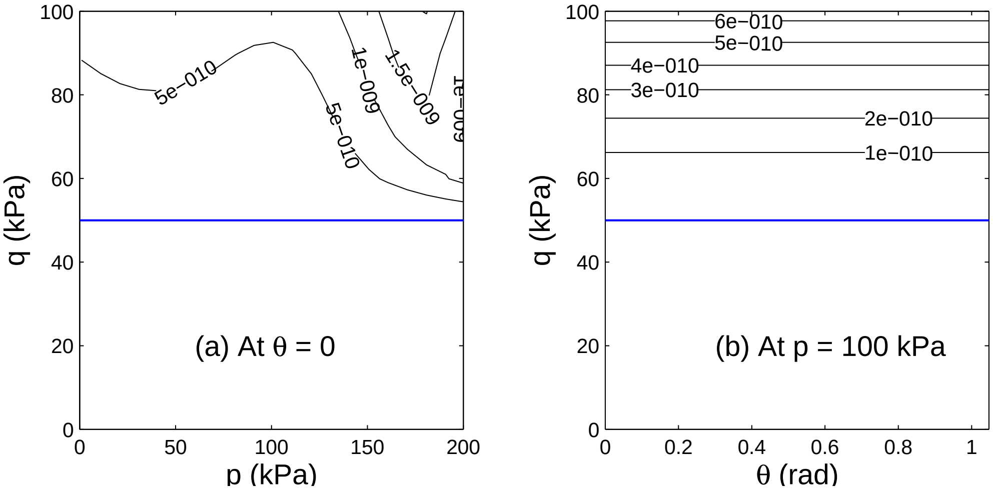

Figure 305.1: Normalized iso-error maps of von Mises model with linear isotropic hardening.

Figures 305.3 and 305.4 show the iso-error maps for the von Mises model with Armstrong-Frederick translational kinematic hardening. The hardening parameters are $h_a = 5\times10^4$ kPa and $C_r = 2.5\times10^3$. It can be seen that errors are very small which proves the good performance of the implicit algorithm. The iso-error map gives a good trend, i.e., the further away from the yield surface, the errors become more pronounced; the normalized errors are pressure-independent, which fits well the feature of von Mises model; the iso-error lines in the $q-\theta$ figure are parallel to the yield surface and are independent of the Lode's angle θ, which again fits well with von Mises model which is only q-related.

The second test examples are Drucker-Prager model with yield surface constant $q/p = 0.8$. Linear

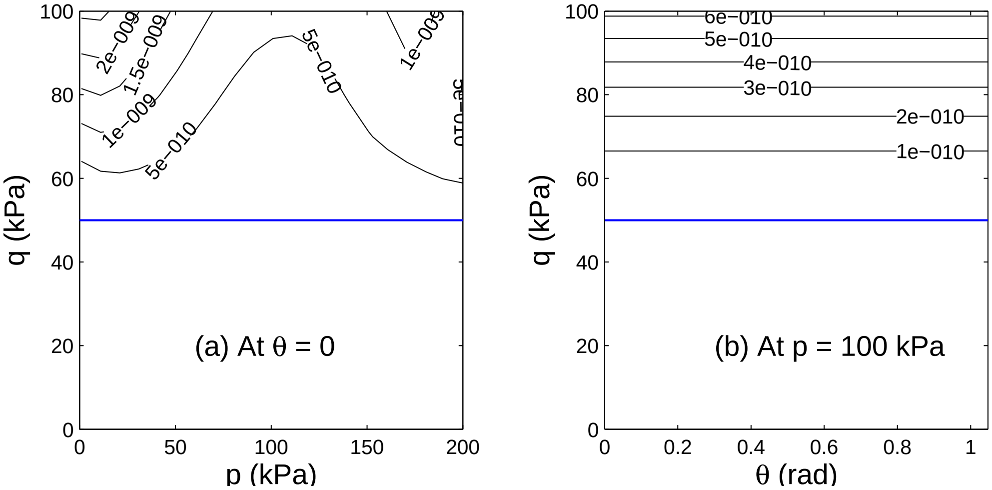

Figure 305.2: Relative iso-error maps of von Mises model with linear isotropic hardening.

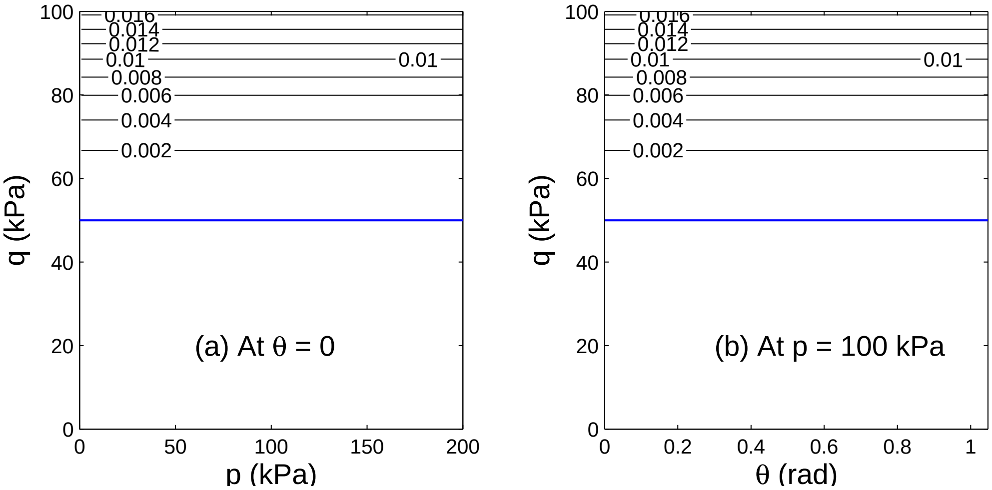

Figure 305.3: Normalized iso-error maps of von Mises model with Armstrong-Frederick kinematic hardening.

elasticity parameters are Young's modulus $E = 1\times10^5$ kPa, and Poisson's ratio $\nu = 0.25$.

The iso-error maps for perfectly plastic Drucker-Prager model are shown in Figures 305.5 and 305.6. The blue lines represents the yield surface boundary. It can be seen that the error magnitudes are as small as 10^{-11} to 10^{-9}. Again, these errors are so small that we can consider that the implicit algorithm give accurate solutions numerically.

Another Drucker-Prager model is with Armstrong-Frederick rotational kinematic hardening, and the parameters are $h_a = 20$, $C_r = 2$. The iso-error maps are shown in Figures 305.7 and 305.8. Unlike

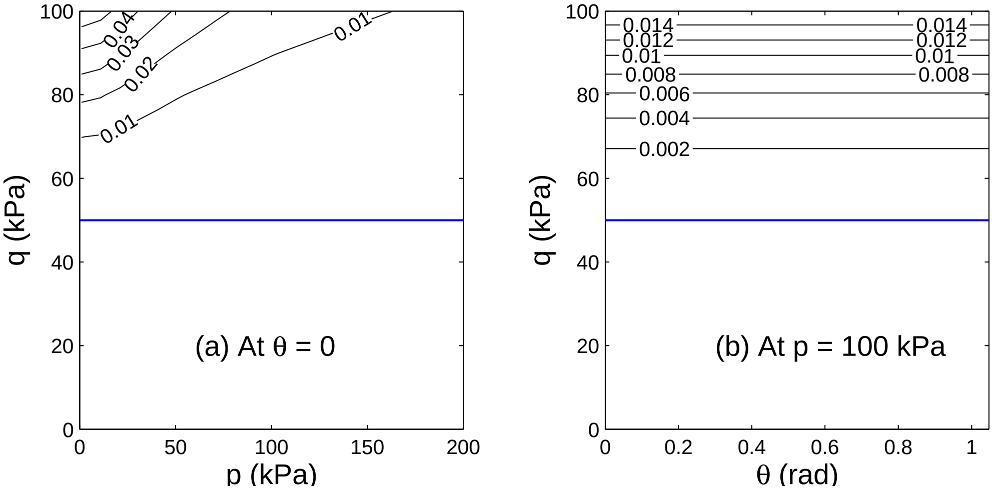

Figure 305.4: Relative iso-error maps of von Mises model with Armstrong-Frederick kinematic hardening.

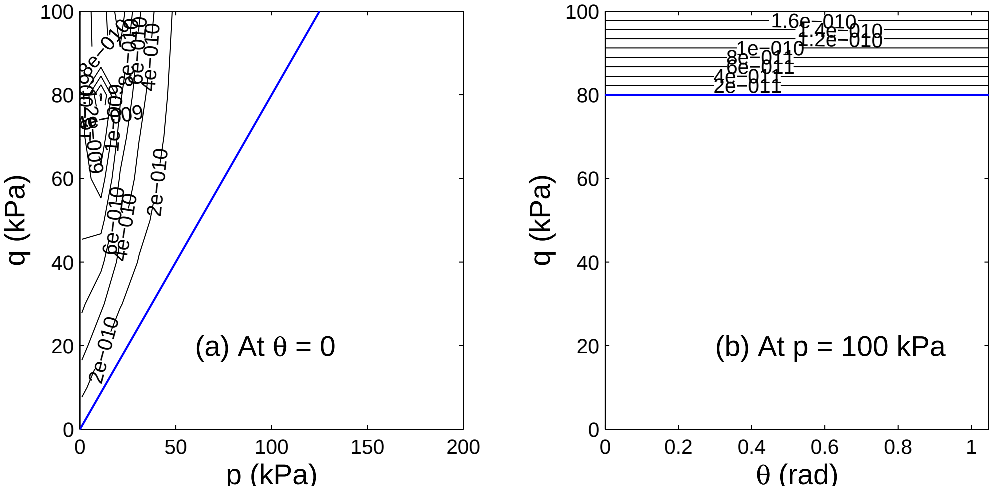

Figure 305.5: Normalized iso-error maps of Drucker-Prager perfectly plastic model.

von Mises model, the normalized errors are pressure-dependent, which fits well the feature of Drucker-Prager model; the iso-error lines in the $q - \theta$ figure are parallel to the yield surface and are independent of the Lode's angle θ, which still fits well with Drucker-Prager model which does not consider the third stress invariant, Lode's angle θ. From the relative iso-error maps in Figure 305.8, very dense iso-error lines are investigated in the region of small pressure, which is evidently due to the cone apex singularity of Drucker-Prager yield surface.

From the error analysis by the above von Mises and Drucker-Prager models, One finds that the implemented implicit algorithm can offer accurate solutions for simple models with simple hardening laws,

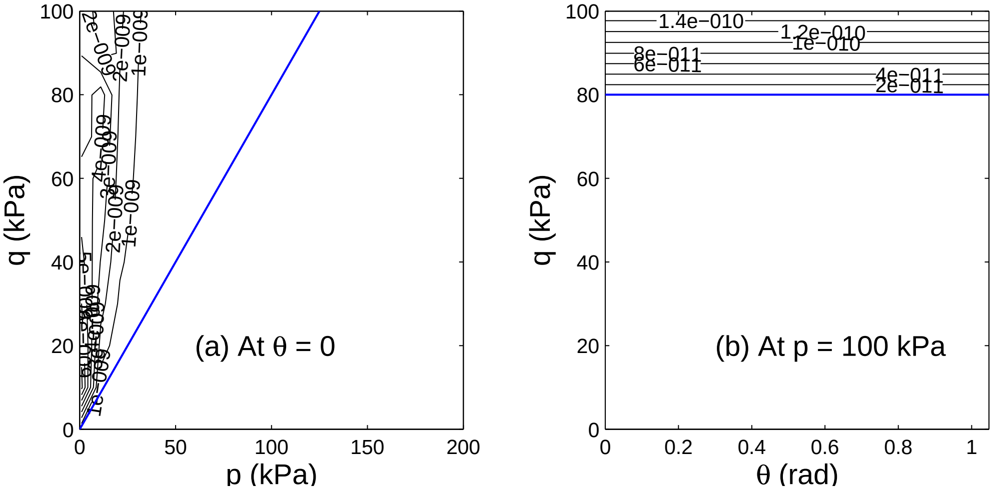

Figure 305.6: Relative iso-error maps of Drucker-Prager perfectly plastic model.

e.g. von Mises model with linear hardening and Drucker-Prager model with perfectly plastic hardening (no hardening). Complicated hardening laws increases the error even for simple plastic models, although the errors are still small. These observations match the well known conclusion that the error of the implicit algorithm is pretty dependent on the smoothness of the solution. The implemented implicit algorithm proves very robust for von Mises and Drucker-Prager model with simple or complicated hardening laws.

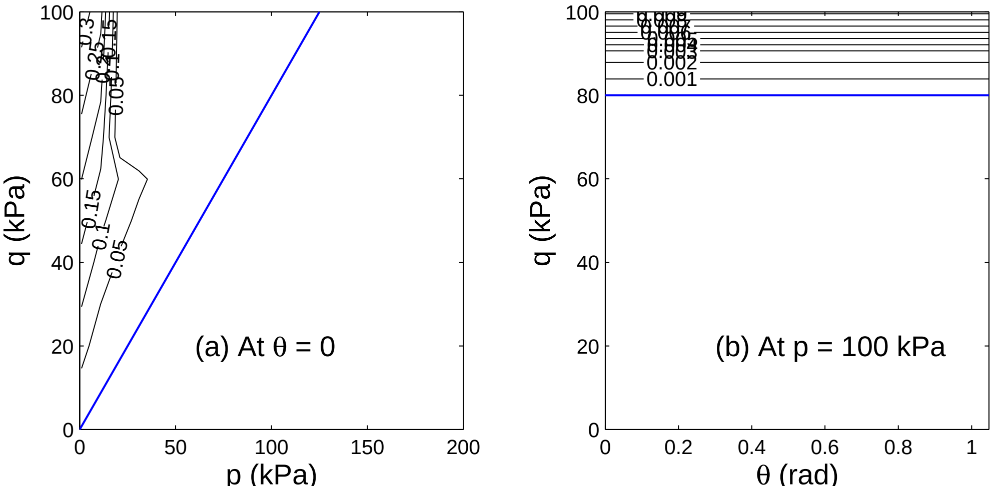

Figure 305.7: Normalized iso-error maps of Drucker-Prager model with Armstrong-Frederick kinematic hardening.

Figures 305.9 and 305.10 present the iso-error maps of Dafalias-Manzari model. The initial void ratio is 0.8, and the other parameters are from Dafalias and Manzari (2004a). The blue lines represents

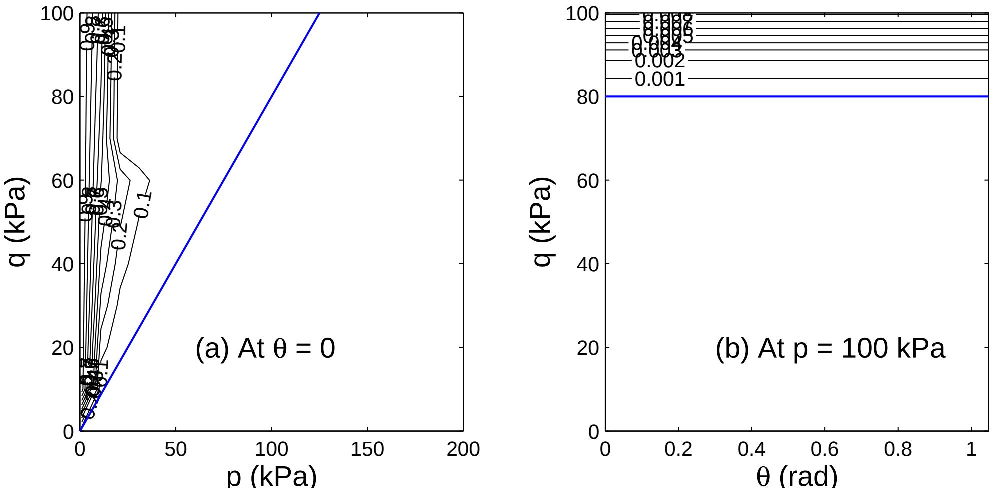

Figure 305.8: Relative iso-error maps of Drucker-Prager model with Armstrong-Frederick kinematic hardening.

the yield surface boundary (slope ratio $m = 0.01$). Unlike von Mises and Drucker-Prager models, the iso-error lines in the $q - \theta$ figure of Dafalias-Manzari model are not parallel to the yield surface and are dependent of the Lode's angle θ, which was one of the highlighting improvements upon the previous version (Manzari and Dafalias, 1997). From Figure 305.10, when the predicted stress q close to 100 kPa, or or about 100 times the yield strain increment, the relative errors can reach up to 100%, which implies that even for implicit algorithm, Dafalias-Manzari model still requires small strain increments. However, when $q < 30$ kPa, or about 30 times of the yield strain increment, the relative errors are less than 5%, excepts at the region close to the yield surface apex.

It should be pointed out that errors for the complex Dafalias-Manzari model are much bigger than those of simple models (e.g. von Mises and Drucker-Prager), due to its high non-linearity. However, if the predicted stress (or in other words, the strain increment) is small enough, the algorithm errors are within a small tolerant range.

Figures 305.9 and 305.10 are based on an approach of averaged elastic moduli. Instead, Figures 305.11 and 305.12 present iso-error maps based on constant elastic moduli approach.

305.2.2 Constitutive Level Convergence

In the implemented implicit algorithm, the iteration continues until the absolute value of yield function and the residue norm of considering variables are less than some small tolerances, or if by equations,

$$|f| \leq Tol1; \quad r_{norm} = \|\mathbf{r}\| \leq Tol2 \tag{305.4}$$

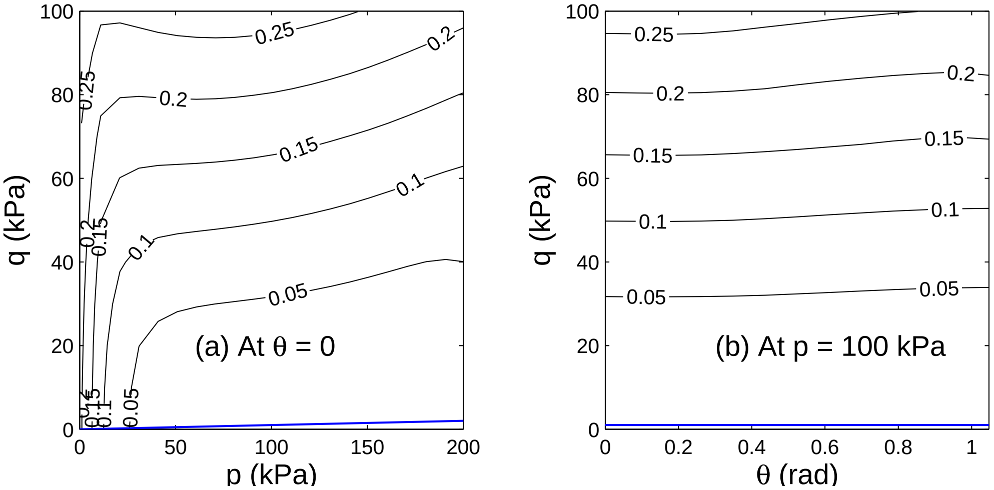

Figure 305.9: Normalized iso-error maps of Dafalias-Manzari model with average elastic moduli.

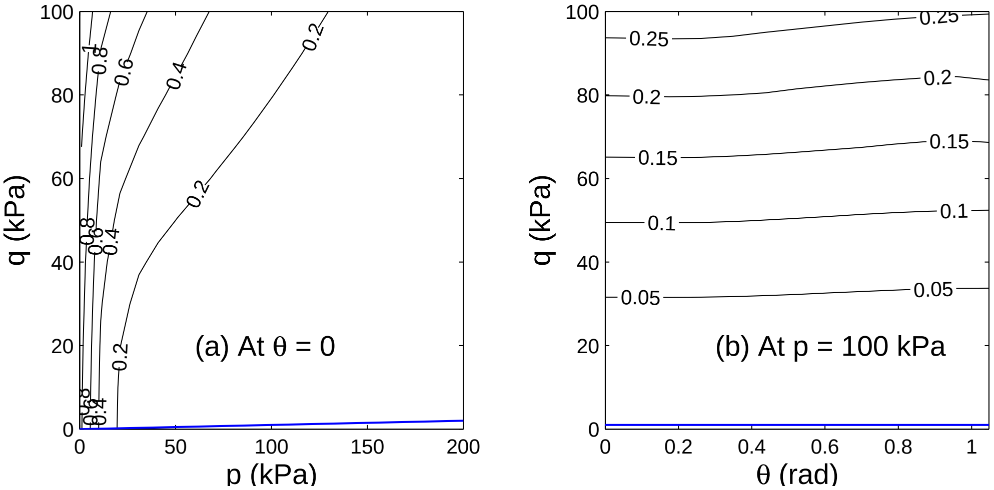

Figure 305.10: Relative iso-error maps of Dafalias-Manzari model with average elastic moduli.

Three examples including simple von Mises model with linear isotropic hardening, relative complicated Drucker-Prager model with Armstrong-Frederick kinematic hardening, and even more complicated Dafalias-Manzari model considering fabric dilation effect are presented here to show the constitutive level convergence performances for the implemented implicit algorithm. In all these examples, both $|f|$ and r_{norm} v.s. iteration numbers are plotted. Iteration number 0 represents the 'virtual' iteration number before return mapping implicit iteration cycle. $|f|$ at iteration number 0 thus means $|f|$ at the first predicted stress for each load increment; there is no value of r_{norm} at iteration number 0. A tolerance of $Tol1 = Tol2 = 1\times10^{-7}$ is for both $|f|$ and r_{norm}. The iteration stops when $|f| \leq Tol1$

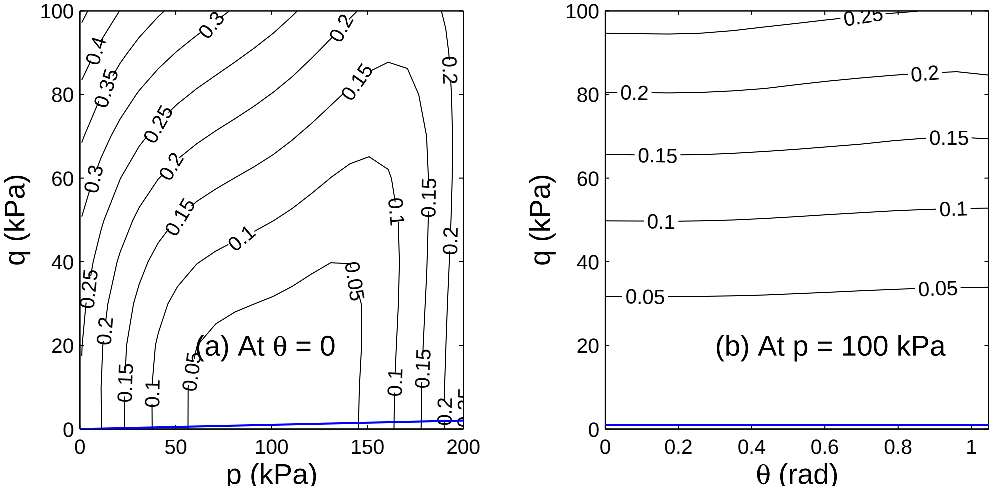

Figure 305.11: Normalized iso-error maps of Dafalias-Manzari model with constant elastic moduli.

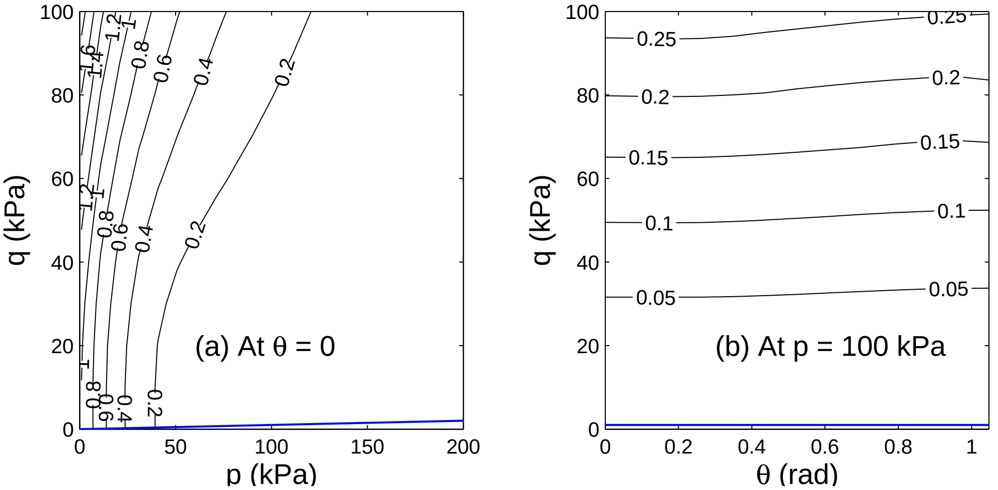

Figure 305.12: Relative iso-error maps of Dafalias-Manzari model with constant elastic moduli.

and $r_{norm} =\leq Tol2$ are satisfied, even if there is only one iteration number. The initial stress is an isotropic stress state of $p_0 = 100$ kPa. The undrained-like load increment is adopted by strain control as $\epsilon_{11} = -2\epsilon_{22} = -2\epsilon_{33} = n \times \Delta\epsilon$, where n is the load increment number and $\Delta\epsilon$ is the strain increment interval, ϵ_{ij} are strain components.

Figure 305.13 shows the typical constitutive level convergence performance for von Mises model with linear isotropic hardening. The input parameters are Young's Modulus $E = 1 \times 10^5$ kPa, Poisson's ratio $\nu = 0.25$, the material strength $k = 50$ kPa, and the linear isotropic hardening modulus $H = 2 \times 10^4$ kPa. The strain increment interval $\Delta\epsilon$ is set 2×10^{-4}. It can be seen that for this simple example, only two iteration steps are needed and $|f|$ and r_{norm} are far smaller than the tolerances and in fact close to the machine floating error value, or in other words, the stresses are exactly at the yield surface and the residue norm is zero.

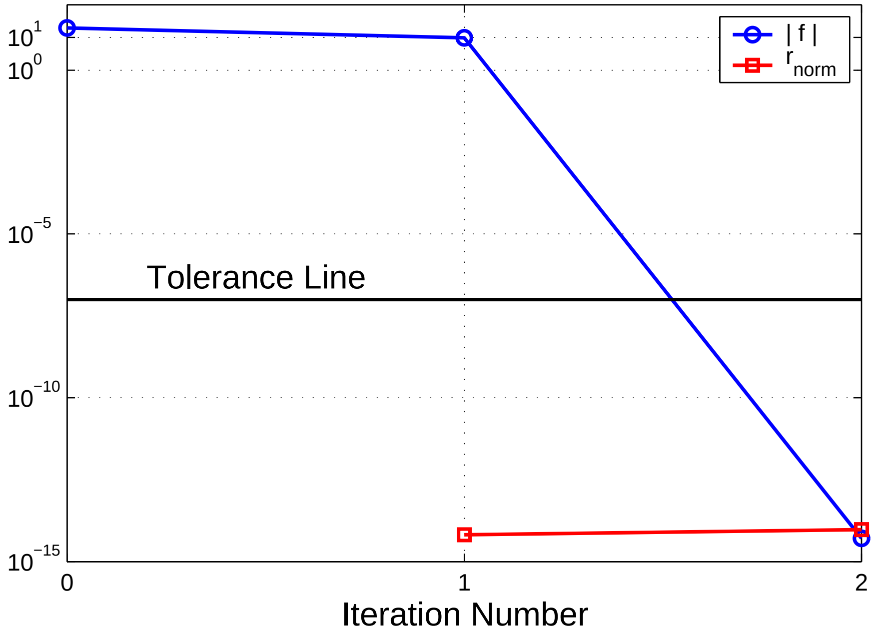

Figure 305.13: Typical convergence for von Mises model with linear isotropic hardening (tolerance value 1×10^{-7}).

Figure 305.14 shows the typical constitutive level convergence performance for Drucker-Prager model with Armstrong-Frederick kinematic hardening. The input parameters are Young's Modulus $E = 1 \times 10^{4}$ kPa, Poisson's ratio $\nu = 0.25$, the material q/p ratio is 0.8, and the Armstrong-Frederick parameters are $h_a = 20$, $C_r = 2$. The strain increment interval $\Delta\epsilon$ is set -2×10^{-4}. For this example, both $|f|$ and r_{norm} are stably decreasing with the increasing iteration number; However, $|f|$ and r_{norm} show different rates; $|f|$ needs 5 iteration steps while r_{norm} needs 7 iteration steps; The convergence rate of r_{norm} lags behind that of $|f|$.

Figure 305.15 shows the typical constitutive level convergence performance for the complicated Dafalias-Manzari model considering fabric dilation effect. The input parameters are as in Table 305.1, and the initial void ration is set as 0.8. Different from the above examples, The strain increment interval $\Delta\epsilon$ is set a much smaller value of -1×10^{-5}. In this example, again, both $|f|$ and r_{norm} are stably decreasing with the increasing iteration number; However, $|f|$ and r_{norm} show different rates; $|f|$ needs less iteration steps than r_{norm}; The convergence rate of r_{norm} lags behind that of $|f|$. It should be mentioned here for this complicated Dafalias-Manzari model considering fabric dilation effect,

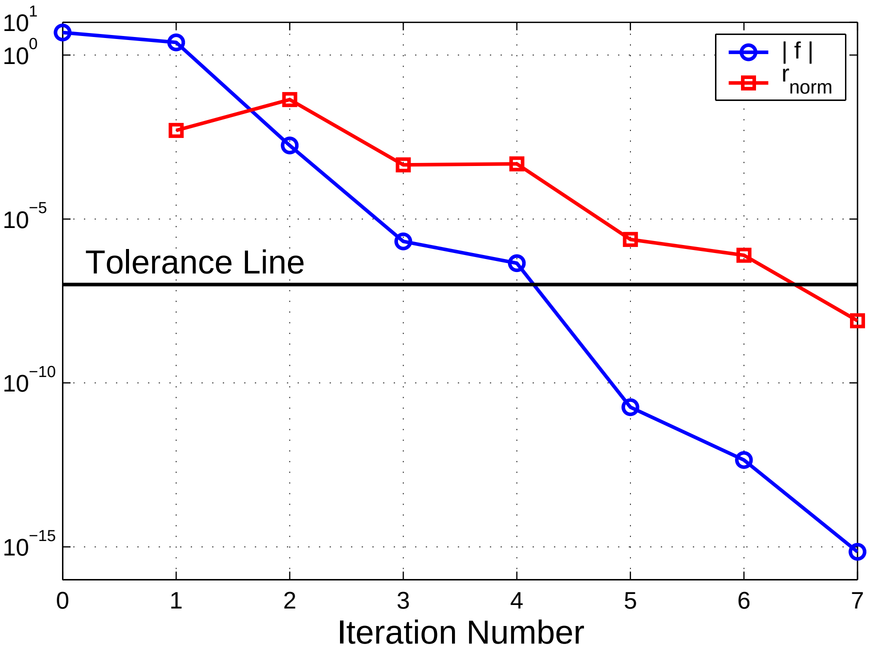

Figure 305.14: Typical convergence for Drucker-Prager model with Armstrong-Frederick kinematic hardening (tolerance value 1×10^{-7}).

the typical constitutive level convergence performance is similar to that of Drucker-Prager model with Armstrong-Frederick kinematic hardening, but with much smaller strain increment interval.

From the above examples, it is clear that the simpler the model is , the better constitutive level convergence performances are observed. This is consistent to the error assessment in section 305.2.1. Generally, the implemented implicit algorithm shows stable constitutive level convergence performances provided an appropriate small strain increment interval for the material model.

305.3 Validation of Constitutive Model Predictions

305.3.1 Dafalias Manzari Material Model

Validation is performed by comparing experimental (physical) results and numerical (constitutive) simulations for the Toyoura sand. It should be noted that we have not done validation against 2D or 3D tests (say centrifuge tests) as characterization of sand used in centrifuge experiments is usually less than complete for use with advanced constitutive models. Moreover, as our approach seeks to make predictions of prototype behavior, scaling down models (and using them for comparison with numerical predictions) brings forward issues of physics of scaling which we would rather stay out of. The material parameters

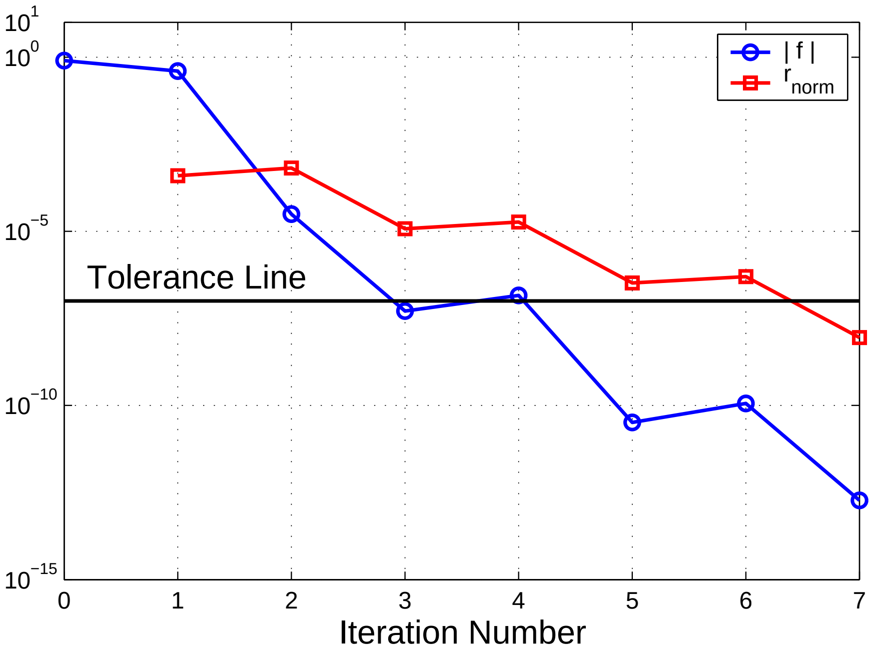

Figure 305.15: Typical convergence for Dafalias-Manzari model (tolerance value 1×10^{-7}).

used are from Dafalias and Manzari (2004a) and are listed in Table (305.1). Several simulated results are compared with the experimental data published by Verdugo and Ishihara (1996).

Figure (305.16) presents both loading and unloading triaxial drained test simulation results for a relatively low triaxial isotropic pressure of 100 kPa but with different void ratios of $e_0 = 0.831, 0.917, 0.996$ at the end of isotropic compression. During the loading stage, one can observes the hardening and then softening together with the contraction and then dilation for the denser sand, while only hardening together with contraction for the looser sand. The significance of the state parameter to the soil modeling is clear from the very different responses with different void ratios at the same triaxial isotropic pressure.

Figure (305.16) also shows both loading and unloading triaxial drained test simulation results for a relatively high triaxial isotropic pressure of 500 kPa but with different void ratio of e_0=0.810, 0.886, 0.960 at the end of isotropic compression. Similar phenomenon are observed as with tests (physical and numerical) for relatively low triaxial isotropic pressure. However, due to the higher confinement pressure, the stress-strain responses are higher at the same strain, which proves the significant pressure dependent feature for the sands.

Figure (305.17) presents both loading and unloading triaxial undrained test simulation results for a dense sand with the void ratio of e_0=0.735 at the end of isotropic compression but with different

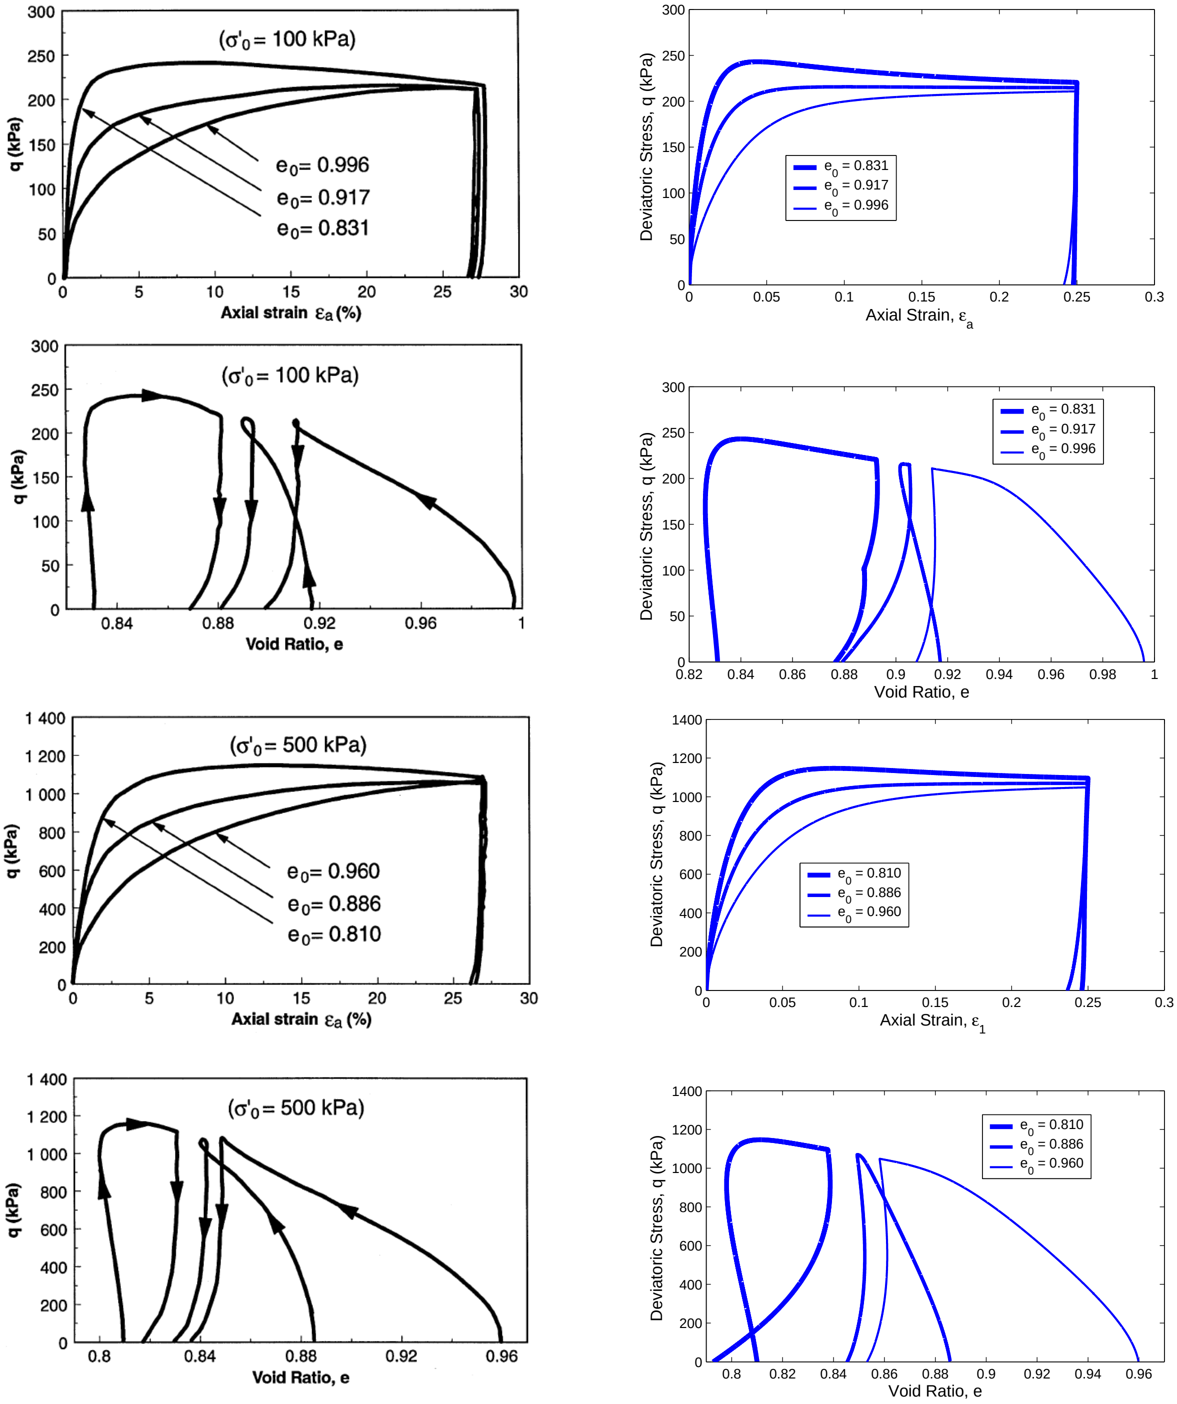

Figure 305.16: Left: Experimental data; Right: Simulated results.

Table 305.1: Material parameters of Dafalias-Manzari model.

material parameter		value	material parameter		value
Elasticity	G_0	125 kPa	Plastic modulus	h_0	7.05
	v	0.05		c_h	0.968
Critical sate	M	1.25		n_b	1.1
	c	0.712	Dilatancy	A_0	0.704
	λ_c	0.019		n_d	3.5
	ξ	0.7	Fabric-dilatancy	z_{max}	4.0
	e_r	0.934		c_z	600.0
Yield surface	m	0.01			

isotropic compression pressures of $p_0 = 100, 1000, 2000, 3000$ kPa. During the loading stage, one observes that each of responses are close to the critical state line for the very various range of isotropic compression pressures. For the higher isotropic compression pressure, the contraction response with softening is clearly observed, while for the smaller isotropic compression pressure, it is a dilation response without softening.

Close matching of physical testing data with constitutive predictions represents a satisfactory validation of our material model. This validation with previous verification gives us confidence that predictions (presented in next section) represent well the real, prototype behavior.

Chapter 306

Verification and Validation for Static and Dynamic Finite Element Level Solution Advancement Algorithms

(1994-2003-2009-2012-2015-2017-2019-)

(In collaboration with Prof. José Antonio Abell Mena and Dr. Yuan Feng)

306.1 Chapter Summary and Highlights

306.2 Verification for Static Solution Advancement

306.3 Verification for Dynamic Solution Advancement

Spectral Radii, Argyris and Mlejnek (1991)...

- Test consists of a 2-DOF system periods $T_1 = 4.0\,\mathrm{s}$ and $T_2 = 1.0\,\mathrm{s}$.
- Different integration steps.
- Different values of method parameters (α, β, γ).
- Results are compared with theoretical predictions for algorithmic damping and period shifts.

306.3.1 Verification for Dynamic Solution Advancement, Newmark Method

(Newmark, 1959)

Iff

$$\gamma \geq \frac{1}{2}, \quad \beta \geq \frac{1}{4}(\gamma + \frac{1}{2})^2 \tag{306.1}$$

the procedure is unconditionally stable and second-order accurate.

Different values for γ and β can be used to create various integration methods:

- For $\gamma = 0.5$ (and corresponding $\beta = 0.25$) there is no numerical damping.
- Any γ value greater than 0.5 will introduce numerical damping.
- Trapezoidal rule or average acceleration method for $\beta = 1/4$ and $\gamma = 1/2$,
- Linear acceleration method for $\beta = 1/6$ and $\gamma = 1/2$,
- Explicit, central difference method for $\beta = 0$ and $\gamma = 1/2$.
- Strongest numerical damping values is obtained for values $\beta = 1$ and $\gamma = 2/3$, as spectral ratio $\rho_\infty = 0$ (Hughes (1987), page 502)

For more details see chapter 108 on page 537.

Following Argyris and Mlejnek (1991); Hughes (1987), to calculate the analytic ξ and analytic $\bar{\omega}$ a matrix A is constructed. The explicit definition of amplification matrix A for the Hilber Hughes Taylor (HHT) family of algorithms (where Newmark is obtained by setting $\gamma = 0$) is

$$A = \frac{1}{D}\begin{bmatrix} 1+\alpha\beta\Omega^2 & 1 & \frac{1}{2}-\beta \\ -\gamma\Omega^2 & 1-(1+\alpha)(\gamma-\beta)\Omega^2 & 1-\gamma-(1+\alpha)(\frac{1}{2}\gamma-\beta)\Omega^2 \\ -\Omega^2 & -(1+\alpha)\Omega^2 & -(1+\alpha)(\frac{1}{2}-\beta)\Omega^2 \end{bmatrix} \tag{306.2}$$

where

$$\begin{aligned} D =& 1+(1+\alpha)\beta\Omega^2 \\ \Omega =& \omega\triangle t \\ \omega =& (K/M)^{\frac{1}{2}} \end{aligned} \tag{306.3}$$

The eigenvalue of amplification matrix A will be two complex conjugate roots $\lambda_{1,2}$ and a so-called spurious root λ_3 which satisfy $|\lambda_3| < |\lambda_{1,2}| \leq 1$. The roots $\lambda_{1,2}$ will be

$$\lambda_{1,2} = A \pm Bi \tag{306.4}$$

Then, the analytic damping ratio ξ and analytic period $\bar{\omega}$ becomes

$$\begin{aligned} \bar{\xi} =& -ln(A^2+B^2) \\ \bar{\omega} =& \bar{\Omega}/\triangle t \\ \bar{\Omega} =& arctan(B/A) \end{aligned} \tag{306.5}$$

306.3.2 Verification Example Description.

A one degree of freedom (DOF) example was made to verify the Newmark and HHT algorithm for Real-ESSI simulator. The example was plot below in Fig.(306.7). The beam stiffness and the mass were designed to make the natural period to be 1 second. In the first loading stage, the beam was given a horizontal force to generate an initial displacement. By the way, at the top node, all DOFs were fixed except the DOF along initial displacement. Then, in the second loading stage, the beam start free vibration.

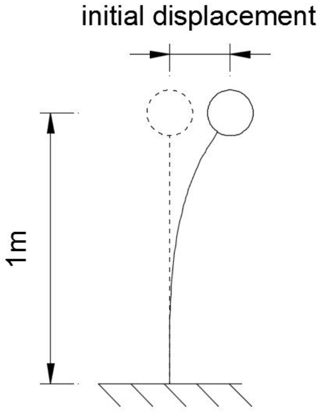

Figure 306.7: Verification example description.

The results were listed and plotted below.

Table 306.1: Verification results for the Newmark solution advancement algorithm.

306.3.3 Verification for Dynamic Solution Advancement, Hilber-Hughes-Taylor Method

(Hilber et al., 1977), (Hughes and Liu, 1978a) and (Hughes and Liu, 1978b)

If the parameters α, β and γ satisfy

$$-1/3 \leq \alpha \leq 0, \quad \gamma = \frac{1}{2}(1-2\alpha), \quad \beta = \frac{1}{4}(1-\alpha)^2 \tag{306.6}$$

it is unconditionally stable and second-order accurate (Argyris and Mlejnek, 1991; Hughes, 1987).

Chapter 307

Verification and Validation for Static and Dynamic Behavior of Single Phase, Solid Elements

(1989-1994-2011-2015-2017-2019-)

(In collaboration with Dr. Yuan Feng, and Prof. Han Yang)

307.1 Chapter Summary and Highlights

307.2 Verification of Static, Single Phase Solid Modeling and Simulation

307.2.1 Beam theory

This section provides basic beam theory that is used for verification solutions.

Problem description: Length=6m, Width=1m, Height=1m, F=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (307.1).

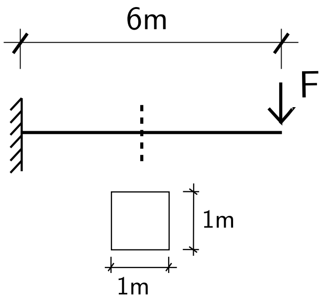

Figure 307.1: Problem description for cantilever beams.

The basic idea to calculate the shear deformation of a beam is

$$\delta = \frac{FL}{GA_v} \tag{307.1}$$

where A_v is the not the gross cross sectional area of the beam. A_v should be the shear area. Thus,

$$\kappa = \frac{A}{A_v} \tag{307.2}$$

where κ is the form factor, shear correction factor or shear deformation coefficient, A is the gross sectional area and A_v is the shear area of the section.

REWRITE, use bibtex! The history of κ value is long.

1. Timoshenko (1940)[1] define the form factor for rectangular section is 1.5.
2. Cowper (1970)[2] gave the formula for the form factor:

$$\kappa = \frac{12 + 11\nu}{10(1 + \nu)} \tag{307.3}$$

---

[1] Strength of materials, Timoshenko, Krieger Pub Co, 1940

[2] Cowper, G. R. "The shear coefficient in Timoshenko's beam theory." Journal of applied mechanics 33.2 (1966): 335-340.

3. Renton (1991) [3] provided a closed form solution for shear area of rectangular sections. For a rectangular section of depth $2a$ and breadth $2b$.

$$\kappa = \frac{6}{5} + (\frac{\nu}{1+\nu})^2 \sum_{m=0}^{\infty}\sum_{n=1}^{\infty} \frac{144(b/a)^4}{\pi^6(2m+1)^2 n^2[(2m+1)^2(b/2a)^2+n^2]} \tag{307.4}$$

For square cross section, $b = a$, therefore,

$$\kappa = \frac{6}{5} + (\frac{\nu}{1+\nu})^2 \sum_{m=0}^{\infty}\sum_{n=1}^{\infty} \frac{144}{\pi^6(2m+1)^2 n^2[(2m+1)^2(1/2)^2+n^2]} \tag{307.5}$$

To simplify the equation above, according to the Renton (1991), the intermediate values are given by

$$\kappa = \frac{6}{5} + C_1(\frac{\nu}{1+\nu})^2(\frac{b}{a})^4 \tag{307.6}$$

where C_1 is the parameter determined by the ratio of a and b. When $b = a$, the equation becomes

$$\kappa = \frac{6}{5} + 0.1392(\frac{\nu}{1+\nu})^2 \tag{307.7}$$

307.2.2 Verification of 8 node brick cantilever beam (static)

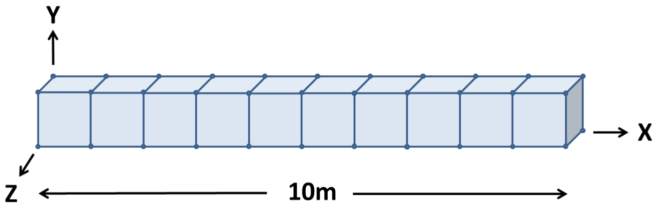
Problem description: Lenght=10m, Force=4N, E=100000Pa, $I = \frac{1}{12}$

Theoretical displacement:

$$d = \frac{PL^3}{3EI} = \frac{4 \times 1000}{3 \times 100000 \times \frac{1}{12}} = 0.16m \tag{307.8}$$

Numerical simulation results:

1m element size (10 elements):

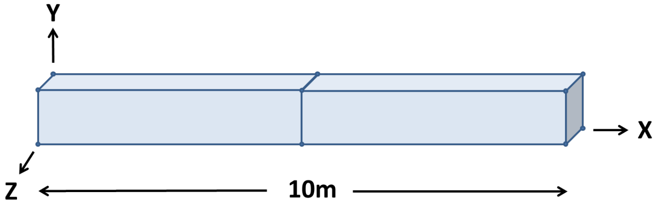


$$error = \frac{0.16 - 0.1072}{0.16} = 33\% \tag{307.9}$$

5m element size (2 elements):

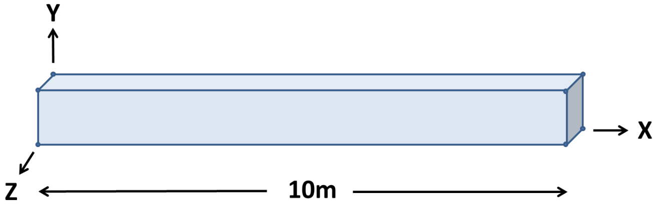
---

[3] Renton, J. D. "Generalized beam theory applied to shear stiffness." International Journal of Solids and Structures 27.15 (1991): 1955-1967.



$$error = \frac{0.16 - 0.011911}{0.16} = 92.5\% \qquad (307.10)$$

10m element size (1 element):



$$error = \frac{0.16 - 0.00315}{0.16} = 98\% \qquad (307.11)$$

1m element size with 10% nodal offset (10 elements):

$$error = \frac{0.16 - 0.1057}{0.16} = 34\% \qquad (307.12)$$

1m element size with 20% nodal offset (10 elements):

$$error = \frac{0.16 - 0.1016}{0.16} = 36\% \qquad (307.13)$$

307.2.3 Verification of 27 node brick cantilever beam (static)

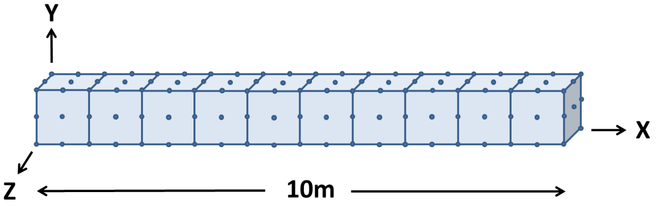
Problem description: Lenght=10m, Force=9N, E=100000Pa, $I = \frac{1}{12}$

Theoretical displacement:

$$d = \frac{PL^3}{3EI} = \frac{9 \times 1000}{3 \times 100000 \times \frac{1}{12}} = 0.36m \qquad (307.14)$$

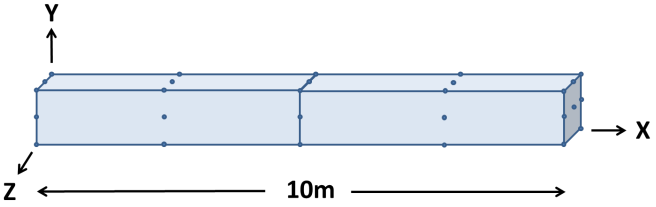
Numerical simulation results:

1m element size (10 elements):



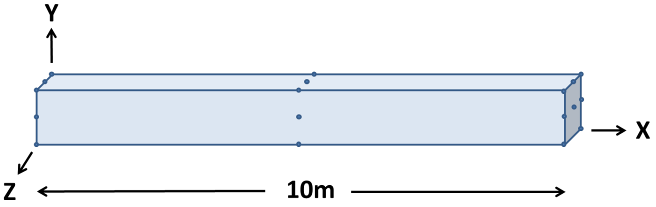
$$error = \frac{0.361721 - 0.36}{0.36} = 0.47\% \qquad (307.15)$$

5m element size (2 elements):



$$error = \frac{0.36 - 0.345719}{0.36} = 3.96\% \qquad (307.16)$$

10m element size (1 element):



$$error = \frac{0.36 - 0.279989}{0.36} = 22\% \qquad (307.17)$$

1m element size with 10% nodal offset (10 elements):

$$error = \frac{0.361225 - 0.36}{0.36} = 0.35\% \qquad (307.18)$$

1m element size with 20% nodal offset (10 elements):

$$error = \frac{0.36 - 0.359741}{0.36} = 0.07\% \qquad (307.19)$$

1m element size with 30% nodal offset (10 elements):

$$error = \frac{0.36 - 0.357004}{0.36} = 0.83\% \tag{307.20}$$

1m element size with 40% nodal offset (10 elements):

$$error = \frac{0.36 - 0.352604}{0.36} = 2\% \tag{307.21}$$

307.2.4 Verification of 8NodeBrick cantilever beams

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (307.2).

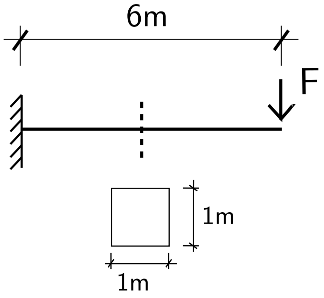


Figure 307.2: Problem description for cantilever beams.

Theoretical displacement (bending and shear deformation):

$$\begin{aligned} d &= \frac{FL^3}{3EI} + \frac{FL}{GA_v} \\ &= \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} \\ &= \frac{100N \times 6^3 m^3}{3 \times 10^8 N/m^2 \times \frac{1}{12} m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7 N/m^2 \times 1m^2 \times \frac{5}{6}} \\ &= 8.64 \times 10^{-4} m + 0.144 \times 10^{-4} m \\ &= 8.784 \times 10^{-4}\ m \end{aligned} \tag{307.22}$$

Numerical model:

The 8NodeBrick elements are shown in Figure (307.6).

An example Real-ESSI script is shown below.

All the Real-ESSI results are listed in Table (307.1). The theoretical solution is 8.784E-04 m.

Table 307.1: Results for 8NodeBrick cantilever beams of different element numbers.

Element number	1	2	6
8NodeBrick	4.61E-05 m	1.59E-04 m	5.84E-04 m
Error	94.75%	81.87%	33.52%

The errors are plotted in Figure (307.7).

The Real-ESSI model fei/DSL files for the table above are HERE.

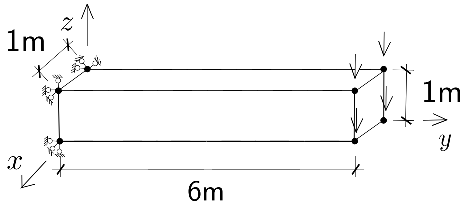

Figure 307.3: One 8NodeBrick element.

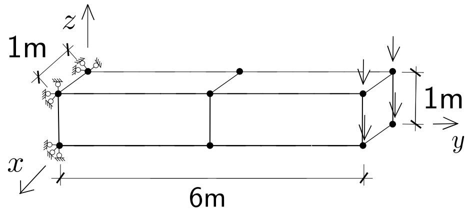

Figure 307.4: Two 8NodeBrick elements.

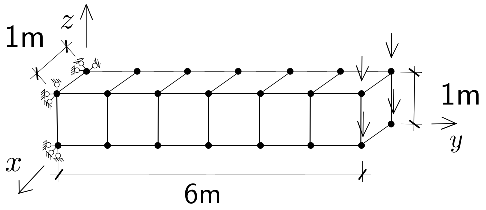

Figure 307.5: Six 8NodeBrick elements.

Figure 307.6: 8NodeBrick elements for cantilever beams.

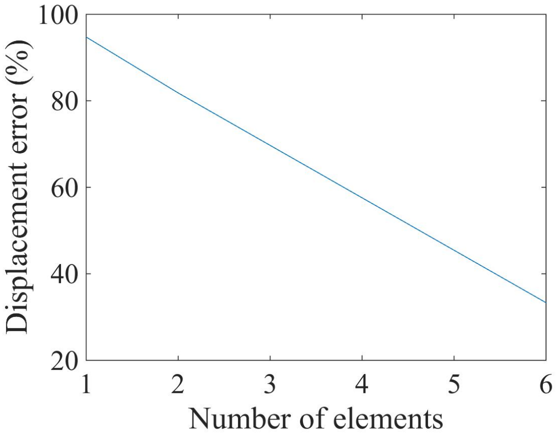

Figure 307.7: 8NodeBrick cantilever beam for different element number Displacement error versus Number of elements

307.2.5 Verification of 8NodeBrick cantilever beam for different Poisson's ratio

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0 - 0.49$. The force direction was shown in Figure (307.8).

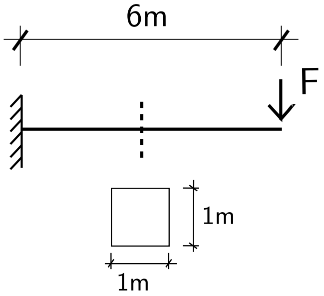

Figure 307.8: Problem description for cantilever beams of different Poisson's ratios.

The theoretical solution for $\nu = 0.0$ was calculated below, while the solution for other Poisson's ratio are calculated by the similar process.

Theoretical displacement (bending and shear deformation):

$$\begin{aligned} d &= \frac{FL^3}{3EI} + \frac{FL}{GA_v} \\ &= \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} \\ &= \frac{100N \times 6^3 m^3}{3 \times 10^8 N/m^2 \times \frac{1}{12} m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7 N/m^2 \times 1m^2 \times \frac{5}{6}} \\ &= 8.64 \times 10^{-4} m + 0.144 \times 10^{-4} m \\ &= 8.784 \times 10^{-4}\ m \end{aligned} \tag{307.23}$$

The rotation angle at the end:

$$\theta = \frac{FL^2}{2EI} = \frac{100N \times 6^2 m^2}{2 \times 10^8 N/m^2 \times \frac{1}{12} m^4} = 2.16 \times 10^{-4}\ rad = 0.0124^\circ \tag{307.24}$$

The 8NodeBrick elements for cantilever beams of different Poisson's ratios are shown in Figure (307.9):

All the displacement results are listed in Table (307.2) - (307.4).

Using the same geometry, the element was meshed usingm much smaller element (0.5m).

Finally, in the same geometry, the element side length was cut into 0.25m.

The errors are plotted in Figure (307.10).

The Real-ESSI model fei/DSL files for the table above are HERE.

307.2.6 Test of irregular shaped 8NodeBrick cantilever beams

Cantilever model was used as an example. Three different shapes are tested.

In the first test, the upper two nodes of each element are moved one half element size along the $y-axis$, while the lower two nodes are kept at the same location. The element shape was shown in Figure (307.12).

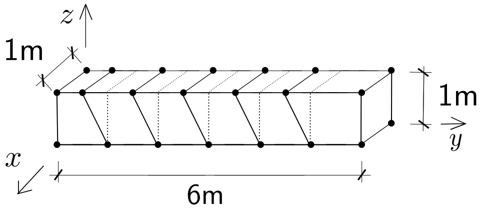

Figure 307.12: 8NodeBrick cantilever beams for irregular Shape 1.

In the second test, the upper two nodes of each element are moved 90% element size along the $y-axis$, while the lower two nodes are moved 90% element size in the other direction along the $y-axis$. The element shape was shown in Figure (307.13).

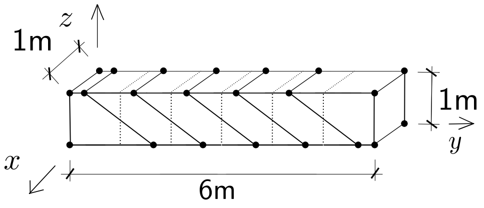

Figure 307.13: 8NodeBrick cantilever beams for irregular Shape 2.

In the third test, the upper two nodes of each element are moved one half element size with different directions along the $y-axis$, while the lower two nodes are kept at the same location. The element shape was shown in Figure (307.14).

The boundary conditions are shown in Figures (307.17), (307.20) and (307.23).

The Real-ESSI results are listed in Table (307.8).

The errors are listed in Table (307.9) and (307.10).

The Real-ESSI model fei/DSL files for the table above are HERE.

Then, the irregular beam was divided into small elements.

Problem description: Length=12m, Width=2m, Height=2m, q=400N/m, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (307.24).

Figure 307.33: 8NodeBrick clamped beam for different element number˙ Displacement error versus Number of division

307.2.7 Verification of 8NodeBrick stress in cantilever beams

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (307.34).

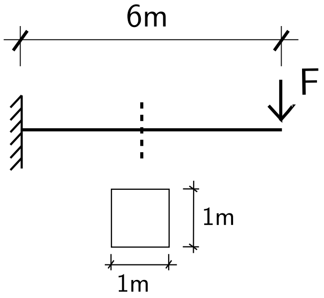

Figure 307.34: Problem description for cantilever beams of stress verification.

The theoretical solution for the stress was calculated below.

The 8NodeBrick elements are shown in Figure (307.35).

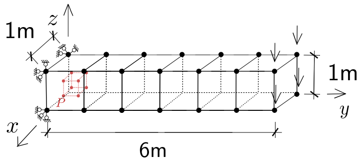

Figure 307.35: 8NodeBrick for cantilever beams of stress verification.

The bending moment at the Gassian Point is

$$M = F(L - P_y) = 100N \times (6 - 0.2113)m = 578.87N \cdot m \tag{307.30}$$

The bending modulus is

$$I = \frac{bh^3}{12} = \frac{1}{12}m^4 \tag{307.31}$$

Therefore, the theoretical stress is

$$\sigma = \frac{M \cdot z}{I} = \frac{578.87N \cdot m \times (0.5 - 0.2113)m}{\frac{1}{12}m^4} = 2005Pa \tag{307.32}$$

To get a better result, the same geometry beam was also cut into small elements. When more elements are used, the theoretical stress was calculated again with the new coordinates. The calculation process is similar to the process above.

The numerical models are shown in Figures(307.36), (307.37) and (307.38).

Number of division 1:

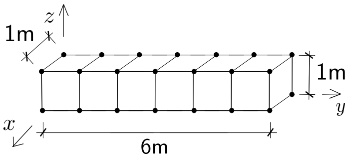

Figure 307.36: 8NodeBrick stress with element side length 1.0m.

Number of division 2:

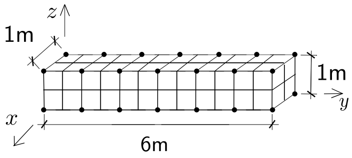

Figure 307.37: 8NodeBrick stress with element side length 0.5m.

Number of division 4:

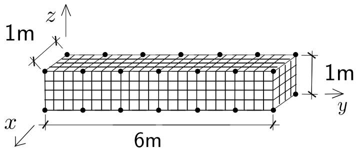

Figure 307.38: 8NodeBrick stress with element side length 0.25m.

All the stress results are listed in Table (307.14).

Table 307.14: Results for 8NodeBrick stress with more elements.

Element Type	Element side length		
	1 m	0.5 m	0.25 m
8NodeBrick	1270.17 Pa	2418.60 Pa	3085.48 Pa
Theoretical	2005.26 Pa	2789.23 Pa	3191.27 Pa
Error	36.66%	13.29%	3.31%

The errors are plotted in Figure (307.41).

The Real-ESSI model fei/DSL files for the table above are HERE.

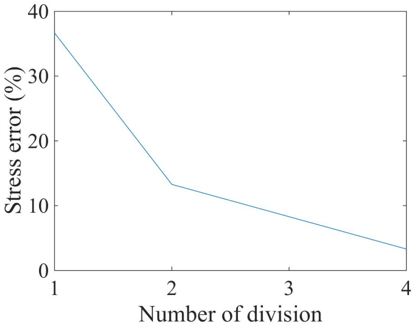

Figure 307.39: Error scale 0% - 40%.

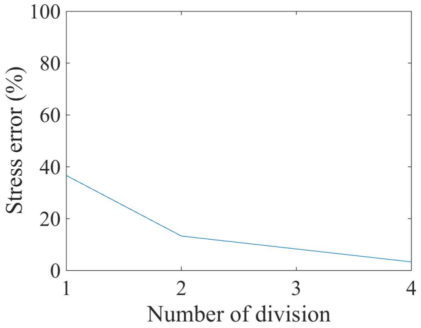

Figure 307.40: Error scale 0% - 100%.

Figure 307.41: 8NodeBrick cantilever beams for stress verification˙ Stress error versus Number of division

307.2.8 Verification of 8NodeBrick square plate with four edges clamped

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are clamped.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \; N \cdot m \tag{307.33}$$

The theoretical solution is

$$d = \alpha_c \frac{qa^4}{D} = 0.00406 \times \frac{100N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \; N \cdot m} = 2.2015 \times 10^{-3} m \tag{307.34}$$

where α_c is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[4] α_c is 0.00406.

The 8NodeBrick are shown in Figures (307.42) - (307.47).

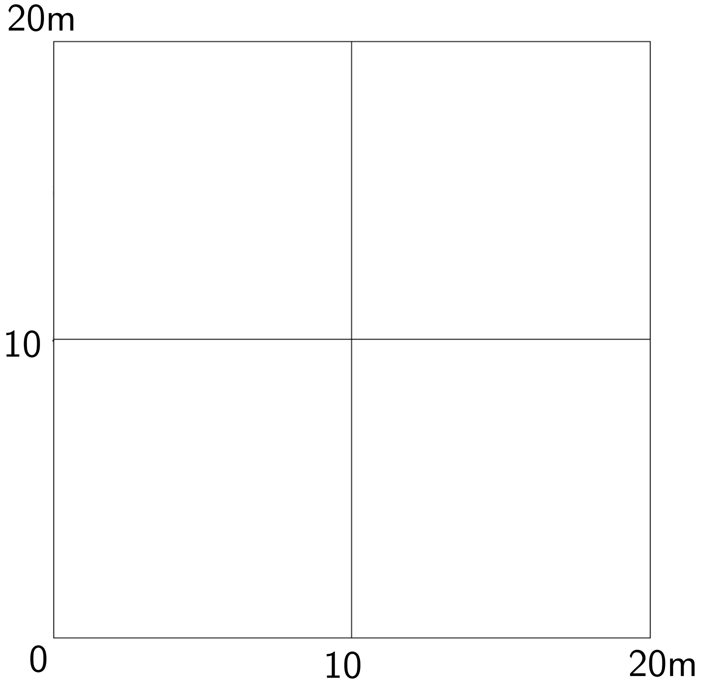

Figure 307.42: 8NodeBrick edge clamped square plate with element side length 10m.

The results are listed in Table (307.15).

The errors are listed in Table (307.2.8).

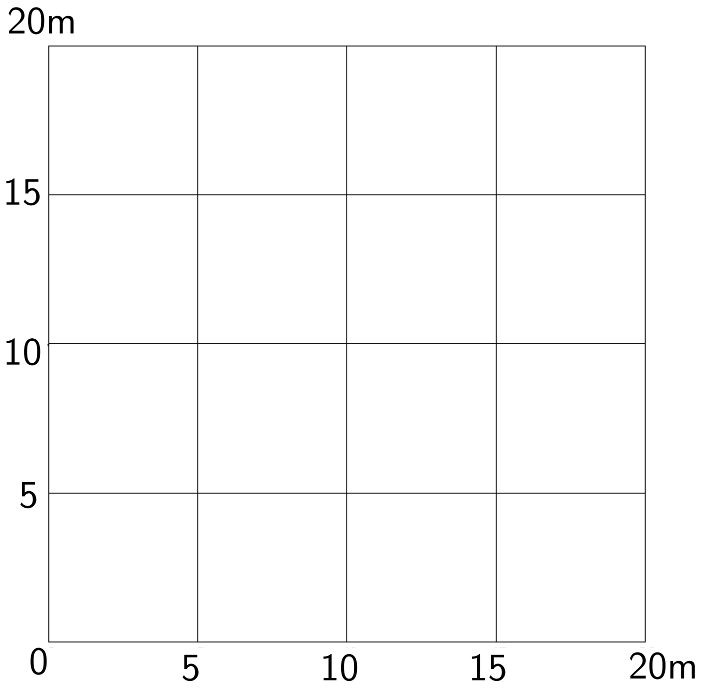

Figure 307.43: 8NodeBrick edge clamped square plate with element side length 5m.

307.2.9 Verification of 8NodeBrick square plate with four edges simply supported

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are simply supported.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \ N \cdot m \tag{307.35}$$

The theoretical solution is

$$d = \alpha_s \frac{qa^4}{D} = 0.00126 \times \frac{100N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \ N \cdot m} = 7.0936 \times 10^{-3} m \tag{307.36}$$

where α_s is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[5] α_s is 0.00126.

307.2.12 Verification of 8NodeBrick Finite Element for Boussinesq Problem

307.2.12.1 Introduction

The Boussinesq problem is finding the displacement distribution in the isotropic linearly elastic half-space, subject to a concentrated load applied on the surface and perpendicular to it. The Boussinesq problem diagram is shown in Fig.(307.166).

Boussinesq problem is widely used in geotechnical engineering, especially when designing a foundation which transfers the superstructure load to the soil. To estimate the foundation settlements, it is important to have a reliable numerical solution for the Boussinesq problem.

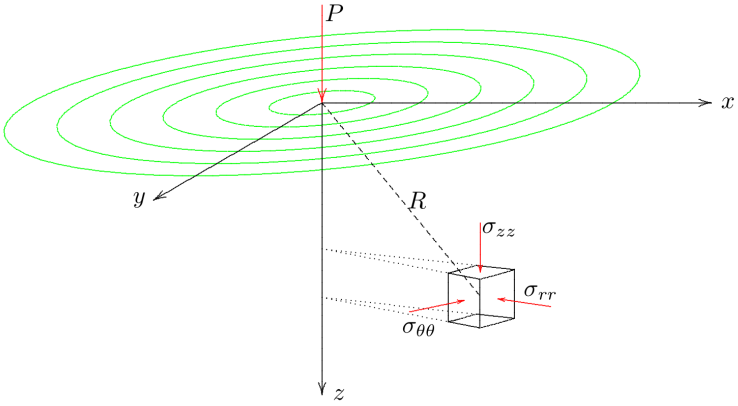

Figure 307.70: Boussinesq problem description. (Figure Reference: Verruijt, Arnold, and Stefan Van Baars. Soil mechanics. Delft, 2007.)

In 1885, the French scientist Joseph Boussinesq solved the analytic solutions of displacements in the homogeneous isotropic linear elastic half space. In general, the vertical displacement of the surface is

$$z = 0: \quad u_z = \frac{P(1-\nu^2)}{\pi E R} \tag{307.41}$$

where P is the vertical load, ν is the Poisson's ratio, E is the elastic modulus, and R is the distance from the measured point to the loading point.

In this section, the Real-ESSI numerical solution is verified by the analytic solution for the Boussinesq problem.

307.2.12.2 Description of the Verification Model

Since the problem is cylindrical symmetry, a quarter of the entire cube was employed to represent the whole cube. The reduced model was shown in Fig.(307.167).

The side length is 20 meters and the load P is 1N. The elastic modulus $E = 1 \times 10^3 Pa$ and the Poisson's ratio $\nu = 0.0$.

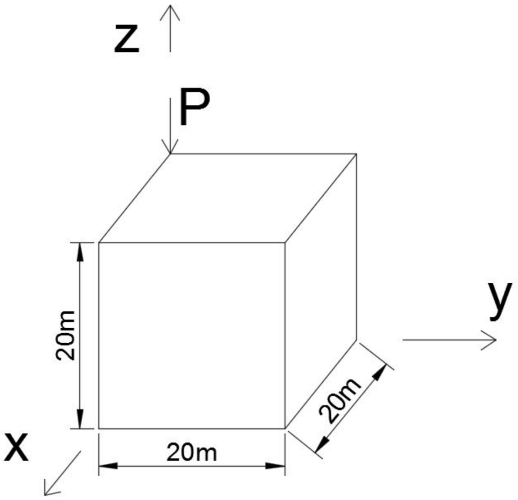

Figure 307.71: Reduced model (One quarter model) for the point load on the half space

The boundary conditions are shown in Fig.(307.72) and (307.73).

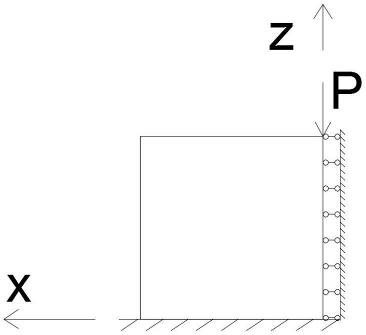

Figure 307.72: X-Z view for the reduced model

307.2.12.3 Results

Analytic solution for this model

According to the previous introduction, the analytic solution on the surface for this problem is

$$z = 0: \quad u_z = \frac{P(1-\nu^2)}{\pi E R} = \frac{1}{10^3 \pi} \frac{1}{R} \tag{307.42}$$

On the face $x = 0$, the distance R on the surface is actually the value of y, therefore, the analytic

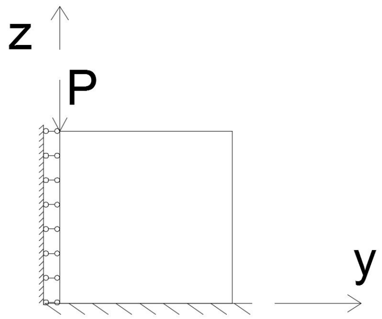

Figure 307.73: Y-Z view for the reduced model

solution is

$$u_z = \frac{1}{10^3 \pi R} = \frac{1}{10^3 \pi} \frac{1}{y} \tag{307.43}$$

As long as the y values are substituted, the displacement u_z is obtained immediately.

Real-ESSI solution with 8NodeBrickLT

In Real-ESSI, 8NodeBrickLT elements were used to simulate this model. Each element is $2m \times 2m \times 2m$. Since the model is $20m \times 20m \times 20m$, the element number is $10 \times 10 \times 10 = 1000$. The vertical displacement at the surface was recorded.

Since the model is symmetric, when the results were plotted, the other half results were obtained by symmetry.

Comparison between the analytic and 8NodeBrickLT solution

The Real-ESSI and analytic results were plotted in Fig.(307.74). Note that the analytic solution for location $y = 0$ is infinity, which was not plotted in the figure below.

307.2.12.4 Error Analysis

1. Mismatch at the loading point.

   First of all, when $x = 0$ at the loading point, the analytic solution is infinite. From the perspective of practical engineering, this analytic solution is flawed because the displacement cannot be infinite. The infinite solution is due to the elastic assumption. In consideration of the plasticity, the analytic solution will not be infinite.

   In Real-ESSI, the displacement at the loading point is not infinite because the infinite value is averaged by the integration during the finite element calculation. Also, at the loading point,

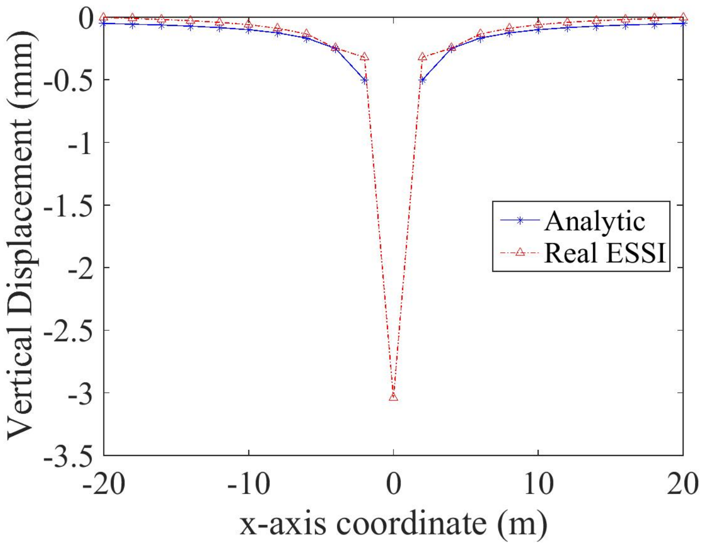

Figure 307.74: Comparison between analytic solution and Real-ESSI 8NodeBrickLT solution

27NodeBrickLT has a much larger displacement than that of 8NodeBrickLT. This is because 27NodeBrickLT has a relatively denser mesh than 8NodeBrickLT. So the maximum value at the loading point is higher than that of 8NodeBrickLT.

2. Mismatch at other locations.

   Except at the loading point, the analytic solution is not exactly equal to the numerical solution at other locations. This is because the verification example employs a simplified bounded cube to represent unbounded half space. The original analytic solution is for the half space, which is not true for the verification model. Not only the horizontal space but also the bottom space are removed from the model. This means the analytic solution is not perfect for this bounded cube. However, since the cube is very great, the analytic solution is similar to the Real-ESSI numerical solution. In addition, the brick elements are also verified by other models, like beam, plate and shells.

307.2.13 Verification of 8NodeBrick Finite Element for Collapsed Brick Shapes

307.2.13.1 Test procedure

With reference to the "patch test" put forward by Taylor et al. (1986), the test procedures are:

- A standard solution is given by testing two different loading modes on a single normal 8 node brick element: (1) Pure confinement loading, where same pressure are applied on three different directions. (2) Simple shearing, where shearing force is applied on four nodes of top layer, while four nodes on bottom layer are totally fixed. Linear elastic material is adopted here with Young's modulus $E = 125\text{MPa}$ and Poisson's ratio $\mu = 0.25$. The setup of standard test is shown in Figure 307.75.

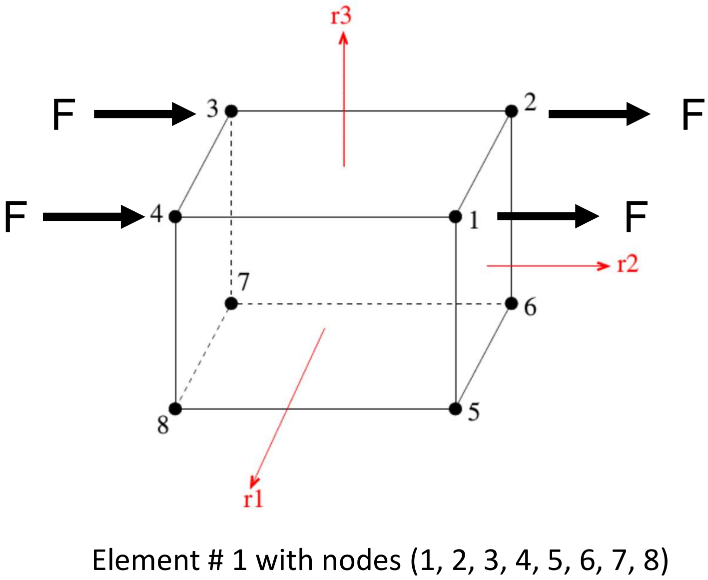

Figure 307.75: Setup of standard 8-node element.

- Build the same geometric model with collapsed 8 node brick elements and conduct numerical simulation under the same loading and boundary conditions as first step.

  Specifically, the geometric configure for 7-node collapsed element is shown in Figure 307.76, where the cubic consists of two 7-node collapsed elements. A dummy node 11 is generated at the same location as node 2.

  The geometric configuration for 6-node collapsed element is shown in Figure 307.77. Again the cubic is composed of two 6-node collapsed elements. Two dummy Real-ESSI nodes 9 and 10 are

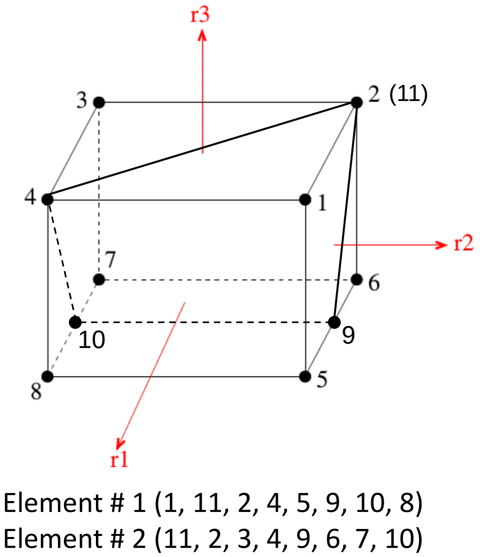

Figure 307.76: Geometric configuration of numerical test for 7-node collapsed element.

generated at the same location with original node 1 and 2.

And Figure 307.78 gives the geometric configuration of 5-node collapsed element, where the cubic is divided into 3 5-node elements.

- Compare the response of models in step 1 and step 2. If the difference is small enough, the strategy described in section ?? is feasible and valid.

307.2.13.2 Test result

The comparison of displacement response for confinement loading is shown in Figure 307.79. Figure 307.80 demonstrates the test results of simple shearing loading. It can be seen that the simulation results of these types of collapsed element are close to result of standard 8 node brick element. The line of 6 node collapsed element is almost overlap with the line of standard test. Collapsed 7-node element and 5-node element experience certain decrease of accuracy. The main error reflects on the decrease of stiffness. Both bulk modulus and shear modulus of 7-node element and 5-node element are around 7% lower than the standard 8-node element.

307.2.14 Verification of 27 node brick cantilever beam (static)

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (307.81).

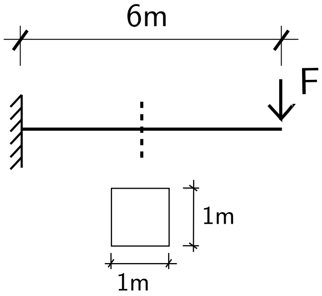

Figure 307.81: Problem description for cantilever beams.

Theoretical displacement (bending and shear deformation):

$$d = \frac{FL^3}{3EI} + \frac{FL}{GA_v} = \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} = \frac{100N \times 6^3 m^3}{3 \times 10^8 N/m^2 \times \frac{1}{12} m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7 N/m^2 \times 1m^2 \times \frac{5}{6}} = 8.64 \times 10^{-4} m + 0.144 \times 10^{-4} m = \tag{307.44}$$

Numerical model:

The 27NodeBrick elements are shown in Figure (307.85).

All the Real-ESSI results are listed in Table (307.23).

Table 307.23: Results for 27NodeBrick cantilever beams of different element numbers.

Element number	1	2	6
27NodeBrick	7.07E-04 m	8.50E-04 m	8.75E-04 m
Error	19.52%	3.19%	0.34%

The errors are plotted in Figure (307.88).

The Real-ESSI model fei/DSL files for the table above are HERE.

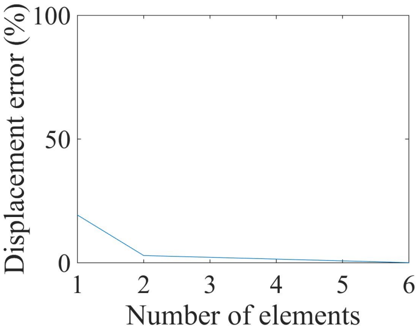

Figure 307.87: Error scale 0% - 100%.

Figure 307.88: 27NodeBrick cantilever beam for different element number˙ Displacement error versus Number of elements

307.2.15 Verification of 27NodeBrick cantilever beam for different Poisson's ratio

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0 - 0.49$. The force direction was shown in Figure (307.89).

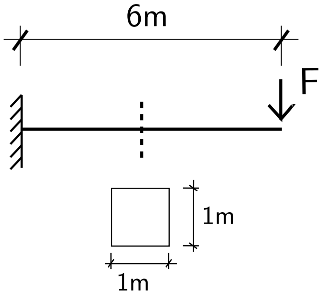

Figure 307.89: Problem description for cantilever beams of different Poisson's ratios.

The theoretical solution for $\nu = 0.0$ was calculated below, while the solution for other Poisson's ratio is calculated by the similar process.

Theoretical displacement (bending and shear deformation):

$$\begin{aligned} d &= \frac{FL^3}{3EI} + \frac{FL}{GA_v} \\ &= \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} \\ &= \frac{100N \times 6^3m^3}{3 \times 10^8N/m^2 \times \frac{1}{12}m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7N/m^2 \times 1m^2 \times \frac{5}{6}} \\ &= 8.64 \times 10^{-4}m + 0.144 \times 10^{-4}m \\ &= 8.784 \times 10^{-4}\ m \end{aligned} \tag{307.45}$$

The rotation angle at the end:

$$\theta = \frac{FL^2}{2EI} = \frac{100N \times 6^2m^2}{2 \times 10^8N/m^2 \times \frac{1}{12}m^4} = 2.16 \times 10^{-4}\ rad = 0.0124^{\circ} \tag{307.46}$$

The 27NodeBrick elements for cantilever beams of different Poisson's ratios are shown in Figure (307.90).

All the displacement results are listed in Table (307.24).

The errors are plotted in Figure (307.93).

The angle results are listed in Table (307.27).

The errors are plotted in Figure (307.96).

The Real-ESSI model fei/DSL files for the table above are HERE.

Then, different values of elastic modulus were also tried. The errors are plotted below.

According to Fig.(307.97)), the different values of elastic modulus will not influence the error.

However, the different Poisson's ratio will influence the error. The error will increase with the Poisson's ratio increase.

Table 307.25: Displacement results for 27NodeBrick cantilever beams with element side length 0.5 m.

Poisson's ratio	27NodeBrick displacement	Theory displacement (bending)	Theory displacement (shear)	Theory displacement(all)	Error

307.2.16 Test of irregular shaped 27NodeBrick cantilever beams

Cantilever model was used as an example. Three different shapes are tested.

In the first test, the upper two nodes of each element were moved one half element size along the $y - axis$, while the lower two nodes were kept at the same location. The element shape was shown in Figure (307.98).

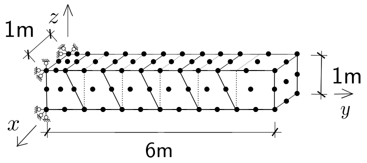

Figure 307.98: 27NodeBrick cantilever beams for irregular Shape 1.

In the second test, the upper two nodes of each element were moved 90% element size along the $y-axis$, while the lower two nodes were moved 90% element size in the other direction along the $y-axis$. The element shape was shown in Figure (307.99).

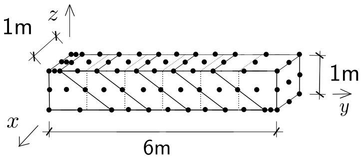

Figure 307.99: 27NodeBrick cantilever beams for irregular Shape 2.

In the third test, the upper two nodes of each element are moved one half element size with different directions along the $y - axis$, while the lower two nodes were kept at the same location. The element shape was shown in Figure (307.100).

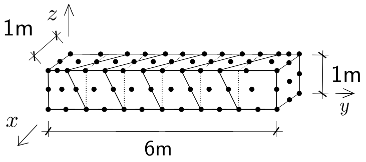

Figure 307.100: 27NodeBrick cantilever beams for irregular Shape 3.

The boundary conditions are shown in Figure (307.103), (307.106) and (307.109) .

The Real-ESSI results are listed in Table (307.30).

The errors are listed in Table (307.31) and (307.32).

307.2.17 Verification of 27NodeBrick stress in cantilever beams

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (307.126).

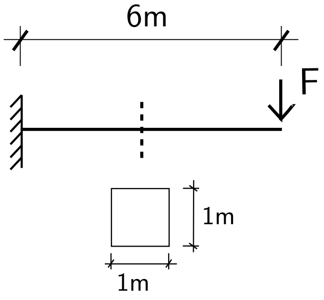

Figure 307.126: Problem description for cantilever beams of stress verification.

The theoretical solution for the stress was calculated below.

The 27NodeBrick elements are shown in Figure (307.127).

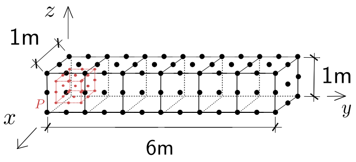

Figure 307.127: 27NodeBrick for cantilever beams of stress verification.

The bending moment at the Gassian Point is

$$M = F(L - P_y) = 100N \times (6 - 0.1127)m = 588.73N \cdot m \tag{307.48}$$

The bending modulus is

$$I = \frac{bh^3}{12} = \frac{1}{12}m^4 \tag{307.49}$$

Therefore, the theoretical stress is

$$\sigma = \frac{M \cdot z}{I} = \frac{588.73N \cdot m \times (0.5 - 0.1127)m}{\frac{1}{12}m^4} = 2736Pa \tag{307.50}$$

To get a better result, the same geometry beam was also cut into small elements. When more elements are used, the theoretical stress was calculated again with the new coordinates. The calculation process is similar to the process above.

The numerical models are shown in Figure (307.128), (307.129) and (307.130).

Number of division 1:

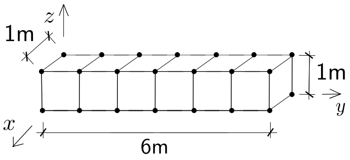

Figure 307.128: 27NodeBrick stress with element side length 1.0m.

Number of division 2:

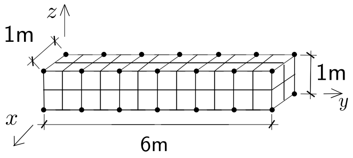

Figure 307.129: 27NodeBrick stress with element side length 0.5m.

Number of division 4:

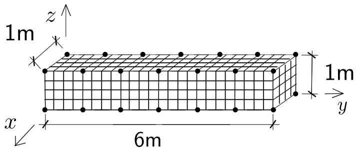

Figure 307.130: 27NodeBrick stress with element side length 0.25m.

All the stress results are listed in Table (307.36).

Table 307.36: Results for 27NodeBrick stress with more elements.

Element Type	Element side length		
	1 m	0.5 m	0.25 m
27NodeBrick	2719.81 Pa	3198.19 Pa	3464.76 Pa
Theoretical	2736.17 Pa	3164.27 Pa	3381.18 Pa
Error	0.60%	1.07%	2.47%

Figure 307.133: 27NodeBrick cantilever beams for stress verification˙ Stress error versus Number of division

307.2.18 Verification of 27NodeBrick square plate with four edges clamped

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are clamped.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \; N \cdot m \tag{307.51}$$

The theoretical solution is

$$d = \alpha_c \frac{qa^4}{D} = 0.00406 \times \frac{100 N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \; N \cdot m} = 2.2015 \times 10^{-3} m \tag{307.52}$$

where α_c is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[8] α_c is 0.00406.

The 27NodeBrick are shown in Figure (307.134) - (307.139).

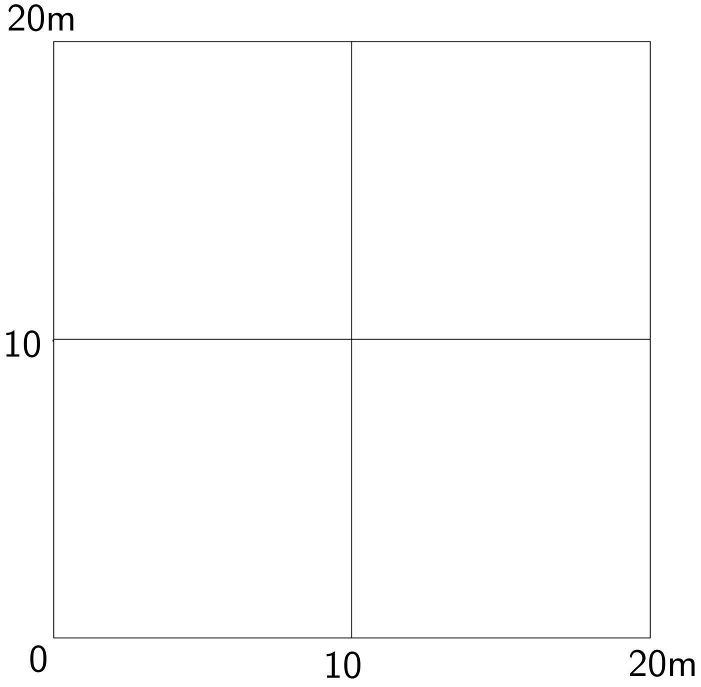

Figure 307.134: 27NodeBrick edge clamped square plate with element side length 10m.

The results were listed in Table (307.37).

307.2.19 Verification of 27NodeBrick square plate with four edges simply supported

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are simply supported.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \ N \cdot m \tag{307.53}$$

The theoretical solution is

$$d = \alpha_s \frac{qa^4}{D} = 0.00126 \times \frac{100 N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \ N \cdot m} = 7.0936 \times 10^{-3} m \tag{307.54}$$

where α_s is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[10] α_s is 0.00126.

The 27NodeBrick were shown in Figure (307.141) - (307.146).

307.2.22 Verification of 27NodeBrick Finite Element for Boussinesq Problem

307.2.22.1 Introduction

The Boussinesq problem is finding the displacement distribution in the isotropic linearly elastic half-space, subject to a concentrated load applied on the surface and perpendicular to it. The Boussinesq problem diagram is shown in Fig.(307.166).

Boussinesq problem is widely used in geotechnical engineering, especially when designing a foundation which transfers the superstructure load to the soil. To estimate the foundation settlements, it is important to have a reliable numerical solution for the Boussinesq problem.

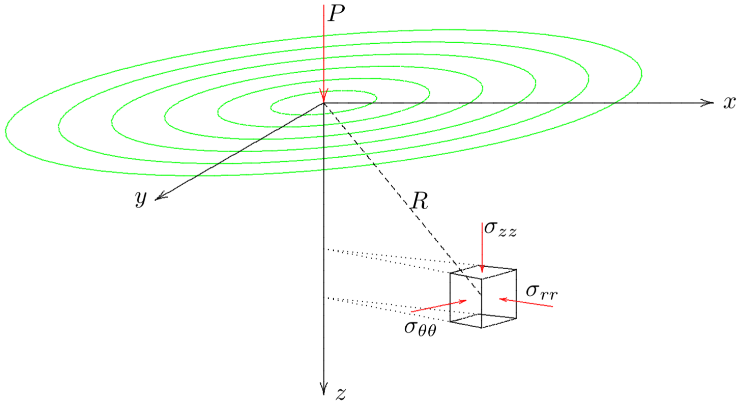

Figure 307.166: Boussinesq problem description (Figure Reference: Verruijt, Arnold, and Stefan Van Baars. Soil mechanics. Delft, 2007.)

In 1885, the French scientist Joseph Boussinesq solved the analytic solutions of displacements in the homogeneous isotropic linear elastic half space. In general, the vertical displacement of the surface is

$$z = 0: \quad u_z = \frac{P(1-\nu^2)}{\pi E R} \tag{307.59}$$

where P is the vertical load, ν is the Poisson's ratio, E is the elastic modulus, and R is the distance from the measured point to the loading point.

In this section, the Real-ESSI numerical solution is verified by the analytic solution for the Boussinesq problem.

307.2.22.2 Description of the Verification Model

Since the problem is cylindrical symmetry, a quarter of the entire cube was employed to represent the whole cube. The reduced model was shown in Fig.(307.167).

The side length is 20 meters and the load P is 1N. The elastic modulus $E = 1 \times 10^3 Pa$ and the Poisson's ratio $\nu = 0.0$.

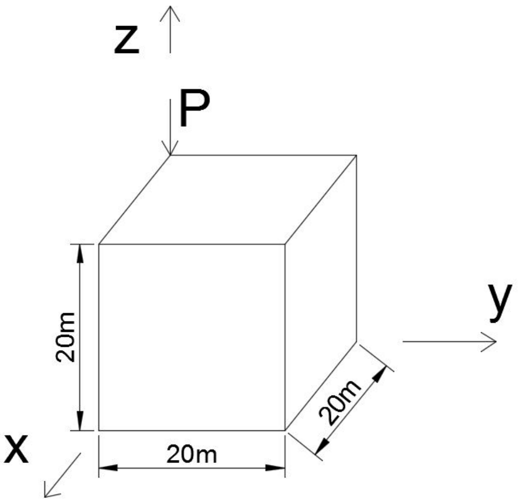

Figure 307.167: Reduced model (One quarter model) for the point load on the half space

The boundary conditions are shown in Fig.(307.168) and (307.169).

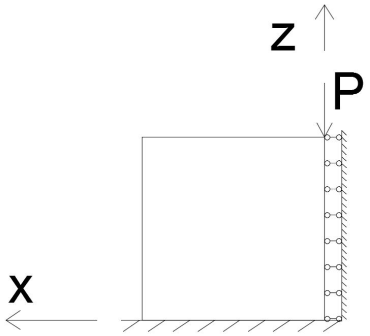

Figure 307.168: X-Z view for the reduced model

307.2.22.3 Results

Analytic solution for this model

According to the previous introduction, the analytic solution on the surface for this problem is

$$z = 0 : \quad u_z = \frac{P(1-\nu^2)}{\pi E R} = \frac{1}{10^3 \pi} \frac{1}{R} \tag{307.60}$$

On the face $x = 0$, the distance R on the surface is actually the value of y, therefore, the analytic

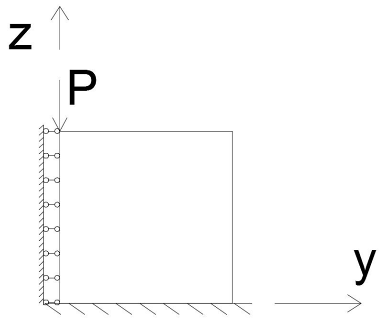

Figure 307.169: Y-Z view for the reduced model

solution is

$$u_z = \frac{1}{10^3 \pi R} = \frac{1}{10^3 \pi} \frac{1}{y} \tag{307.61}$$

As long as the y values are substituted, the displacement u_z is obtained immediately.

Real-ESSI solution with 27NodeBrickLT

In Real-ESSI, 27NodeBrickLT elements were used to simulate this model. Each element is $2m \times 2m \times 2m$. Since the model is $20m \times 20m \times 20m$, the element number is $10 \times 10 \times 10 = 1000$. The vertical displacement at the surface was recorded.

Since the model is symmetric, when the results were plotted, the other half results were achieved by symmetry.

Comparison between the analytic and 27NodeBrickLT solution

The Real-ESSI and analytic results were plotted in Fig.(307.170). Note that the analytic solution for location $y = 0$ is infinity, which was not plotted in the figure below.

307.2.22.4 Error Analysis

1. Mismatch at the loading point.

   First of all, when $x = 0$ at the loading point, the analytic solution is infinite. From the perspective of practical engineering, this analytic solution is flawed because the displacement cannot be infinite. The infinite solution is due to the elastic assumption. In consideration of the plasticity, the analytic solution will not be infinite.

   In Real-ESSI, the displacement at the loading point is not infinite because the infinite value is averaged by the integration during the finite element calculation. Also, at the loading point,

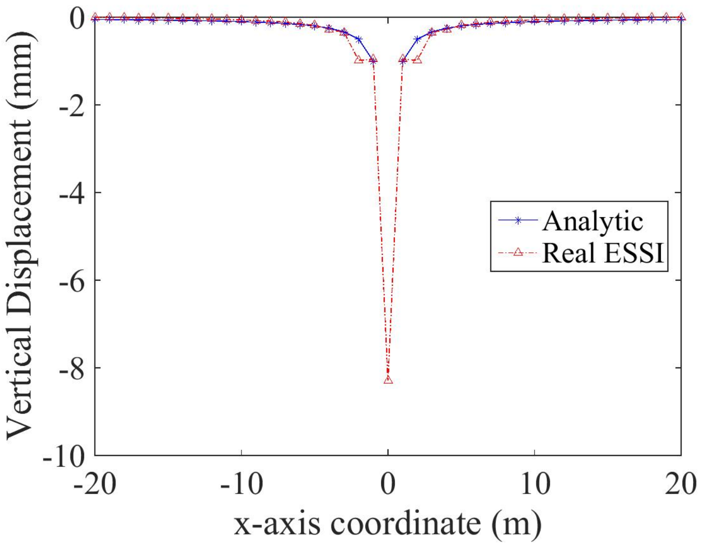

Figure 307.170: Comparison between analytic solution and Real-ESSI 27NodeBrickLT solution

27NodeBrickLT has a much larger displacement than that of 8NodeBrickLT. This is because 27NodeBrickLT has a relatively denser mesh than 8NodeBrickLT. So the maximum value at the loading point is higher than that of 8NodeBrickLT.

2. Mismatch at other locations.

   Except at the loading point, the analytic solution is not exactly equal to the numerical solution at other locations. This is because the verification example employs a simplified bounded cube to represent unbounded half space. The original analytic solution is for the half space, which is not true for the verification model. Not only the horizontal space but also the bottom space are removed from the model. This means the analytic solution is not perfect for this bounded cube. However, since the cube is very great, the analytic solution is similar to the Real-ESSI numerical solution. In addition, the brick elements are also verified by other models, like beam, plate and shells.

308.4 Timoshenko Beam

Models used:

- Model with 27-node-brick model is used as the benchmark. The model is $10\mathrm{m} \times 10\mathrm{m} \times 60\mathrm{m}$, each element is $2\mathrm{m} \times 2\mathrm{m} \times 2\mathrm{m}$, so there are $5 \times 5 \times 30 = 750$ elements in total.
- Model with 5 Timoshenko beams are used to test the performance of the Timoshenko element. Material properties and cross-section properties are kept the same as those of the brick model. Various values of the shear correction factor are tested.
- Model with 5 Bernoulli beam elements is also tested.
- For both beam models, consistent mass is used.

Input files for all the models shown are available HERE.

Figures of models are shown below:

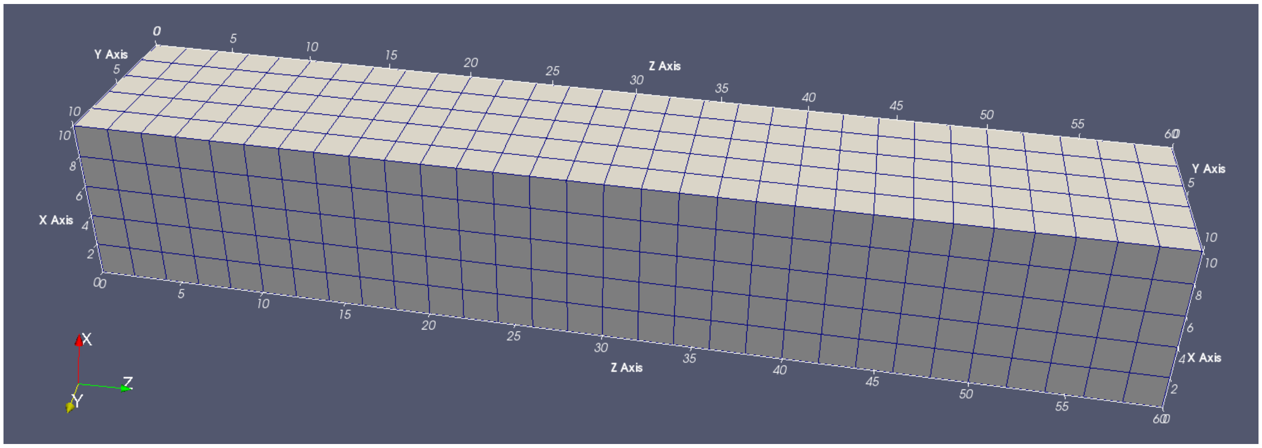

Figure 308.6: Cantilever model made of 27-node-brick elements.

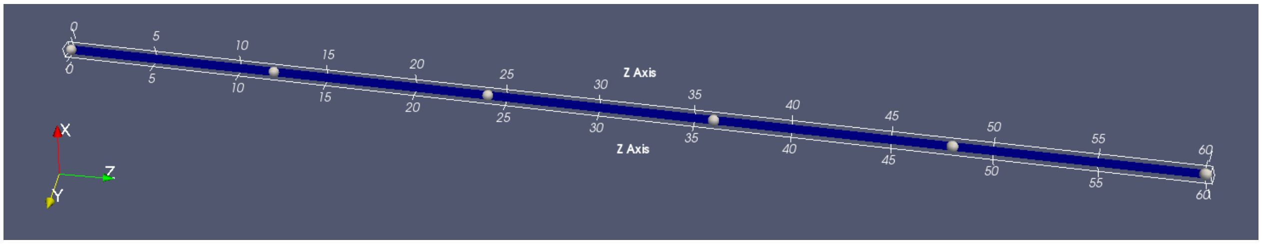

Figure 308.7: Cantilever model made of multiple Timoshenko or Bernoulli elements.

Eigenanalysis results are shown in the following table and figures.

Table 308.2: Comparison of eigenfrequencies for 27-node-brick, Timoshenko beam with different shear correction factors, and Bernoulli beam models.

Eigenmode		Eigenfrequency (Hz)

308.5 Verification of Shell (Felippa-ANDES) Finite Element Modeling and Simulation

The verification and validation of the behavior of the ANDES (Assumed Natural Deviatoric Strain) shell finite element implemented in essi is described in this section. The verification is split up into several cases intended to test different aspects of the implementation. The tests are based on well-known closed form solutions to elasticity problems which can be modelled using shells. Further, the verification is divided into static and dynamic tests.

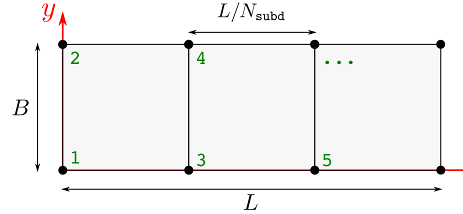
308.5.1 Static Tests

The purpose of the static tests is to verify that the stiffness matrices generated by the 4 Node ANDES Shell are useful to approximate well known cases of solutions to beam theory.

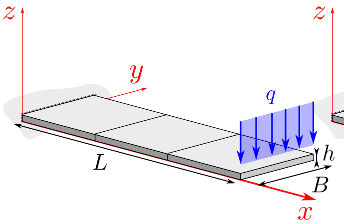
Tests are done to verify the bending component and the membrane component independently, because the behaviour of both is assumed de-coupled in this linear implementation.

308.5.1.1 Bending Component Verification

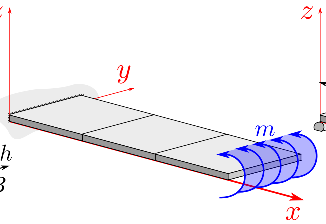
These tests compare the bending performance of a simple mesh of ANDES shells for the case of simple (Bernoulli) beam examples.



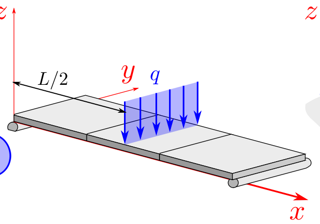
Mesh



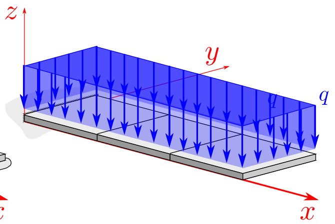
Test 1



Test 2



Test 3



Test 4

Test 1: Concentrated transversal tip load

The test file for this case can be found in

(ESSI SOURCE FOLDER)/Verification_Examples/...
.../Static_and_Dynamic_Behavior_of_Structural_Elements/...
.../Shell_ANDES/static/Test_shell_andes_1_bending_transverse.fei

For a prismatic beam made of a homogeneous elastic isotropic material of modulus of elasticity E, cross section I and length L we have that, under Bernoulli-Euler theory, the displacement at the tip due to a concentrated load P is

$$\delta_{\text{tip}} = \frac{PL^3}{3EI}$$

and for this test case's geometry

$$\delta_{\text{tip}} = \frac{qBL^3}{3EBh^3/12} = \frac{4qL^3}{Eh^3}$$

With the purpose of measuring the errors as percent agreement with the theoretical results, the load q is computed such that the tip displacement is 100 units. Thus, in terms of the geometry of the problem.

$$q = 100 \times \frac{Eh^3}{4L^3}$$

This force is translated into nodal equivalent forces by applying half the total load qB to each tip node in the vertical direction and fixing the x direction rotational degrees of freedom for the tip nodes.

The parameters chosen for this case are

```
h = 1*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 1*m; // Beam length
B = 0.2*m; // Beam width
rho = 0*kg/m^3; // Mass density
```

For different number of subdivisions, here are the results of the tip displacement.

N_{subd}	u_z	N_{subd}	u_z	N_{subd}	u_z
2	96.2118	42	100.009	83	100.002
7	100.096	48	100.007	89	100.002
13	100.068	54	100.006	95	100.002
19	100.039	60	100.005	101	100.002
25	100.024	66	100.004	107	100.001
31	100.016	72	100.003	112	100.001
37	100.012	77	100.003		

The element displays sensitivity to the aspect ratio of its sides. Indeed, chosing a different set of parameters

```
h = 1*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 1*m; // Beam length
B = 0.2*m; // Beam width
rho = 0*kg/m^3; // Mass density
```

yields slightly different results

N_{subd}	u_z	N_{subd}	u_z	N_{subd}	u_z
2	93.7897	42	99.9958	83	100.001
7	99.5267	48	99.998	89	100.001
13	99.8587	54	99.9993	95	100.001
19	99.9409	60	100.	101	100.001
25	99.9713	66	100.001	107	100.001
31	99.985	72	100.001	112	100.001
37	99.992	77	100.001		

Test 2: Concentrated tip moment

The test file for this case can be found in

`(ESSI SOURCE FOLDER)/Verification_Examples/...`

`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`

`.../Shell_ANDES/static/Test_shell_andes_2_bending_transverse.fei`

Analogous to the previous test, for a cantilever beam with a tip moment the tip rotation is

$$\theta_{\text{tip}} = \frac{ML}{EI}$$

and for this test case's geometry

$$\theta_{\text{tip}} = \frac{mBL}{EBh^3/12} = \frac{12mL}{Eh^3}$$

In this case, the parameters are selected such that this tip rotation is of 100 units. Execution of the test case shows that with $N_{\text{subd}} = 2$ the theoretical value is met with 100% accuracy. This is because the moment field is constant inside the beam and the elements are capable of reproducing this field with accuracy.

Test 3: Concentrated mid-span transversal load

This case is similar to test case 1. The accuracy for 2 elements is 96.2% agreement with the theoretical solution. For $N_{\texttt{subd}} = 4$ (4 elements total) the accuracy climbs to 99.7%. The test file for this case can be found in

`(ESSI SOURCE FOLDER)/Verification_Examples/...`

`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`

`.../Shell_ANDES/static/Test_shell_andes_3_bending_transverse.fei`

Test 4: Transversal distributed load

The distributed load is generated by accelerating the beam transversally with an acceleration which produces a 100 (unit) displacement. This provides an indirect test to the mass matrix which will be further tested in dynamic tests. The uniformly distributed load q which produces the δ_{tip} unit displacement and the corresponding tip rotation are

$$q = 8\frac{EI}{L^4}\delta_{\text{tip}} \qquad \text{and} \qquad \theta_{y\text{tip}} = \frac{4}{3L}\delta_{\text{tip}}$$

from this value, the required acceleration is computed as

$$a = \frac{q}{\rho BH}$$

where ρ is the unit-weight of the material used to compute the mass matrix.

For two subdivisions (6 nodes) the results of the two nodes located at the tip of the beam are

```
Node : 5
 ux = 0.000000, rx = 30.550500
 uy = 0.000000, ry = -133.333000
 uz = 102.541000, rz = 0.000000
Node : 6
 ux = 0.000000, rx = -30.550500
 uy = 0.000000, ry = -133.333000
 uz = 102.541000, rz = 0.000000
```

First, a 2.5% accuracy is reached in the tip displacement. Second, it is noteworthy to mention that the current formulation of the mass matrix will produce rotations around the x axis for the nodes. One reason for this is that the chosen mass matrix is not consistent with the stiffness matrix instead, it is borrowed from a similar element [1] [2] [3]. The reason behind this decision is the fact that the very accurate ANDES stiffness formulation lacks a displacement interpolation scheme which is necessary to produce

---

[3] C. A. Felippa and P. G. Bergan, A triangular plate bending element based on an energy-orthogonal free formulation, Comp. Meth. Appl. Mech. Engrg., 61, 129{160, 1987.

a consistent mass matrix. Furthermore, restraining these x roation degrees of freedom does not lead to an improved solution.

For 4 subdivisions, the results at the tip are:

```
Node : 9
 ux = 0.000000, rx = 31.671000
 uy = 0.000000, ry = -133.333000
 uz = 100.891000, rz = 0.000000
Node : 10
 ux = 0.000000, rx = -31.671000
 uy = 0.000000, ry = -133.333000
 uz = 100.891000, rz = 0.000000
```

and for 20.

```
Node : 41
 ux = 0.000000, rx = 32.095800
 uy = 0.000000, ry = -133.333000
 uz = 100.039000, rz = 0.000000
Node : 42
 ux = 0.000000, rx = -32.095800
 uy = 0.000000, ry = -133.333000
 uz = 100.039000, rz = 0.000000
```

and back to 2 subdivisions but this time with an aspect ratio $L/B = 2$, by changing B so that the expected tip displacement remains the same, we get

```
Node : 5
 ux = 0.000000, rx = 3.890200
 uy = 0.000000, ry = -133.333000
 uz = 99.810100, rz = 0.000000
Node : 6
 ux = 0.000000, rx = -3.890200
 uy = 0.000000, ry = -133.333000
 uz = 99.810100, rz = 0.000000
```

which shows that the effect of the inconsistent mass matrix is ameliorated for elements with a better aspect ratio. The elements in this case are square in shape since $L/B = 2$ and $N_{\texttt{subd}} = 2$.

In conclusion increasing accuracy for bending problems not only involves making the elements smaller but also improving their aspect ratio. This is especially critical in dynamic problems (or self weight problems). The test file for this case can be found in

`(ESSI SOURCE FOLDER)/Verification_Examples/...`

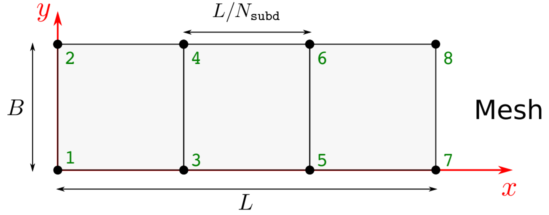
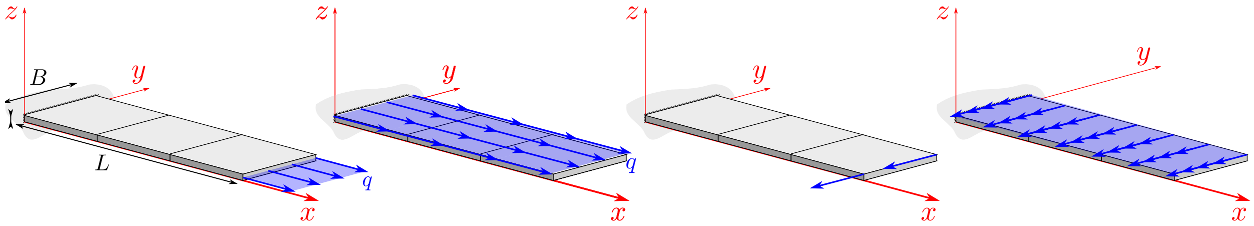
`.../Shell_ANDES/static/Test_shell_andes_4_bending_transverse.fei`

308.5.1.2 Membrane Component Verification

These tests compare the performance of the membrane component of the ANDES Shell by modelling simple beams and comparing the approximation with Bernoulli-beam theoretical results.





Test 5 Test 6 Test 7 Test 8

Test 5: Longitudinal tip load

The parameters used to test this case are,

```
h = 0.2*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 30*m; // Beam length
B = 3*m; // Beam width
rho = 0.0*kg/m^3; // Mass density
delta_tip = 100*m; // Target tip displacement

Nsubd = 2; // Number of side subdivisions
```

the tip load was computed to give $\delta_{\text{tip}} = 100$ from

$$F_{\text{tip}} = \frac{AE}{L}\delta_{\text{tip}}$$

Additionally, the tip rotation degrees of freedom about z axis (`rz`) were fixed to enforce the uniform loading condition. The results for 2 subdivisions observed at the two tip nodes is

```
Node : 5
 ux = 100.000000, rx = 0.000000
 uy = -0.000000, ry = 0.000000
 uz = 0.000000, rz = 0.000000
Node : 6
 ux = 100.000000, rx = 0.000000
 uy = -0.000000, ry = 0.000000
 uz = 0.000000, rz = 0.000000
```

The test file for this case can be found in `(ESSI SOURCE FOLDER)/Verification_Examples/...`
`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`
`.../Shell_ANDES/static/Test_shell_andes_5_membrane_axial.fei`

Test 6: Longitudinal self-weight load

As in test 4, the distributed load for this test was generated by using an acceleration field with a magnitude such that it generates 100 units of displacement in DOF `ux`. The required body force q (per unit length) is derived from linear elasticity to be

$$q = \frac{2EA}{L^2}\delta_{\text{tip}}$$

from which the acceleration is found to be given by $a = \dfrac{q}{\rho BH}$. The tip nodes were fixed to move only in the x direction. The model parameters used for this test are,

```
h = 1*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 1*m; // Beam length
B = 1*m; // Beam width
rho = 100*kg/m^3; // Mass density
delta_tip = 100*m; // Target tip displacement

Nsubd = 2; // Number of side subdivisions
```

and the tip displacements

```
Node : 5
 ux = 100.000000, rx = 0.000000
 uy = 0.000000, ry = 0.000000
 uz = 0.000000, rz = 0.000000
Node : 6
 ux = 100.000000, rx = 0.000000
 uy = 0.000000, ry = 0.000000
 uz = 0.000000, rz = 0.000000
```

Which means that in the quadratic displacement field coming from a uniform external load can be captured exactly by this element.

The test file for this case can be found in `(ESSI SOURCE FOLDER)/Verification_Examples/...`
`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`
`.../Shell_ANDES/static/Test_shell_andes_6_membrane_axial.fei`

Test 7: Transversal tip load This test is identical to test 1, except the beam mesh is placed sideways so that the membrane component is used instead of the bending one. Since the membrane part can capture deformation due to shear, the ratio L/B is set to 10 so that this does not affect the results.

```
h = 0.2*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 10*m; // Beam length
B = 1.0*m; // Beam height
rho = 0*kg/m^3; // Mass density
d_tip = 100*m; // Target tip displacement

Nsubd = 10; // Number of side subdivisions
```

Results at the tip show less than 1% error with theoretical results when shear component is made small.

```
Node : 21
 ux = -7.513920, rx = 0.000000
 uy = -100.650000, ry = 0.000000
 uz = 0.000000, rz = -15.072400
Node : 22
 ux = 7.513920, rx = 0.000000
 uy = -100.650000, ry = 0.000000
 uz = 0.000000, rz = -15.072400
```

It would be interestign to test this component vs. a beam theory which incorporates deformation due to shear such as Timoshenko beams.

The test file for this case can be found in `(ESSI SOURCE FOLDER)/Verification_Examples/...`
`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`
`.../Shell_ANDES/static/Test_shell_andes_7_membrane_transverse.fei`

Test 8: Transversal self-weight load This test is analogous to test 4, except the membrane component is being tested instead of the bending. Again, the L/B ratio is kept at 10 to avoid shear deformation creeping into the results perceptively.

```
h = 1*m; // Shell thickness
Eshell = 1*N/m^2; // Elastic modulus
nu = 0.0; // Poisson's ratio
L = 10*m; // Beam length
B = 0.5*m; // Beam width
rho = 100*kg/m^3; // Mass density
delta_tip = 100*m; // Target tip displacement

Nsubd = 10; // Number of side subdivisions
```

Displacement results at the tip nodes show less than 1% error when compared to Bernoulli beam theory.

```
Node : 21
 ux = 3.325110, rx = 0.000000
 uy = 99.780900, ry = 0.000000
 uz = 0.000000, rz = 13.301200
```

```
Node : 22
 ux = -3.325110, rx = 0.000000
 uy = 99.780900, ry = 0.000000
 uz = 0.000000, rz = 13.301200
```

The test file for this case can be found in `(ESSI SOURCE FOLDER)/Verification_Examples/...`

`.../Static_and_Dynamic_Behavior_of_Structural_Elements/...`

`.../Shell_ANDES/static/Test_shell_andes_8_membrane_transverse.fei`

308.5.2 Dynamic Tests

The purpose of the dynamic tests is to verify that the mass matrix adopted for these elements (which is not consistent with the stiffness) is adequate for Dynamic analysis. Also tested herein are the geometric transformations.

Again, the tests are divided into bending and membrane components which are tested independently. Also, an eigenvalue analysis is performed to verify accordance with theoretical results for continuous Bernoulli beams. Finally, geometric transformations are tested by performing an eigenvalue analysis for the same (unrestrained) beam in different orientations (pitch, yaw and roll) which should have invariant eigenvalues.

308.5.2.3 Geometric Transformations

308.6 Verification of 4NodeANDES elements

308.6.1 Verification of 4NodeANDES cantilever beams

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (308.10).

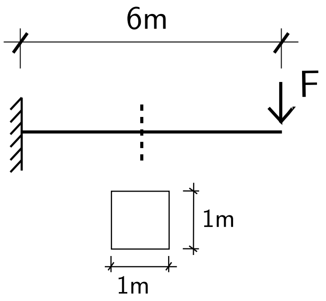

Figure 308.10: Problem description for cantilever beams.

Theoretical displacement (bending and shear deformation):

$$
\begin{aligned}
d &= \frac{FL^3}{3EI} + \frac{FL}{GA_v} \\
&= \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} \\
&= \frac{100N \times 6^3 m^3}{3 \times 10^8 N/m^2 \times \frac{1}{12} m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7 N/m^2 \times 1m^2 \times \frac{5}{6}} \\
&= 8.64 \times 10^{-4} m + 0.144 \times 10^{-4} m \\
&= 8.784 \times 10^{-4}\ m
\end{aligned}
\tag{308.1}
$$

4NodeANDES element model:

- Force direction: perpendicular to plane (bending)

When the force direction is perpendicular to the plane, only the bending deformation is calculated in 4NodeANDES elements.

The 4NodeANDES elements were shown in Figure (308.14).

- Force direction: inplane force

When the force direction is inplane, both the bending and shear deformation are calculated in 4NodeANDES elements.

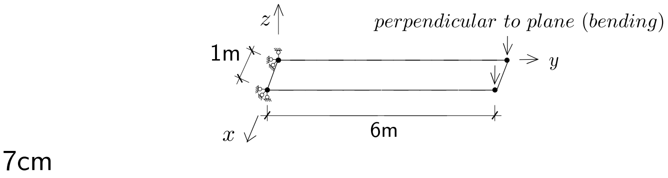

Figure 308.11: One 4NodeANDES element.

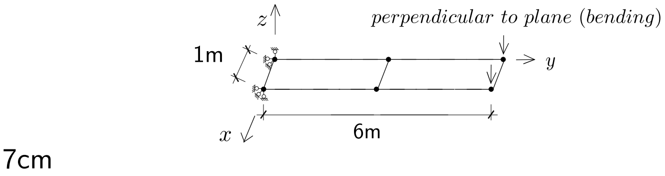

Figure 308.12: Two 4NodeANDES elements.

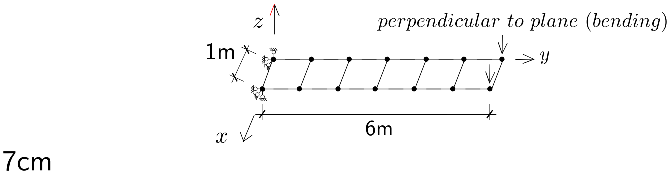

Figure 308.13: Six 4NodeANDES elements.

Figure 308.14: 4NodeANDES elements for cantilever beams under force perpendicular to plane.

The 4NodeANDES elements under inplane force were shown in Figure (308.18).

The Real-ESSI results for the force perpendicular to plane (bending) were listed in Table (308.3). The theoretical solution is 8.784E-04 m. The Real-ESSI results for the inplane force were listed in Table (308.4).

Table 308.3: Results for 4NodeANDES cantilever beams under the force perpendicular to plane (bending).

Element number	1	2	6
4NodeANDES	6.56E-04 m	8.27E-04 m	8.86E-04 m
Error	25.34%	5.87%	0.83%

The theoretical solution is 8.784E-04 m.

The errors were plotted in Figure (308.21).

The Real-ESSI model fei/DSL files for the table above are HERE.

308.6.2 Verification of 4NodeANDES cantilever beam for different Poisson's ratio

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0 - 0.49$. The force direction was shown in Figure (308.22).

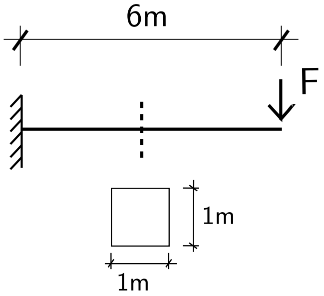

Figure 308.22: Problem description for cantilever beams of different Poisson's ratios.

The theoretical solution for $\nu = 0.0$ was calculated below, while the solution for other Poisson's ratio were calculated by the similar process.

Theoretical displacement (bending and shear deformation):

$$\begin{aligned} d &= \frac{FL^3}{3EI} + \frac{FL}{GA_v} \\ &= \frac{FL^3}{3E\frac{bh^3}{12}} + \frac{FL}{\frac{E}{2(1+\nu)}\frac{bh}{\kappa}} \\ &= \frac{100N \times 6^3 m^3}{3 \times 10^8 N/m^2 \times \frac{1}{12} m^4} + \frac{100N \times 6m}{\frac{10}{2} \times 10^7 N/m^2 \times 1m^2 \times \frac{5}{6}} \\ &= 8.64 \times 10^{-4} m + 0.144 \times 10^{-4} m \\ &= 8.784 \times 10^{-4}\ m \end{aligned} \tag{308.2}$$

The rotation angle at the end:

$$\theta = \frac{FL^2}{2EI} = \frac{100N \times 6^2 m^2}{2 \times 10^8 N/m^2 \times \frac{1}{12} m^4} = 2.16 \times 10^{-4}\ rad = 0.0124^\circ \tag{308.3}$$

The 4NodeANDES elements for cantilever beams of different Poisson's ratios were shown in Figure (308.23) and (308.24):

The Real-ESSI results for the force perpendicular to plane (bending) were listed in Table (308.5) - (308.7).

The errors were plotted in Figure (308.27).

The Real-ESSI results for the inplane force were listed in Table (308.8) - (308.10).

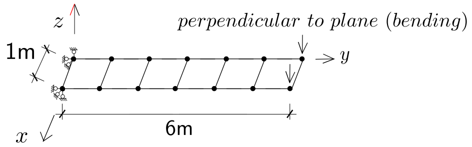

Figure 308.23: 4NodeANDES elements for different Poisson's ratios under the force perpendicular to plane (bending).

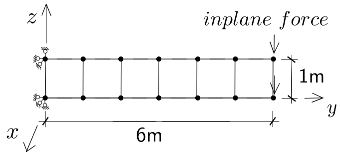

Figure 308.24: 4NodeANDES elements for different Poisson's ratios under the inplane force.

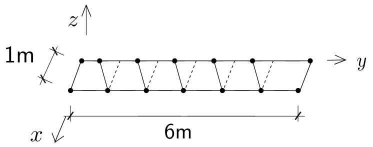
308.6.3 Test of irregular shaped 4NodeANDES cantilever beams

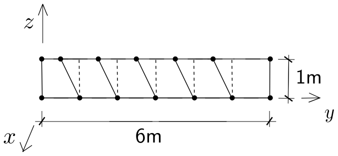
Cantilever model was used as an example. Three different shapes were tested.

In the first test, the upper two nodes of each element were moved one half element size along the $y-axis$, while the lower two nodes were kept at the same location. The element shape was shown in Figure (308.39).



7cm

Figure 308.37: Horizontal plane.



7cm

Figure 308.38: Veritical plane.

Figure 308.39: 4NodeANDES cantilever beam for irregular Shape 1.

In the second test, the upper nodes of each element were moved 50% element size along the $y-axis$, while the lower nodes were moved 50% element size in the other direction along the $y-axis$. The element shape was shown in Figure (308.42).

In the third test, the upper two nodes of each element were moved 90% element size with different directions along the $y-axis$, while the lower nodes were moved 90% element size in the other direction along the $y-axis$. The element shape was shown in Figure (308.45).

The boundary conditions were shown in Figures (308.48), (308.51) and (308.54).

The Real-ESSI results were listed in Table (308.17).

The errors were listed in Tables (308.18) and (308.19).

The Real-ESSI model fei/DSL files for the table above are HERE.

Then, the beam was divided into small elements.

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. Use the shear deformation coefficient $\kappa = 1.2$. The force direction was shown in Figure (308.55).

308.6.4 Verification of 4NodeANDES square plate with four edges clamped

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are clamped.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \ N \cdot m \tag{308.5}$$

The theoretical solution is

$$d = \alpha_c \frac{qa^4}{D} = 0.00406 \times \frac{100 N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \ N \cdot m} = 2.2015 \times 10^{-3} m \tag{308.6}$$

where α_c is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[4] α_c is 0.00406.

The 4NodeANDES were shown in Figures (308.77) - (308.82).

308.6.5 Verification of 4NodeANDES square plate with four edges simply supported

Problem description: Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are simply supported.

The load is the uniform normal pressure on the whole plate.

The plate flexural rigidity is

$$D = \frac{Eh^3}{12(1-\nu^2)} = \frac{10^8 N/m^2 \times 1^3 m^3}{12 \times (1-0.3^2)} = 9.1575 \times 10^6 \; N \cdot m \tag{308.7}$$

The theoretical solution is

$$d = \alpha_s \frac{qa^4}{D} = 0.00126 \times \frac{100 N/m^2 \times 20^4 m^4}{9.1575 \times 10^6 \; N \cdot m} = 7.0936 \times 10^{-3} m \tag{308.8}$$

where α_s is a coefficient, which depends on the ratio of plate length to width. In this problem, the coefficient[5] α_s is 0.00126.

Chapter 309

Verification and Validation for Static and Dynamic Behavior of Special Elements (Contacts/Interfaces/Joints, Gap/Frictional, Isolators)

(2010-2011-2016-2017-2019-2021-)

(In collaboration with Prof. Sumeet Kumar Sinha and Dr. Yuan Feng, and Prof. Han Yang)

309.1 Chapter Summary and Highlights

309.2 Verification of Static Penalty Contact/Interface/Joint Element Modeling and Simulation

References for interface elements: Hird and Russell (1990), AG (2020).

This section presents the verification of Penalty Stiffness based Frictional Contact/Interface/Joint Element using analytical simple solutions to verify the numerical solutions obtained by the application of the developed model. The examples show the response of element for different cases. Solution sensitivity on penalty stiffness is also discussed in details for those examples.

Theoretically, the penalty stiffness should be infinite, but for numerical stability of the solution, it can go upto 10^{16}. This is because for a double precision computer, machine epsilon $\epsilon \approx 10^{-16}$ and thus the corresponding displacement for the penalty springs can go low only till 10^{-16}. For all the cases considred below in this cases, the convergence criteria was as $||\delta U|| <= 10^{-12}$.

309.2.1 Static Normal Contact/Interface/Joint Verification

A Two-bar truss example is considered here to verify the normal contact/interface/joint for different normal loading conditions and different penalty stiffness K_n. This is an example of normal loading on a 1-D contact/interface/joint between two bars separated by an initial gap of $\delta_{in} = 0.1m$. An illustrative diagram of the problem statement is shown below.

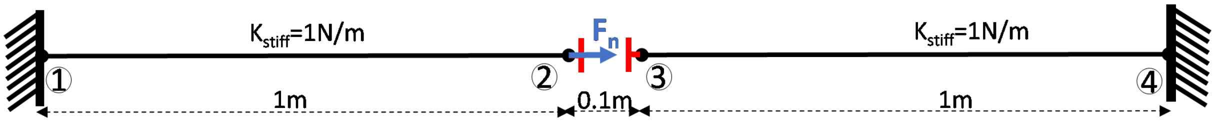

Figure 309.1: Illustration of two bar normal Contact/Interface/Joint problem under monotonic loading with inital gap.

A snapshot of the code for the contact/interface/joint element is shown below. The Real-ESSI model fei/DSL files for this example can be downloaded HERE.

```
add element #3 type FrictionalPenaltyContact with nodes (2,3)
 normal_stiffness =1e10*N/m
 tangential_stiffness = 1e10*Pa*m
 normal_damping = 0*kN/m*s
 tangential_damping = 0*kN/m*s
 friction_ratio = 0.3
 contact_plane_vector = (1,0,0);
```

309.2.1.1 Case 1: Monotonic Loading with initial gap $\delta_{in} = 0.1m$

In this case a force of 0.3N is applied to Node 2. From Figure 309.2, the solution converges to the analytical result for $K_n = 100N/m$ i.e 100 times the stiffness of bar element. Please note that, the for penalty stiffness $> 10e15$, the convergence fails (when the bars contact/interface/joint mode chnges), as the global stiffness matrix becomes *ill conditions*. Thus, the penalty stiffness cannot be too large.

309.2.1.2 Case 2: Monotonic Loading with no initial gap $\delta_{in} = 0m$

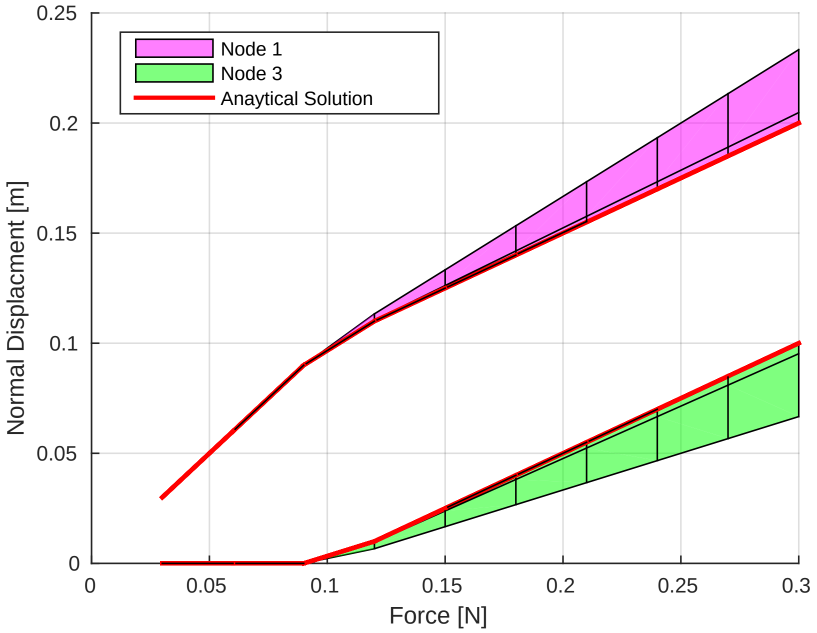
In this case a force of 0.3N is applied to Node 2. From Figure 309.3, the solution again converges to the analytical result for $K_n = 100N/m$ i.e 100 times the stiffness of bar element.

309.2.1.3 Case 3: Cyclic Loading with initial gap $\delta_{in} = 0.1m$

For cyclic loading cases considered below, the loading force F_n applied is shown in Figure 309.4. From Figure 309.5, the solution again converges to the analytical result for $K_n = 100N/m$ i.e 100 times the stiffness of bar element.

309.2.1.4 Case 4: Cyclic Loading with no initial gap $\delta_{in} = 0m$

The same cyclic load shown in Figure 309.4 is again applied fpor this case. From Figure ??, the solution again converges to the analytical result for $K_n = 100N/m$ i.e 100 times the stiffness of bar element.



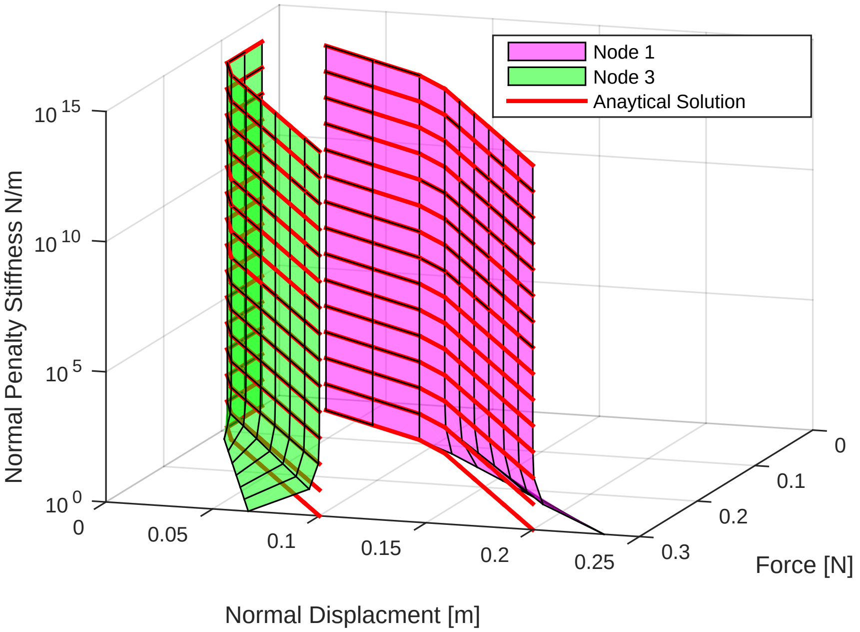


Figure 309.2: Displacements of Node 2 and Node 3 with change in normal penalty stiffness for $\delta_{in} = 0.1m$

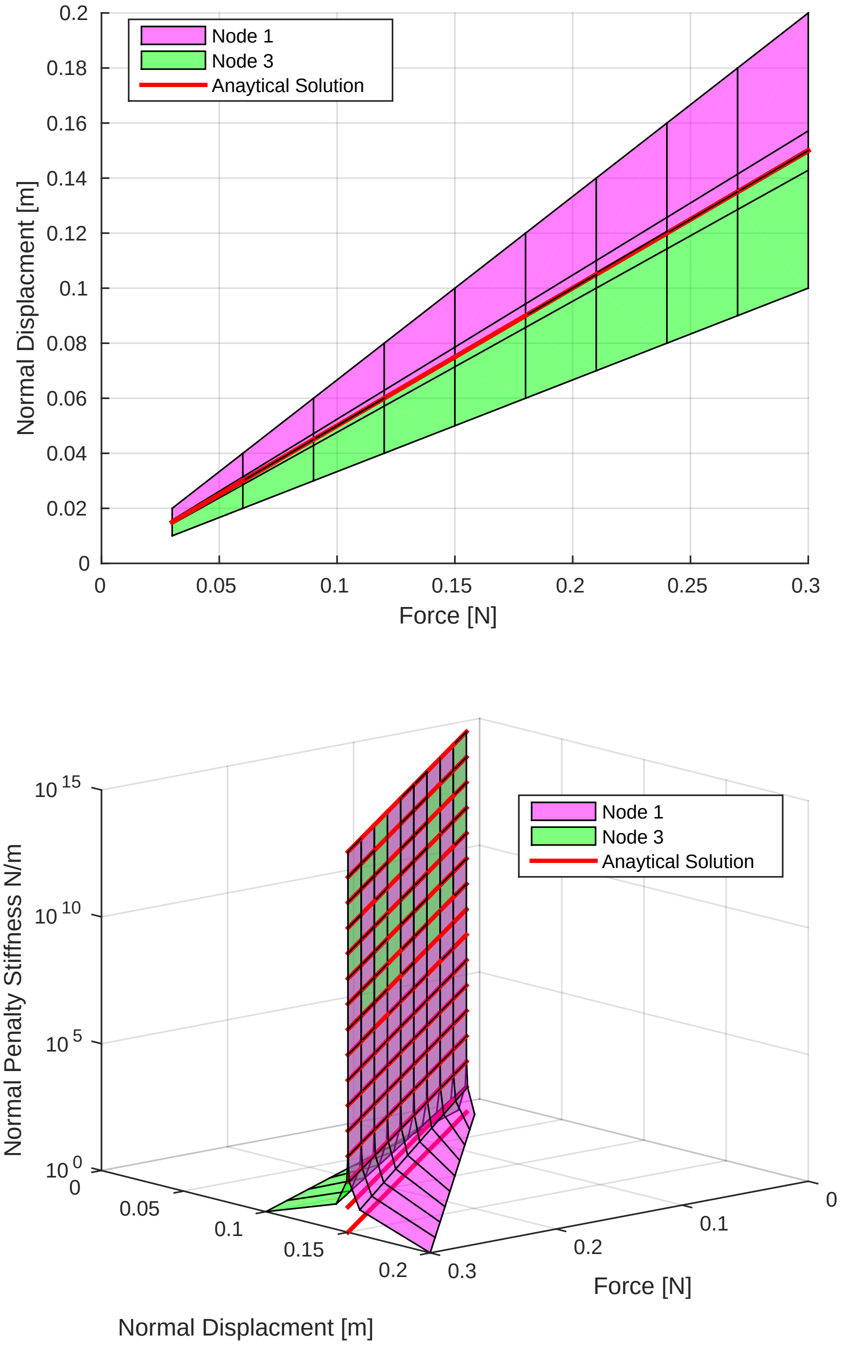

Figure 309.3: Displacements of Node 2 and Node 3 with change in normal penalty stiffness for $\delta_{in} = 0m$

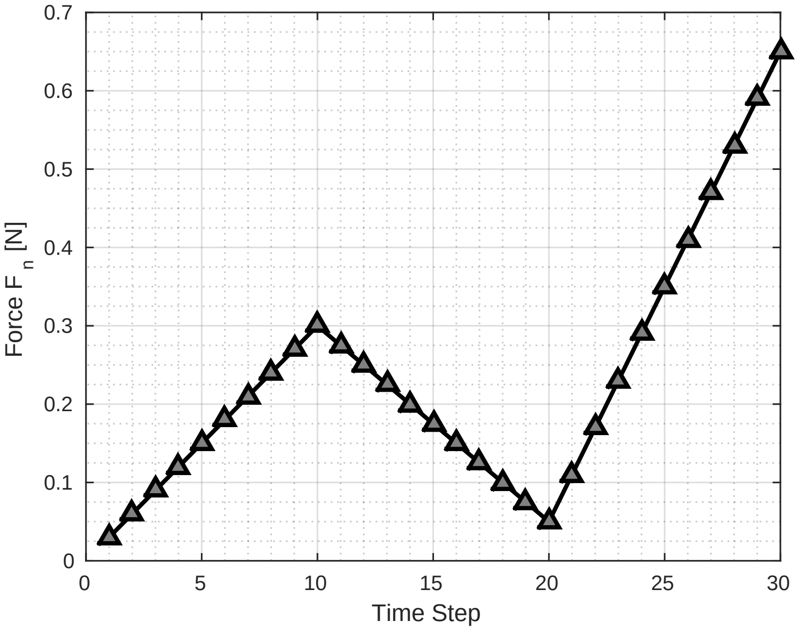

Figure 309.4: Cyclic normal load applied on two bar contact/interface/joint problem.

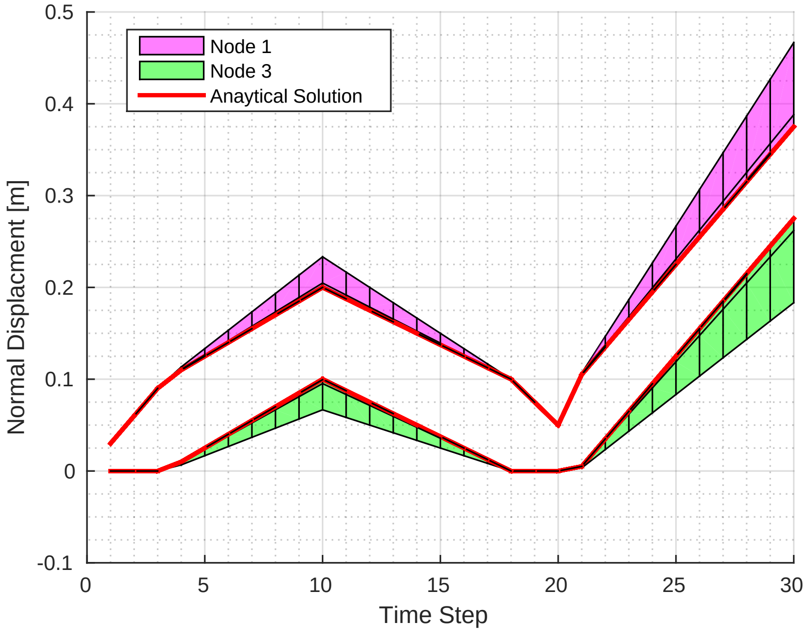

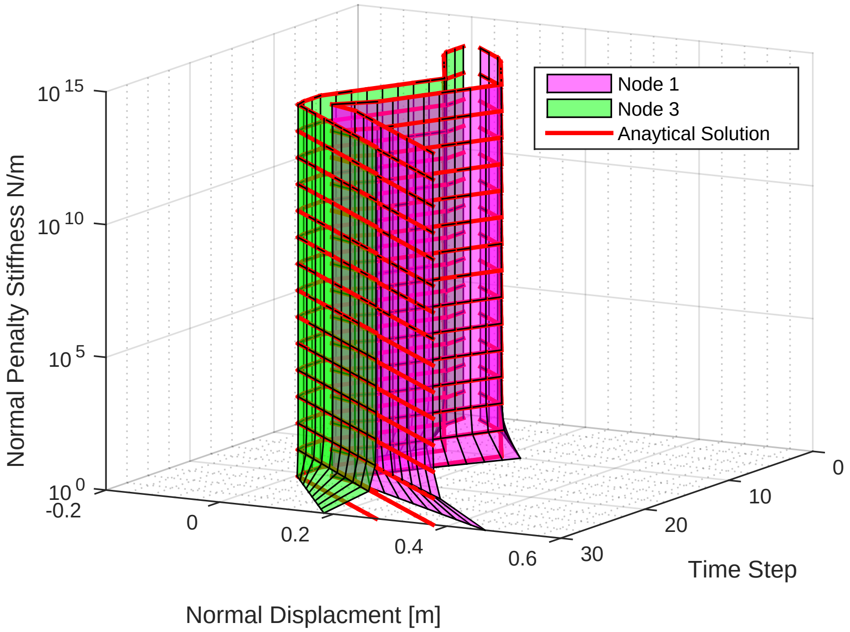

Figure 309.5: Displacements of Node 2 and Node 3 with change in normal penalty stiffness for $\delta_{in} = 0m$

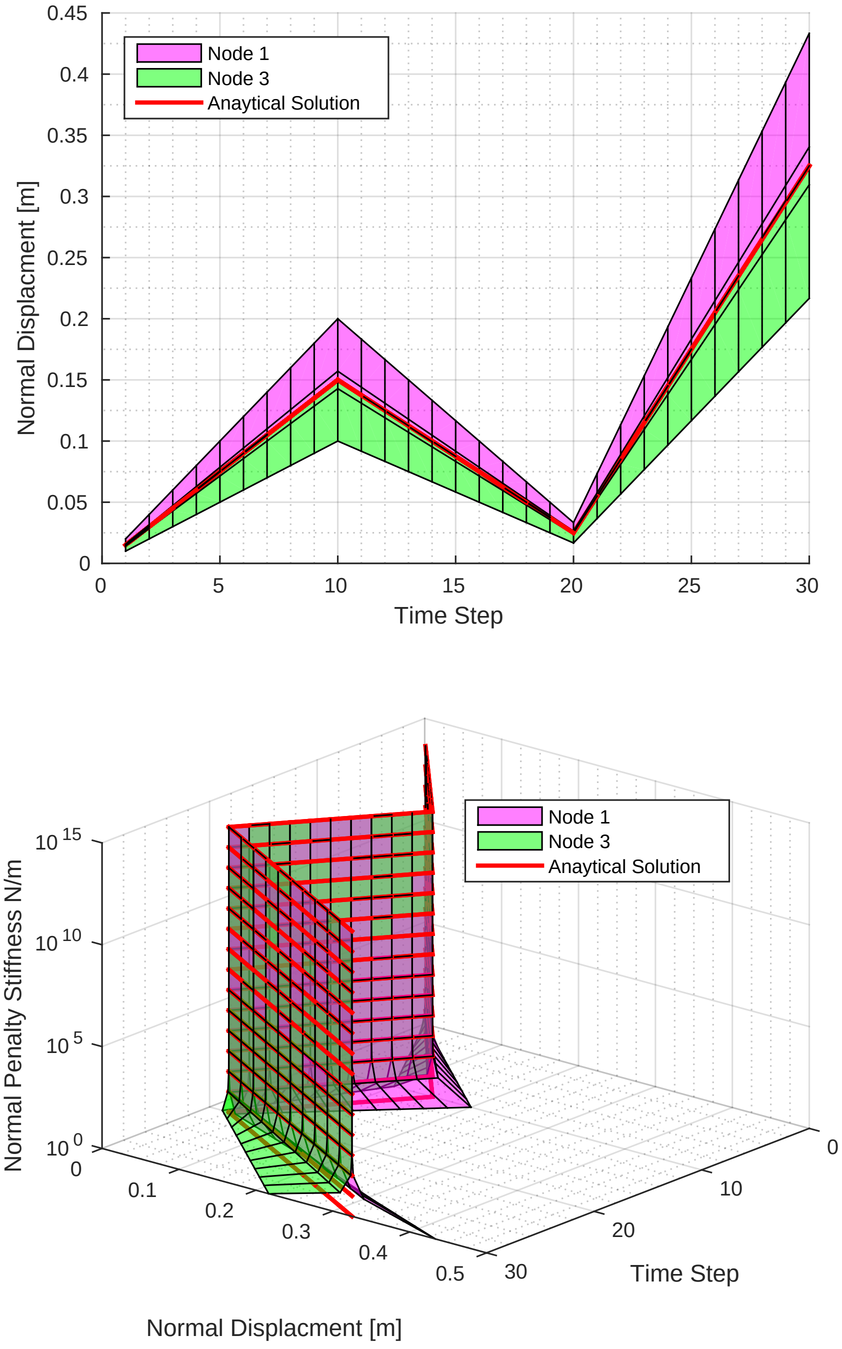

Figure 309.6: Displacements of Node 2 and Node 3 with change in normal penalty stiffness for $\delta_{in} = 0m$

309.2.2 Static Frictional Tangential Contact/Interface/Joint Verification

A simple 3-D truss example with Normal confinement in z-direction of $F_N = 0.5N$, friction coefficient $\mu = 0.2$ and shear loading of magnitude $F_s = 0.5N$ is considered to verify the tangential behaviour of contact/interface/joint element. Different cases as dicussed below are considered.

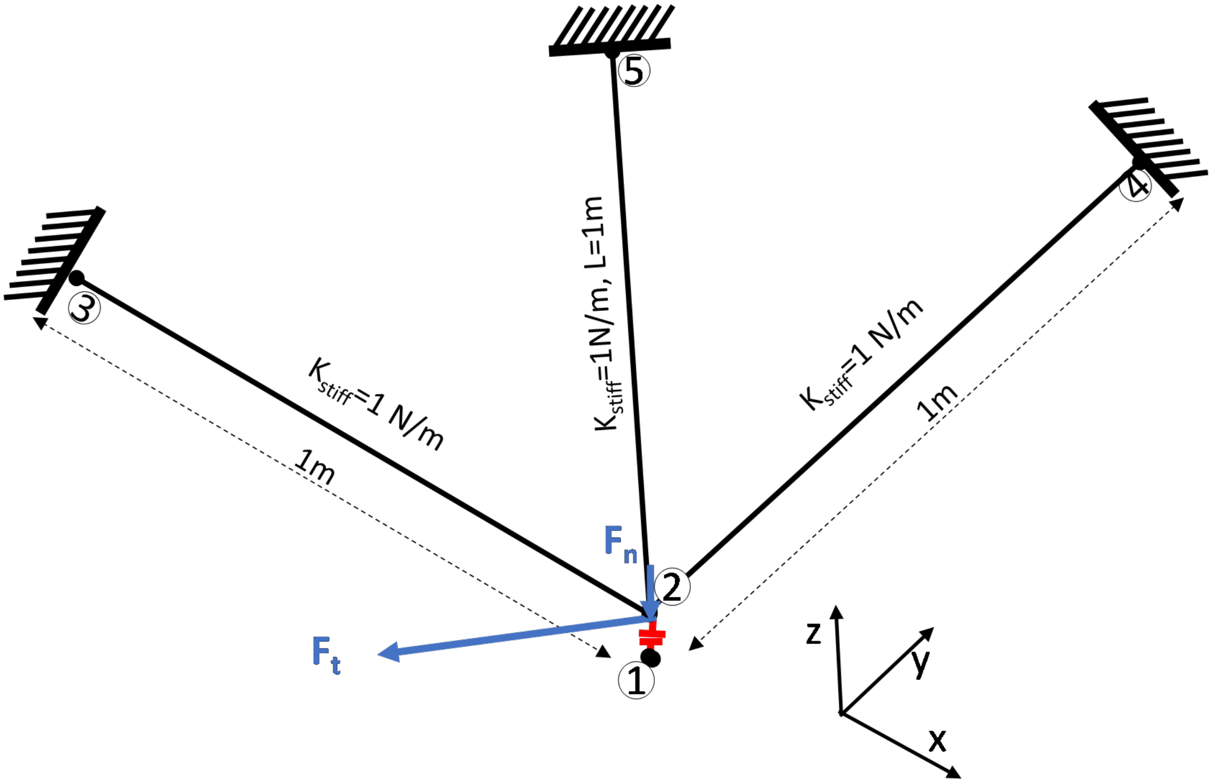

Figure 309.7: Illustration of 3-D three bar contact/interface/joint problem.

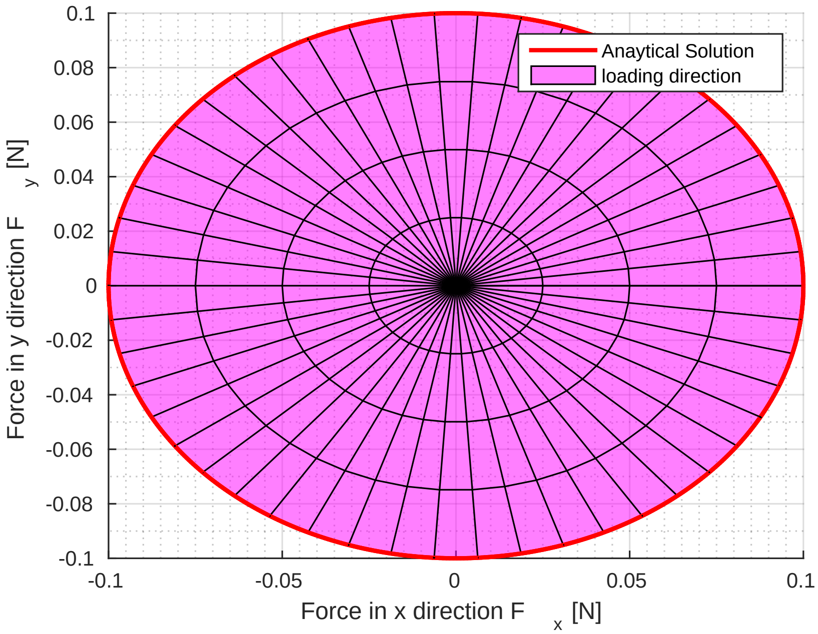
A snapshot of the properties of contact/interface/joint element os shown below. The Real-ESSI model fei/DSL files for this example can be downloaded HERE.

```
add element #4 type FrictionalPenaltyContact with nodes (1,2)
 normal_stiffness =1e10*N/m
 tangential_stiffness = 1e10*Pa*m
 normal_damping = 0*kN/m*s
 tangential_damping = 0*kN/m*s
 friction_ratio = 0.2
 contact_plane_vector = (0,0,1);
```

309.2.2.1 Case 1: Verfication of the yield surface for different loading angles with fixed normal confinement.

A Shear force of magnitude of $F_s = 0.5N$ was applied in 20 steps in different loading directions. The response of the contact/interface/joint element and the displacement of node 2 is shown in Figure 309.8 and Figure 309.9 respectively . It can be bserved that the contact/interface/joint element slips at magnitude of force $||F||- > (F_n = 0.5) * (\mu = 0.2) - > 0.1N$ for all loading angles.

In Figure 309.9, it can be observed that for the first 4 steps, there is no (zero) displacement for node 2 because of the stick case. When the load exceeds $0.1N$, slip occurs and node 2 starts to undergo deformation.



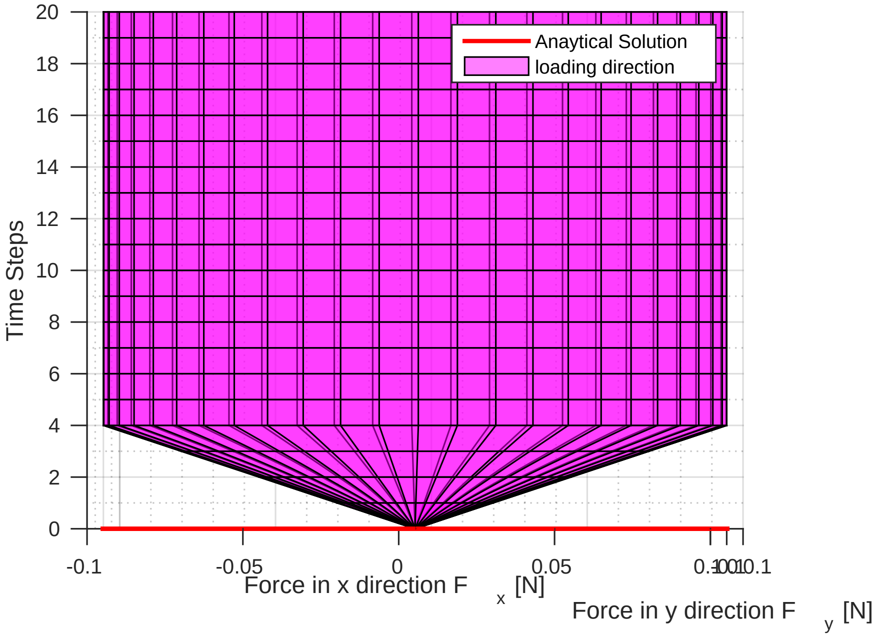


Figure 309.8: Response of contact/interface/joint element for different loading angles for confinement of $0.5N$ and coefficient of friction as 0.2

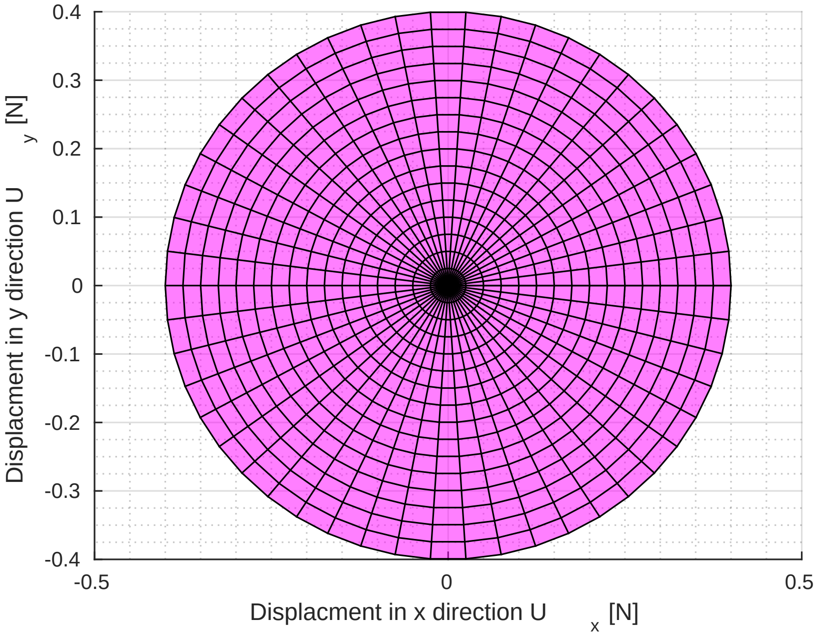
.



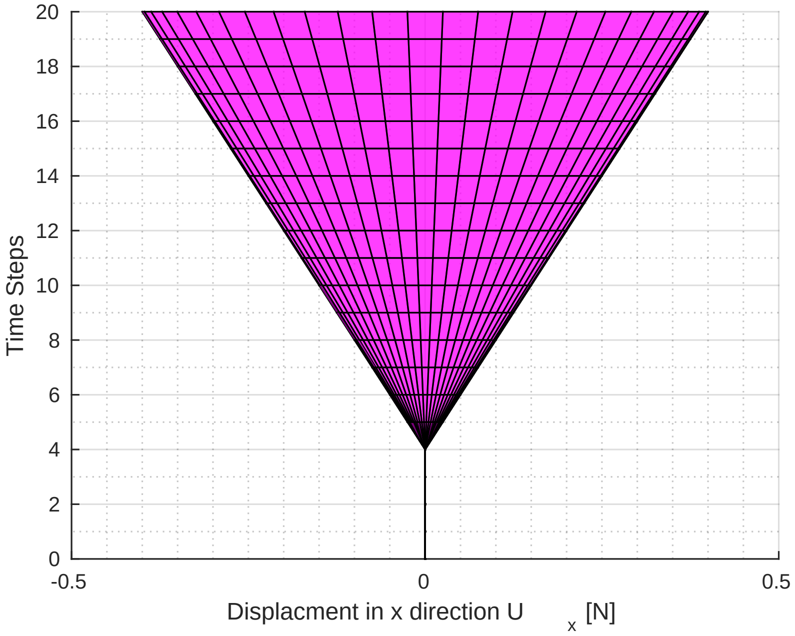


Figure 309.9: Displacement of Node No. 2 in x and y direction for different loading angles for confinement of $0.5N$ and coefficient of friction as 0.2

.

309.3 Verification of Static and Dynamic Contact/interface/Joint Element Modeling and Simulation

Solution verification of the contact/interface/joint element formulation and its implementation is presented in what follows. Analytical simple solutions for the frictional contact/interface/joint element are used to verify numerical solutions obtained by application of the developed model. The examples provided show the response of the contact element in several situations. Initially, the element is tested by connecting two nodes that each have *3dof*, subsequently, the element is even implemented to simulate a contact/interface/joint between two nodes that each have *7dof* and two nodes with different dofs: *3dof* for the first one and *7dof* for the second one.

The parameters used for the contact/interface/joint element are listed in Table 309.1.

Parameter	Value
C_N [kN/m]	10420
$\overline{v}_{max}$ [m]	0.001
K_T [kN/m]	1e7
μ [-]	0.6

Table 309.1: Contact/interface/joint element parameters.

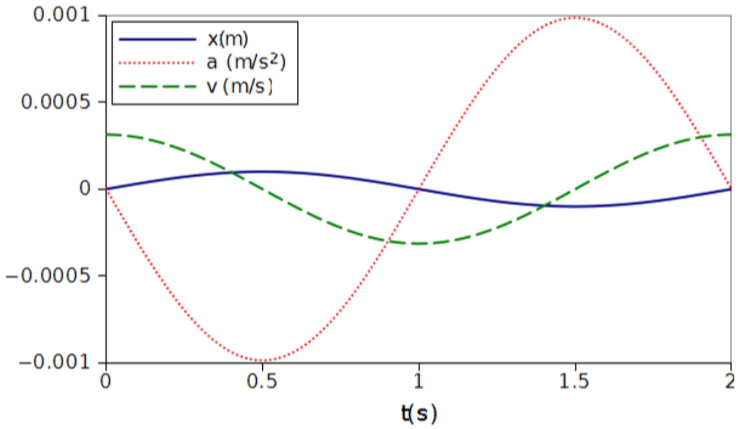

Figure 309.10: Input signal: time history of displacement, acceleration and velocity.

309.3.1 Truss Examples

The first example (Figure 309.11) represents five nodes: `1,2,3,4,5`. Nodes `2,3,4,5` are connected by three truss elements and a contact/interface/joint element links node `1` and `2`. All degrees of freedom of nodes `1,3,4,5` are fixed, whereas a sine wave displacement time-history (Figure 309.10) is applied to node `2` along `x` direction and the normal force acting within the contact/interface/joint element is recorded. The results, represented in Figure 309.12, show the normal response of this new contact/interface/joint element. As the timestep decreases, the force-displacement curves tends to be similar to the one represented by (??).

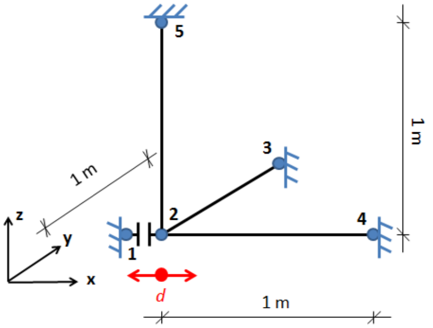

Figure 309.11: System composed of one contact/interface/joint element and three truss elements. A sine wave displacement time-history is applied to node (2).

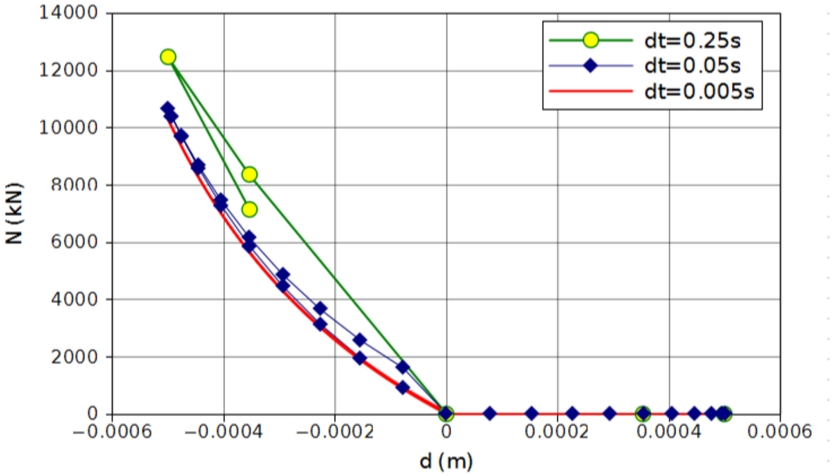

Figure 309.12: Normal force vs normal-relative displacement in contact/interface/joint element.

The second example (Figure 309.13) shows the tangential response of this new contact/interface/joint element. The geometry of the problem is the same as Figure 309.11, but an axial force (p = 1140 kN), constant in time, and a sine wave time-history displacement are applied to node 2. The results, represented in Figure 309.14, show that the response is not dependent on the timestep used for the analysis. Due to the elastic-perfectly-plastic behavior, associated with Mohr-Coulomb yield criteria, the maximum shear force (t_{max}) that the contact/interface/joint element can sustain is 684 kN , equal to $t_{max} = \mu \cdot p = 0.6 \cdot 1140 kN$.

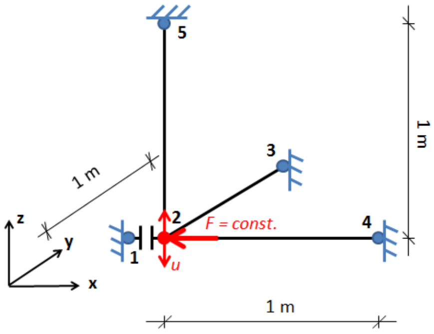

Figure 309.13: Same system used in Figure 309.11. A normal force constant in time (F = 1140 kN) and a sine wave displacement time history are applied to node (2).

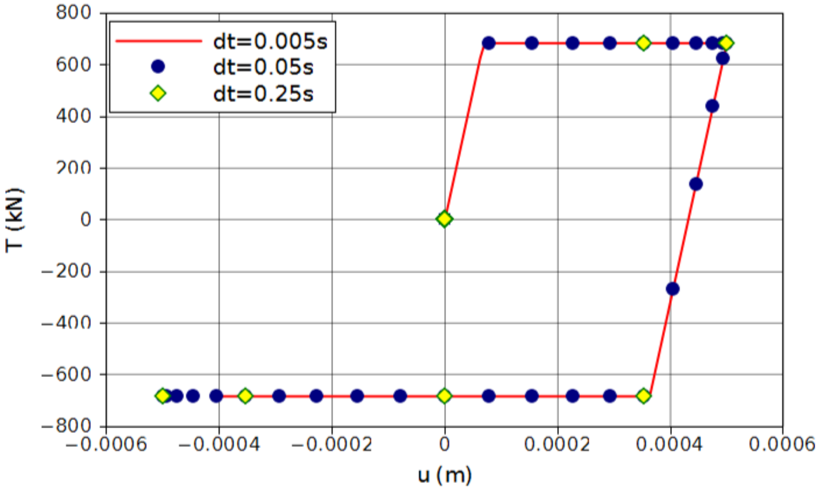

Figure 309.14: p = 1140 kN. Transversal force in the contact/interface/joint element vs transversal-relative displacement

309.3.2 Single Brick Element Examples

The contact/interface/joint element is now used to connect each node (`5,6,7,8`) of the bottom face of an eight node hexahedral element (`hex8`) to the corresponding node attached to the ground (`1,2,3,4`).

A linear elastic constitutive model is used for the eight node brick and the parameters are listed in Table 309.2.

Parameter	Value
E [kPa]	1.5e10
ν [-]	0.0

Table 309.2: Brick Element Parameters

In the first example (Figure 309.15) the time-history displacement, shown in Figure 309.10, is applied in the vertical direction to each node of the top surface of the brick element (`9,10,11,12`) and the time-history normal force induced in each contact element is represented in Figure 309.16. It is worth noting that the normal force is positive if the displacement of the top surface is downward, whereas it is zero if the detachement occurs caused by the upward movement.

Through the second example, shown in Figure 309.17, the transversal response of the contact/interface/joint elements is highlighted. The vertical normal force ($F_v = 50kN$), constant in time, and a horizontal time-history displacment are applied to each node of the top surface and the transversal response is shown in Figure 309.18. As stated in section 309.3.1, the maximum shear force that the contact element can sustain is is 30 kN , equal to $t_{max} = \mu \cdot p = 0.6 \cdot 50kN$.

The third example is focused on the transversal response of the contact/interface/joint element under variable normal forces. In fact, a sine wave time-history horizontal displacement and a vertical force are applied to each node of the top surface of the brick. The normal force is variable in time according to the factor ($Fact(t)$) shown in Figure 309.20 and the vertical force is computed as $F_v(t) = Fact(t) \cdot F_{v,max}$, and $F_{v,max}$ equal to 50 kN. The response of the contact element, shown in Figure 309.21, is independent of the timestep used for the analysis enphasizing the correct numerical implementation.

309.3.3 Double Brick Element Examples

Few other examples are produced taking in consideration two brick elements. The constitutive model used for these two brick elements is linear elastic with the same parameters listed in Table 309.2. Vertical and horizontal time-history displacement are applied to the top surface, shown in Figure 309.22 and Figure 309.23, and variable vertical forces are considered in the example represented in Figure 309.24. The results are the same shown in Figure 309.16, Figure 309.18 and Figure 309.19.

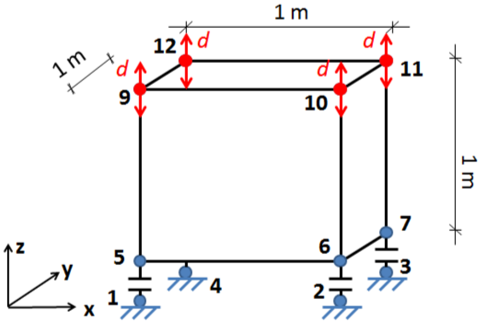

Figure 309.15: Eight-node brick element over four contact/interface/joint elements. A sine wave time-history vertical displacement applied to each node of the top surface.

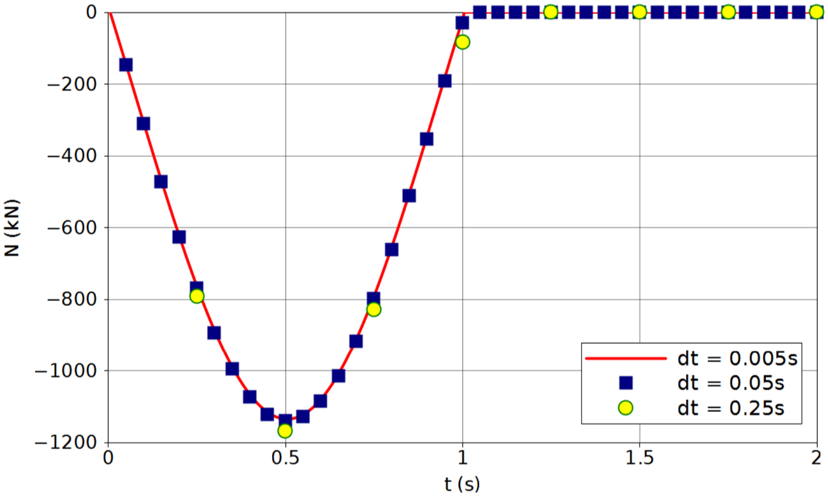

Figure 309.16: Normal force vs time in each contact element.

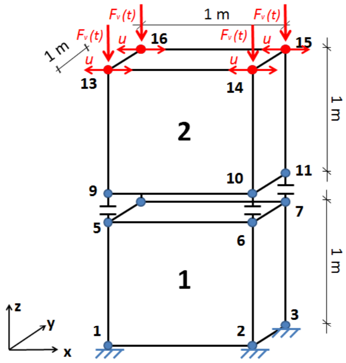

Figure 309.24: Two eight-node brick elements connected by four contact/interface/joint elements. Vertical force, variable in time, and horizontal time-history displacement applied to the nodes of the top surface.

309.4 Verification of Static and Dynamic Coupled (Saturated) Contact/Interface/Joint Element Modeling and Simulation

309.4.1 Dry u-p-U Contact/Interface/Joint

A single brick *u*-*p*-*U* finite element is used to model an oedometric compression shown in Figure 309.25. Horizontal displacements and pore pressure are fixed in each node in order to guarantee the one-dimensional and dry conditions. Since the ground is modeled as an undeformable and impermeable layer (`1,2,3,4`), vertical soil and fluid displacements are fixed. The time-history displacement, shown in Figure 309.10, is applied in vertical direction to each node of the top surface (`9,10,11,12`).

The time-history normal force induced in each contact/interface/joint element is represented in Figure 309.16 and compared with the one obtained with the dry brick element with *u* formulation, shown in Figure 309.15. It is worth noting that the normal force patterns are perfectly overlapped: this is due to the fact that excess pore pressure is fixed to zero and the oedometric stiffness are the same in the two cases.

Parameter	Symbol	Value
Young's Modulus	E $[kPa]$	$1.5 \cdot 10^{10}$
Poisson ratio	ν [-]	0.0

Table 309.3: Soil parameters.

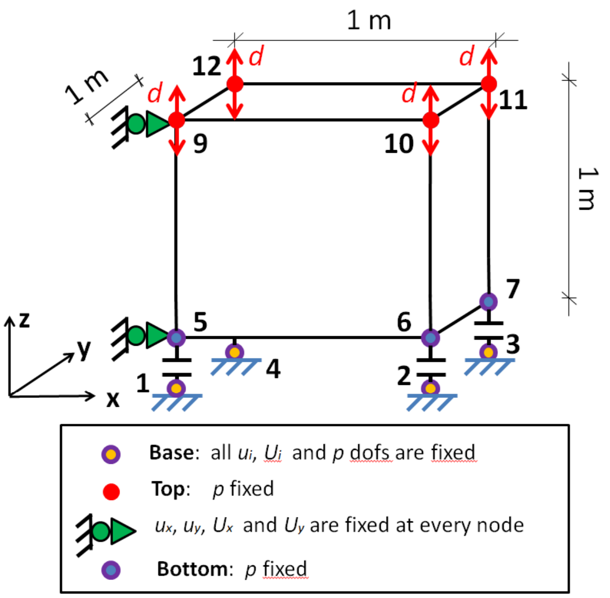

Figure 309.25: Single eight-node brick element. The nodes of the bottom surface are connected to the ground floor through contact/interface/joint elements. Vertical time-history displacement applied to the nodes of the top surface.

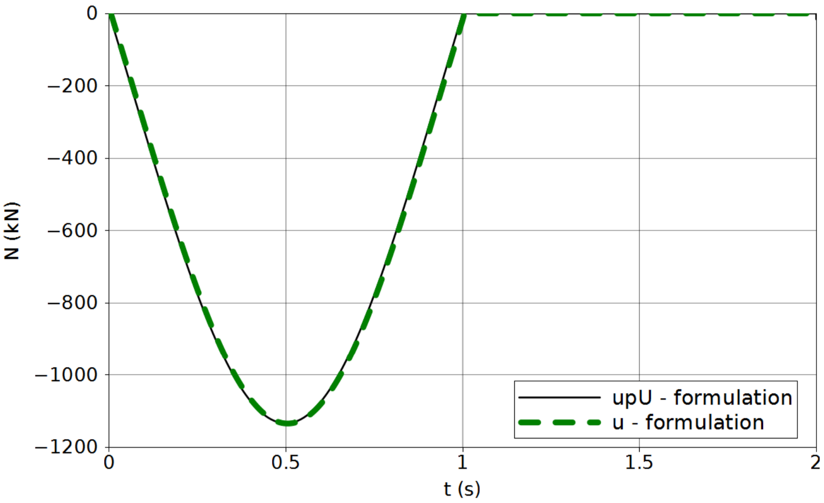

Figure 309.26: Normal force vs time in each contact/interface/joint element. *u-formulation* represents the results shown in Figure 309.16 whereas *upU-formulation* represents the results obtained through the model shown in Figure 309.25.

309.4.2 u-p-U Contact/Interface/Joint

A column of four brick *u-p-U* finite elements is used to model the horizontal layer. The height of the soil column is 1 m and the height of each element has dimensions $1m \cdot 1m \cdot 1m$, illustrated in Figure 309.27.

The following boundary conditions are applied to the model. As the bottom of the column is modeled as an undeformable and impermeable layer, both the solid and fluid displacements are fixed. The pore pressure is kept constant as zero at the top surface of the soil column because of the perfectly drained condition. In order to simulate the 1D compression problem, all the lateral movement of the solid and fluid phase are constrained so that the vertical displacement is the only non-zero displacement. A vertical time-history displacement, shown in Figure 309.10, is applied to the solid *dof* of the top surface nodes. In order to simulate the one dimensional compression, all the degrees of freedom at the same level are connected in a masterslave fashion.

The nodes of the bottom surface (`5,6,7,8`) are connected to the ground (`1,2,3,4`) through contact/interface/joint elements. Under the hypothesis of laminar flow, no cavitation and one-dimensional type of problem, the water has to fill up all the voids generated into the media while the displacement filed is acting on the top surface. This means that if the soil and the ground are separated because of the detachment of the contact/interface/joint element, the water has to fill the gap. Even the pore pressure at both sides of the gap has to assume the same value. Such boundary conditions can be introduced by adding masterslave between each node of the bottom surface (`5,6,7,8`) and the corresponding one belonging to the ground (`1,2,3,4`).

In this paragraph a parametric study is performed in order to examine the performance of this *u-p-U* contact/interface/joint element. The analyses consider several configuration of permeability and soil stiffness. In fact, three values of elastic modulus (E) are taken into consideration referring to a Stiff, Medium and Soft soil (called respectively `StS`, `MS` and `SoS`) and three values of the darcy permeability are similarly defined. All soil and contact/interface/joint parameters are listed respectively in Table 309.4 and Table 309.1.

This kind of excitation (a sine wave) applied at the top of the model is clearly composed of waves of all kinds of frequency, expetially at the initial strong change in acceleration and velocity for $t = 0s$. Due to this fact, a fairly dense mesh of 100 u-p-U brick finite elements of dimensions $1m \cdot 1m \cdot 1cm$ was chosen. Therefore, the time step Δt needs to be limited to $\Delta t = \Delta h/v$, where v is the highest wave velocity. In our case, the temporal integration involves 4000 steps of , which allows a maximum wave velocity of . The propagation velocity can be calculated by the following equation given by de Boer et al. (1993) and is equal to

$$v = \sqrt{\frac{n^2(1-\nu)E}{(1+\nu)(1-2\nu)[n^2(1-n)\rho_s + (1-n)^2 n\rho_f]}} \tag{309.1}$$

The artificial oscillation are diminished by introducing some numerical damping into the analysis through $\alpha = 0.6$ and $\beta = 0.3025$ for the Newmark integrator.

Figure 309.27: Four eight-node brick elements. The nodes of the bottom surface are connected to the ground floor through contact/interface/joint elements. Vertical time-history displacement applied to the nodes of the top surface.

The specific permeability, k and the time needed for completion of the 1D consolidation process, t, can be estimated using the darcy permeability K through (309.2) and (309.3) respectively, where ρ_w is the mass density of the fluid (water), g is the acceleration of gravity equal to $9.81 m/s^2$, H is the thickness of the soil layer and E_{oed} is the one dimensional soil stiffness:

$$k = \frac{K}{\rho_w \cdot g} \tag{309.2}$$

$$t = \frac{H^2}{c_v} = \frac{H^2 \cdot \rho_w \cdot g}{K \cdot E_{oed}} \tag{309.3}$$

The time t is computed and listed in Table 309.4.2 for each soil type condition. As can be seen, for the stiff soil (`StS`), the consolidation time is much lower than the loading acting on the top surface, therefore no excess pore pressure is developped into the soil and drained response is occurred.

Chapter 310

Verification and Validation for Coupled, Porous Solid – Pore Fluid Problems

(2000-2003-2007-2009-2010-2016-2017-2020-2021-)

(In collaboration with Prof. Zhao Cheng, Dr. Panagiota Tasiopoulou, Ms. Fatemah Behbehani, Prof. Han Yang and Mr. Yusheng Yang)

310.1 Chapter Summary and Highlights

310.2 Introduction

presented here are verification examples for u-p-U formulation. Examples include:

1. Drilling of a borehole
2. The case of a spherical cavity
3. Consolidation of a soil layer
4. Line injection of a fluid in a reservoir
5. Shock wave propagation
6. Vertical Consolidation of a soil layer by Coussy (2004)
7. One dimensional shock wave propagation with a step displacement boundary condition by Gajo and Mongiovi (1995)
8. One dimensional shock wave propagation with step loading at the surface by de Boer et al. (1993)
9. One dimensional shock wave propagation with a step velocity boundary condition by Hiremath et al. (1988)

310.3 Drilling of a well

310.3.1 The Problem

Let us consider an infinite half space domain composed of an isotropic, homogeneous and saturated thermoporoelastic material. At its reference state, it is assumed that the temperature, fluid pressure and stress fields are uniform and equal respectively, to T_0, p_0 and $\boldsymbol{\sigma}^0 = \sigma^0\mathbf{1}$(with $\sigma^0 < 0$). At time $=$ 0, an infinite cylinder of radius r_0 is instantaneously drilled parallel to the vertical axis Oz. It is filled with a fluid of the same nature as that saturating the porous medium but at a different pressure and temperature at the values of p_1 and T_1 respectively. The interface $r = r_0$ between the well and the porous medium is assumed to be in thermodynamic equilibrium.

In cylindrical coordinates $(r,\ \theta,\ z)$, the boundary conditions can be summarized as follows (see Fig.310.1):

$$
\begin{aligned}
t \leq 0 \rightarrow \qquad & \boldsymbol{\sigma}^0 = \sigma^0\mathbf{1} \qquad p(r) = p_0 \qquad T(r) = T_0 && (310.1)\\
t > 0 \rightarrow \qquad & \sigma_{rr}(r_0) = -p_1 \qquad \sigma_{r\theta}(r_0) = \sigma_{rz}(r_0) = 0\\
\sigma_{rr}(r \rightarrow \infty) \rightarrow \sigma^0 \qquad & \sigma_{r\theta}(r \rightarrow \infty) = \sigma_{rz}(r \rightarrow \infty) \rightarrow 0\\
& p(r_0, t) = p_1 \qquad p(r \rightarrow \infty) \rightarrow p_0\\
& T(r_0) = T_1 \qquad T(r \rightarrow \infty) \rightarrow T_0 && (310.2)
\end{aligned}
$$

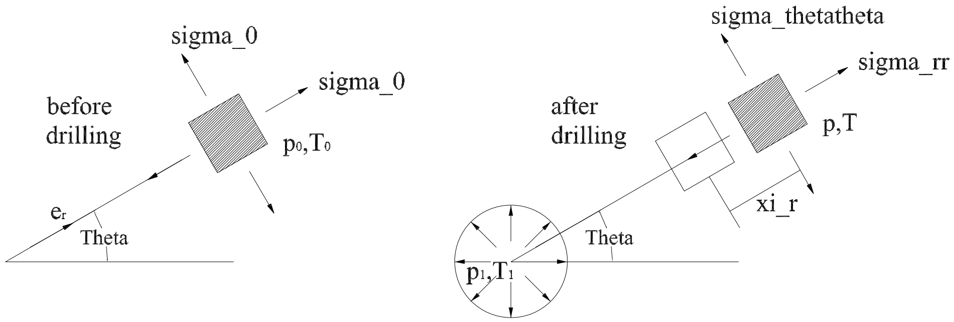

Figure 310.1: Boundary Conditions for Drilling of a Borehole

310.3.2 Analytical Solution

Since the well is assumed to be infinite long in its vertical axis Oz, the analysis is performed under plane strain hypothesis($\epsilon_{zz} = 0$). Therefore,

$$\boldsymbol{\xi} = \xi^r(r)e_r \qquad p = p(r) \qquad T = T(r) \tag{310.3}$$

in which ξ^r is the radial displacement. In cylindrical coordinates, Eqn. 310.48 yields

$$\epsilon_{rr} = \frac{\partial \xi^r}{\partial r} \qquad \epsilon_{\theta\theta} = \frac{\xi^r}{r} \qquad other \qquad \epsilon_{ij} = 0 \tag{310.4}$$

Based on the constitutive equations from Coussy (1995), it follows that

$$\sigma_{rr} = \sigma^0 + \lambda_0(\frac{\partial \xi^r}{\partial r} + \frac{\xi^r}{r}) + 2\mu\frac{\partial \xi^r}{\partial r} - b(p - p_0) - 3\alpha K_0(T - T_0) \tag{310.5}$$

$$\sigma_{\theta\theta} = \sigma^0 + \lambda_0(\frac{\partial \xi^r}{\partial r} + \frac{\xi^r}{r}) + 2\mu\frac{\xi^r}{\partial r} - b(p - p_0) - 3\alpha K_0(T - T_0) \tag{310.6}$$

$$\sigma_{zz} = \sigma^0 + \lambda_0(\frac{\partial \xi^r}{\partial r} + \frac{\xi^r}{r}) - b(p - p_0) - 3\alpha K_0(T - T_0) \tag{310.7}$$

$$other \qquad \sigma_{ij} = 0 \tag{310.8}$$

Finally combined with the Eqns. 310.5-310.8, it yields the near field or long-term solution (Coussy, 1995)

$$\xi^r = \frac{\sigma^0 + p_1}{2\mu}\frac{r_0{}^2}{r} + \frac{r_0[b(p_1 - p_0) + 3\alpha_0 K_0(T_1 - T_0)]}{2(\lambda_0 + 2\mu)}(\frac{r}{r_0} - \frac{r_0}{r}) \tag{310.9}$$

$$\sigma_{rr} = -p_1\frac{r_0{}^2}{r^2} - \{\sigma_0 - \frac{\mu[b(p_1 - p_0) + 3\alpha K_0(T_1 - T_0)]}{\lambda_0 + 2\mu}\}(1 - \frac{r_0{}^2}{r^2}) \tag{310.10}$$

$$\sigma_{\theta\theta} = (2\sigma_0 + p_1)\frac{r_0{}^2}{r^2} - \frac{\mu[b(p_1 - p_0) + 3\alpha K_0(T_1 - T_0)]}{\lambda_0 + 2\mu}(1 + \frac{r_0{}^2}{r^2}) \tag{310.11}$$

$$\sigma_{zz} = \sigma^0 - \frac{2\mu}{\lambda_0 + 2\mu}[b(p_1 - p_0) + 3\alpha K_0(T_1 - T_0)] \tag{310.12}$$

And the diffusion process can be achieved if that the time are large enough with respect to the characteristics diffusion time relative to point r. When the boundary conditions for $r = r_0$ in fluid pressure and temperature which are $p = p_1$ and $T = T_1$ apply for the whole model, the following equations correspond to the undrained solution of the instantaneous drilling of a borehole in an infinite elastic medium.

$$\xi^r = \frac{\sigma^0 + p_1}{2\mu}\frac{r_0{}^2}{r} \qquad \sigma_{rr} = \sigma^0 - (\sigma_0 + p_1)\frac{r_0{}^2}{r^2}$$
$$\sigma_{\theta\theta} = \sigma^0 + (\sigma^0 + p_1)\frac{r_0{}^2}{r^2} \qquad \sigma_{zz} = \sigma_0 \tag{310.13}$$

310.3.3 Discussion of the Results

As the problem is Axisymmetric, we construct the model as a quarter of a donut. The inside diameter of the donut is 10 cm and the outside diameter is 1 m. To accommodate both the plain strain hypothesis and the geometry of the element for finite element, the thickness of the model is chosen to be 5 cm. The final mesh is generated as Fig.310.2. And the boundary conditions is as follows: As a consequence of plain strain problem, all the movements for solid and fluid in vertical direction Oz are suppressed; the solid and fluid displacement for the nodes along the X axis and Y axis are fixed in Y and X direction respectively for the reason of axisymmetry; the nodes along the outside perimeter are fixed in the solid and fluid displacement with the assumption of infinite medium. the pressure is translated into nodal forces

Parameter	Symbol	Value	Units

Young's Modulus	E	1.2E+6	kN/m^2
Solid Bulk Modulus	K_s	3.6E+7	kN/m^2
Fluid Bulk Modulus	K_f	1.0E+17	kN/m^2
Solid Density	ρ_s	2.7	ton/m^3
Fluid Density	ρ_f	1.0	ton/m^3
Porosity	n	0.4	-

Table 310.1: Material Properties used to study borehole problem

and applied on the nodes along the inside perimeter. For simplicity, the hydrostatic stress σ_0 is equal to zero and with the assumption of thermodynamic equilibrium through the process, the temperature factor can be neglected. Also the initial fluid pressure p_0 is set to be 0 kPa. The analytical solution is studied below using the following set of parameters shown in Table 310.1.

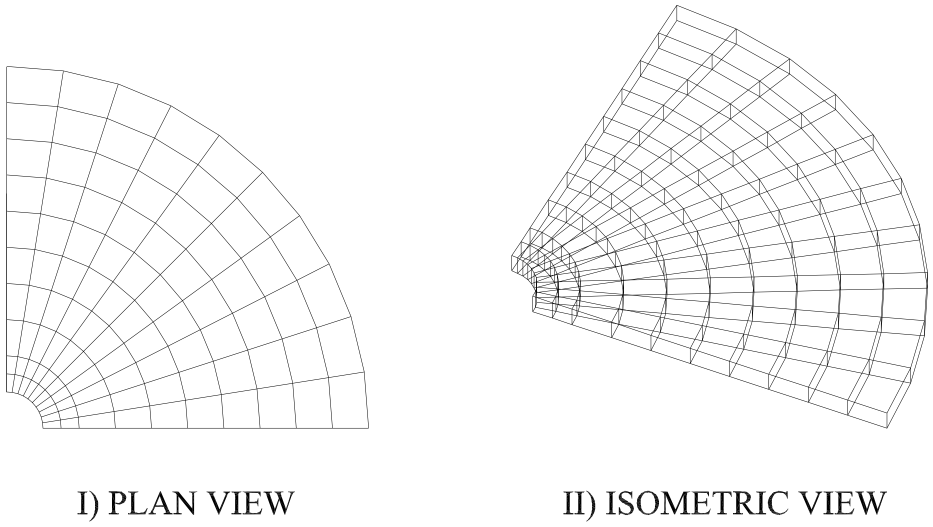

Figure 310.2: The mesh generation for the study of borehole problem

In the analysis, ten loading cases for final fluid pressure from 10 kPa to 100 kPa are studied. And by manipulating the permeability, it is possible to investigate both the drained behavior and undrained behavior. For the drained behavior, we choose the permeability as $k = 3.6 \times 10^{-4} m/s$, which is a typical value for sand, the comparison between the close solution and experimental result is shown in Fig.310.3. From the results, we can see that along the inside perimeter, the close solution and experimental result provide very good agreement to each other. But as the increase of the radius, we can see the analytical solution is getting more and more distant from the experimental results. In another word, the analytical solution can be interpreted as that with the increase from the loading surface, the radial displacement is larger. This is unreasonable in the point of view in soil mechanics. While the experimental result show the effect that with the increase of the radial distance, the radial displacement is decreasing.

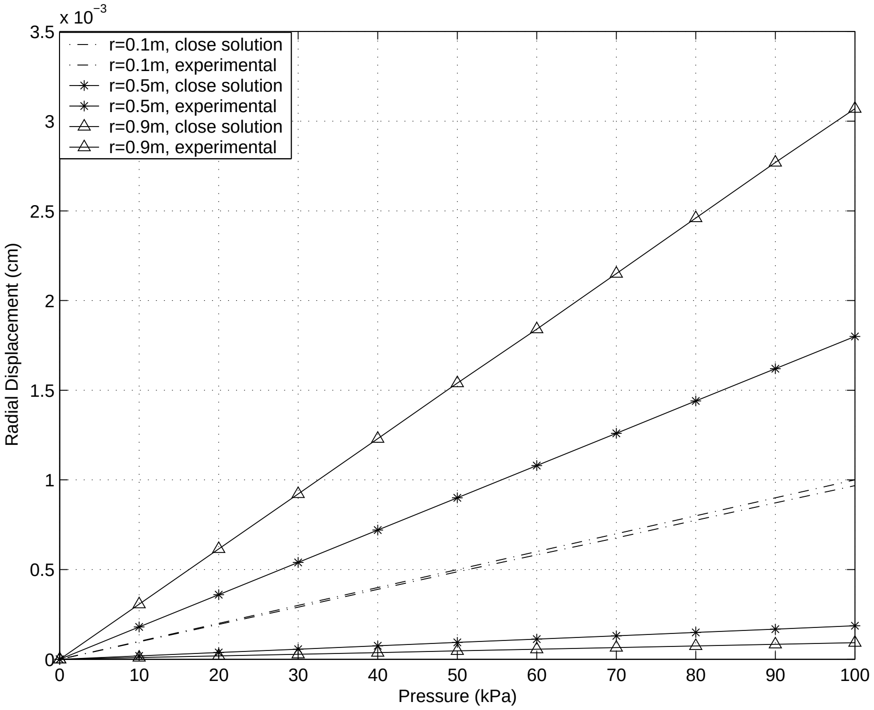

Figure 310.3: The comparison of radial solid displacement between analytical solution and experimental result for drained behavior

For the undrained behavior, the permeability of $k = 3.6 \times 10^{-8} m/s$ is selected as a representative value for typical clayey soil. The comparison between the close solution and experimental result is provided as well. From the Fig.310.4 we can see that, the analytical solution is linearly away from the experimental result by a ratio of approximately 1.6. It should also be noticed that the close solution of the drained and undrained behavior for the nodes along the inside perimeter are exactly the same, which is contradictory to the definition of drained and undrained behavior. For the drained behavior, as the water easily dissipate from the soil body, the problem can be treated with the knowledge of continuum mechanics using the parameters of the solid skeleton. While for the undrained behavior, with the involvement of the pore water, the elastic parameters for the mixture should be different, so the response will not be the same as well. As a result of this, the experimental results give a more reasonable conclusion.

As for the drained behavior, the fluid totally flows out of the soil body and all excessive pore pressure

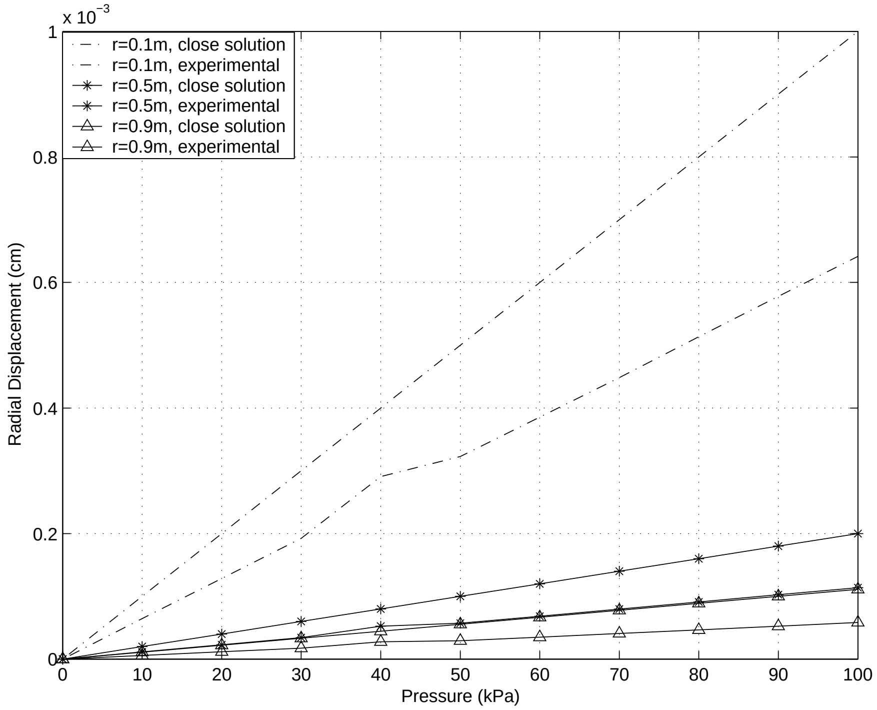

Figure 310.4: The comparison of radial solid displacement between analytical solution and experimental result for undrained behavior

dissipates, there is small coupling between the solid and fluid phase. We can use the continuum mechanics to treat this problem. Here introduces a problem of an infinite cylindrical tube, with the inner radius R_1 and outer radius R_0, subjected to an internal pressure P_1 and an external pressure P_2. The displacement field as follows (S.Timoshenko and D.H.Young, 1940):

$$\xi^r = \frac{{R_1}^2 P_1}{2({R_0}^2 - {R_1}^2)}\left(\frac{r}{\lambda + \mu} + \frac{{R_0}^2}{\mu r}\right) \tag{310.14}$$

With $P_0 = 0$ and take the limit of $R_0 \to \infty$, we can obtain the following equation:

$$\xi^r = \frac{P_1}{2\mu}\frac{{R_1}^2}{r} \tag{310.15}$$

which is identical to Eq.310.10. Also to minimize the effect of infinite boundary, we introduce the result from another model which is exactly the same as the previous one besides the expansion of the outer radius to 30m. At the final fluid pressure of 50 kPa, the results are shown in Fig.310.5. From the plot we can make a conclusion that the undrained analytical solution from Coussy (1995) is actually the drained solution and the undrained solution still needs to be investigated.

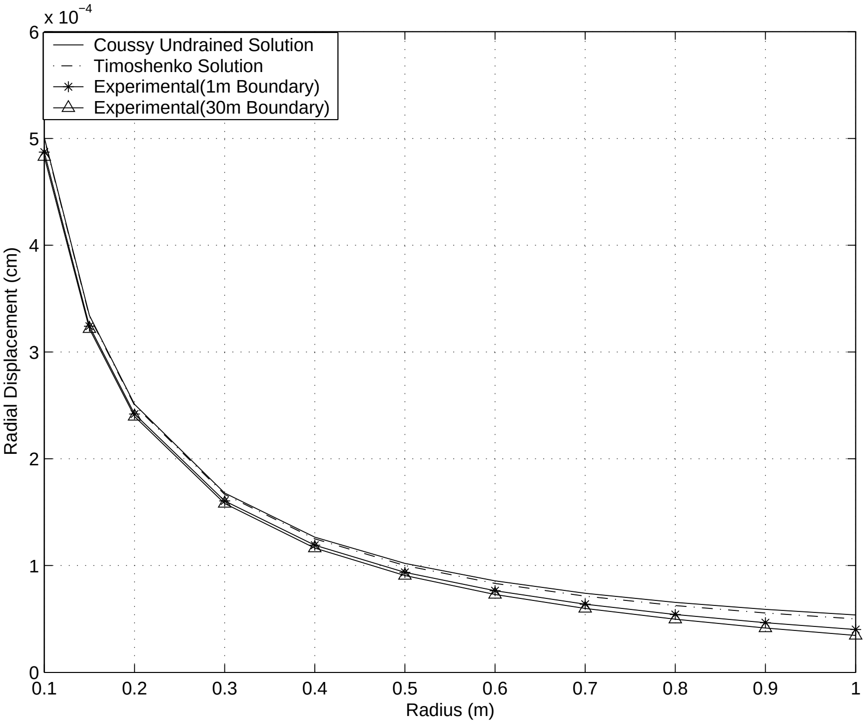

Figure 310.5: The comparison of radial solid displacement between two analytical solutions and expanded boundary

310.4 The Case of a Spherical Cavity

310.4.1 The Problem

Considering a medium composed of an isotropic, homogeneous, saturated thermoporoelastic material. In its initial state, it is assumed that the temperature, fluid pressure and stress fields are uniform and equal respectively, to T_0, p_0 and $\boldsymbol{\sigma}^0 = \sigma^0\mathbf{1}$(with $\sigma^0 < 0$). At time t= 0, a spherical cavity of radius r_0 is immediately drilled and filled with the same saturating fluid in the medium. For $t > 0$, the temperature and the pressure of the fluid are kept constant with the value of T_1 and p_1 respectively. The interface $r = r_0$ between the well and the porous medium is assumed to be in the thermodynamic equilibrium.

In spherical coordinates (r, θ, φ), the boundary conditions can be summarized as follows:

$$t \leq 0 \rightarrow \qquad \boldsymbol{\sigma}^0 = \sigma^0 \mathbf{1} \qquad p(r) = p_0 \qquad T(r) = T_0 \tag{310.16}$$

$$\begin{aligned} t > 0 \rightarrow \qquad & \sigma_{rr}(r_0) = -p_1 \qquad \sigma_{r\theta}(r_0) = \sigma_{r\varphi}(r_0) = 0 \\ \sigma_{rr}(r \rightarrow \infty) \rightarrow \sigma^0 \qquad & \sigma_{r\theta}(r \rightarrow \infty) = \sigma_{r\varphi}(r \rightarrow \infty) \rightarrow 0 \\ & p(r_0, t) = p_1 \qquad p(r \rightarrow \infty) \rightarrow p_0 \\ & T(r_0) = T_1 \qquad T(r \rightarrow \infty) \rightarrow T_0 \end{aligned} \tag{310.17}$$

Strictly speaking, the expressions for $r \rightarrow \infty$ are not boundary conditions. They are complementary conditions to be satisfied by the solution. It is used to model that at the point far from the disturbed area, the state of the medium are held as its initial state.

310.4.2 Analytical Solution

This is a problem of spherical symmetry. The radial displacement is the only non-zero displacement and all the fields are r and t dependent. Therefore,

$$\boldsymbol{\xi} = \xi^r(r) e_r \qquad p = p(r) \qquad T = T(r) \tag{310.18}$$

in which ξ^r is the radial displacement. In spherical coordinates, Eqn.310.18 yields

$$\epsilon_{rr} = \frac{\partial \xi^r}{\partial r} \qquad \epsilon_{\theta\theta} = \frac{\xi^r}{r} \qquad other \qquad \epsilon_{ij} = 0 \tag{310.19}$$

Based on the constitutive equations from Coussy (1995), it follows that

$$\sigma_{rr} = \sigma^0 + \lambda_0 (\frac{\partial \xi^r}{\partial r} + \frac{\xi^r}{r}) + 2\mu \frac{\partial \xi^r}{\partial r} - b(p - p_0) - 3\alpha K_0 (T - T_0) \tag{310.20}$$

$$\sigma_{\theta\theta} == \sigma_{\varphi\varphi} = \sigma^0 + \lambda_0 (\frac{\partial \xi^r}{\partial r} + \frac{\xi^r}{r}) + 2\mu \frac{\xi^r}{\partial r} - b(p - p_0) - 3\alpha K_0 (T - T_0) \tag{310.21}$$

$$other \qquad \sigma_{ij} = 0 \tag{310.22}$$

Finally combined with the Eqns. 310.19-310.22, it yields the near field or long-term solution (Coussy, 1995)

$$\xi^r = \frac{\sigma^0 + p_1}{4\mu} \frac{{r_0}^3}{r^2} + \frac{r_0 [b(p_1 - p_0) + 3\alpha K_0 (T_1 - T_0)]}{2(\lambda_0 + 2\mu)} (1 - \frac{{r_0}^2}{r^2}) \tag{310.23}$$

$$\sigma_{rr} = -p_1 \frac{{r_0}^3}{r^3} + \sigma_0 (1 - \frac{{r_0}^3}{r^3}) - \frac{2\mu [b(p_1 - p_0) + 3\alpha K_0 (T_1 - T_0)]}{\lambda_0 + 2\mu} (\frac{r_0}{r} - \frac{{r_0}^3}{r^3}) \tag{310.24}$$

$$\sigma_{\theta\theta} = \sigma_{\varphi\varphi} = p_1 \frac{{r_0}^3}{2r^3} - \sigma_0(1 + \frac{{r_0}^3}{2r^3}) - \frac{\mu[b(p_1 - p_0) + 3\alpha K_0(T_1 - T_0)]}{\lambda_0 + 2\mu}[\frac{r_0}{r}(1 + \frac{{r_0}^2}{r^2})] \tag{310.25}$$

And the diffusion process can be achieved if that the time are large enough with respect to the characteristics diffusion time relative to point r. When the boundary conditions for $r = r_0$ in fluid pressure and temperature which are $p = p_1$ and $T = T_1$ apply for the whole model, the following equations correspond to the undrained solution of the instantaneous drilling of a borehole in an infinite elastic medium.

$$\xi^r = \frac{\sigma_0 + p_1}{4\mu} \frac{{r_0}^3}{r^2} \qquad \sigma_{rr} = -p_1 \frac{{r_0}^3}{r^3} + \sigma_0(1 + \frac{{r_0}^3}{r^3})$$

$$\sigma_{\theta\theta} = \sigma_{\varphi\varphi} = p_1 \frac{{r_0}^3}{2r^3} + \sigma_0(1 + \frac{{r_0}^3}{2r^3}) \tag{310.26}$$

310.4.3 Discussion of the Results

The model is constructed as a quarter of a half ball. The cavity radius is $10cm$. As the outside boundary is fixed, to minimize the possibility of the sudden increase of the fluid bulk modulus, the outside radius of the sphere is set to be 2 m. The final mesh is generated as Fig.310.6. And the following boundary conditions apply: The nodes on XZ and YZ plane are fixed for solid and fluid displacement in Y and X direction respectively; the vertical solid and fluid displacement for the nodes on the XY plane are suppressed; for the nodes along the outside surface, to satisfy the complementary conditions, all the solid and fluid displacements are set to be zero as well. The pressure is translated in to nodal forces and applied in the radial direction. For simplicity, the hydrostatic stress σ_0 is equal to zero and with the assumption of thermodynamic equilibrium through the process, the temperature factor can be neglected. Also the initial fluid pressure p_0 is set to be 0 kPa. The analytical solution is studied below using the following set of parameters shown in Table 310.2.

As the same procedure in the previous drilling of borehole problem, we compared both the drained and undrained behavior. The drained and undrained behavior are tested by the permeability of $k = 3.6 \times 10^{-4} m/s$ and $k = 3.6 \times 10^{-8} m/s$ respectively. In drained behavior, we can see along the cavity surface, the experimental result of the radial displacement match the analytical solution very well. While with the increase of the radius, the decrease of the radial displacement for close solution is much smaller that of the experimental results. For the undrained behavior, we can see the radial displacement of the experimental results are always smaller than the close solution. Again it should be noted that the close solutions for the drained and undrained behavior along the cavity surface are exactly the same. This can be explained in the same way as the previous drilling of the borehole problem. When the experimental results from drained behavior are compared with the analytical undrained solution, it is observed they provide good agreement to each other as well.

310.5 Line Injection of a fluid in a Reservoir

310.5.1 The Problem

Liquid water is usually injected into a reservoir from a primary well in order to recover the oil from a secondary well in petroleum engineering. This induces a problem of injecting a fluid into a cylindrical well of negligible dimensions.

Consider a reservoir of infinite extent composed of an isotropic, homogeneous and saturated poroelastic material. Through a cylindrical well of negligible dimensions, the injection of the same fluid is performed in all directions orthogonal to the well axis forming the Oz axis of coordinates. As a result of the axisymmetry and cylindrically infinite, all quantities spatially depends on r only. The injection starts at time $t = \Gamma$ and stops at time $t = \Gamma$. The flow rate of fluid mass injection is constant and equal to

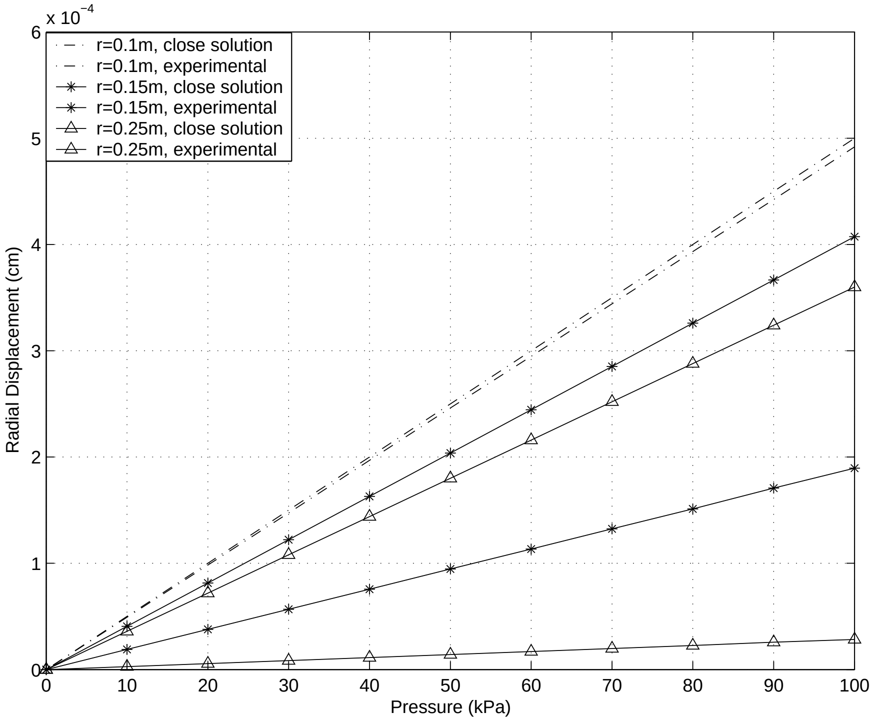

Figure 310.7: The comparison of radial solid displacement between analytical solution and experimental result for drained behavior

q.As a finite amount of Ω of fluid mass is injected instantaneously(i.e. $\Gamma q \to \Omega as \Gamma \to 0$).

310.5.2 Analytical Solution

This is a problem of cylindrically symmetry. Consequently the cylindrical coordinates(r,θ,z)is adopted. The vector of relative flow of fluid mass $\boldsymbol{w}$ reads

$$\boldsymbol{w} = w(r,t)e_r \tag{310.27}$$

where e_r is the unit vector along the radius. Using the fluid mass balance relationship, it yields

$$\int_0^r \frac{\partial m}{\partial t}(r,t) 2\pi r dr = q - 2\pi r w(r,t) \qquad \forall r,t \tag{310.28}$$

In addition, we require the fluid flow to reduce to zero infinitely far from the well

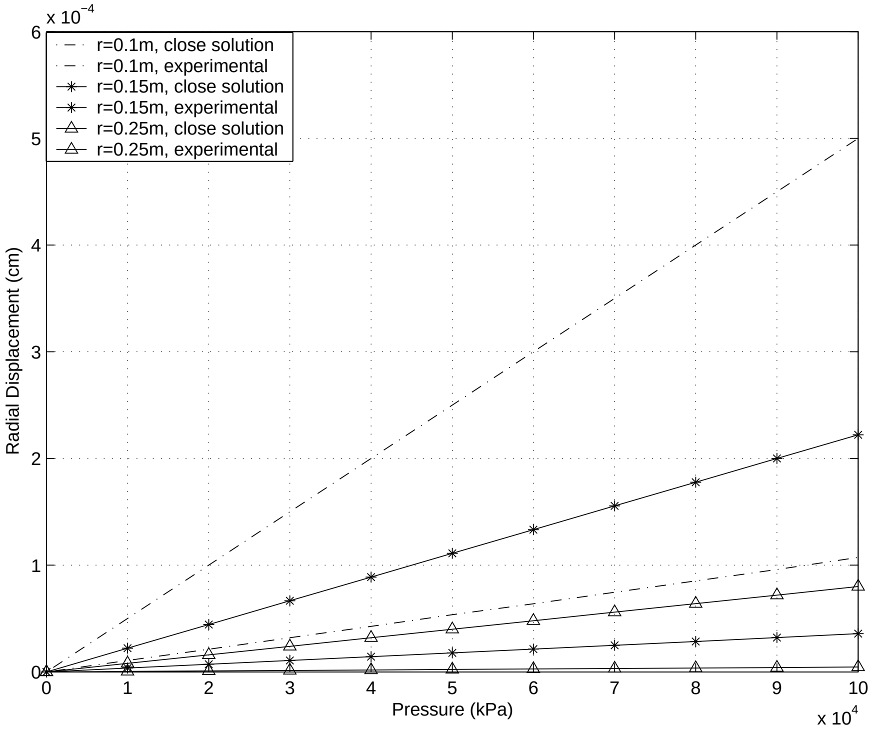

Figure 310.8: The comparison of radial solid displacement between analytical solution and experimental result for undrained behavior

$$rw \to 0 \qquad r \to \infty \qquad t < \infty$$

$$\int_0^\infty \frac{\partial m}{\partial t}(r,t) r dr = \frac{q}{2r} \qquad \forall 0 < t < \infty \tag{310.29}$$

Based on above Eqs.310.28-310.29, the radial displacement is derived in the form

$$p = \frac{\Omega}{4\pi \rho_0^{fl} k t} exp(-\frac{r^2}{4c_m t})$$

$$\xi_r = \frac{b\boldsymbol{M}\Omega}{2\pi \rho_0^{fl}(\lambda + 2\mu) r}[1 - exp(-\frac{r^2}{4c_m t})] \tag{310.30}$$

Using the constitutive equation, the stress field can be derived as follows:

$$\sigma_{rr} = -2\mu \frac{\xi_r}{r} \qquad \sigma_{\theta\theta} = 2\mu \frac{\xi^r}{r} - \frac{2\mu b}{\lambda_0 + 2\mu} p$$

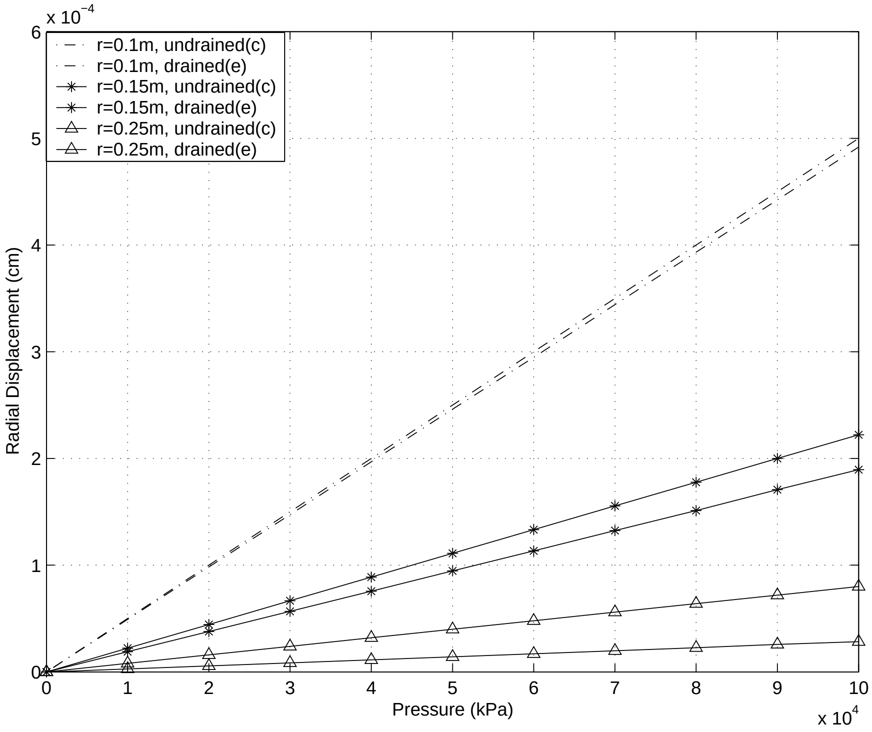

Figure 310.9: The comparison of radial solid displacement between analytical solution for undrained behavior and experimental result for drained behavior

$$\sigma_{zz} = -\frac{2\mu b}{\lambda_0 + 2mu} p \tag{310.31}$$

310.5.3 Discussion of the Results

As a result of axisymmetry, the model can be constructed as a quarter of a pie. The radius of the pie is 1 m and the thickness of the pie is 5 cm. A cylindrical well is drilled at the center of the pie, and its radius is 1 cm, which can be neglected in dimension when compared with the whole pie. The final mesh is shown as Fig.310.10. And the boundary conditions is as follows: As a consequence of plain strain problem, all the movements for solid and fluid in vertical direction Oz are suppressed; the solid and fluid displacement for the nodes along the X axis and Y axis are fixed in Y and X direction respectively for the reason of axisymmetry; the nodes along the outside perimeter are fixed in the solid and fluid displacement with the assumption of infinite medium. To the difference with the previous problems, the traction boundary conditions are applied on the fluid displacement. It should be noted that the Ω mention in the above equations is the volume of the fluid injected per unit of vertical well length and has a unit of m^3/m. In order to generate the volume of 1 cm^3/m, the corresponding fluid displacement of the nodes along the well has been calculated and applied as a step function at the time of 0 sec. For simplicity, the initial fluid pressure p_0 is set to be 0 kPa. The analytical solution is studied below using the following set of parameters shown in Table 310.3.

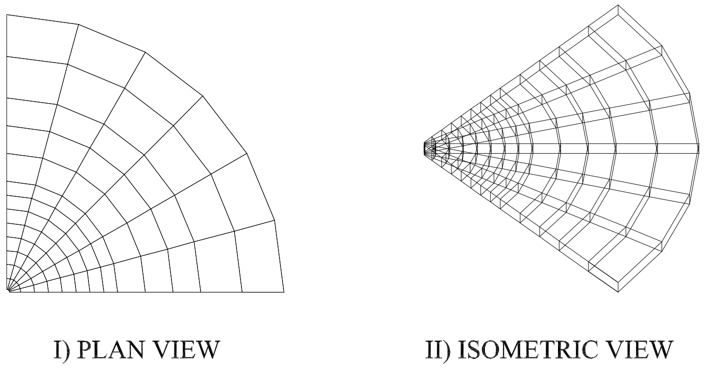

Figure 310.10: The mesh generation for the study of line injection problem

In the analysis, the pore pressure and the radial displacement are studied. The results are recorded from three points at the radius of 10 cm, 50 cm and 85 cm. The close solution and experimental results are shown in Fig.?? and Fig.??. As the time step is set to be 1 sec, the first data point starts at the time of 1 sec. From the pore pressure plot we can see that the build-up of the pore pressure reach the peak value of 34 kPa at the radius of 85 cm. With the decrease of the radius, the pore pressure decreases as well. This can be explained by the fact that the closer the point to the injection location, the earlier and the larger load is applied, so the pore pressure dissipates faster. And as time passes by, we can see the pore pressure progressively dissipates and finally almost reaches the same value within the model. The same phenomena can be been observed from the radial solid displacement. The maximum solid displacement occurs at the radius of 85 cm, which means more coupling between the solid and fluid phase, as consequence, the pore pressure should have the largest value. This corresponds to the previous result. With the increase of the time, the radial solid displacement get closer to zero, which means the fluid moves out the solid skeleton.

310.6 Shock Wave Propagation in Saturated Porous Medium

In order to verify the dynamic behavior of the system, an analytic solution developed by Gajo (1995) and Gajo and Mongiovi (1995) for 1C shock wave propagation in elastic porous medium was used. A model was developed consisting of 1000 eight node brick elements, with boundary conditions that mimic 1D behavior. In particular, no displacement of solid $(u_x = 0, u_y = 0)$ and fluid $(U_x = 0, U_y = 0)$ in x and y directions is allowed along the height of the model. Bottom nodes have full fixity for solid $(u_i = 0)$ and fluid $(U_i = 0)$ displacements while all the nodes above base are free to move in z direction for both solid and fluid. Pore fluid pressures are free to develop along the model. Loads to the model consist of a unit step function (Heaviside) applied as (compressive) displacements to both solid and fluid phases of the model, with an amplitude of 0.001 cm. The u–p–U model dynamic system of equations was integrated using Newmark algorithm (see section 108.3). Table 310.4 gives relevant parameters for this verification.

Two set of permeability of material were used in our verification. The first model had permeability set $k = 10^{-6}$ cm/s which creates very high coupling between porous solid and pore fluid. The second model had permeability set to $k = 10^{-2}$ cm/s which, on the other hand creates a low coupling between porous solid and pore fluid. Comparison of simulations and the analytical solution are presented in Figure 310.14.

Before proceeding to the analysis, the following assumptions are made: For high-frequency components, the permeability remains constant; thus, the dependency of the permeability on the frequency is neglected. Unless specified, all the models in this report are elastic isotropic.

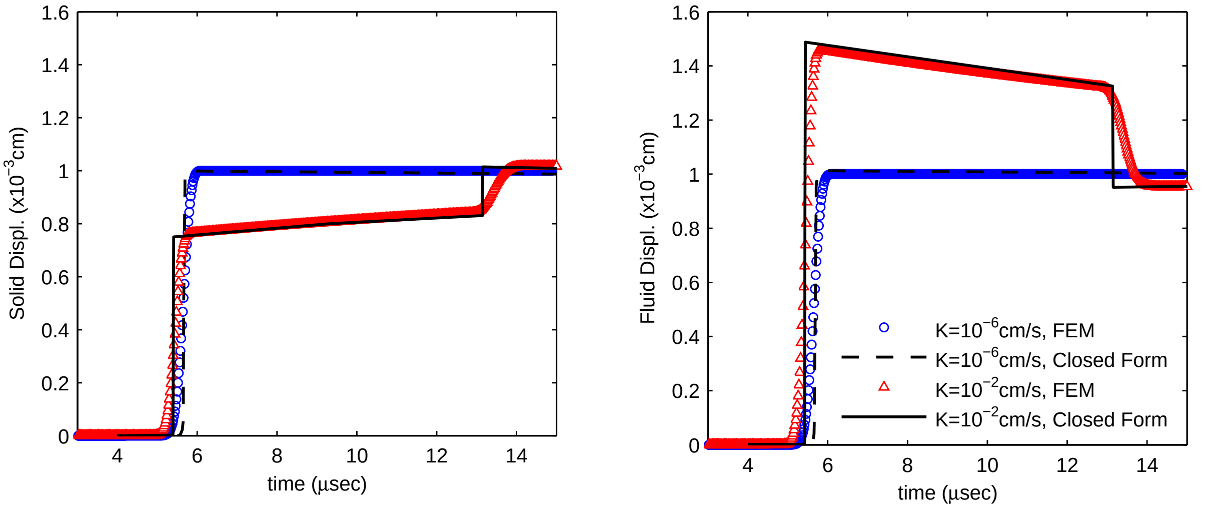

Figure 310.14: Compressional wave in both solid and fluid, comparison with closed form solution.

310.7 Vertical Consolidation of a soil layer by Coussy (2004)

310.7.1 Brief review of Analytical Solution for Consolidation by Coussy (2004)

The consolidation process can be defined as follows: When an elastic soil layer is subjected to an external change in mean normal stress, immediately the water will alone sustain this increment of mean normal stress and cause the build-up the excessive pore water pressure. In the progress of the flow of the water to the surface, the load is gradually transferred to the soil skeleton and the excessive pore water pressure will dissipate. At the same time, the settlement of the soil layer occurs. As settlement is usually a major concern in geotechnical engineering, this is a key problem in soil mechanics.

Consider a soil layer composed of an isotropic, homogeneous and saturated thermoporoelastic material. The layer has a thickness of h in the Oy direction and of infinite extent in the two other directions Ox and Oy. The layer is underlain by a rigid and impervious base at $y = 0$. And the top surface at $y = h$ is so perfectly drained that the pore pressure is held constant as zero.

At the initial state of the soil layer, the thermal effects are neglected so that the boundary conditions follow that:

$$t \leq 0 \rightarrow \qquad y = h \qquad p = 0 \tag{310.32}$$

$$y = 0 \qquad \frac{\partial p}{\partial z} = 0 \tag{310.33}$$

At time $t = 0$, tan instantaneous vertical load $-\varpi e_y$ is suddenly applied on the top surface $y = h$, the induced boundary conditions require that

$$t > 0 \rightarrow \qquad y = h \qquad \boldsymbol{\sigma} e_y = -\varpi e_y \tag{310.34}$$

The undeformability of the substratum reads

$$y = 0 \qquad \xi = 0 \tag{310.35}$$

The impermeability implies

$$y = 0 \qquad -w \cdot e_y = -w_y = 0 \tag{310.36}$$

The problem is then to determine the new fields of fluid pressure, stress and displacement induced by the external loading.

Since this is a one-dimensional problem, the only non-zero displacement is the vertical displacement ξ^y. But in particular the fluid pressure depends only on y and t.

$$\boldsymbol{\xi} = \xi^y(y,t)e_y \qquad p = p(y,t) \tag{310.37}$$

Based on the constitutive equations from Coussy (2004), it follows that

$$\sigma_{yy} = (\lambda_0 + 2\mu)\frac{\partial \xi^y}{\partial y} + bp \tag{310.38}$$

$$\sigma_{xx} = \sigma_{zz} = \frac{\lambda_0}{(\lambda + 2\mu)}\sigma_{yy} - \frac{2\mu b}{\lambda_0 + 2\mu}p \tag{310.39}$$

And because the fluid pressure p must be an ordinary function of time t, although the derivative of p is infinite at time $t = 0$ according to the consolidation equation (Coussy, 2004), the discontinuity of the fluid pressure p at time $t = 0$ must satisfy

$$p(y, t = 0^{+}) = \eta\varpi \qquad \varpi = \frac{\nu - \nu_0}{(1-\nu)(1-2\nu_0)b} \tag{310.40}$$

where ν and ν_0 are the drained and undrained Poisson ratio, respectively. For time $t > 0$, the vertical stress $\sigma_{yy} = -\varpi$ is constant in time and space, therefore the diffusion equation reads

$$t > 0 \qquad c_m \frac{\partial^2}{\partial y^2} p = \frac{\partial}{\partial t} p \tag{310.41}$$

Collecting the above results, finally the fluid pressure reads

$$p(y,t) = \eta\varpi \sum_{n=0}^{\infty} \frac{4(-1)^n}{\pi(2n+1)} cos[\frac{(2n+1)\pi}{2}\frac{y}{h}] exp[-\frac{(2n+1)^2\pi^2}{4}\frac{t}{\tau}] \tag{310.42}$$

Each term of the series decreases exponentially with respect to the ratio $\frac{t}{\tau}$, in which τ is a characteristics consolidation time

$$\tau = \frac{h^2}{c_m} \qquad c_m = \boldsymbol{kM}\frac{\lambda_0 + 2\mu}{\lambda + 2\mu} \tag{310.43}$$

where λ and λ_0 are the drained and undrained Lame coefficient, respectively. Given by the Eqn.310.39, the only non-zero displacement ξ^y satisfies

$$\frac{\partial \xi^y}{\partial y} = \frac{1}{\lambda_0 + 2\mu}(\sigma_{yy} + bp) \tag{310.44}$$

By substituting the value of $-\varpi$ of the vertical stress and expression of (310.44), the series converges and it can integrated term by term yielding

$$\xi^y(y,t) = \frac{\varpi}{\lambda_0 + 2\mu}(\frac{y}{h} + \frac{8\eta b}{\pi^2}) \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^2} sin[\frac{(2n+1)\pi}{2}\frac{y}{h}] exp(-\frac{(2n+1)^2\pi^2}{4}\frac{t}{\tau}] \tag{310.45}$$

$$\tag{310.46}$$

Using Eqn.310.46 and substitute $y = h$, the settlement can be expressed as

$$s(t) = s_{\infty} + (s_{0^+} - s_{\infty}) \sum_{n=0}^{\infty} \frac{8}{\pi^2(2n+1)^2} exp\{-\frac{(2n+1)^2\pi^2}{4}\frac{t}{\tau}\} \tag{310.47}$$

$$s_{0^+} = \frac{h\varpi}{\lambda + 2\mu} \qquad s_{\infty} = \frac{h\varpi}{\lambda_0 + 2\mu} \tag{310.48}$$

310.7.2 Numerical Analysis

A soil column of ten brick $u-p-U$ finite elements is used to model the horizontal layer. The height of the soil column is 10 m and the height of each element has dimensions $1m \times 1m \times 1m$, illustrated in Fig. 310.15. The material properties, shown in Table 310.5, are chosen as representative values for the natural soil deposit. Developed $u-p-U$ finite element model, can simulate realistic compressibility of the pore fluid. However, it is important to note that the analytical solution for the vertical consolidation is based on the assumption that both the soil particles and the pore fluid (water) are completely incompressible. A uniform vertical pressure of 400 kPa is applied on the top surface of the soil column. The numerical analysis was performed in two stages:

(I) Self-Weight application (see Figures 310.15 to 310.19).

(II) Consolidation with drainage at top due to uniform vertical pressure of 400 kPa at the surface (see Figures 310.20 to 310.26).

Table 310.5: Material Properties used to study consolidation of a soil layer.

Parameter	Symbol	Value
gravity acceleration	g	9.81 m/s^2
soil matrix Young's Modulus	E	10×10^3 kN/m^2
soil matrix Poisson's ratio	v	0.25
solid particle density	ρ_s	2.65×10^3 kg/m^3
water density	ρ_f	1.0×10^3 kg/m^3
solid particle bulk modulus	K_s	37.0×10^6 kN/m^2
fluid bulk modulus	K_f	2.2×10^6 kN/m^2
porosity	n	0.46
Biot coefficient	α	1.0

The following boundary conditions are applied to the model (Fig 310.27): As the bottom of the soil column is modeled as an undeformable and impermeable layer, both the solid and fluid displacements are fixed. The pore pressure is kept constant as zero at the top surface of the soil column because of the perfectly drained condition. In order to simulate the 1D consolidation problem, all the lateral movement of the solid and fluid phase are suppressed so that the vertical displacement is the only non-zero displacement for the intermediate nodes. To capture both the long term (t >0.1 sec) and short term (t <0.1 sec) response of the soil column, two different time steps are adopted: 0.1 sec and 0.005 sec, respectively. In order to observe the dissipation of the excessive pore water pressure in a reasonable

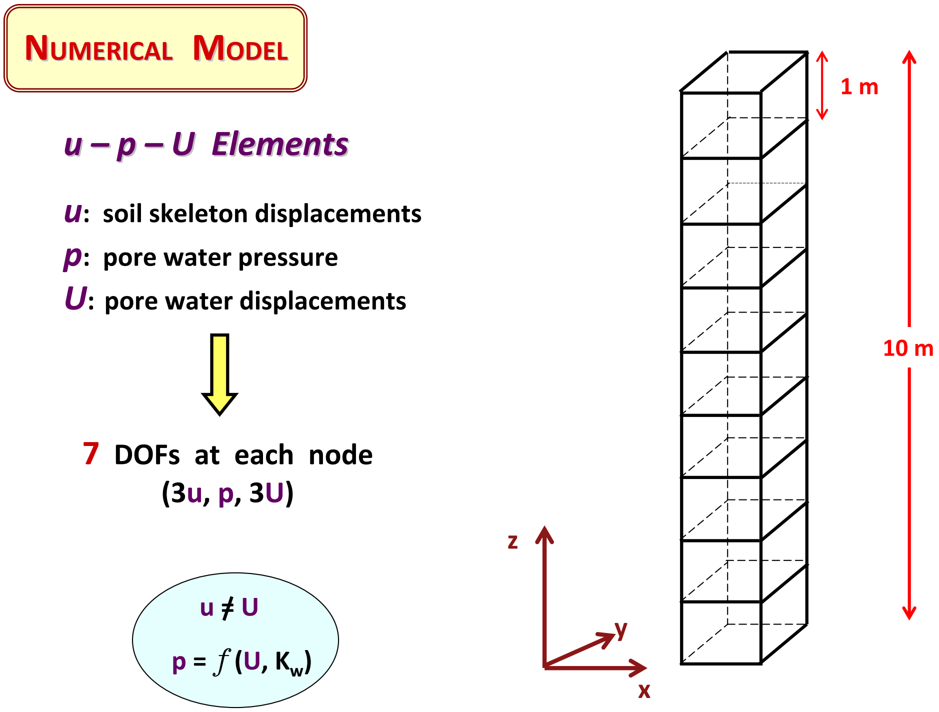

Figure 310.15: Numerical Simulation of self weigh application and consolidation of a soil layer using u-p-U brick elements.

and convenient period, we select $k = 1.0 \times 10^{-4} m/s$ as the value for the permeability. To cure the artificial oscillation, some numerical damping is introduced into the analysis by using $\gamma = 0.6$ and $\beta = 0.3025$ for the Newmark integrator. Fig. 310.20 illustrates the physical geometry of the problem whereas Fig. 310.21 shows the numerical modeling.

Based on the above parameters, the other relative parameters can be calculated as follows:

The bulk modulus of the mixture:

$$K = \frac{E}{3(1-2\nu)} = 6.67 \times 10^3 kPa \tag{310.49}$$

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)} = 6.67 \times 10^3 kPa \quad \mu = \frac{E}{2(1+\nu)} = 4 \times 10^3 kPa \tag{310.50}$$

The Biot coefficient:

$$b = 1 - \frac{K}{K_s} = 0.9998 \tag{310.51}$$

The undrained bulk modulus of the mixture:

$$N = \frac{K_s}{b-n} = 6.85 \times 10^7 kPa \quad M = \frac{K_f N}{K_f + Nn} = 4.47 \times 10^6 kPa \tag{310.52}$$

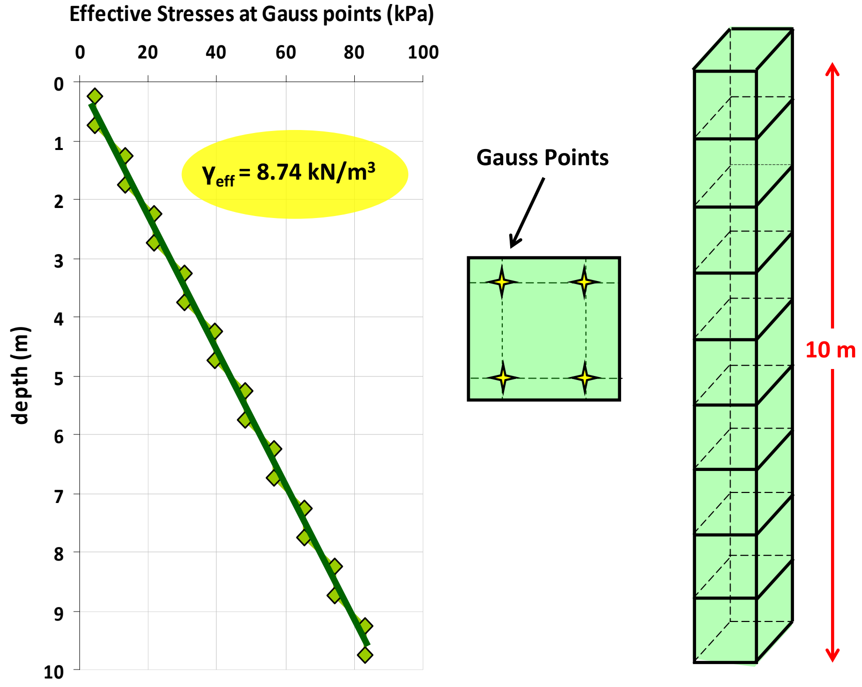

Figure 310.16: The distribution of the vertical effective stresses with depth due to self-weight. The stresses are calculated at the Gauss points within each brick element. The stresses obtained from the numerical analysis are equal for all the Gauss points within the element, due to the compatibility of deformations at the element interfaces.

$$K_u = K + b^2 M = 4.4 \times 10^6 kPa \tag{310.53}$$

The diffusion coefficient and characteristic time of consolidation:

$$c_f = \frac{kM}{\gamma_w} \frac{K + \frac{4\mu}{3}}{K_u + \frac{4\mu}{3}} = 1.2 m^2/s \qquad t = \frac{h^2}{c_f} = 83.33 s \tag{310.54}$$

310.7.3 Discussion of Numerical Results - Conclusions

The stage of self weight application shows in Fig. 310.19 that the expected estimated settlement is quite close to the one obtained from the analysis. The difference in the two values is due to the stress distribution coming out of the analysis which is slightly different than the one considered in theory (see Fig. 310.16) and possibly due to the compressibility of soil particles in the numerical analysis.

In Fig.310.24, the normalized fluid pressure is plotted against the location for various normalized times. For normalized time $T_v = 0.1$, only the nodes close to the top free flow surface display the dissipation of the pore pressure. The experimental result provide good agreement with the analytical

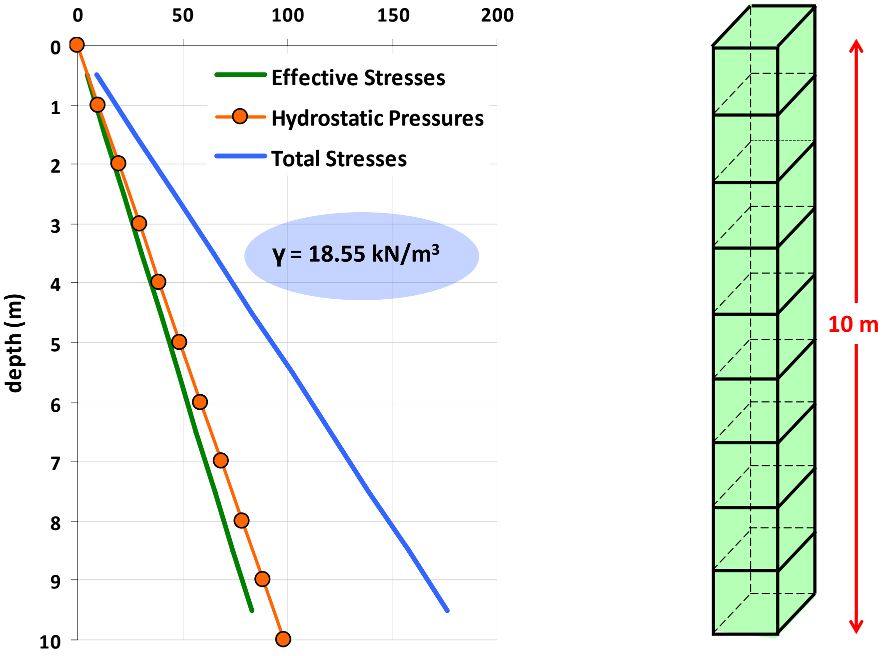

Figure 310.17: The distribution of the hydrostatic pore pressures, the effective and total stresses with depth, obtained from the numerical analysis after self-weight application.

solution. With the increase of the normalized time, we can clearly see the tendency of the dissipation of the water. At normalized time $T_v = 1.0$ (natural time t $=$ 83 sec), the maximum normalized pore pressure is only about 0.11. It can be concluded that the numerical analysis can effectively demonstrate the process of the dissipation of the pore pressure.

In Fig. 310.26, the change of the porosity is predicted due to the consolidation of the soil layer. Both the change of volume of the soil $(0.1782m^3)$ and the fluid $(0.1794m^3)$ have been calculated. Theoretically, these two values should be the same, according to the fact that the settlement of the soil layer is due the fluid which is squeezed out, assuming that the soil grains are incompressible. However, this difference in the values is due to the compressibility of the soil grains, which was not considered infinite in the numerical analysis.

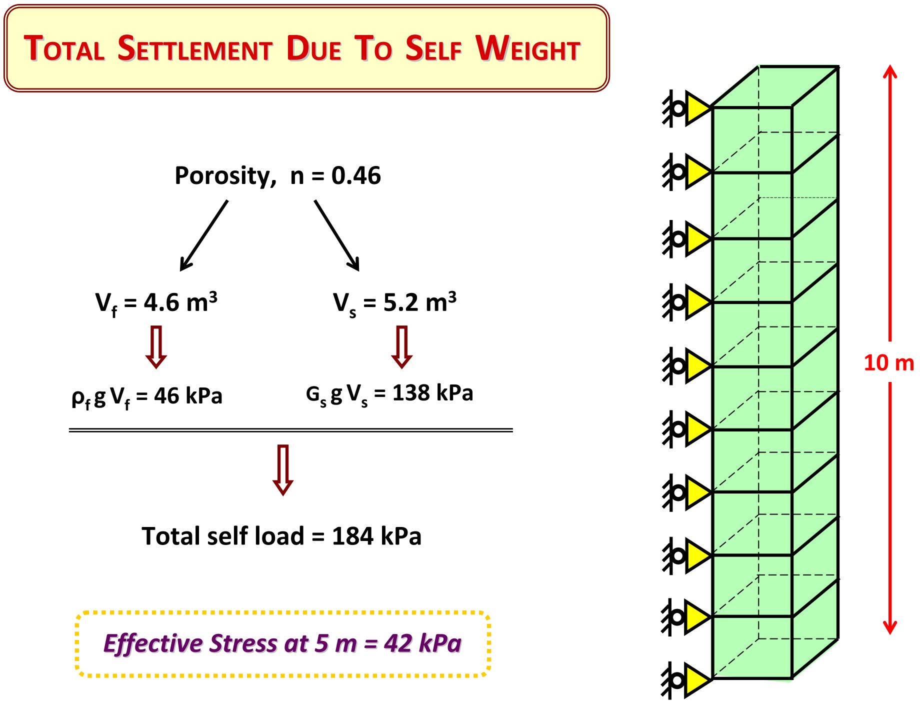

Figure 310.18: Estimation of the total self load, as it is obtained from the numerical analysis, given the porosity and the densities of the fluid (ρ_f) and the grains (ρ_s or G_s).

310.8 One dimensional wave propagation in elastic porous media subjected to step displacement boundary condition

310.8.1 Brief review of Analytical Solution by Gajo and Mongiovi (1995)

An one-dimensional exact analytical solution of the Biot's equations is provided by Gajo and Mongiovi (1995) for the completely general solution of the transient problem in saturated, linear, elastic, porous media. The analytical solution was obtained was obtained by Fourier series. This solution is considered to be completely general because it is not based on any assumptions with respect to the inertial, viscous or mechanical coupling. Furthermore, it can be applied to any type of boundary-initial value problem.

The advantage of this analytical solution consists of showing the mechanics of dispersive wave propagation in saturated elastic solids. This is achieved by allowing the detailed analysis of wave fronts of the first and second kind of longitudinal waves and by analyzing accurately the effects of each term of coupling on the transient behavior of saturated porous media. In particular, since each term of the Fourier series represents a frequency component of the excitation signal, the analytical solution can

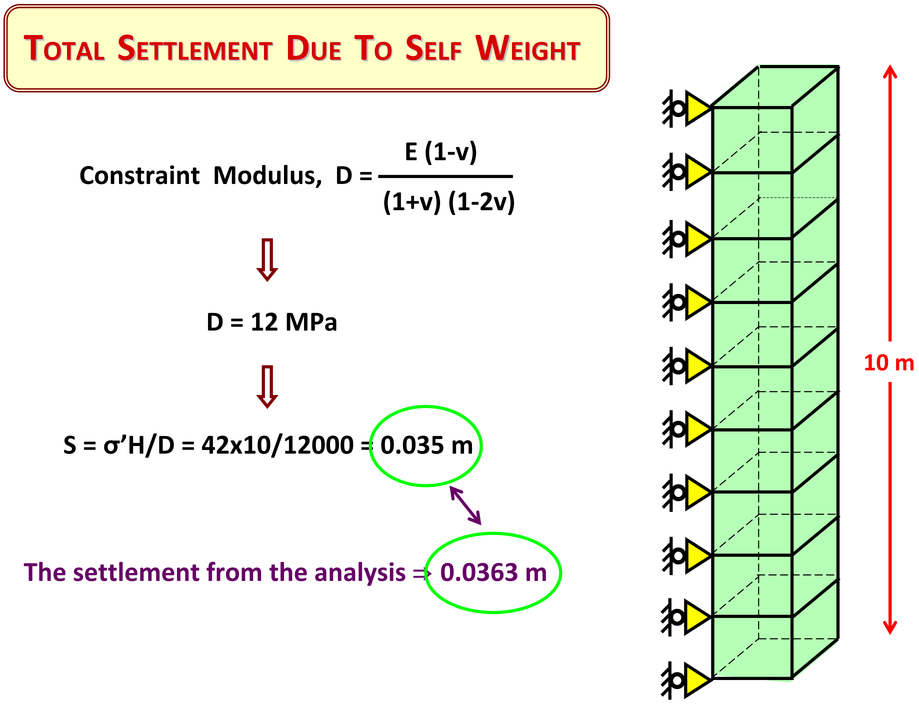

Figure 310.19: Prediction of the total settlement due to self-weight and comparison with the numerical result.

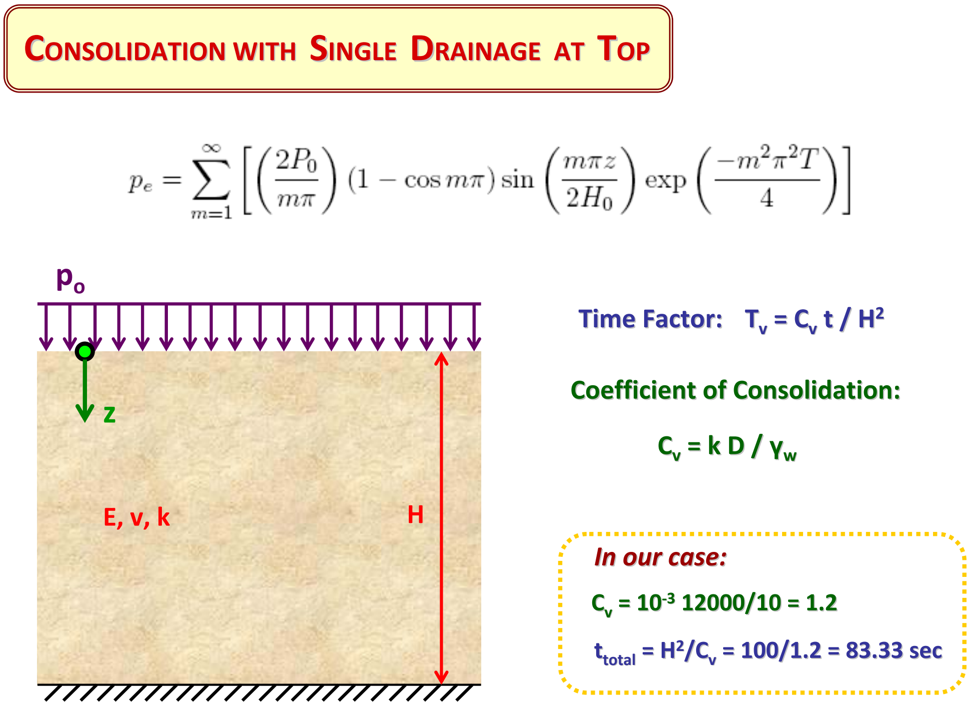
describe the behavior of each frequency component. Thus, it can illustrate the mechanics of dispersive wave propagation in which higher frequencies propagate with two waves and lower frequencies with only one wave, as a function of permeability and travel length.

Considering the above mentioned arguments, the analytical solution can provide a useful comparative term towards the verification and the validation of the existing numerical solutions based on the finite element method. Such a study was conducted by Gajo et al. (1994), by comparing analytical results with numerical ones obtained by a $u-p-U$ numerical formulation.

In the paper by Gajo and Mongiovi (1995), the transient response of porous media is shown for typical material properties of a natural granular deposit and for different degrees of viscous coupling. Specifically, analytical results are given from the solution of the following one-dimensional boundary value problem: at the top and bottom surfaces of a soil layer of finite thickness L, the excitation consisting of a step displacement boundary condition (Heaviside function) is applied to both solid and fluid phases. This problem can demonstrate better the mechanics of dispersive wave propagation, since the step excitation contains waves of all kind of frequencies. The analytical solution is relative only to the first arrival of the waves of the first and second kind.



CONSOLIDATION WITH SINGLE DRAINAGE AT TOP

$$p_e = \sum_{m=1}^{\infty} \left[\left(\frac{2P_0}{m\pi} \right) (1 - \cos m\pi) \sin \left(\frac{m\pi z}{2H_0} \right) \exp \left(\frac{-m^2\pi^2 T}{4} \right) \right]$$

Time Factor: $T_v = C_v \, t / H^2$

Coefficient of Consolidation:

$C_v = k \, D / \gamma_w$

In our case:

$C_v = 10^{-3} \; 12000/10 = 1.2$

$t_{total} = H^2/C_v = 100/1.2 = 83.33$ sec

310.8.2 Numerical Analysis

Numerical examples for three different values of viscous coupling ($k = 10^{-8} cm^3 s/g$, $k = 10^{-6} cm^3 s/g$, $k = 10^{-5} cm^3 s/g$) were solved in order to verify the previously mentioned $u - p - U$ formulation in a wide range of drag. The numerical model used for the simulation of the 1C shock wave propagation consists of 400 u-p-U brick finite elements of dimensions $0.01cm \times 0.01cm \times 0.01cm$ creating a soil column 4cm thick. Figure 310.28 illustrates the transition from the physical configuration of the problem to its numerical simulation. Table 310.6 shows the soil properties of the numerical model.

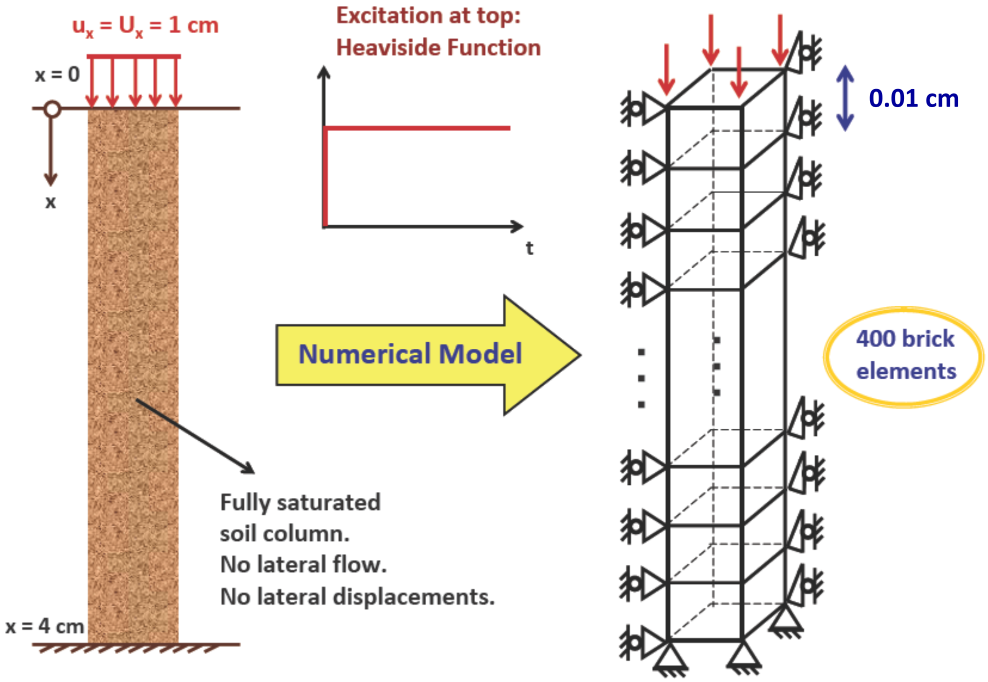

Figure 310.28: The numerical model used for the verification of the finite element implementation through comparison with the analytical results provided by Gajo and Mongiovi (1995).

At the top surface of the soil column, a step displacement of $1.0 \times 10^{-3} cm$ is applied both to the solid and the fluid phase. Only the vertical displacement is free. There is no lateral flow or displacement. The degree of freedom related to the pore pressures is constrained at the top surface to be equal to the atmospheric pressure and is free at the rest of the nodes. The base of the model is rigid and impervious.

This kind of excitation (Heaviside function) applied at the top of the model, results clearly in waves of all kinds of frequency, first due to its nature and secondarily due to the way of its application. This fact together with the great stiffness of the solid skeleton (see Table 310.6 require a very dense spatial

discretization. Here, 400 u-p-U brick finite elements of dimensions $0.01cm \times 0.01cm \times 0.01cm$, following similar discretization with Gajo et al. (1994). The time step, δt required needs to be limited to

$$\delta t < \frac{\delta h}{v} \tag{310.55}$$

$$\tag{310.56}$$

where v is the highest wave velocity. In our case, the temporal integration involves 800 steps of $2.0 \times 10^{-8} sec$, which allows a maximum wave velocity of $5.0 \times 10^5 m/s$.

Two different time integration methods where used: i) The Newmark integrator and ii) The Hilber-Hughes-Taylor (HHT) Integrator. Sets of parameters, assuring unconditionally numerical stability, were chosen for both integrators. For the case of Newmark integrator (see Figures 310.29 - 310.44), the following sets of parameters were used:

a) $\gamma = 0.5$ and $\beta = 0.25$,

b) $\gamma = 0.6$ and $\beta = 0.3025$,

c) $\gamma = 0.7$ and $\beta = 0.4$.

310.8.3 Discussion of Numerical Results - Conclusions

Biot has shown than when dissipation is present, each frequency component propagated with its own velocity. Thus, especially in the case of numerical solutions using a finite element procedure, the response is very sensitive to the numerical damping introduced to the system. Generally, a drawback of all types types of numerical solutions is the distortion and the smearing of the wave fronts, which are linked to the highest frequency that is allowed by the computational grid and the numerical damping due to the time integration method. The numerical results presented here, show a larger rise time than the analytical solution, that it could potentially be improved by using a finer spatial and temporal discretization.

In particular, the dissipation of high frequency oscillations is achieved more efficiently by the Newmark integrator that the HHT one. Due to the fact that the filtering of high frequencies is less in case of HHT integrator, the smearing of the wave front of the first kind of longitudinal waves is not so extensive as in the Newmark case. Obviously, for both cases, as the numerical damping increases by changing the sets of parameters, the rise time of the water fronts increases too. It is also worth mentioning that the rise time of the wave front of the second kind low-frequency longitudinal wave is even longer than that of the first kind.

Figures 310.41 and 310.44 illustrate the comparative results for all the three different values of viscous coupling using the Newmark integration method. In general, it is worth noting that the numerical results are in good agreement with the main characteristics of the mechanics of dispersive wave propagation in fully saturated, porous media, as indicated by the analytical results. For example, numerical results well demonstrate that during the propagation of the first wave, the solid and fluid displacement are in phase with each other, whereas during the propagation of second wave, the displacements of the two phases are in opposition. Overall, the finite element solutions reproduce correctly the forms of wave propagation for a wide range of permeability.

310.9 One dimensional wave propagation in elastic porous media subjected to step loading at the surface

310.9.1 Brief review of Analytical Solution by de Boer et al. (1993)

An analytical solution for the one-dimensional transient wave propagation fluid-saturated elastic porous media is provided by de Boer et al. 1993. The fluid-saturated porous material is modeled as a two phase system composed of an incompressible solid phase and an incompressible fluid phase. An exact analytical solution is obtained via Laplace transform technique considering initial and boundary conditions, which exhibits only one independent compressive wave in both the solid and fluid phases, as a result of the incompressibility constraint.

The problem configuration, which the analytical solution is addressed to, consists of an one-dimensional infinitely long column, separated from the half-space of a fluid-saturated porous elastic skeleton material. The motion of both the solid and the fluid materials is constrained to occur in the vertical direction. Loading as a function of time, $\sigma(z = 0, t) = f(t)$, is applied to the half space surface boundary by a permeable punch with ideal permeability. Homogeneous pore distribution and free pore fluid surface are assumed. The wave motion in the porous medium is expressed by the solid and fluid displacements or the solid extra stresses, respectively, but it cannot be expressed by the pore pressure which is just the Lagrangian multiplier corresponding to the incompressibility constraint of the medium.

In particular, in the paper by de Boer et al. (1993), the solid and the fluid displacements, the solid skeleton extra stresses and the pore pressure are given with respect to time and with respect to different depths in the soil column within the framework of three loading forms: i) sinusoidal, ii) step loading and iii) impulsive loading. These results can be taken for a quantitative comparison to various numerical solutions.

310.9.2 Numerical Analysis

Numerical example for the step loading case was solved in order to verify the previously mentioned $u-p-U$ formulation. The numerical model used for the simulation of the 1C shock wave propagation consists of 1000 u-p-U brick finite elements of dimensions $1cm \times 1cm \times 1cm$ creating a soil column $10m$ thick. Obviously, the numerical simulation of a semi infinite soil column is not possible; thus, a soil column of thickness of 10 cm was considered adequate for the current problem configuration. Figure 310.57 illustrates the transition from the physical configuration of the problem to its numerical simulation. Table 310.7 shows the soil properties of the numerical model, which are the same with those used for the analytical results presented in the paper by de Boer et al. (1993).

The only difference is noted on the elastic modulus, which was selected to be $20MN/m^2$ for the numerical solution (FEM) instead of $30MN/m^2$, as it is mentioned in the previously mentioned paper. This is due to the fact that the numerical results indicated that the results given in the paper correspond to a soil column with elastic modulus equal to $20MN/m^2$ instead of $30MN/m^2$. Moreover, it should be mentioned that the solid and fluid compressibility were given realistic values (see Table 310.7), which practically means that the two constituents are incompressible.

At the top surface of the soil column, a step loading of $\sigma(z = 0, t) = 3kN/m^2$ is applied to the solid part, as a nodal load equally distributed to the four top nodes. The nodal load is expressed as:

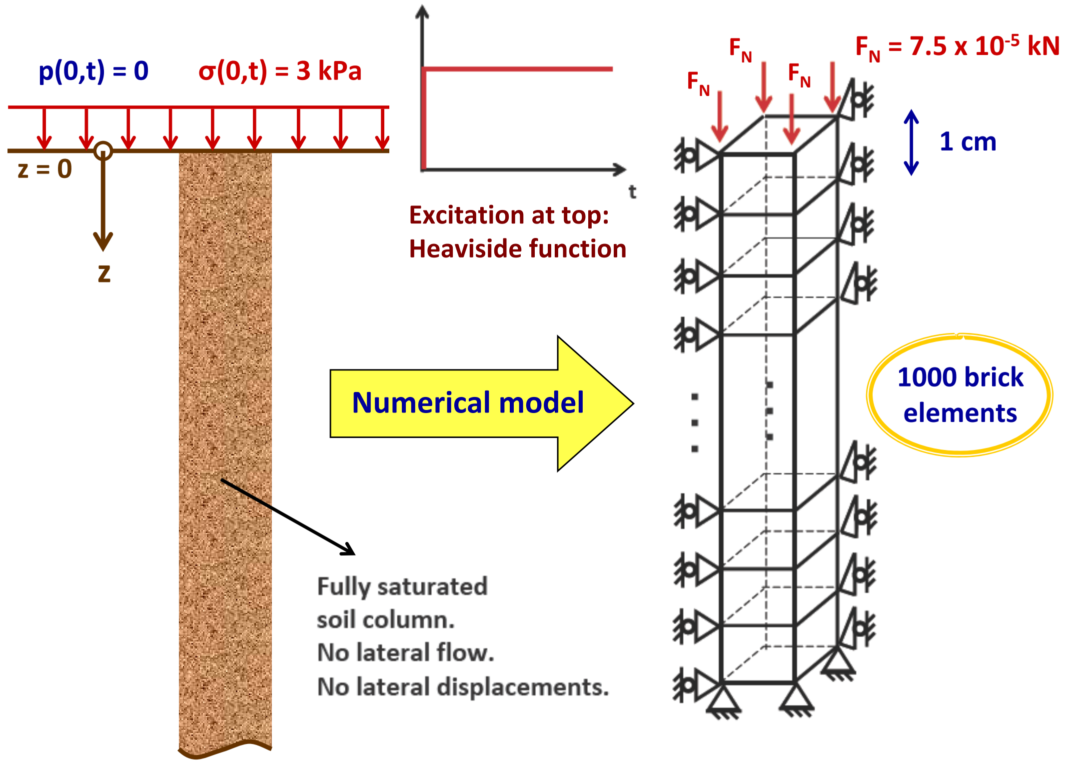

Figure 310.57: The numerical model used for the verification of the finite element implementation through comparison with the analytical solution provided by de Boer et al. (1993).

$$F_N(z=0,t) = \frac{\sigma(z=0,t)\times A}{4} = \frac{3kN/m^2 \times 0.01m \times 0.01m}{4} = 7.5 \times 10^{-5} kN \tag{310.57}$$

Only the vertical displacement is free. There is no lateral flow or displacement. The degree of freedom related to the pore pressure is constrained at the top surface to be equal to the atmospheric pressure, while it is free at the rest of the nodes. The base of the model is rigid and impervious.

This kind of excitation (Heaviside function) applied at the top of the model, results clearly in waves of all kinds of frequency, first due to its nature and secondarily due to the way of its application. Due to this fact, a fairly dense mesh of 1000 u-p-U brick finite elements of dimensions $1cm \times 1cm \times 1cm$ was chosen. The time step, δt required needs to be limited to

$$\delta t < \frac{\delta h}{v} \tag{310.58}$$

$$\tag{310.59}$$

Table 310.7: Soil Properties for 1C shock wave propagation for the problem by de Boer et al. (1993)

Parameter	Symbol	Value
gravity acceleration	g	$9.81\ m/s^2$
soil matrix Young's Modulus	E	$20 \times 10^3\ kN/m^2$
soil matrix Poisson's ratio	ν	0.2
soil matrix Lame's constant	λ	$5.55 \times 10^3\ kN/m^2$
soil matrix shear modulus	μ	$8.33 \times 10^3\ kN/m^2$
solid particle density	ρ_s	$2.0 \times 10^3\ kg/m^3$
water density	ρ_f	$1.0 \times 10^3\ kg/m^3$
solid particle bulk modulus	K_s	$36.0 \times 10^6\ kN/m^2$
fluid bulk modulus	K_f	$2.177 \times 10^6\ kN/m^2$
porosity	n	0.33
Darcy's permeability	k_D	$0.01\ m/s$

where v is the highest wave velocity. In our case, the temporal integration involves 4000 steps of $1.0 \times 10^{-4} sec$, which allows a maximum wave velocity of $100 m/s$. The propagation velocity can be calculated by the following equation given by de Boer et al. (1993) and is equal to $90.7 m/s$.

$$v = \sqrt{\frac{n^2(\lambda\ +\ 2\mu)}{n^2(1-n)\rho_s\ +\ (1-n)^2(n\rho_f)}} = 90.7 m/s \tag{310.60}$$

The Newmark time integration method was used, which dissipates more efficiently the high frequencies introduced in the system due to numerics than HHT integrator, as shown in section 4.3. The following set of parameters was chosen, assuring unconditionally numerical stability: $\gamma = 0.7$ and $\beta = 0.4$.

310.9.3 Discussion of Numerical Results - Conclusions

Figures 310.58 to 310.67 illustrate the comparative results between analytical and numerical solution. In general, it is worth noting that the numerical results are in good agreement, with respect to time and with respect to depth, with those obtained by the analytical solution. The responses of the medium due to step loading are indicative of the consolidation process in case of a free pore water surface. The solid moves downwards, indicating that settlement occurs and the fluid is squeezed out from the pore volume creating an upward flow. During the consolidation process, the extra solid skeleton stresses increase with time at a certain depth. However, they decrease with the distance from the loading surface at a certain time. In opposition to the extra solid skeleton stresses, the pore pressure decreases with time tending to zero, while it increases with depth.

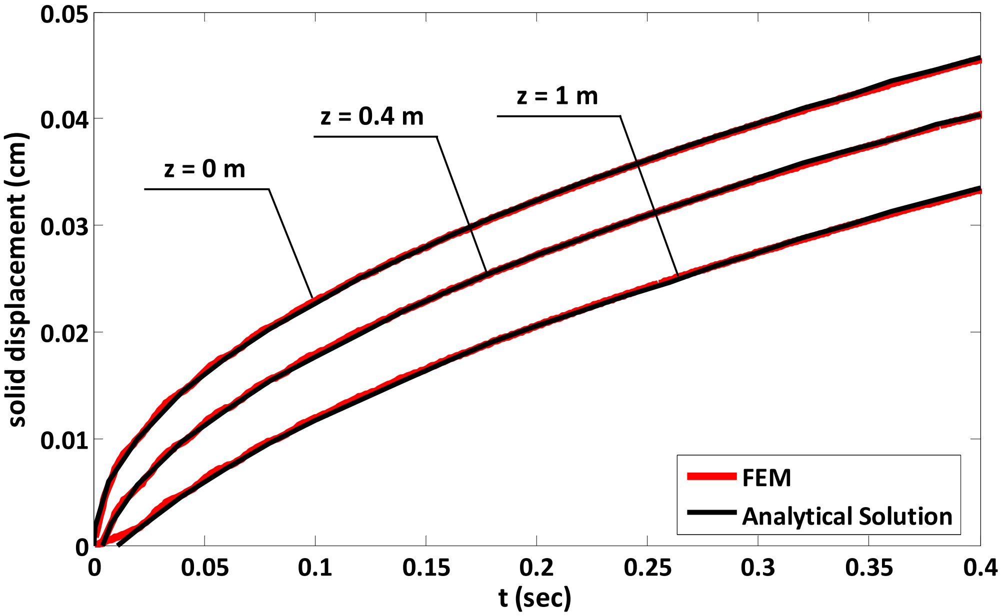

Figure 310.58: Time history of solid displacements at different depths due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

Overall, it is worth mentioning that the results obtained from the finite element procedure practically coincide with the ones given by the analytical solution. The only difference is located to the pore pressure (see Figures 310.64 to 310.67), where numerical response is oscillatory in contrast to the analytical solution. This may be due to the high frequencies introduced to the system by the temporal and spatial discretization and/or the compressibility of the solid and fluid phases. It should be mentioned again, that in the analytical solution, the two constituents are assumed incompressible whereas in the numerical model, the solid and fluid bulk moduli have realistic values (see Table 310.7. That is why in Figure 310.68, numerical examples with different values of fluid compressibility were solved. It is obvious that the oscillations decrease as the the fluid becomes more and more compressible because the stiffness of the system decreases and the high frequencies are dissipated faster. Moreover, Figure 310.68 indicated that better quantitative agreement between the numerical and analytical solution is achieved when the bulk modulus of the fluid is 2.2×10^6 kPa - realisic value - instead of 2.2×10^9 kPa, which would be expected since the pore fluid is assumed to be incompressible in the framework of the analytical solution. Comparing the pore pressures obtained from these two cases, it can be observed that the pore pressure

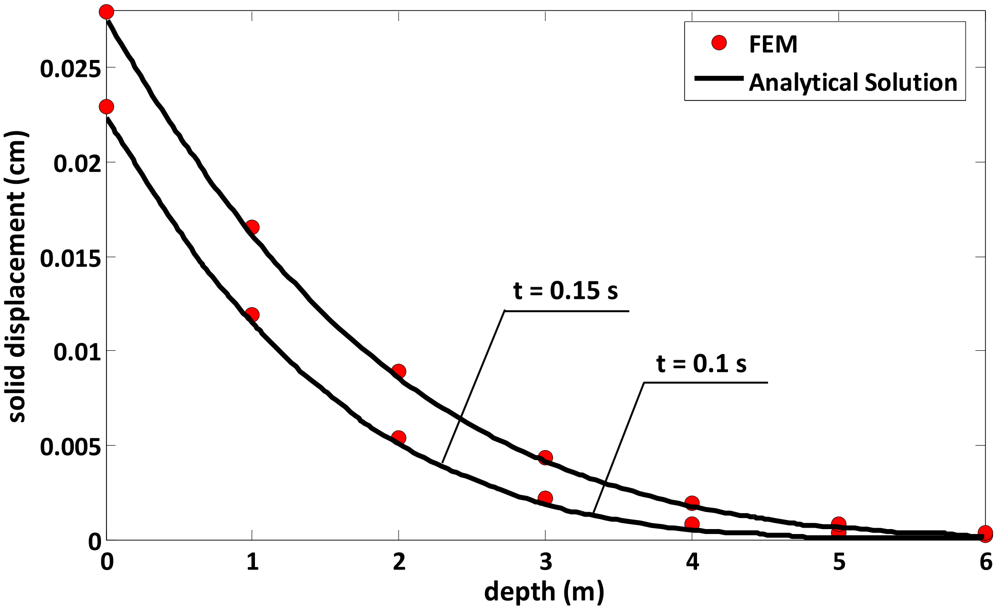

Figure 310.59: Response of solid displacements versus depth at different time moments due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

generation in the more compressible fluid is slightly higher than that of the almost incompressible fluid because of the existence of the oscillatory waves, as mentioned by (Zienkiewicz and Shiomi, 1984).

310.10 One dimensional wave propagation in elastic porous media subjected to step velocity boundary condition

310.10.1 Brief review of Analytical Solution by Hiremath et al. (1988)

Hiremath et al. (1988) present a solution of Biot's dynamic equation of motion for one-dimensional wave propagation in a fluid-saturated linear elastic isotropic soil using Laplace transformation followed by numerical inversion. This study is considered to be an extension of the exact transient solution presented by Garg et al. (1974) for two limiting cases of infinitely small and infinitely large viscous coupling. In both cases, a soil column of finite dimension subjected to velocity boundary conditions was analyzed, allowing for reflection of waves at the boundaries.

In particular, Hiremath et al. (1988) examines two cases allowing for weak and strong viscous coupling, or else, as it is referred in the related paper, low and high drag, respectively. Moreover, two different

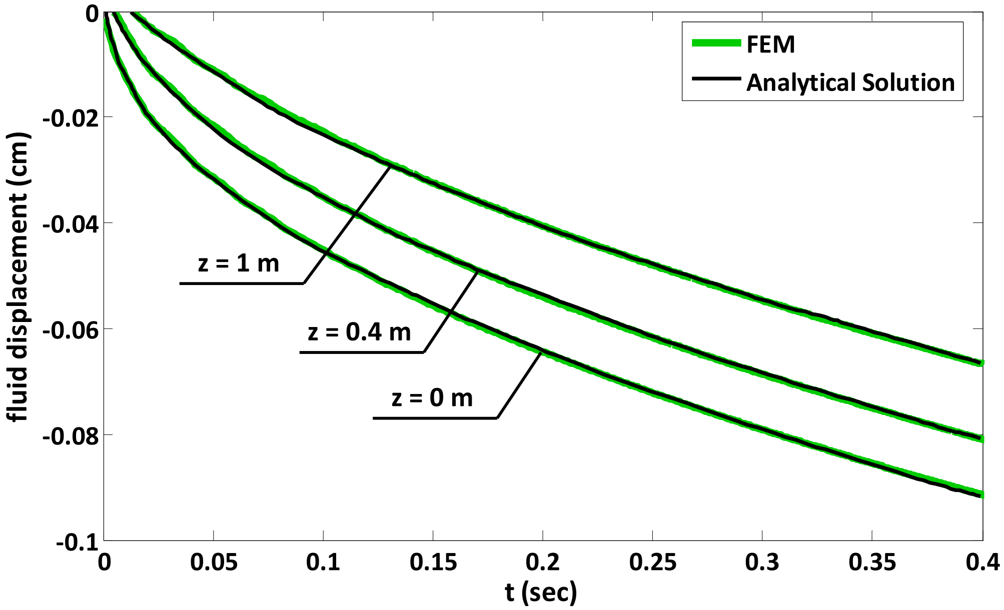

Figure 310.60: Time history of fluid displacements at different depths due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

types of excitations were applied at the boundary surface in terms of solid and fluid velocity. In the first case, a unit step boundary condition boundary condition was applied at the top surface for both solid and fluid phases. In the second case, the fluid velocity specified at the boundary is different from the specified solid velocity increasing gradually to unity over the time scale. The results obtained from the numerical inversion allowed for six reflections of the fast compressional wave of first kind and two reflections of the secondary slow longitudinal wave.

One of the most important observations which both Garg et al. (1974) and Hiremath et al. (1988) concluded to, is that in case of strong viscous coupling (high drag), the material behaves as a single continuum with internal dissipation and the two wave fronts tend to become a single one.

Hiremath et al. (1988) presented a comparison of finite element solution of Biot's equations of motion with one based on numerical inversion of the Laplace transform solution. It is explained in the paper that a proper choice of element type and time domain integration is essential for capturing the results coming from the semi-analytical solution. Moreover, the spatial discretization needs to be combined with an appropriate temporal one, so that the wave does not traverse more than one element length during a single time step. In detail, Hiremath et al. (1988) suggests 100 linear elements of 0.005 m length and 986 time steps of size 10^{-6} sec.

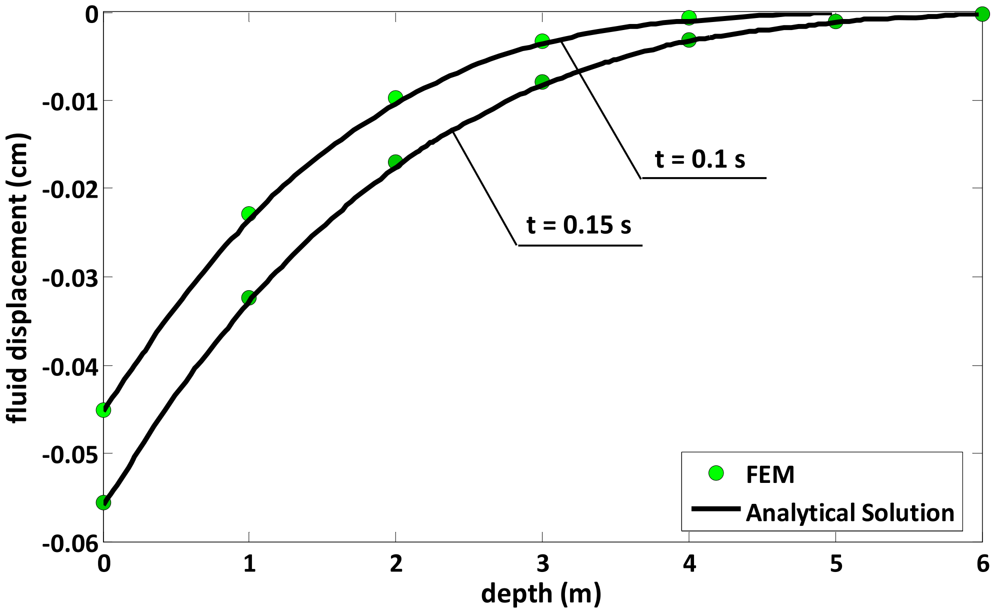

Figure 310.61: Response of fluid displacements versus depth at different time moments due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

310.10.2 Numerical Analysis

Numerical examples for two extreme values of viscous coupling: a) high drag ($k = 0.148 \times 10^{-8} cm^3 s/g$) and b)low drag ($k = 0.148 \times 10^{-2} cm^3 s/g$), were solved in order to verify the previously mentioned $u-p-U$ formulation by comparing the results with the semi-analytical solution provided by Hiremath et al. (1988). The numerical model used for the simulation of the 1C shock wave propagation consists of 100 u-p-U brick finite elements of dimensions $0.005m \times 0.005m \times 0.005m$ creating a soil column 50cm thick. Figure 310.69 illustrates the transition from the physical configuration of the problem to its numerical simulation. Table 310.8 shows the soil properties of the numerical model.

At the top surface of the soil column, a step velocity of $1.0 \times 10^{-2} m/sec$ is applied both to the solid and the fluid phase. Only the vertical translational degrees of freedom are free. The horizontal translational degrees of freedom are constrained so that there is no lateral flow or displacement. The base of the model is rigid and impervious.

This kind of excitation (Heaviside function) applied at the top of the model, results clearly in waves of all kinds of frequency, first due to its nature and secondarily due to the way of its application. This fact together with the great stiffness of the solid skeleton (see Table 310.8 require a very dense spatial

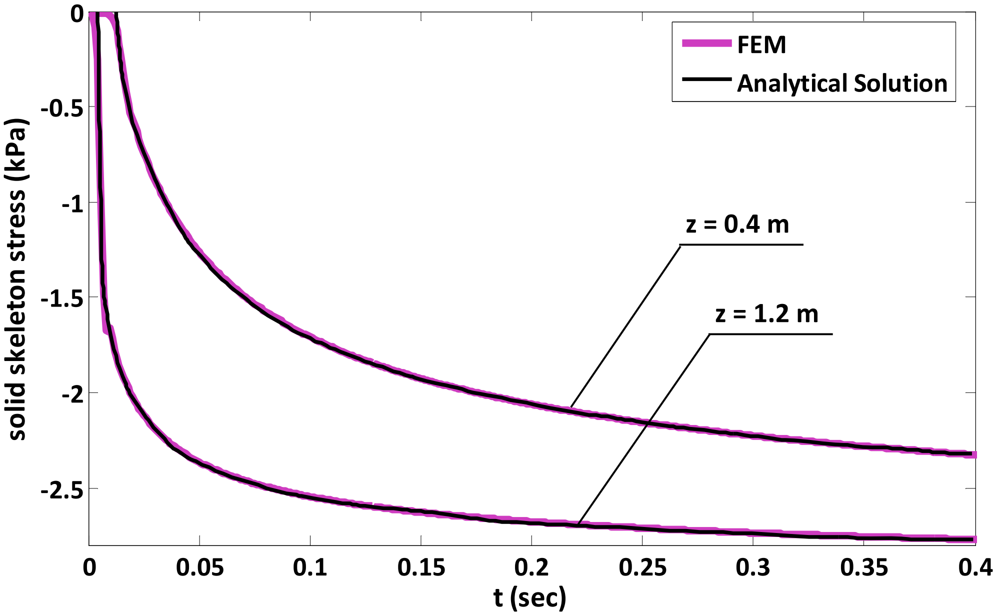

Figure 310.62: Time history of solid skeleton stresses at different depths due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

Table 310.8: Soil Properties for 1C shock wave propagation for example by Hiremath et al. (1988).

Parameter	Symbol	Value
gravity acceleration	g	$9.81\ m/s^2$
soil matrix Young's Modulus	E	$23.21 \times 10^6\ kN/m^2$
soil matrix Poisson's ratio	ν	0.171
solid particle density	ρ_s	$2.66 \times 10^3\ kg/m^3$
water density	ρ_f	$1.0 \times 10^3\ kg/m^3$
solid particle bulk modulus	K_s	$36.0 \times 10^6\ kN/m^2$
fluid bulk modulus	K_f	$2.2 \times 10^6\ kN/m^2$
porosity	n	0.18
Biot coefficient	α	0.6772

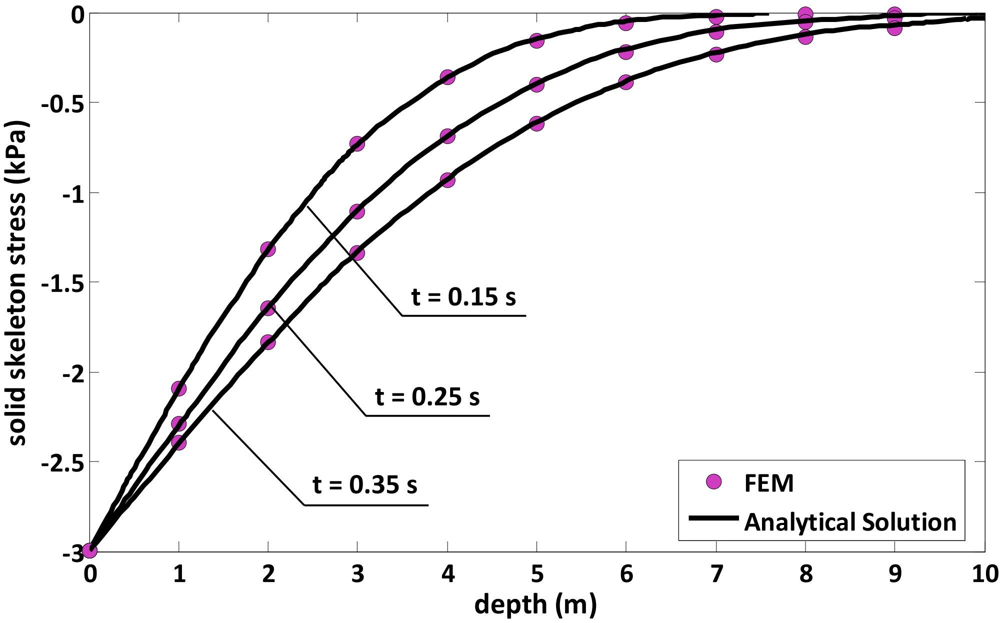

Figure 310.63: Response of solid skeleton stresses versus depth at different time moments due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

discretization. Here, 100 u-p-U brick finite elements of dimensions $0.005m \times 0.005m \times 0.005m$ were chosen, following similar discretization with Hiremath et al. (1988). The time step, δt required needs to be limited to

$$\delta t < \frac{\delta h}{v} \tag{310.61}$$

(310.62)

where v is the highest wave velocity. In our case, the temporal integration involves 1972 steps of $5.0 \times 10^{-7} sec$, in comparison with 986 time steps of size $10^{-6} sec$, used by Hiremath et al. (1988). The time integration method used was the Newmark integrator with parameters: $\gamma = 0.6$ and $\beta = 0.3025$.

310.10.3 Discussion of Numerical Results - Conclusions

Biot has shown than when dissipation is present, each frequency component propagates with its own velocity. Thus, especially in the case of numerical solutions using a finite element procedure, the response is very sensitive to the numerical damping introduced to the system. Generally, a drawback of all types

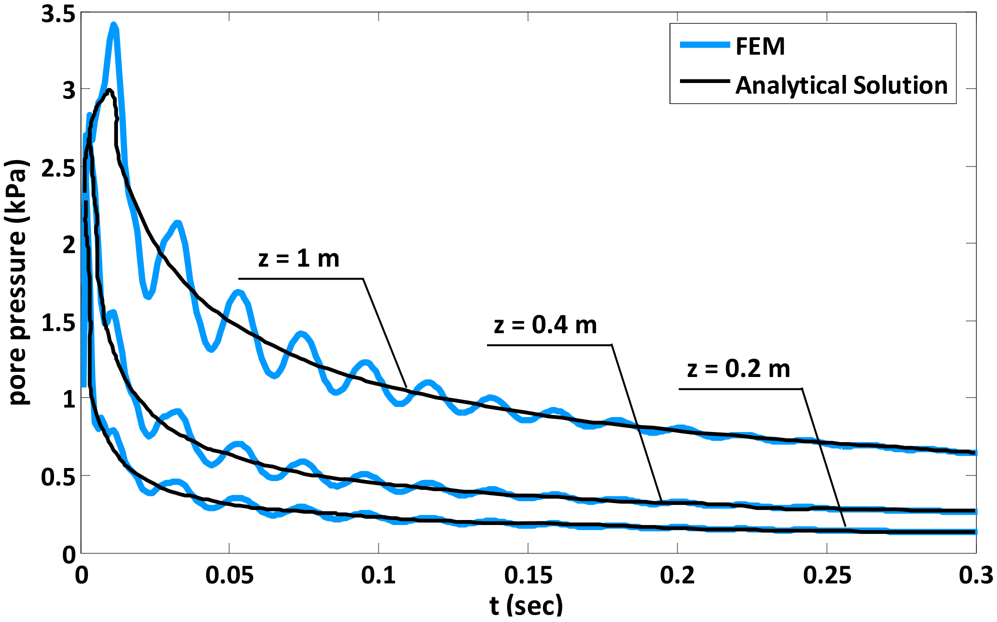

Figure 310.64: Time history of pore pressure at different depths due to step loading. Comparison of numerical results (FEM) with the analytical solution by de Boer et al. (1993).

types of numerical solutions is the distortion and the smearing of the wave fronts, which are linked to the highest frequency that is allowed by the computational grid and the numerical damping due to the time integration method. The numerical results presented here, show some oscillations at the rough changes in velocity due to reflection of wave fronts that could be possibly diminished by using a finer spatial and temporal discretization.

Figures 310.70 to 310.77 illustrate the comparative results for both extreme cases of viscous coupling. In general, it is worth noting that the numerical results are in good agreement with the main characteristics of the mechanics of dispersive wave propagation in fully saturated, porous media, as indicated by the semi-analytical results. For example, numerical results well demonstrate that for the case of strong viscous coupling (high drag), the solid and fluid are in phase with each other, implying that the two-phase material behaves as a single continuum. Overall, the finite element solutions reproduce correctly the trends of wave propagation in both limiting cases of viscous coupling.

Chapter 311

Verification and Validation for Seismic Wave Propagation Problems

(1989-2000-2004-2005-2008-2009-2010-2011-2017-2018-2019-2021-)

(In collaboration with Dr. Nima Tafazzoli, Dr. Matthias Preisig, Dr. Federico Pisanò, Mr. Kohei Watanabe, Mr. Chao Luo, and Dr. Hexiang Wang)

311.1 Chapter Summary and Highlights

311.2 Wavelet Seismic Signals

A wavelet is a wave with specific definitions and parameters. The amplitude of a wavelet usually starts at zero, increases by time and ended up at zero again. Typically a wavelet can be plotted as a brief oscillation such as a the small oscillation recorded by seismogram. There are different types of wavelets each with their own properties used for specific purpose in signal processing. For specific purposes different wavelets might be summed up to come up with new type of wave. A recently developed wavelet analysis has become a powerful tool to analyze the soil-structure systems for transient loads providing information both in time and frequency domains. In wavelet representation the basis functions are localized and contained in finite time domains (Sarica and Rahman (2003)).

311.2.1 Ricker Wavelet

One type of wavelet motions is the Ricker wave (Ryan (1994), Mavroeidis and Papageorgiou (2003)). The formulation of Ricker wavelet is shown in Equations (311.1):

$$R(t) = A \quad (1 - 2\pi^2 f^2 \; t^2) \quad \exp(-\pi^2 f^2 t^2) \tag{311.1}$$

where $R(t)$ is the amplitude of the function in time, A if the maximum amplitude, and f is the peak frequency on the wavelet's frequency spectrum. Figure (311.1) shows the actual time history and fast Fourier transform of Ricker wavelet, where A is taken as 1 and f is taken as $5Hz$. As it is shown, the frequency range of the motion is narrower compared to the real earthquake motion.

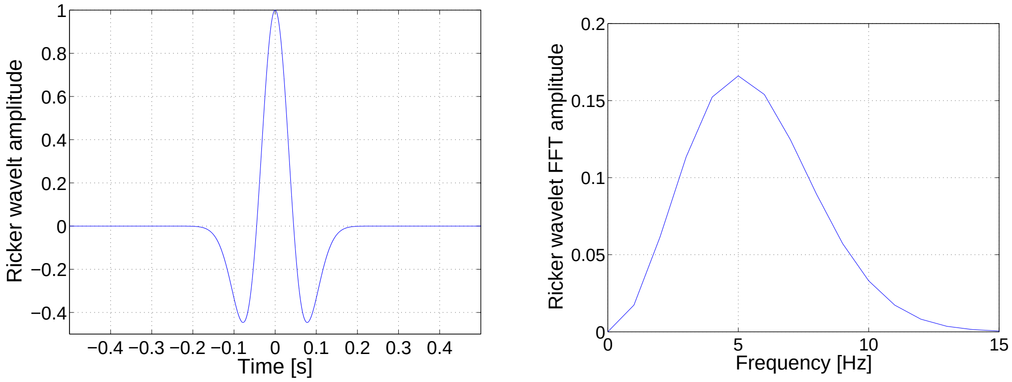

Figure 311.1: Frequency content and a time domain representation of Ricker wavelet

311.2.2 Ormsby Wavelet

Another example of interesting wavelet is called Ormsby wavelet (Ryan (1994)) which features a controllable flat frequency content with formulation shown in Equation (311.2).

$$\begin{aligned} f(t) &= A((\frac{\pi f_4{}^2}{f_4 - f_3} sinc(\pi f_4(t-t_s))^2 - \frac{\pi f_3{}^2}{f_4 - f_3} sinc(\pi f_3(t-t_s))^2) \\ &- (\frac{\pi f_2{}^2}{f_2 - f_1} sinc(\pi f_2(t-t_s))^2 - \frac{\pi f_1{}^2}{f_2 - f_1} sinc(\pi f_1(t-t_s))^2)) \end{aligned} \tag{311.2}$$

where f_1 and f_2 define the lower range frequency band, f_3 and f_4 define the higher range frequency band, A is the amplitude of the function, and t_s is the time that maximum amplitude is happening, and $sinc(x) = sin(x)/x$.

Figure (311.2) shows an example of Ormsby wavelet in time domain and frequency domain. In this case, wave has a flat frequency range of 5Hz to 20Hz. Shown in Figure (311.3) is half of the Ormsby wavelet in frequency domain which the frequency range starts from 0 and remains constant up to $20Hz$. This type of motion could be useful when low frequency range of motions are required for dynamic analysis of the systems.

Such broad band signals could be used to assess different aspects of soil-structure systems and with different incoming wave inclinations. While wavelet time domain motions are not the same as actual earthquakes, the idea is to use them for dynamic analysis of soil-structure systems for possible problems coming out of dynamic behavior, at different frequencies and for different energy input levels.

When used with the DRM, motions developed from different directions, different incident angles and different energies, will create a full envelope of these motions, which then can be used to evaluate performance based response of the soil-structure systems.

311.4 Damping of the Outgoing Waves

311.4.1 Comparison of Rayleigh Damping and Caughey 4th Order Damping

As mentioned before, Caughey damping in general will damp out the motions at specified modes (frequencies) to be specified which could also be the natural frequencies of the system. Depending on the type of damping to be used, the response of those modes would be affected. In order to observe the damping effect on certain modes, a soil profile is made with thickness of $50m$ and shear wave velocity of $100m/s$. For input motion, an Ormsby wavelet with frequency range of 0 to 7 Hz is considered at the base of model. The wave is propagated through the soil layer using the elastic transfer functions and comparison is made between the case which Rayleigh damping is used versus the case which the frequency independent damping is used in the model. The same procedure is done by using Caughey damping.

Figures (311.22) and (311.23) show the base motion (Ormsby wavelet), motion at the surface

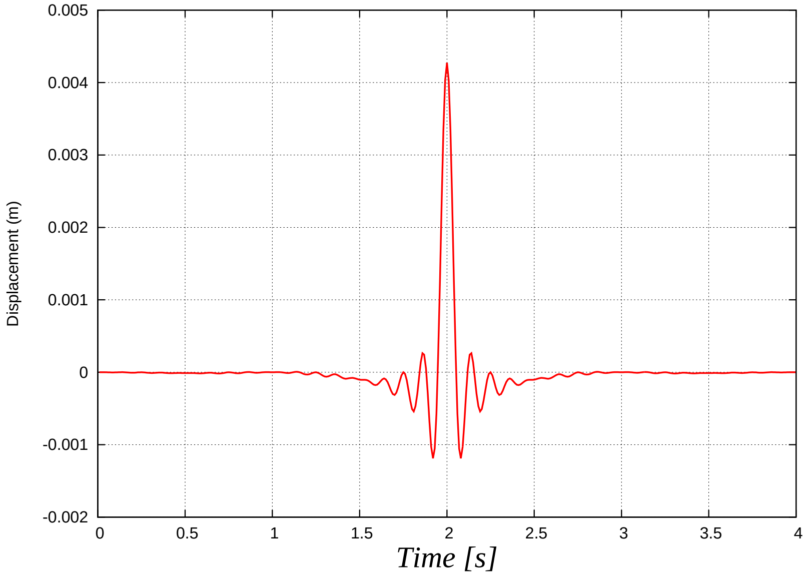

Figure 311.16: Displacement time history of input motion (Ormsby Wavelet)

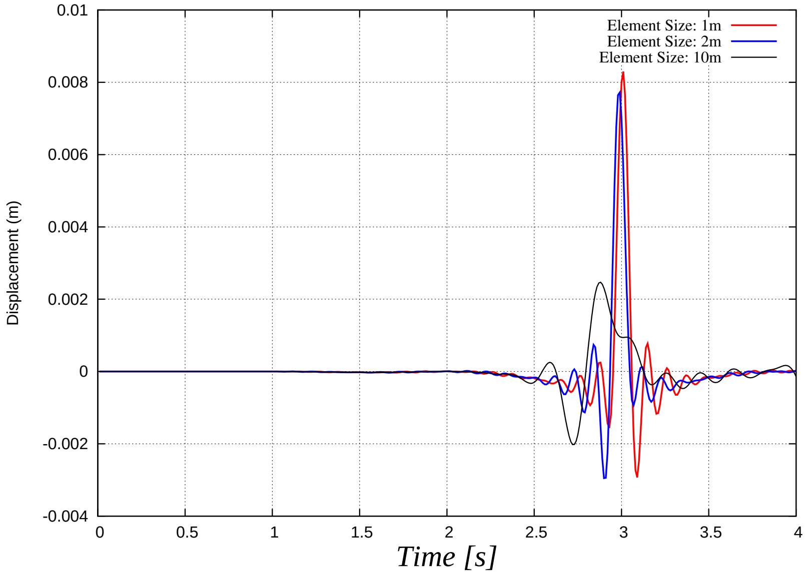

Figure 311.17: Comparison of displacement time histories of case 9, 10, and 11 at top of the model

considering the frequency independent damping, motion at the surface using Rayleigh wave (frequency dependent), motion at the surface using Caughey damping of 4th order (frequency dependent) as well as how Rayleigh and Caughey damping ratio change with frequency. It can be observed how the response is affected at different modes using Rayleigh damping versus using Caughey damping.

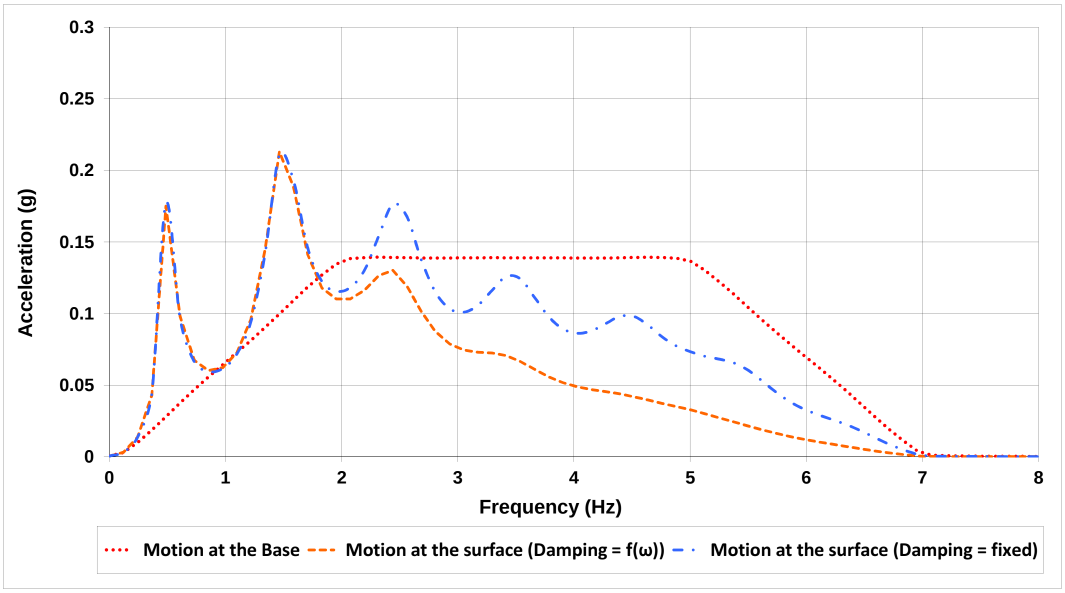

Figure 311.22: Comparison of obtained motion at the surface using frequency independent damping and frequency dependent Rayleigh damping.

311.4.2 Parametric Study on Effect of Rayleigh Damping on Reflected Waves

As mentioned in previous chapter, one of the issues of the modeling in dynamic analysis is reflecting of the motions from the boundaries since there are limitations regarding the size of the problems we can model. In order to reduce the computational cost of the problems, the size of the mesh has to be reduced. By reducing the size of the model the chance of reflecting the motions from the boundaries gets higher since there is less volume for the waves to get dissipated.

There are different ways to reduce reflection of the waves from the numerical boundaries such as PML, viscous dampers, infinite elements, or considering Rayleigh damping for specific elements. Presented here show the results of wave propagation models considering Rayleigh damping. There are different damping patterns used here such as constant damping ratio for all the elements in the damping zone or linear pattern of increasing the damping ratio.

In order to find the Rayleigh damping coefficients, two frequencies have to be considered. In these examples both cases of using the natural frequencies of the soil column and also using the dominant

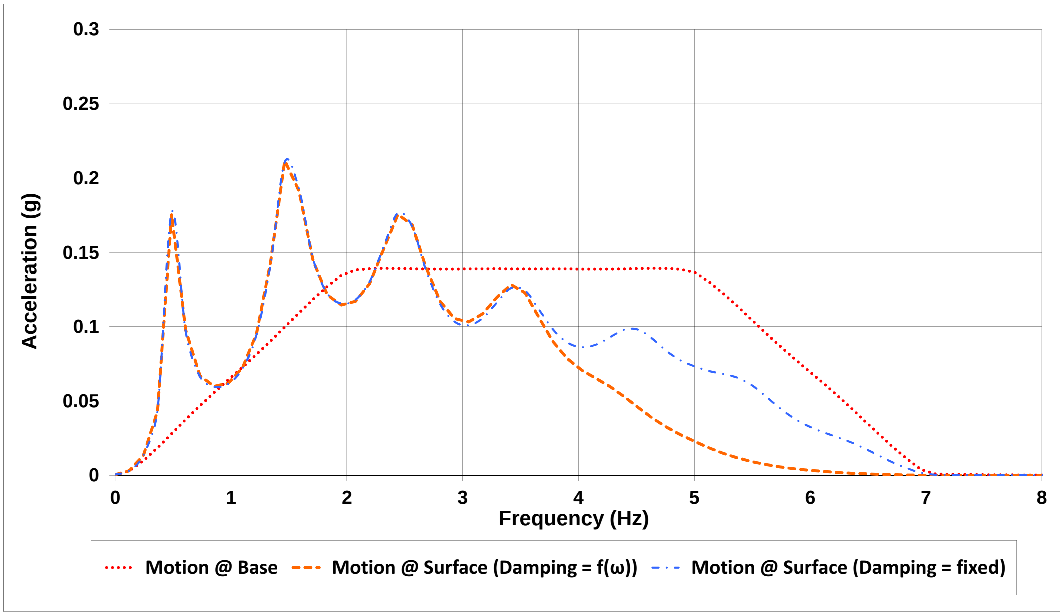

Figure 311.23: Comparison of obtained motion at the surface using frequency independent and frequency dependent Caughey 4th order damping.

periods of the motions are used and comparison is made. Different shear wave velocities and input motion frequencies are used which is mentioned for each case. The input motion considered for simulation is Ricker wavelet considering different dominant frequencies. V_s is the soil profile shear wave velocity and f_r is the frequency of the Ricker wavelet, and xi is the Rayleigh damping ratio at considered frequencies.

The height of the finite element model is $60m$ and boundary conditions are introduced in order to model 1C wave propagation. The motion is imposed at one side of the model and Rayleigh damping is applied to couple of the elements on the other side of the model in order to damp out the waves. Results are recorded at the boundary of damped and undamped zones.

Figure (311.24) shows the comparison of time histories for the soil column with shear wave velocity of $100m/s$ and input motion frequency of $8Hz$. Frequencies used to calculate Rayleigh damping coefficients in this case are natural frequencies of the soil column. The same damping ratio is used for all the damping zone elements. It can be observed that the one with constant damping ratio of 0.5 has done better job in terms of damping out the reflected motions.

Same analysis is done by using frequencies of $6Hz$ and $12Hz$ for the Rayleigh damping. As shown in Figure (311.25), in this case the reflected waves are damped out more comparing to previous case where natural frequencies of the soil were used for Rayleigh damping. This fact shows that the frequencies to be used for calculating the Rayleigh damping coefficients, do not have to be the natural frequencies of the soil which sometimes used in practice and depends on the frequency range of the input motion as well. Since the Ricker wavelet used here has a peak frequency of $8Hz$, the higher values of frequencies should be used for Rayleigh damping coefficients. Figure (311.26) shows the results of the same case except that linear increasing pattern is used for damping ratio of the 5 elements in damping zone. It seems that using the linear pattern starting from 0.3 to 1.1 results in less reflected motions.

The reason could be because of the nature of Rayleigh damping which is frequency dependent. So different damping ratios are observed at different frequencies. In deed by changing the damping ratio at each element, five different patterns of Rayleigh damping are being used which has more capability of absorbing motions with different frequencies and amplitudes.

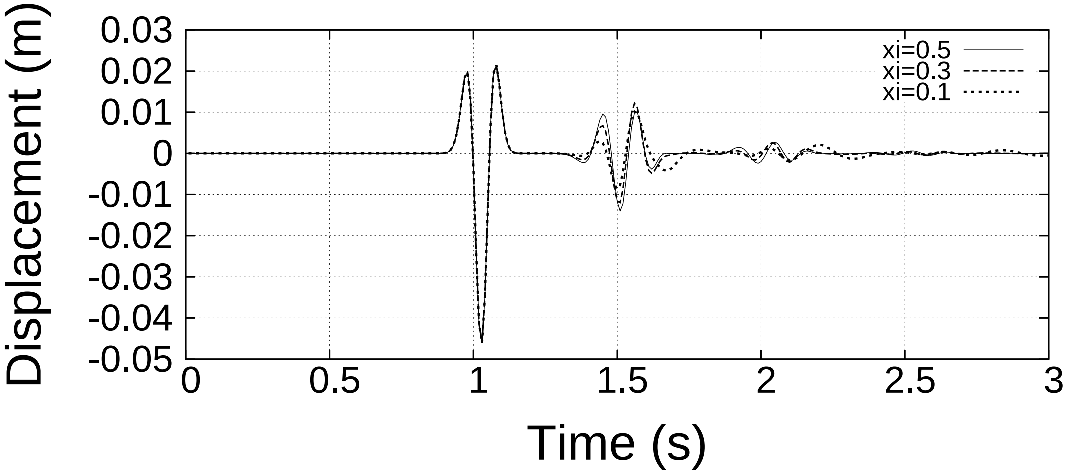

Figure 311.24: Displacement time history considering Rayleigh damping using natural frequencies of the soil, V_s=100m/s , f_r=8Hz

Figures (311.27) and (311.28) show the displacement time histories for same patterns of constant damping ratio for all elements in the damping zone and linearly increasing damping ratios respectively but for shear wave velocity of $V_s = 300m/s$ and input motion frequency of $5Hz$. Same conclusion can be made here as previous case regarding the pattern of damping ratios and frequencies to be used for Rayleigh damping.

Figures (311.29) and (311.30) are comparisons of recorded displacement time histories between patterns of same damping ratio for damping zone elements, damping ratio changes along the length of damping zone, and case of with out damping. Figure (311.29) is the case which shear wave velocity of the soil column is $100m/s$ and frequency of input Ricker motion is $1Hz$ while soil profile used in Figure (311.30) has shear wave velocity of $300m/s$ with input motion frequency of $8Hz$.

It can be observed that in case of having no physical damping, waves are getting trapped in the model and are reflecting back from the boundaries. Displacement time histories obtained from mentioned

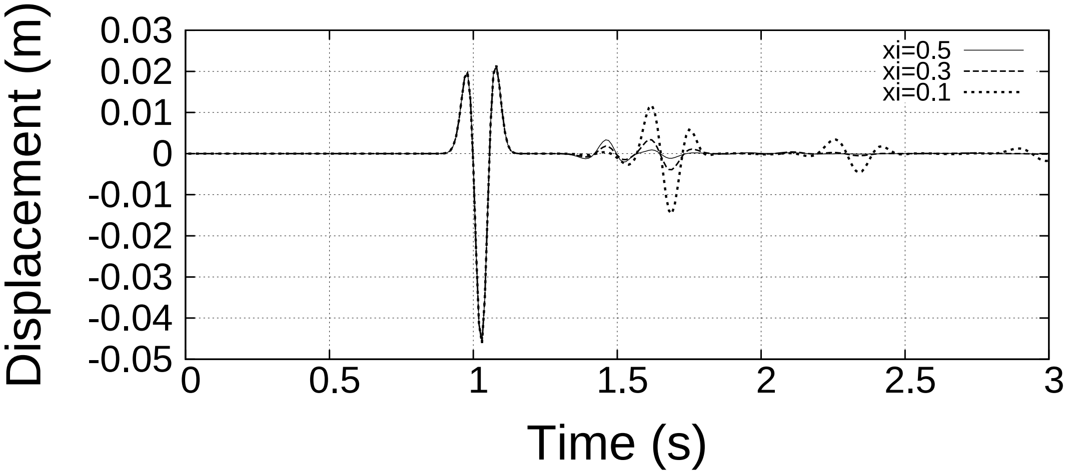

Figure 311.25: Displacement time history considering Rayleigh damping using f1,f2 = 6,12 Hz , V_s=100m/s , f_r=8Hz

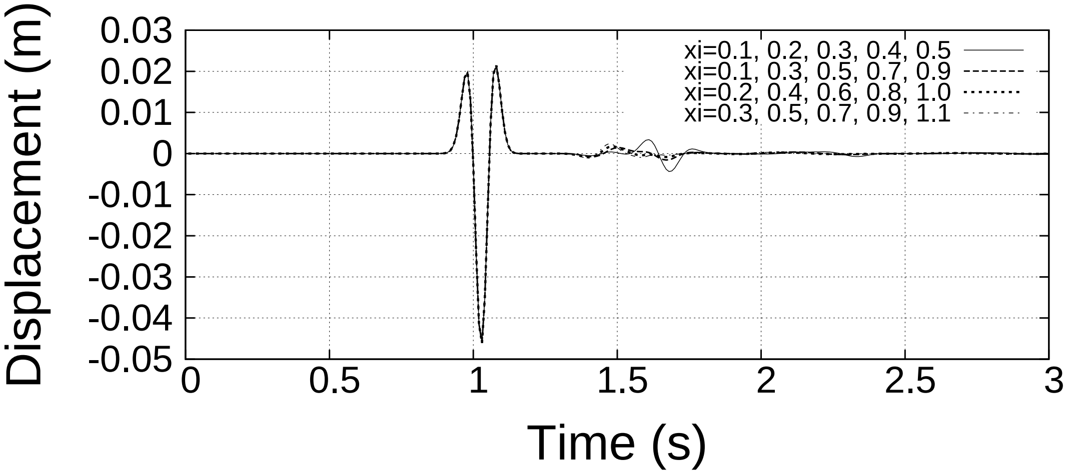

Figure 311.26: Displacement time history considering Rayleigh damping using f1,f2 = 6,12 Hz , V_s=100m/s , f_r=8Hz

patterns of damping ratios have minor differences which does not mean always will be this close but still the pattern of using linearly increasing of damping ratio seems to do a better job for damping the reflecting waves.

In order to have a better understanding of these patterns of damping, wave propagation through the depth of model is recorded for case of shear wave velocity of $100 m/s$ and input motion frequency of $8 Hz$. Displacement time histories in Figures (311.31) to (311.33) show wave propagation through the model for cases of using uniform damping ratios, linearly increasing damping ratios, and with out damping

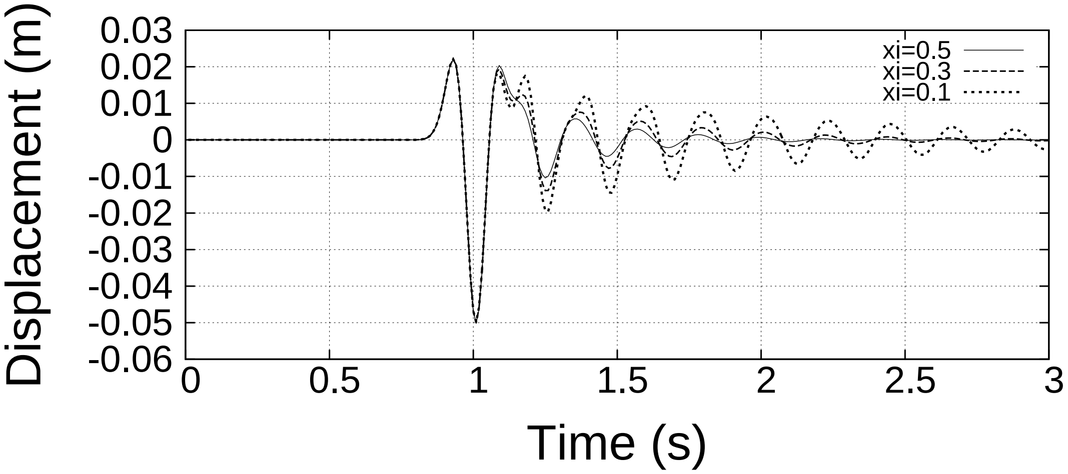

Figure 311.27: Displacement time history considering Rayleigh damping using f1,f2 = 5,8 Hz , V_s=300m/s , f_r=5Hz

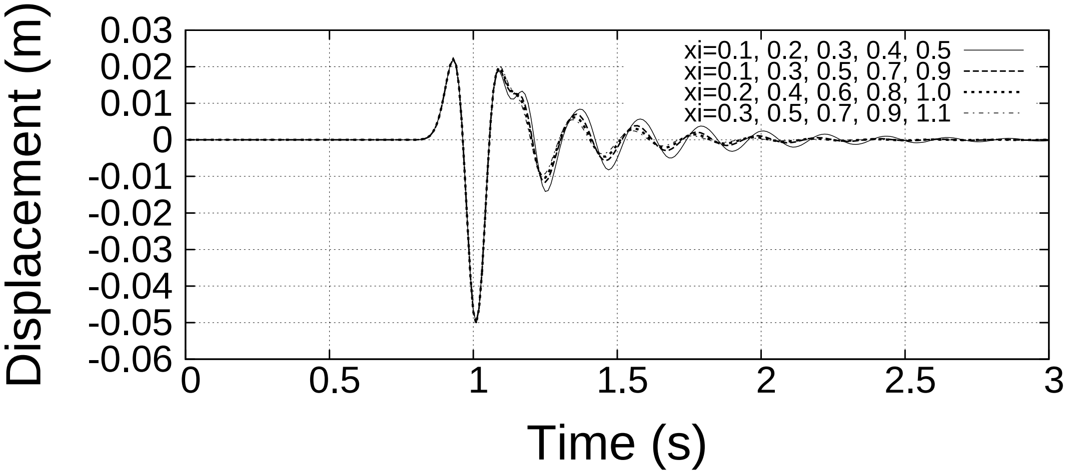

Figure 311.28: Displacement time history considering Rayleigh damping using f1,f2 = 5,8 Hz , V_s=300m/s , f_r=5Hz

respectively. By looking at the wave propagation through the whole soil profile it can be concluded that for this soil profile using the linearly increasing of damping ratios does a better job for damping the reflected motions at different depths.

Figure (311.34) shows the comparison of cumulative total energy time histories for the soil profile with shear wave velocity of $100m/s$ and input motion frequency of $8Hz$ for different Rayleigh damping patterns of uniform, increasing linearly, and case of no damping. What is expected to be observed is that total energy keeps increasing until the input motion gets to zero in time which energy should remain

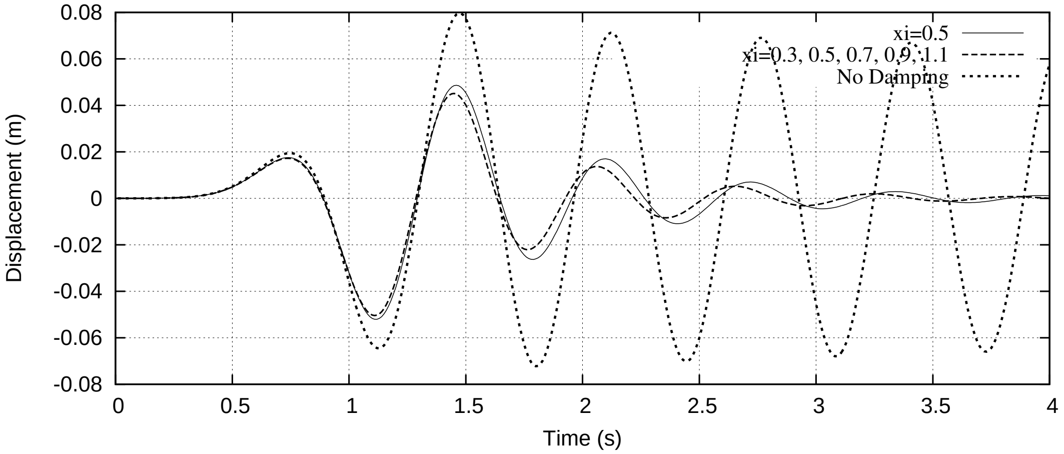

Figure 311.29: Displacement time history considering Rayleigh damping using f1,f2 = 0.5,2 Hz , V_s=100m/s , f_r=1Hz

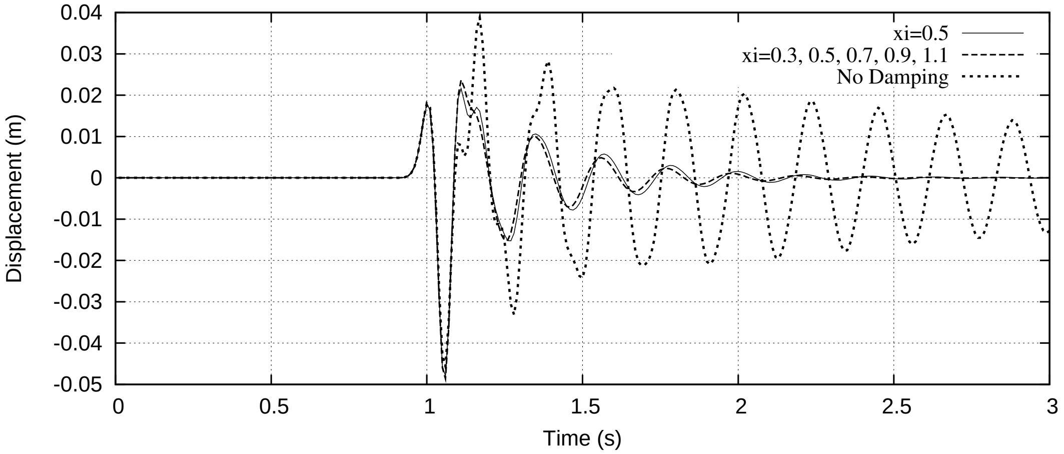

Figure 311.30: Displacement time history considering Rayleigh damping using f1,f2 = 6,12 Hz , V_s=300m/s , f_r=8Hz

constant unless there are waves reflecting back from boundaries. As it is shown, total energy slightly increase by time due to the reflected motions. This difference is much higher for case of no physical damping used since higher portion of the motions will get trapped in the model.

In order to be able to see the effect of size of damping zone on reflected motions, analysis is done on the soil profile with shear wave velocity of $100m/s$ and frequency of $8Hz$ for input motion. Comparison of displacement time histories for different size of the damping zones is shown in Figure (311.35). As expected, by reducing the size of damping zone, more waves are reflecting back from model boundaries.

The effect of number of elements to be used in damping zone is also studied here. Comparison is

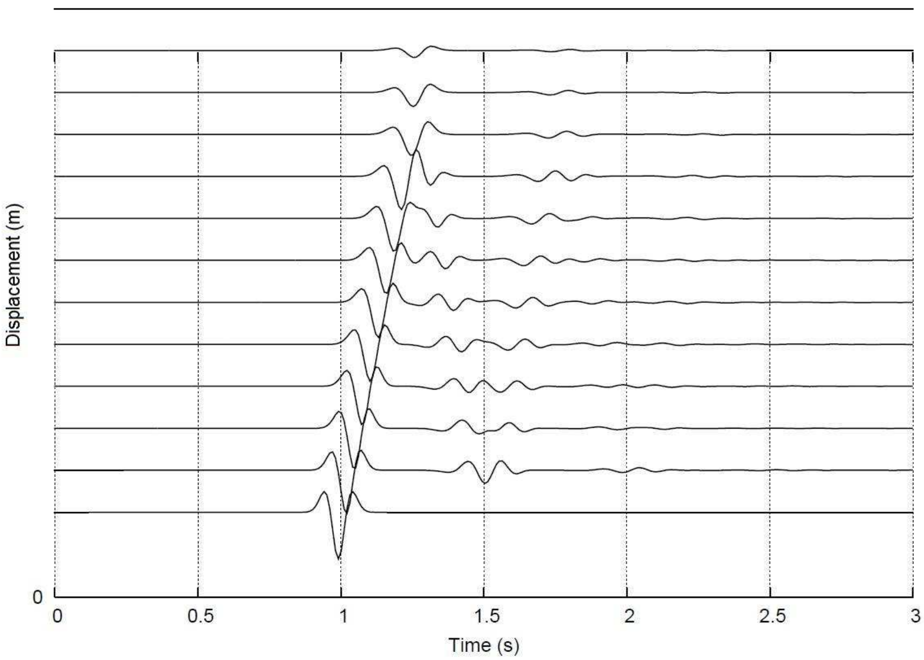

Figure 311.31: Displacement time history in depth considering homogeneous damping (15m), xi=0.5, V_s=100m/s, f_r=8Hz

made for cases which the size of the damping zone is the same but the size of the elements (and therefore number of the elements) in that zone is changed. The size of the damping zone assumed to be $15m$ while the number of the elements used in that zone is considered to be 3, 5, and 15. The comparison for this change of number of the elements is shown in Figure (311.36). Rayleigh damping ratio with pattern of increasing linearly from 0.3 to 1.1 is used. As it is observed, by reducing number of elements in the damping zone, the amount of reflected waves are getting higher.

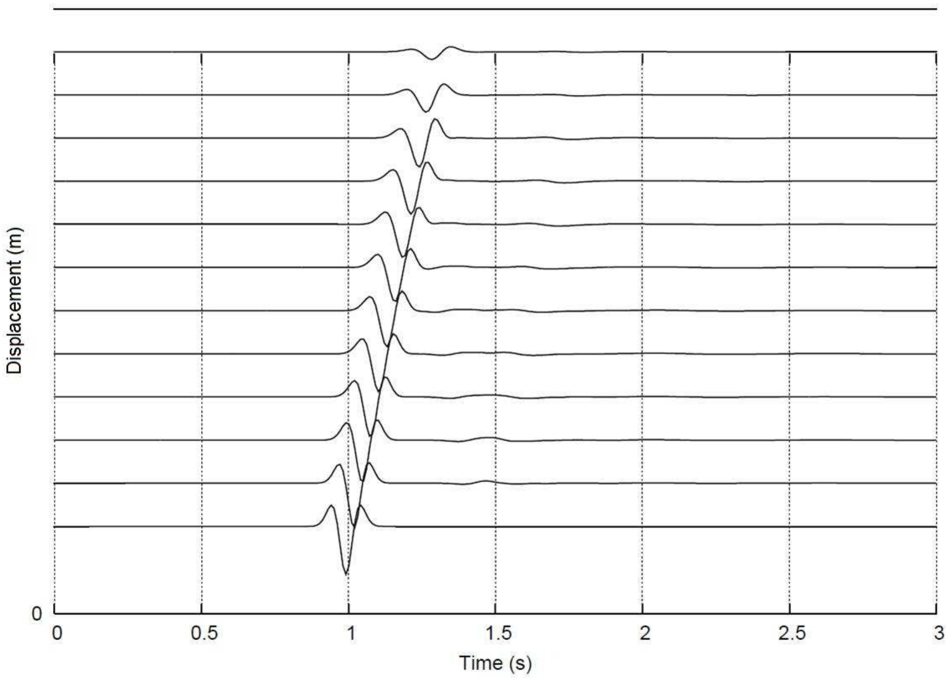

Figure 311.32: Displacement time history in depth considering linear increasing of xi in Rayleigh damping (every 3m), xi=0.3, 0.5, 0.7, 0.9, 1.1, V_s=100m/s, f_r=8Hz

311.5 Mesh Size Effects for Linear (8 Node Brick) and Quadratic (27 Node Brick) Finite Elements on Wave Propagation

Generally, the results of numerical analysis using finite element method technique for the dynamic problem are affected by size of mesh (grid spacing). According to Argyris and Mlejnek (1991), about 10 nodes per wavelengths are required to simulate accurately for the given frequency and fewer than 10 nodes may induce an artificial damping due to the numerical reason.

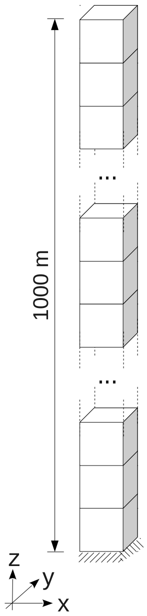

Figure 311.37: One dimensional column test model to inspect the mesh size effect

In this section, mesh size effect is inspected to decide an appropriate size of the mesh to build finite element model for verification. One dimensional column model is built as shown in figure 311.37. Total height of the model is 1000 m. Two models are built with element height of 20 m and 50 m, and each model have two different shear wave velocities (100 m/s and 1000 m/s). Density is set as 2000 kg/m^3, and Poisson's ratio is set as 0.3, for all test models. Various cases are set and tested as shown in table 311.1. Both 8 node and 27 node brick elements are used for all models. Thus, total 24 parametric study cases are inspected. Linear elastic elements are used for all analyses. All analyses are performed in time domain with Newmark dynamic integrator without any numerical damping (γ = 0.5, and β = 0.25, no numerical damping, unconditionally stable).

Ormsby wavelet (Ryan, 1994) is used as an input motion and imposed at the bottom of the model.

Table 311.1: Analysis cases to determine a mesh size

Case number	Vs (m/s)	Cutoff freq. (Hz)	Element height (m)	Max. propagation freq. (Hz)
1	1000	3	10	10
2	1000	8	10	10
3	1000	15	10	10
4	100	3	10	1
5	100	8	10	1
6	100	15	10	1
7	1000	3	20	5
8	1000	8	20	5
9	1000	15	20	5
10	100	3	20	0.5
11	100	8	20	0.5
12	100	15	20	0.5

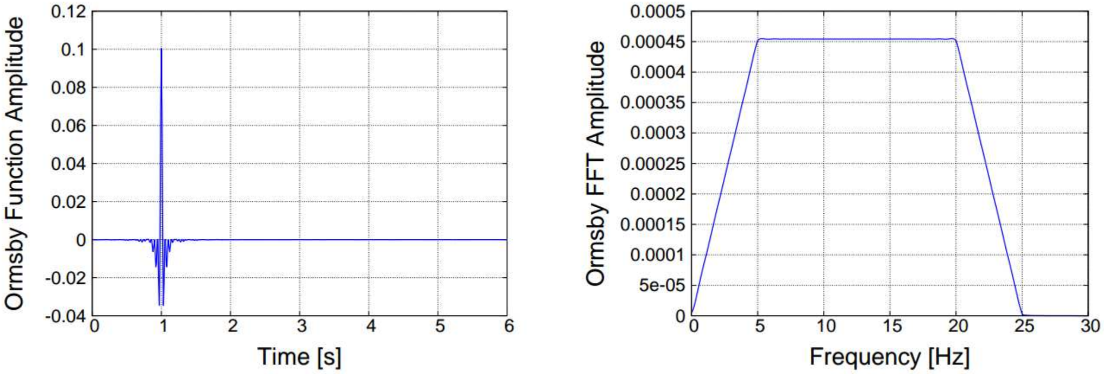

Figure 311.38: Ormsby wavelet in time and frequency domain with flat frequency content from 5 Hz to 20 Hz

Ormsby wavele features a controllable flat frequency content with formulation shown in equation 311.3.

$$
\begin{aligned}
f(t) = \quad & A\left(\left(\frac{\pi {f_4}^2}{f_4 - f_3} sinc(\pi f_4 (t - t_s))^2 - \frac{\pi {f_3}^2}{f_4 - f_3} sinc(\pi f_3 (t - t_s))^2\right)\right. \\
- \quad & \left(\frac{\pi {f_2}^2}{f_2 - f_1} sinc(\pi f_2 (t - t_s))^2 - \frac{\pi {f_1}^2}{f_2 - f_1} sinc(\pi f_1 (t - t_s))^2\right)
\end{aligned}
\tag{311.3}
$$

where f_1 and f_2 define the lower range frequency band, f_3 and f_4 define the higher range frequency band, A is the amplitude of the function, and t_s is the time that maximum amplitude is happening, and

$sinc(x) = sin(x)/x$. Figure 311.38 shows an example of Ormsby wavelet with flat frequency content from 5 Hz to 20 Hz.

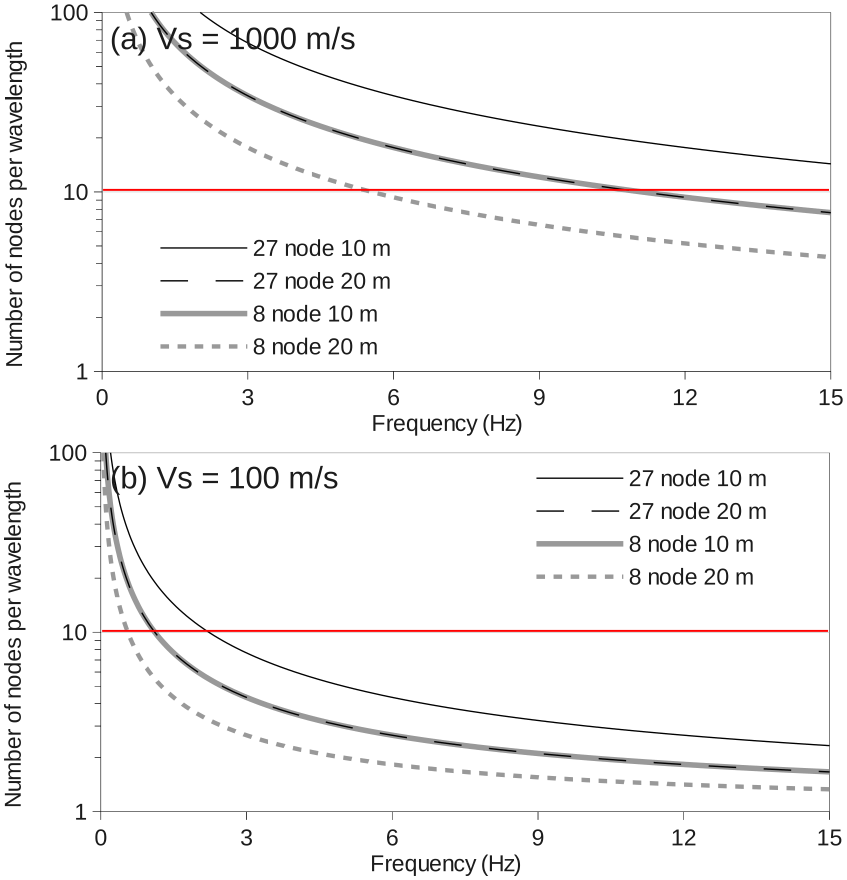

Figure 311.39: Number of nodes per wavelength along frequencies, and element sizes (a) Vs = 1000 m/s (b) Vs = 100 m/s

For this example, cutoff frequencies of Ormsby wavelets are set as 3, 8, and 15 Hz (table 311.1). Figure 311.39 shows number of nodes per wavelength along frequencies and figure 311.40 – 311.46 show comparison of analysis results. As shown in figure 311.40, case 1 and 7 (analysis using Ormsby wavelet with 3 Hz cutoff frequency) predict exactly identical results to the analytic solution in both time and frequency domain. Since, number of nodes per wavelength for both cases are over 10 (see figure 311.39(a) and table 311.1, all cases under 3 Hz shows more than 10 nodes per wavelength), those exact results are expected.

Increasing cutoff frequency from 3 Hz to 8 Hz induces numerical errors as shown in figure 311.41. In frequency domain, both 10 m and 20 m element height model with 27 node brick element predict exactly same results with the analytic one. However, in time domain, asymmetric shape of time history

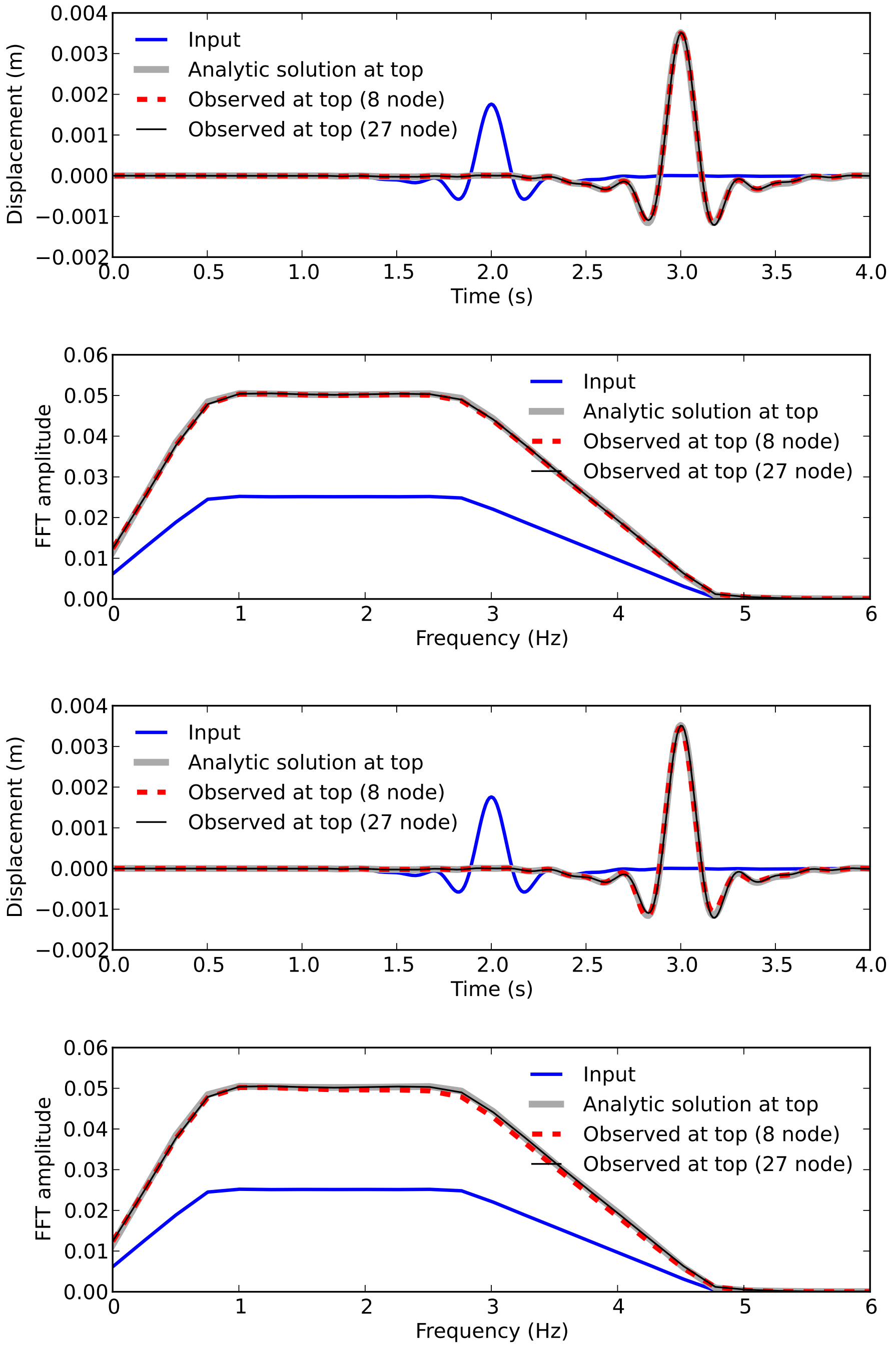

Figure 311.40: Comparison between (a) case 1 (top, Vs = 1000 m/s, 3 Hz, element size = 10m) and (b) case 7 (bottom, Vs = 1000 m/s, 3 Hz, element size = 20m)

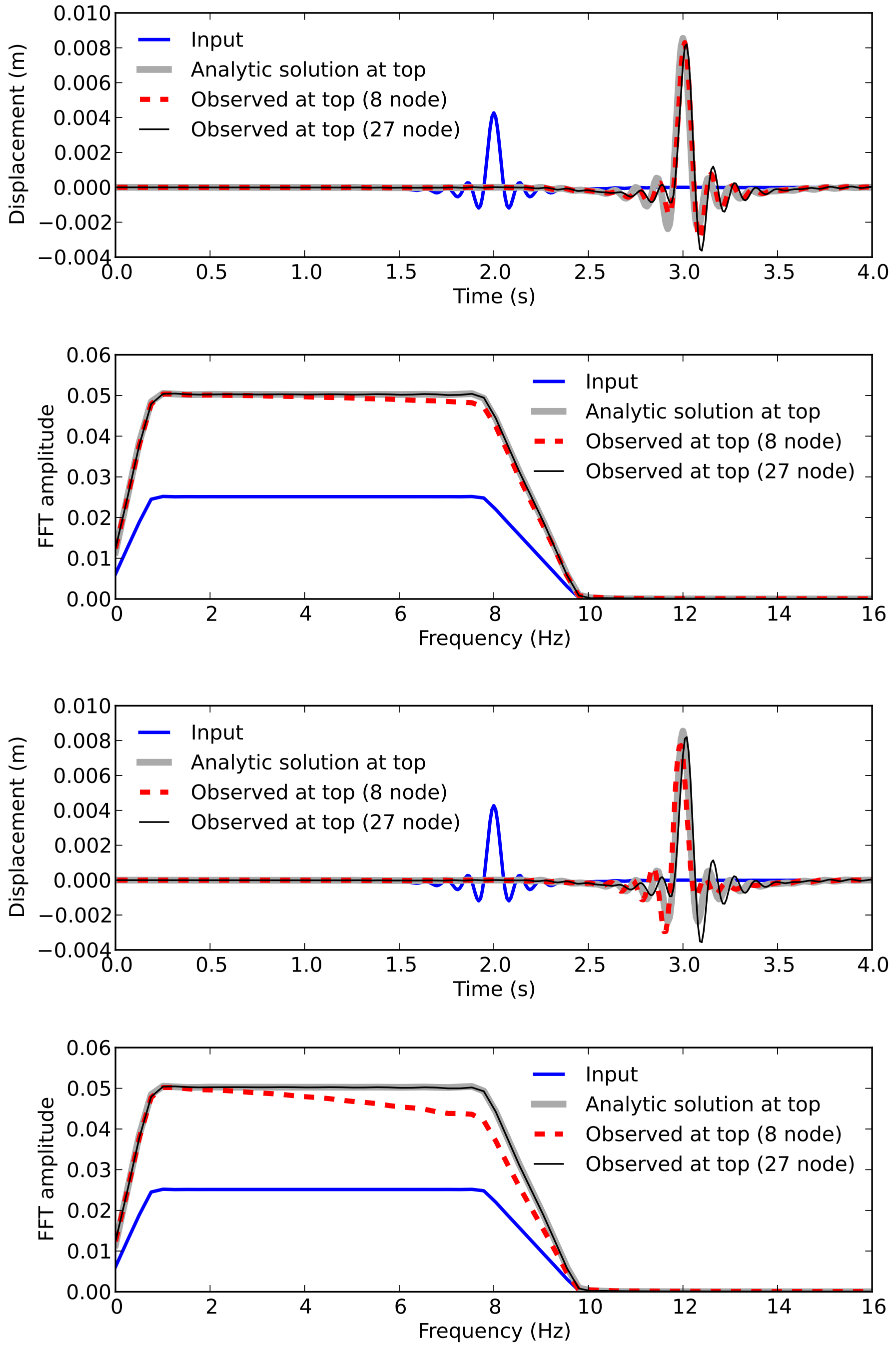

Figure 311.41: Comparison between (a) case 2 (top, Vs = 1000 m/s, 8 Hz, element size = 10m) and (b) case 8 (bottom, Vs = 1000 m/s, 8 Hz, element size = 20m)

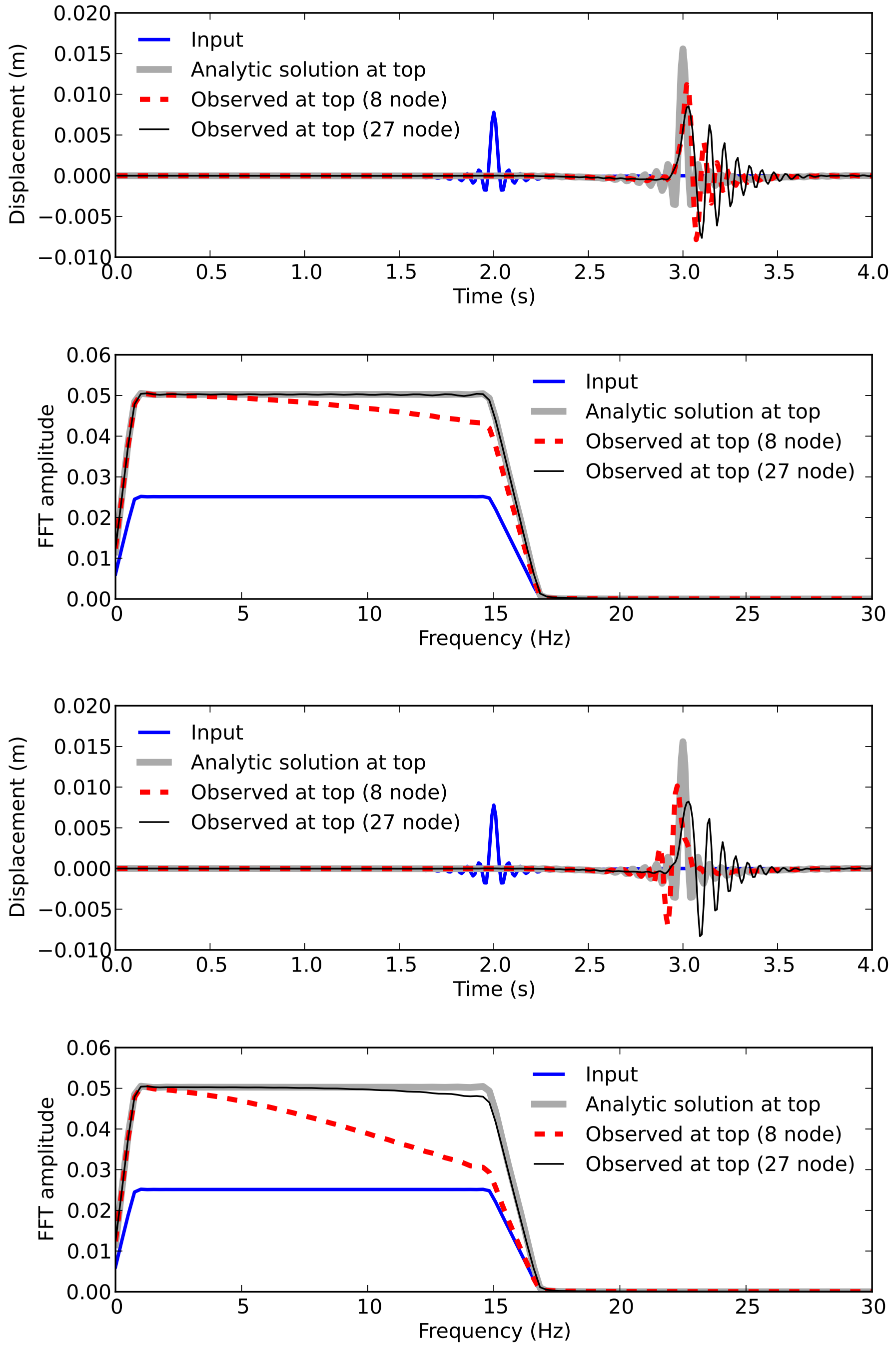

Figure 311.42: Comparison between (a) case 3 (top, Vs = 1000 m/s, 15 Hz, element size = 10m) and (b) case 9 (bottom, Vs = 1000 m/s, 15 Hz, element size = 20m)

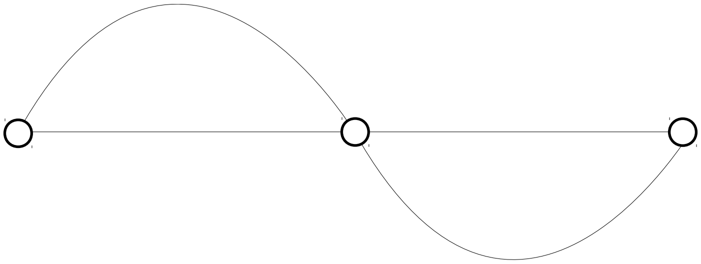

Figure 311.43: Schematic cartoon to show that nodes can behave like frequency contents filter

displacements are observed. Observations from top of 8 node brick element models show more numerical error in both time and frequency domain due to the decreasing number of nodes per wavelength (figure 311.39). Figure 311.42 shows analysis results with 15 Hz cutoff frequency. Results from 27 node brick elements are almost same in frequency domain but asymmetric shapes are also observed in time domain. Decreasing amplitudes in frequency domain along increasing frequencies are observed from 8 node brick element cases.

Figure 311.44 – 311.46 show results predicted from Vs = 100 m/s cases. Similar as Vs = 1000 m/s cases, decreasing amplitude along increasing frequencies are observed in all cases. One interesting observation is bumps in frequency domain which can be seen at natural frequencies (natural modes) of the elements (n th mode of elements, $f = (2n-1)Vs/4H$, 2.5 Hz, 5.0 Hz, and so on). This observation may mean that if certain condition is satisfied between modes and size of the element, it will behave like frequency contents filter. Figure 311.43 shows possible explanation of this observation. As in the case of figure 311.43, nodes (circle in the figure) cannot capture harmonic oscillation of the frequency since amplitude of the oscillation is always zero. As a result, the frequency contents at the frequency cannot be predicted by the analysis.

The results shown here are used as a reference to determine mesh size and frequency range of input motions for the verification.

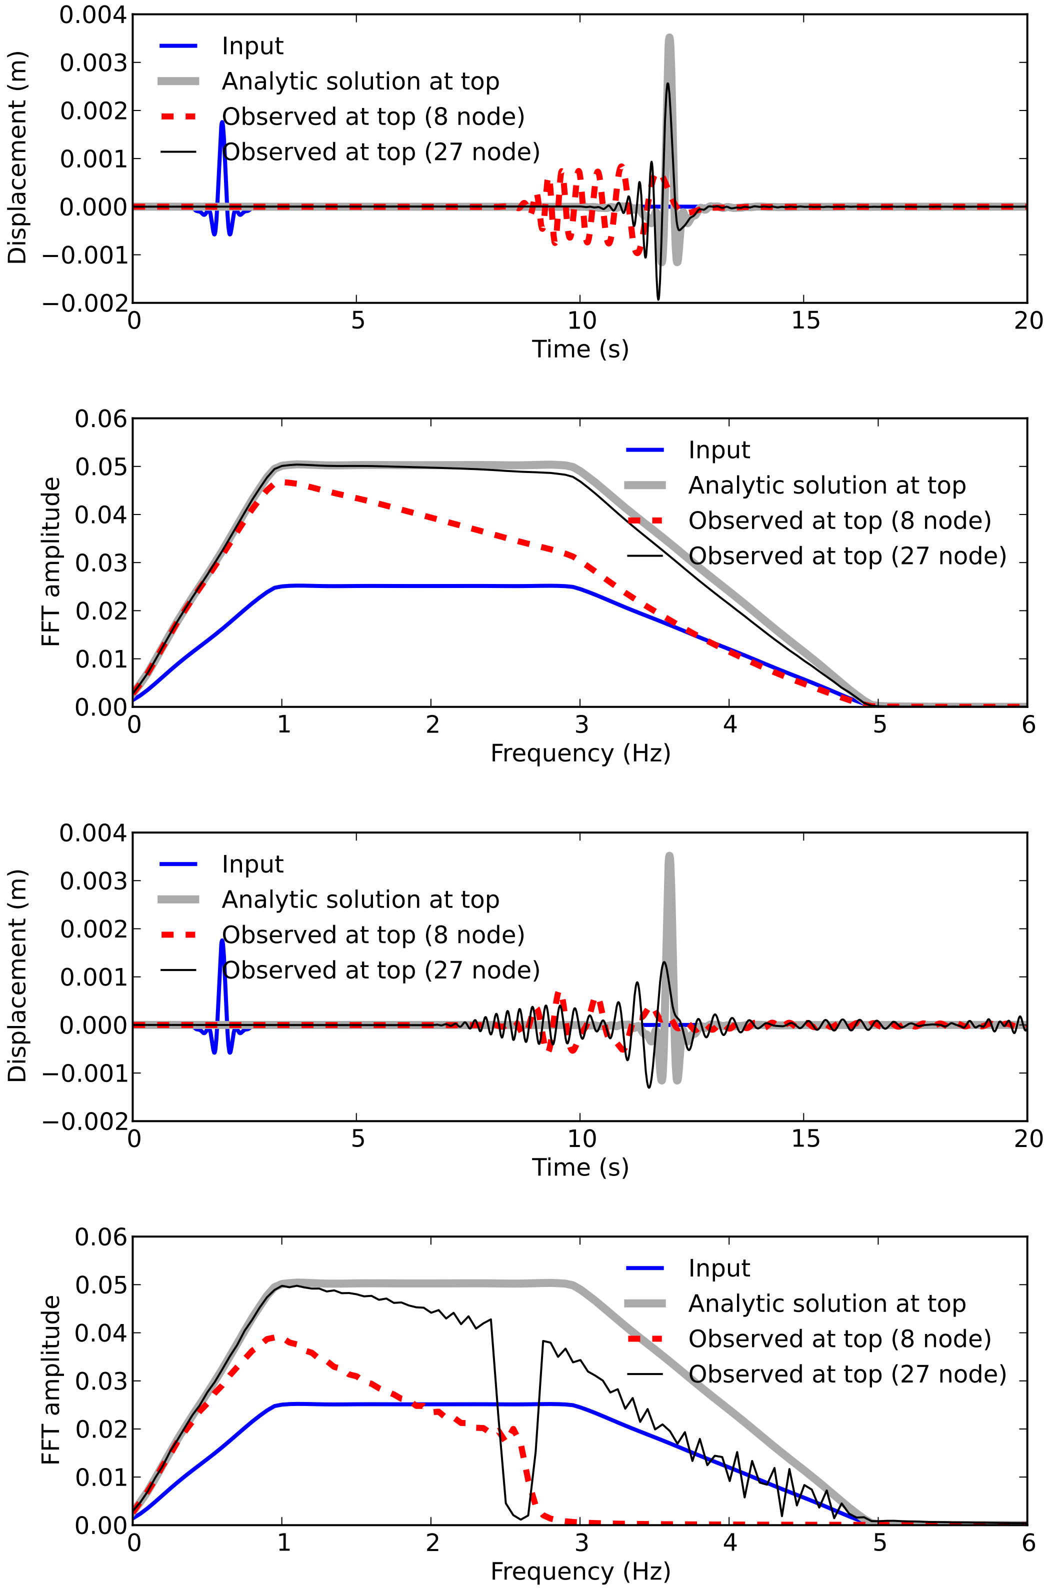

Figure 311.44: Comparison between (a) case 4 (top, Vs = 100 m/s, 3 Hz, element size = 10m) and (b) case 10 (bottom, Vs = 100 m/s, 3 Hz, element size = 20m)

311.6 Verification of the Seismic Input (Domain Reduction Method) for 3C, Inclined Seismic Wave Fields

311.6.1 Inclined, 3C Seismic Waves in a Free Field

In this section verification of the 3C wave propagation problem using Domain Reduction Method will be studied. In order to do so, a finite element model with dimensions of $10000m \times 50m \times 5000m$ is considered. Two cases are studied here with the source of motion (fault) to be located at $(x = 3000m, y = 0, z = 3000m)$ and $(x = 3000m, y = 0, z = 3000m)$. Figures (311.47) and (311.48) show these two models respectively.

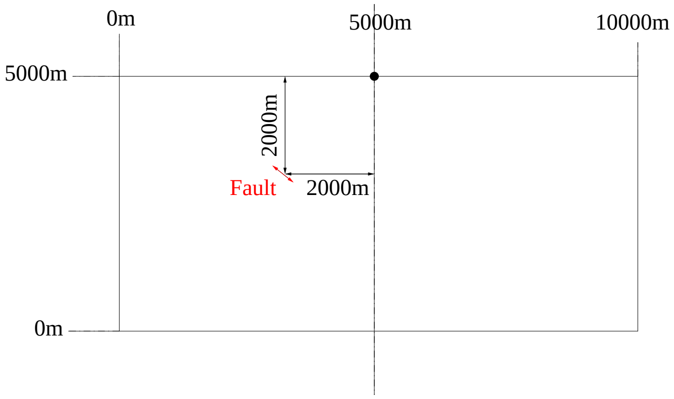

Figure 311.47: Domain to be analyzed for the 1^{st} stage of DRM with fault located at an angle of 45° with respect to the top middle point of the model

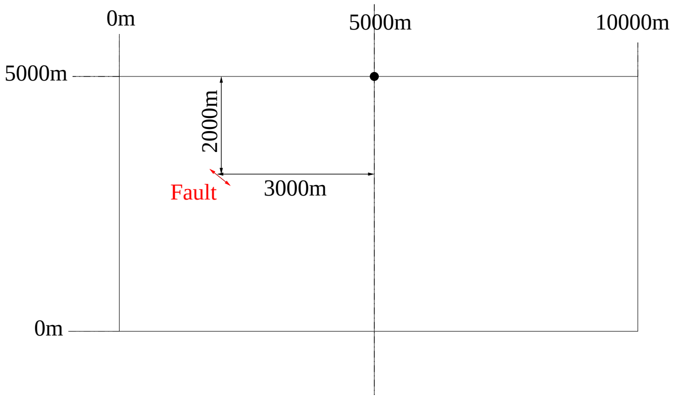

Figure 311.48: Domain to be analyzed for the 1^{st} stage of DRM with fault located at an angle of 34° with respect to the top middle point of the model

The size of the elements is chosen to be $50m$ in all directions for both cases in order to reduce the computational time. The soil parameters are: shear wave velocity of $700m/s$, density of $1800kg/m^3$, and Poisson's ration of 0.1. Analyses for the fault slip model are done by applying the motion at the nodes of one element. This is done in order to represent the the wave propagation starting from the fault using Multiple Support Excitation. This is representing the first stage of analysis of DRM in which a big model including the fault is considered for free field case in order to obtain the required motions for DRM layer. For simulating the second stage of DRM, a smaller model with dimensions of $240m \times 5m \times 70m$ is considered as shown in Figure (311.49). The size of the plastic bowl is $200m \times 5m \times 50m$. Size of the elements for this model is chosen to be $5m$.

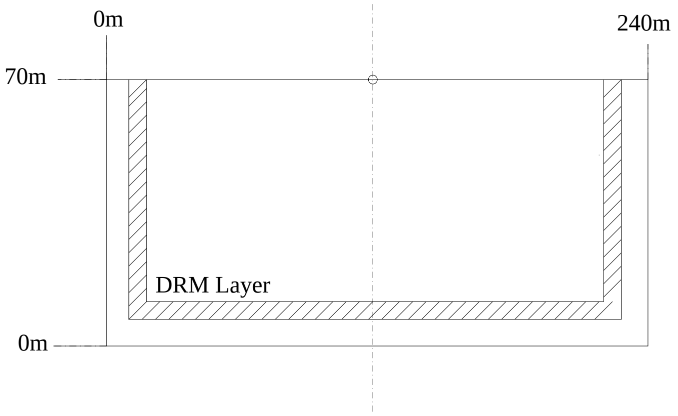

Figure 311.49: Domain to be analyzed for the 2^{nd} analysis stage of DRM with smaller size comparing to the original model

Displacement and acceleration time histories of corresponding nodes of DRM layer are obtained by interpolating between the the results obtained from the first model. These displacement and accelerations are used to calculate the effective forces as an input for DRM analysis. Input motions to be used here are Ricker wave, Morgan Hill, and Kocaeli earthquakes. The maximum allowable frequency to be propagated through this model can be calculated based on Equation (311.4):

$$\Delta h \leq \lambda/10 = V_s/(10 f_{max}) \tag{311.4}$$

Based on the shear wave velocity of $700m/s$ and element size of $50m$, maximum allowable frequency to be propagated through this model would be $1.4Hz$ for the original model and based on element size of $5m$ would be $14Hz$ for the DRM model.

311.6.1.1 Ricker Wavelets

Figure (311.50) show the displacement time history and FFT of Ricker wave of 2^{nd} order with dominant frequency of $1 Hz$ and maximum amplitude occurring at 1 second.

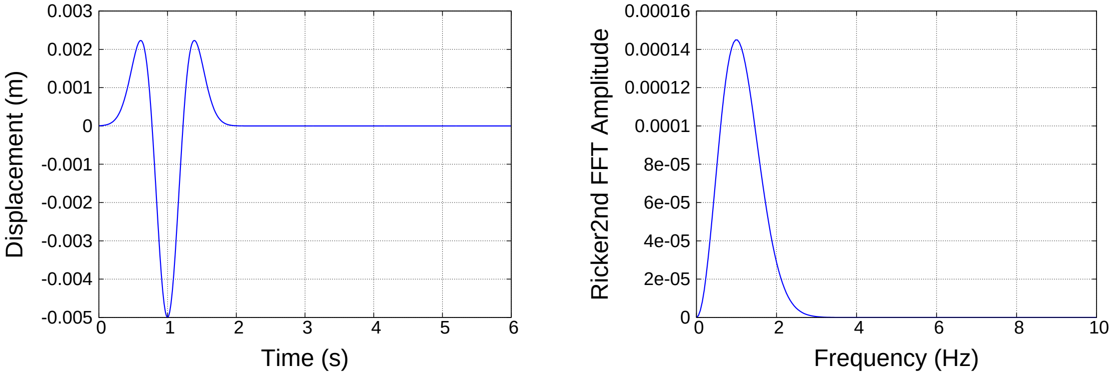

Figure 311.50: Displacement time history and FFT of Ricker wave with dominant frequency of $1 Hz$

The first case to be studied here is the one with the fault source located at $(x = 3000m, y = 0, z = 3000m)$ which has the angle of 45° with respect to the top middle point of the model. Results to be discussed here are comparison of displacement and acceleration time histories at the top middle point of the model $(x = 5000m, y = 0, z = 5000m)$ between the fault slip and DRM models. Comparison of displacement time histories in X and Z directions are shown in Figure (311.51). As it can be observed, the results of DRM model matches perfectly with the ones obtained from the fault slip model.

Figure (311.53) is the displacement and acceleration time history of a point located outside of DRM layer in X direction $(x = 10m, y = 0, z = 40m)$. As mentioned before in definition of DRM, no motion should come out of the DRM layer in case of free field. As shown in these figures, displacement and acceleration time histories at this point are zero which verifies this fact.

The same motion is applied to the model with fault source located at $(x = 2000m, y = 0, z = 3000m)$ which has the angle of 34° with respect to the top middle point of the model. Displacement time histories of the top middle point show the perfect match between results obtained from fault slip model with the ones obtained from DRM mode.

As shown in Figure (311.55), the second motion to be used for analysis is Ricker wave with frequency of $0.5 Hz$ and maximum amplitude occurring at 3 seconds. Figure (311.56) shows the displacement time histories of X and Z directions for the same point as before $(x = 5000m, y = 0, z = 5000m)$. As it is shown, results of the fault slip and DRM model are the same which verifies the solution from DRM formulation for this motion as well.

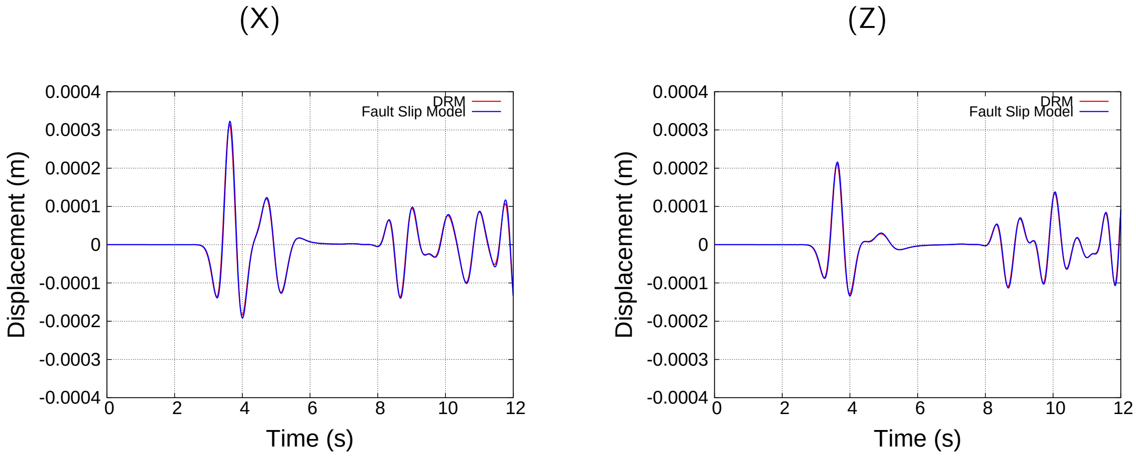

Figure 311.51: Comparison of displacements for top middle point using Ricker wave ($f = 1Hz$) as an input motion

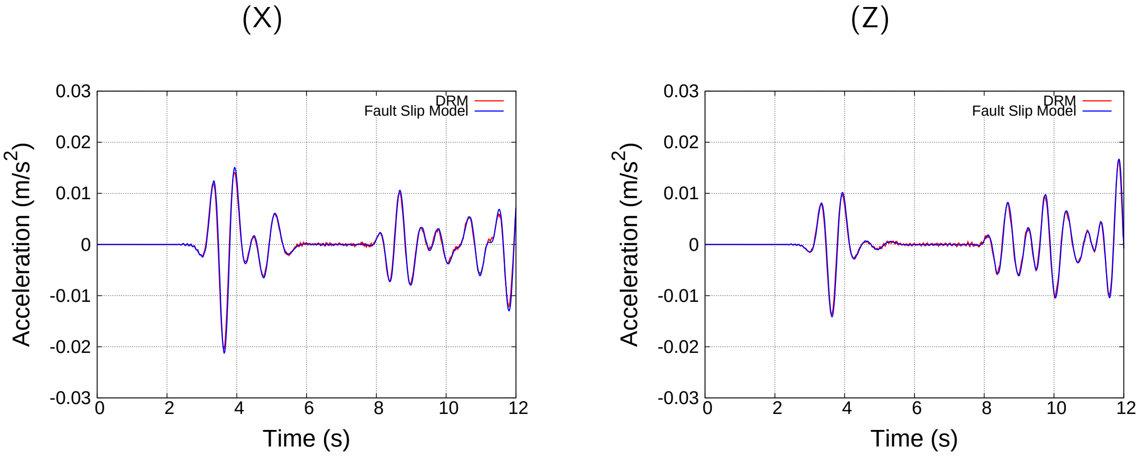

Figure 311.52: Comparison of accelerations for top middle point using Ricker wave ($f = 1Hz$) as an input motion

The third motion to be used is Ricker wave with frequency of $2Hz$ and maximum amplitude happening at 1 second as shown in Figure (311.57). Comparison of displacement time histories between the fault slip and DRM model has been done and shown in Figure (311.58) along X and Z directions respectively.

In this case, results do not match for the top middle point of the model. The main reason is due to the frequency of the motion. The maximum allowable frequency to be propagated in the fault slip model is $1.4Hz$ while it is $14Hz$ in DRM model. Dominant frequency of the Ricker wave as input motion is $2Hz$. Frequencies above the $1.4Hz$ can not be propagated in the fault slip model while they will propagate in

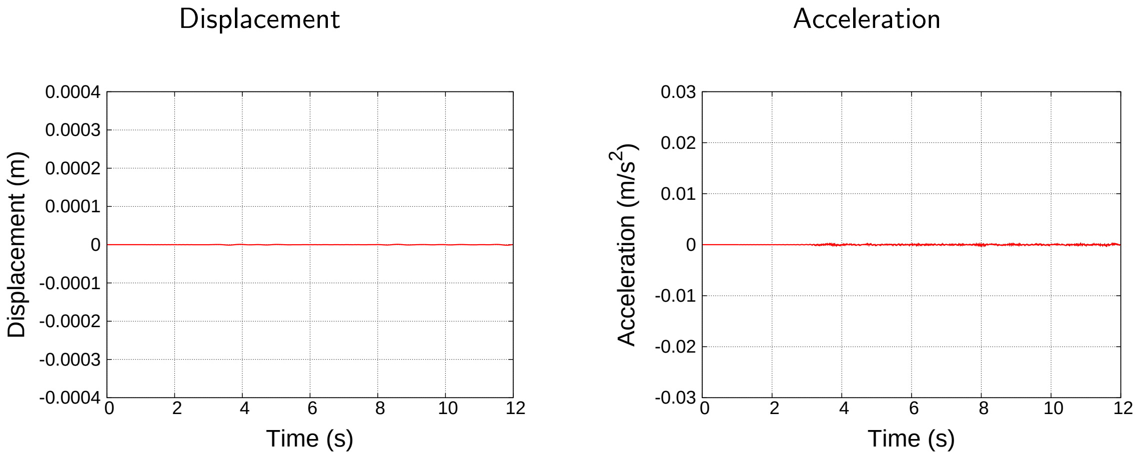

Figure 311.53: Displacement and acceleration time history for a point outside of DRM layer in (x) direction

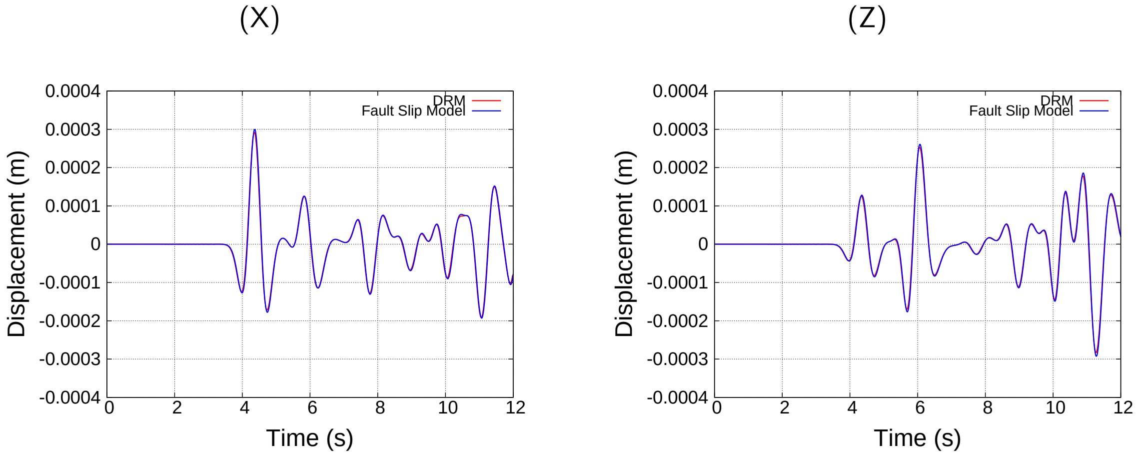

Figure 311.54: Comparison of displacements for top middle point using Ricker wave ($f = 1Hz$) as an input motion

the DRM model. this can change the characteristics of the motion propagating through the model and is the main reason of differences between the obtained results.

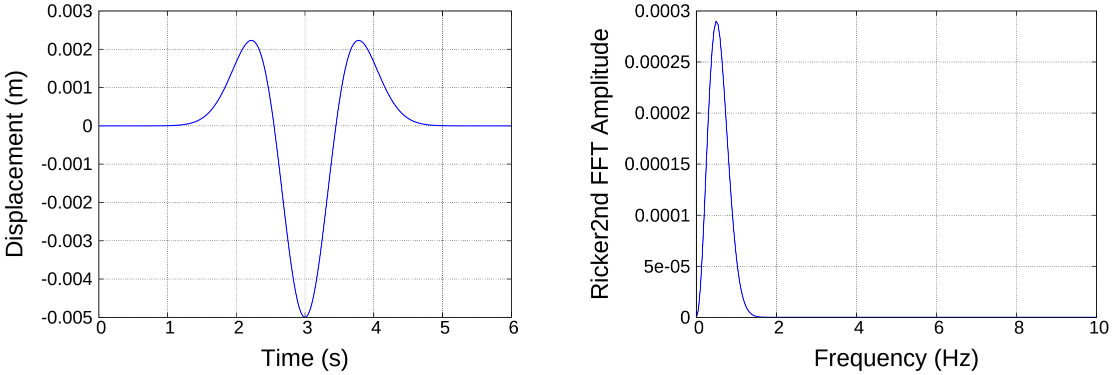

Figure 311.55: Displacement time history and FFT of Ricker wave with dominant frequency of $0.5Hz$

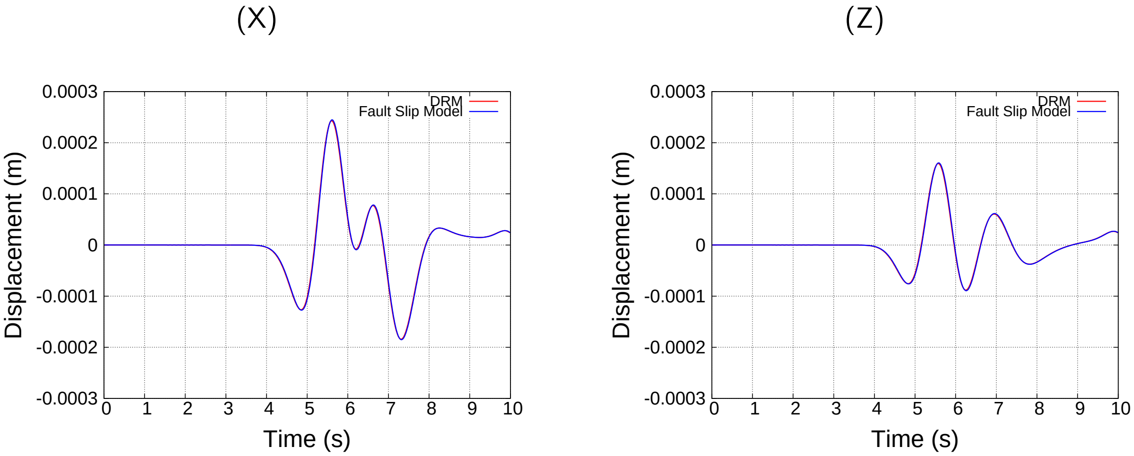

Figure 311.56: Comparison of displacements for top middle point using Ricker wave ($f = 0.5Hz$) as an input motion

311.6.2 Vertical (1C) Seismic Waves in a Free Field

311.6.2.1 Morgan Hill and Kocaeli Earthquakes

In order to investigate more, Morgan Hill and Kocaeli earthquakes are used as an input motions for the same models as before. These earthquakes were recorded during the ground shaking and obtained from PEER motion database. Figure (311.59) shows the acceleration time history and FFT of Morgan Hill earthquake with major frequency range of up to $4Hz$. Acceleration time history and FFT of Kocaeli earthquake are shown in Figure (311.60). Major part of the frequency range for Kocaeli earthquake is up to frequency of $4Hz$.

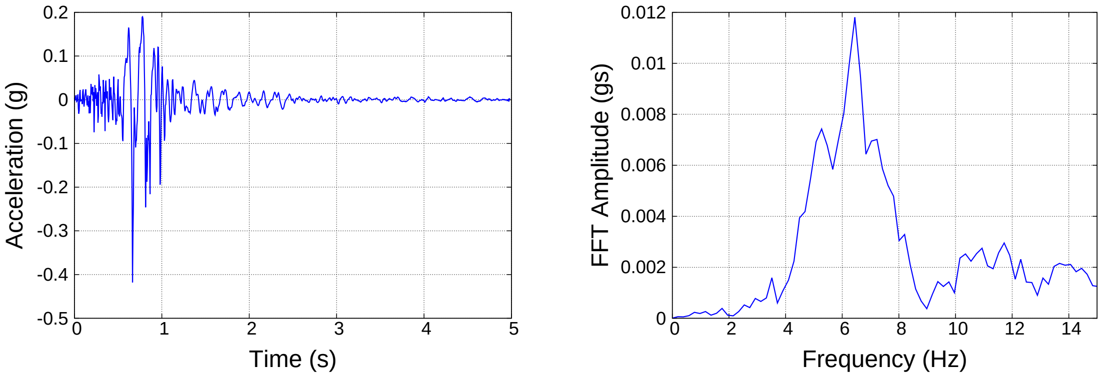

Figure 311.59: Acceleration time history and FFT of Morgan Hill earthquake

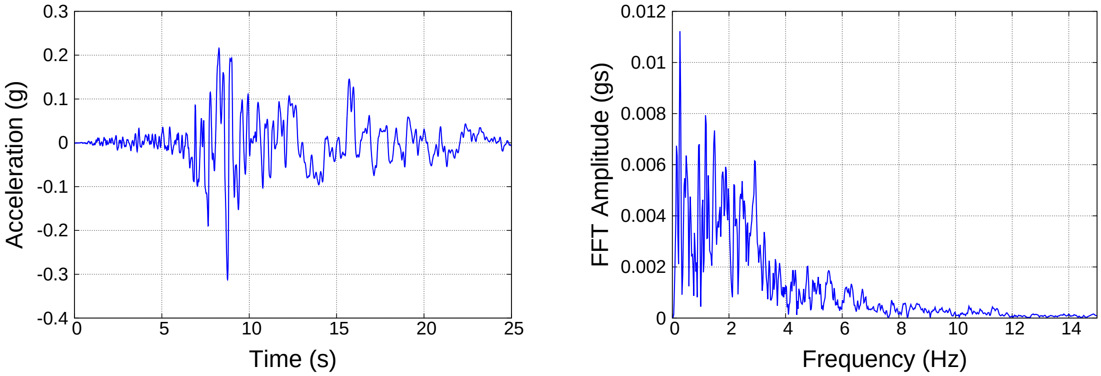

Figure 311.60: Acceleration time history and FFT of Kocaeli earthquake

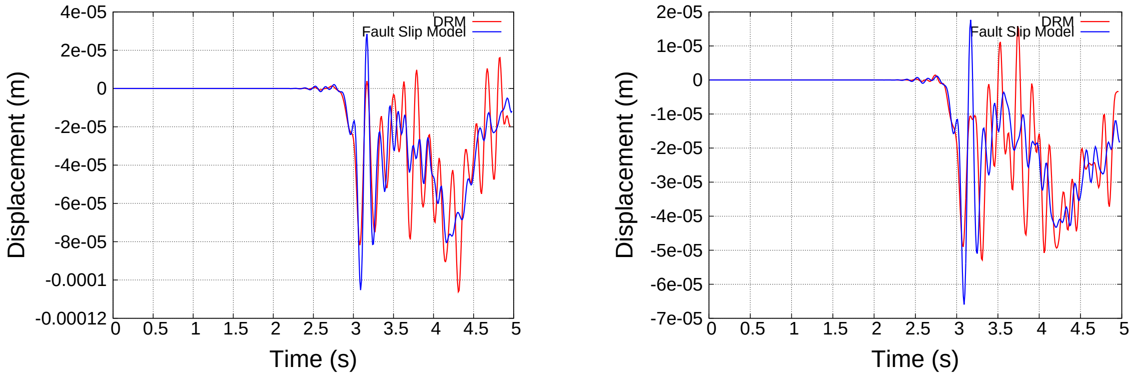
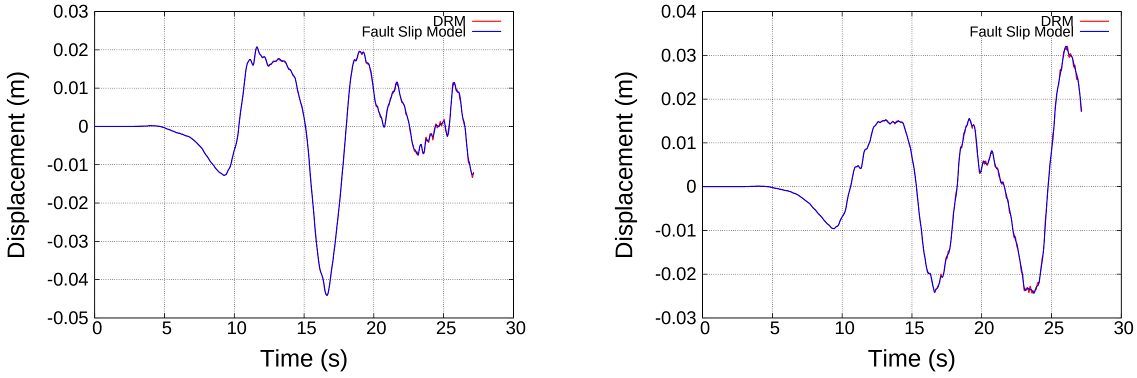
Figure (311.61) shows the displacement time histories of the top middle point of the model for

Morgan Hill earthquake while the ones from Kocaeli earthquake are shown in Figure (311.62). As it is observed, results of fault slip model and DRM model do not match since the majority of the energy in the earthquake is in the range of up to $4Hz$ which is higher than the maximum allowable frequency to be propagated in the original model $(1.4Hz)$.



(X) (Z)

Figure 311.61: Comparison of displacements for top middle point using Morgan Hill earthquake as an input motion



(X) (Z)

Figure 311.62: Comparison of displacements for top middle point using Kocaeli earthquake as an input motion

In order to investigate more regarding the frequency content issue, Kocaeli acceleration time history is considered and frequencies above $1.4Hz$ are filtered out of the record. Acceleration time history and

FFT of the filtered record are shown in Figure (311.63). The majority of the energy is in the frequency range of below $1.4Hz$ while still there are frequencies up to $2Hz$ in the motion as can be observed in FFT of the filtered motion.

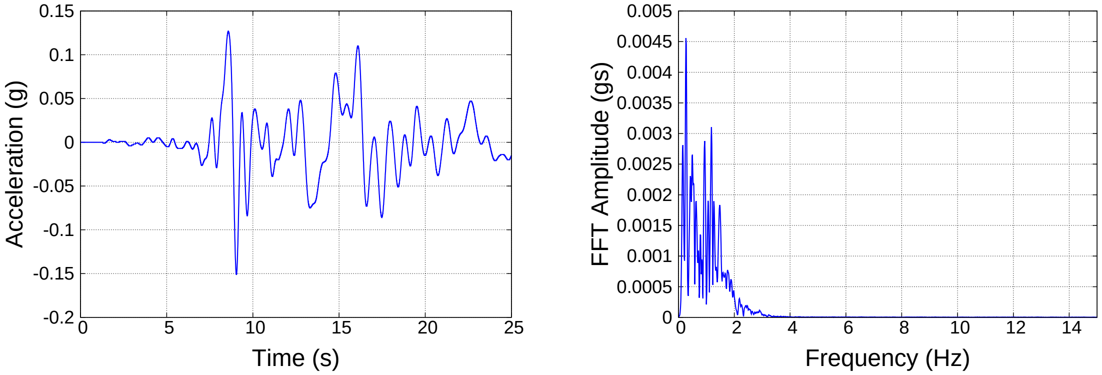


Figure 311.63: Acceleration time history and FFT of filtered Kocaeli earthquake

Figure (311.64) shows the displacement time histories for the same point as the one studied for the actual record. As it is observed, the obtained time histories match perfectly between the case of fault slip and DRM models. Figure (311.65) shows the acceleration time histories. Comparing the time histories shows an acceptable match between the results. There are tiny differences in acceleration time histories (specially at the peaks) which can be due to the fact that there are still frequencies above $1.4Hz$ in the input motion but with much less impact in terms of amplitude.

311.6.3 Earthquake-Soil-Structure Interaction Verification for Simulated Northridge Seismic Motions

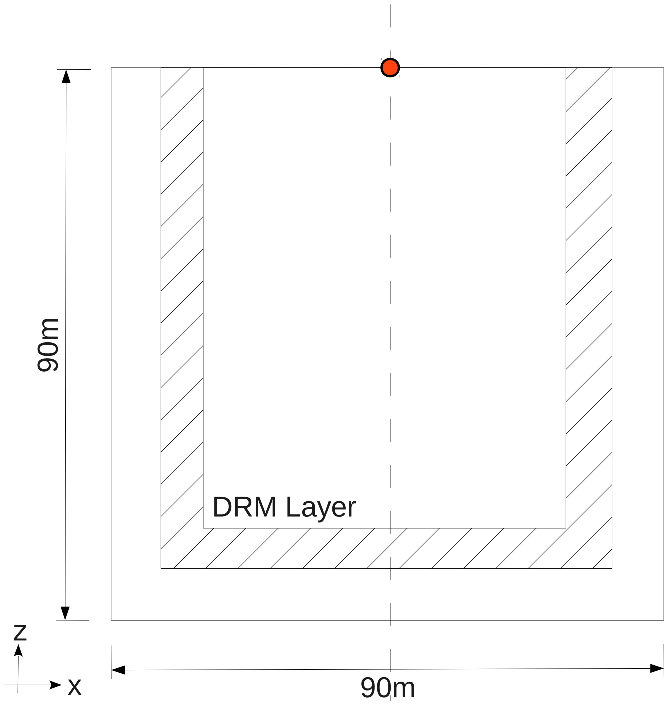

Figure 311.66: Finite element model to be used on analyses with input motions computed by integration equation (x-z plane view)

More realistic example is shown here. Seismic wave fields of Northridge earthquake simulated by program fk are applied as an input motion for this example. Figure 311.66 shows x-z plane view of three dimensional model. Similar as analytic case, using fk program, acceleration and displacement fields are generated at all nodes in DRM layer.

Figure 311.67 shows analysis results observed at the top-midpoint of the finite element model. As shown in figure 311.67, both results show perfect match.

311.6.4 Curious Case of 1C versus 3C modeling

To inspect more, artificial downhole array is prepared as shown in fingure 311.68. Total 2 observation points are set on 0 m, and 50 m depth from the ground surface. one dimensional site response analyses are performed along artificial downhole array usind DEEPSOIL v5.0 (Hashash and Park, 2002). 1D soil column model is built to run DEEPSOIL with identical soil properties to finite element model. Linear time domain site response analyses are performed. Displacements recorded at 200 m depth are used as an input motion. Site response analyses results on the observation points are compared with fk, and

Figure 311.67: Comparison between results computed from program fk and finite element analysis, observed at the top middle point of the finite element model

finite element analyses results.

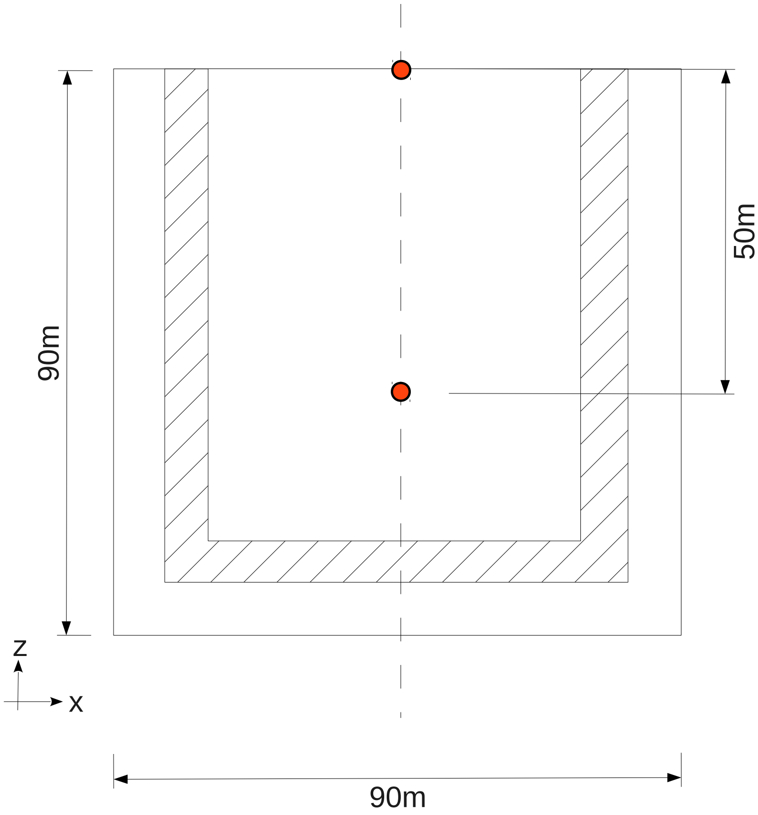

Figure 311.68: Comparison between analytic solution and FEM analysis result observed at top, middle point of the model (SV (imposed on x direction) Ricker wave input with 0°, x component)

Figure 311.69 – 311.74 are analyses results. Figure 311.69, 311.70, and 311.71 show comparison of results observed at the ground surface, EW, NS, and UD components, respectively. For the case of EW and NS components, 1C site response analyses results predict similar response as fk and FEM results compared to UD case. For all cases, 1C analyses results shows larger amplitude especially on UD case, 1Hz frequency contents show unrealistic response amplification. The same trend can be observed at 50 m depth cases (figure 311.72 – 311.74).

Possible explanation are as follows. fk results includes all components of waves (body and surface) and interaction between them. However, 1C wave propagation analyses cannot incorporate such effect. Also, 1C analyses is very sensitive to material properties (stiffness, damping ratio, and so on) and frequency contents of input waves.

311.7 Case History: Simple Structure on Nonlinear Soil

311.7.1 Simplified Models for Verification

Due to the complexity of full scale finite element models it is helpful to perform preliminary tests on simplified models in order to verify the adequacy of the time and mesh discretization with respect to the input motion. It also provides good insight in the performance of the nonlinear material model. To achieve this a series of tests on a one-dimensional soil column have been proposed:

- Static pushover test on nonlinear soil column

  Through the static pushover test the behavior of the nonlinear material model can be verified.

- Dynamic test of elastic soil column

  By applying an earthquake motion to the elastic soil column it can be tested whether the selected grid spacing is capable of representing the motion correctly without filtering out any relevant frequencies. This test also allows to choose appropriate damping parameters. It should be noted that this is additional (small) damping that is used for stability of the numerical scheme and should not be relied upon to provide major energy dissipation. Major energy dissipation should be coming from inelastic deformations of the SFS system.

- Dynamic test of nonlinear soil column

  Finally the stability and the accuracy of the numerical method can be examined by applying the earthquake motion to the nonlinear column of soil. A second analysis with a time step reduced by 50% should not give a significantly different result.

  Furthermore it will be examined how propagation through an elastic-plastic material will change the frequency content of the motion.

311.7.1.1 Model Description

The one-dimensional soil column used for verification has the same depth and element sizes as the 2d and 3d models that will be addressed later. Its total depth is 10.5 meters and it consists of a single stack of 8-node brick elements of 1.5 meters side length. In order to achieve one-dimensional wave propagation in vertical direction the movement of four nodes at each level of depth is constrained to be equal. The input motion is applied to the four nodes at the base of the model. As input motions four time histories from the Northridge Earthquake are selected (Figure 311.75).

The material properties of the soil are given in Table 311.7.1.1.

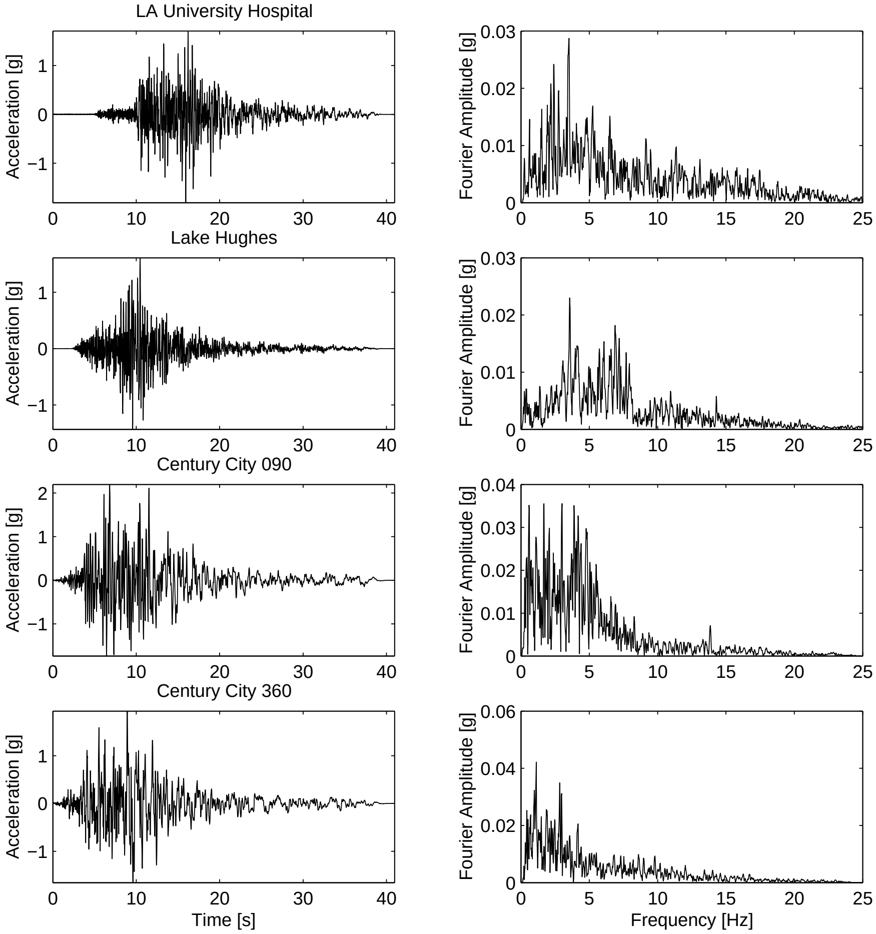

Figure 311.75: Acceleration time histories and Fourier amplitude spectra's of the selected ground motions

Friction angle ϕ'	37°
Undrained shear strength c_u	10 kPa
Mass density ρ	1800 kg/m^3
Shear wave velocity v_s	200 m/s

The discretization parameters, the time step Δt and the maximum grid spacing Δh, are determined following the guidelines outlined in Section 502.3.3. This yields a maximum grid spacing of

$$\Delta h \leq \frac{v_s}{10 f_{max}} = \frac{200}{10\,10} = 2\,\mathrm{m} \tag{311.5}$$

For the following analysis $\Delta h = 1.5$ m is selected. The maximum time step is

$$\Delta t \leq \frac{\Delta h}{v_s} = \frac{1.5}{200} = 0.0075\,\mathrm{s} \tag{311.6}$$

Taking into account a further reduction of the time step by about 60% due to the use of nonlinear material models $\Delta t = 0.002$ s is chosen.

311.7.1.2 Static Pushover Test on Elastic-Plastic Soil Column

For the static pushover test, an elastic perfectly plastic Drucker-Prager material model as specified in Table 311.7.1.1 is used.

After applying self weight a horizontal load of 100 kN is applied to a surface node in increments of 0.1 kN. The system of equations is solved using a full Newton-Raphson algorithm. The predicted shear strength of the first element that is expected to fail, the one at the surface, is:

$$\begin{aligned}\tau_f &= c_u + z\,\rho\,g\,\tan\phi' \\ &= 10 + 0.75\,x\,1.8\,x\,9.81\,\tan 37^\circ \\ &= 19.98\,\mathrm{kPa}\end{aligned} \tag{311.7}$$

where z is the depth of the center of the first element.

Self weight produces the following stresses in the element at the surface:

$$\begin{aligned}\sigma_x = \sigma_y &= 8.83\,\mathrm{kPa} \\ \sigma_z &= 13.24\,\mathrm{kPa}\end{aligned}$$

The maximum shear stress is

$$\tau_{max} = \sqrt{\left(\frac{\sigma_z - \sigma_x}{2}\right)^2 + \tau_{xz}^2} \tag{311.8}$$

The theoretical failure load can be obtained as follows:

$$\begin{aligned}P_f &= \tau_{xz}A \\ &= \sqrt{\tau_f^2 - \left(\frac{\sigma_z - \sigma_x}{2}\right)^2}A \\ &= 44.7\,kN\end{aligned} \tag{311.9}$$

The static failure load is underestimated by about 6%. This accuracy is acceptable for the given model because the boundary conditions cannot assure constant stresses at a given depth (no shear stress is applied to the lateral surfaces).

311.7.1.3 Dynamic Test on Elastic Soil Column

In order to test the spatial discretization of the model an earthquake motion is propagated through an elastic soil column. The grid spacing of the finite element mesh can be considered sufficiently fine if frequencies up to f_{max} = 10 Hz are represented accurately in the numerical analysis. A good way to verify this is to calculate transfer functions between the base and the surface of the soil column.

Because transfer functions don't depend on the input motion they can easily be compared with closed form solutions.

The transfer function of a soil deposit describes the amplification between the frequencies of the motion at the base and at the soil surface:

$$TF(\omega) = \frac{u(z = 0, \omega)}{u(z = H, \omega)} \tag{311.10}$$

where z is the depth measured from the surface and H is the thickness of the soil deposit above the bedrock. $\omega = 2\pi f$ is the circular frequency.

For elastic soil with viscous damping the wave equation can be written as (Kramer, 1996a)

$$\rho \frac{\partial^2 u}{\partial t^2} = G \frac{\partial^2 u}{\partial z^2} + \eta \frac{\partial^3 u}{\partial z^2 \partial t} \tag{311.11}$$

η is the damping coefficient, defined as

$$\eta = \frac{2G}{\omega} \xi \tag{311.12}$$

where ξ is the frequency independent hysteretic material damping.

After solving the wave equation the transfer function can be written as

$$TF(\omega) = \frac{1}{\cos \omega H / v_s^*} \tag{311.13}$$

where v_s^* is the complex shear wave velocity

$$v_s^* = \sqrt{\frac{G^*}{\rho}} = \sqrt{\frac{G(1 + i2\xi)}{\rho}} \tag{311.14}$$

In a finite element model with mass- and stiffness proportional Rayleigh damping the damping coefficient η is constant. Therefore the hysteretic material damping ratio ξ needs to be frequency dependent in order to satisfy Equation 311.12. Solving Equation 311.12 for ξ and substituting it into Equation 311.14 and then into Equation 311.13 yields a new transfer function:

$$TF(\omega) = \frac{1}{\cos\left(\omega H \sqrt{\frac{\rho}{G + i\omega\eta}}\right)} \tag{311.15}$$

Figure 311.76 shows a comparison between the closed form solution and the numerical transfer functions obtained from the finite element analysis. Rayleigh damping is used to obtain the damping matrix $\mathbf{C}$:

$$\mathbf{C} = \alpha \mathbf{M} + \beta \mathbf{K} \tag{311.16}$$

The analysis are performed using stiffness proportional Rayleigh damping of $\beta = 0.001$ and $\beta = 0.01$. No mass proportional damping is applied ($\alpha = 0$). The damping coefficients of the closed form solution are chosen to be $\eta = \beta G$.

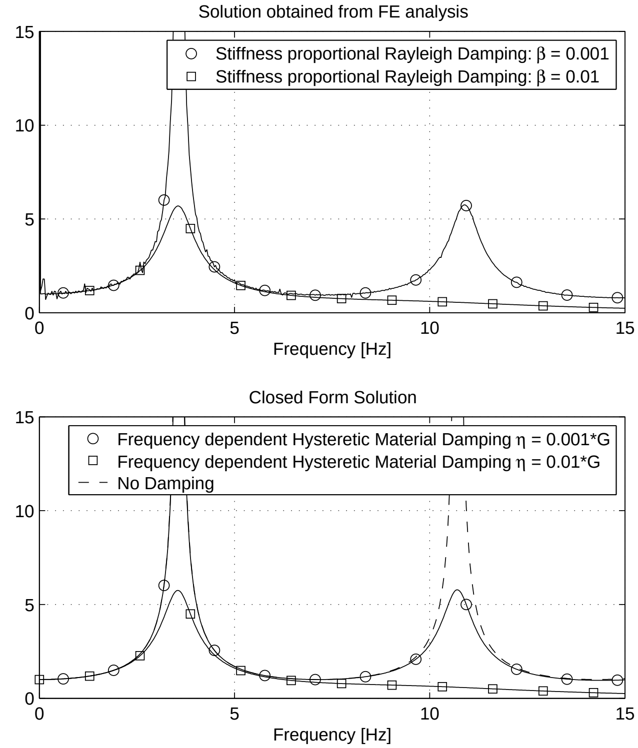

Figure 311.76: Transfer Function between Surface and Base of Soil Layer

It can be seen that the numerical transfer functions are very close to the closed form solutions for $\eta = \beta G$. The peak corresponding to the second natural frequency of the soil layer is slightly shifted to the right in the result of the FE analysis. For the FE analysis the Rayleigh damping cannot be reduced any further as the solution would become unstable. This result proves that a FE analysis involving Rayleigh damping with $\alpha = 0$ and $\beta = \eta / G$ is equivalent to the closed form solution of the wave equation with frequency-dependent hysteretic material damping.

Based on the above observations a stiffness proportional Rayleigh damping of $\beta = 0.01$ is selected for the finite element analysis. This choice damps frequencies above 10 Hz appropriately.

311.7.1.4 Dynamic Test on Elastic-Plastic Soil Column

As the next step an elastic-plastic material model of Drucker-Prager type with kinematic strain hardening has been selected. Previous analysis involving material with isotropic hardening have proved to be unsuitable because energy can only be dissipated as the yield surface expands. For dynamic problems this can lead to an unreasonably large extension of the yield surface, especially if resonance frequencies are present. Therefore only kinematic hardening has been selected in this analysis.

The analysis were performed with four different ground motions using time steps of $\Delta t = 0.002 s$ and

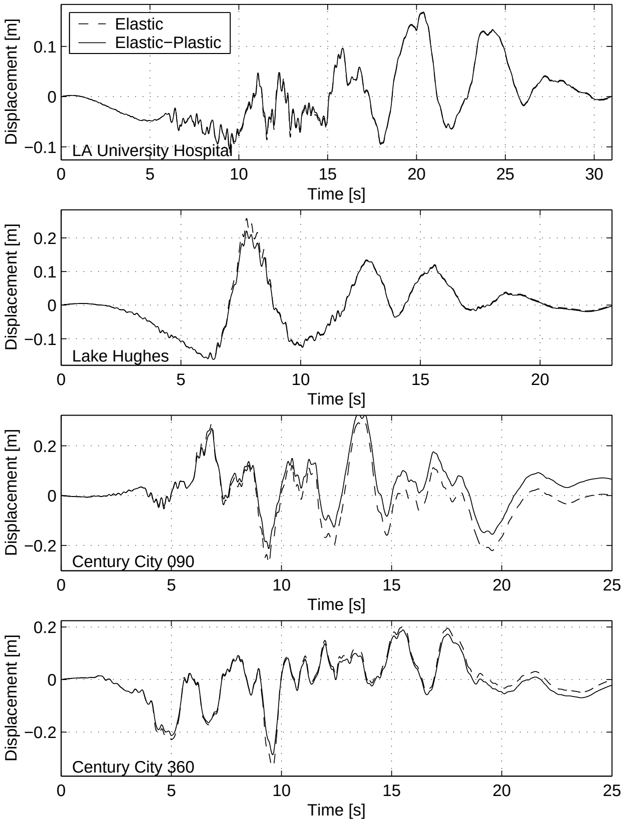

Figure 311.77: Displacement Time-Histories at surface of 1d Soil Column, elastic and elastic-plastic material

$\Delta t = 0.001s$. A linear integrator without iterations within a time step was used. All ground motions were scaled to a maximum acceleration of $1g$. For comparison the analysis were also performed on elastic material. Figure 311.77 shows the displacement time histories at the surface for all four ground motions. While the overall shapes of the displacements are the same as for the elastic case there is some residual plastic displacement resulting in the time histories of the Century City motions.

The Fourier amplitude spectra's of the acceleration recorded at the surface (Figure 311.78) have the same general shape for the case of elastic and elastic-plastic material. The amplification at the first resonance frequency ($f = 4.75Hz$) is bigger in the elastic analysis. Higher frequencies resulting from plastic slip are damped out effectively in the nonlinear analysis.

Figure 311.79 shows the acceleration time history at the upper node of the lowest element, that is the first free node above the base. The record shows large peaks of the order of about 6 g. These peaks are caused by plastic slip and counter balancing of the resulting plastic deformation. The periods of the peaks are of the order of a few time steps, they add a very high frequency component to the

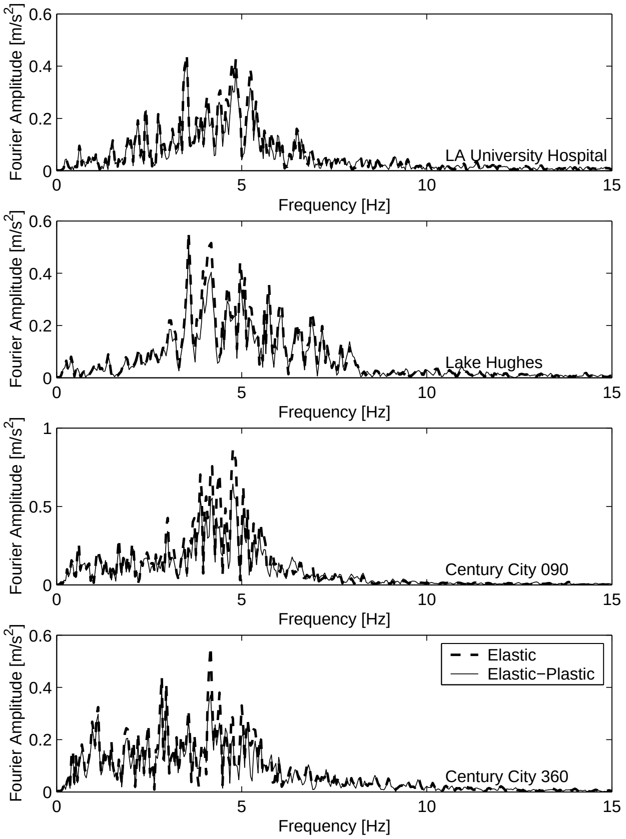

Figure 311.78: Fourier Amplitudes at surface of 1d Soil Column

acceleration. Because these frequencies are due to a purely numerical phenomenon, they should not be allowed to propagate through the model. This can be achieved easily by specifying an appropriate numerical procedure (Newmark with appropriate combination of γ and β) or with Rayleigh Damping.

As for the elastic model transfer functions were also computed for the nonlinear model. In Figure 311.80 the transfer functions between the acceleration at the soil surface and the base are compared. The functions for the nonlinear model are not smooth anymore but the general shape is the same as for the linear elastic model, i.e. the first natural frequency of the layer is clearly visible. The peaks that are present in the range of 25 Hz are purely numerical as they appear due to the division by a very small value.

A second set of analysis performed with half the time step of the previous analysis gives an idea of the accuracy of the numerical method. In Figure 311.81 the difference between the displacement (or acceleration) of the analysis with $\Delta t = 0.002s$ and $\Delta t = 0.001s$, divided by the corresponding maximum

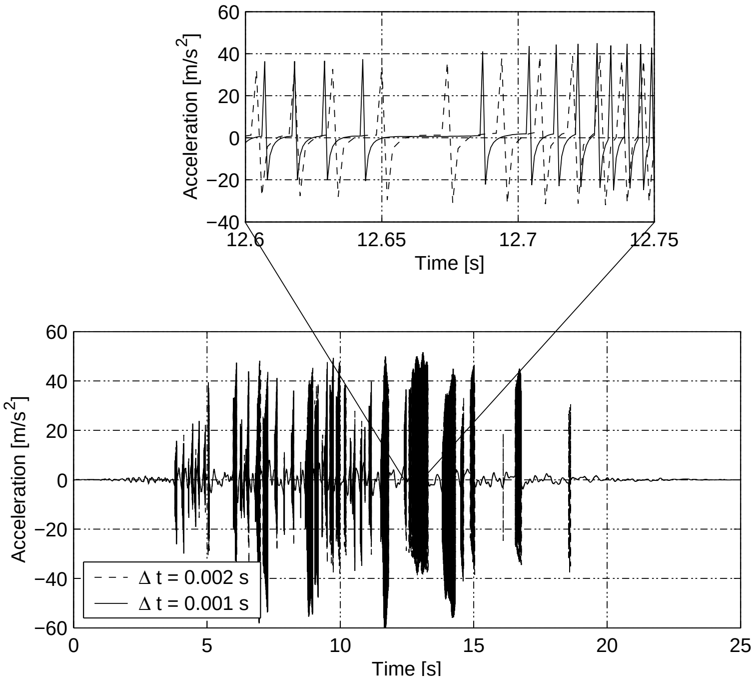

Figure 311.79: Acceleration time history at lowest free node

value is given for the entire time history:

$$\Delta d = \frac{d_{0.002}(t) - d_{0.001}(t)}{\max d_{0.001}} \quad and \quad \Delta a = \frac{a_{0.002}(t) - a_{0.001}(t)}{\max a_{0.001}} \tag{311.17}$$

In Figure 311.82 an integral measure for the difference in displacements and accelerations between the two analysis is given for all depths. The integral measures are defined as

$$diff_d = \frac{1}{\max |d|} \frac{1}{T} \sum_0^T |d_{0.002}(t) - d_{0.001}(t)| \; dt \tag{311.18}$$

$$diff_a = \frac{1}{\max |a|} \frac{1}{T} \sum_0^T |a_{0.002}(t) - a_{0.001}(t)| \; dt \tag{311.19}$$

$$\tag{311.20}$$

The integral differences in accelerations are quite large in the elements that are close to the base, that is where the motion is applied. Toward the surface the difference becomes smaller than 1%. This is a result of the fact that most of the plastic deformation occurs near the base which represents an undesired boundary effect. Again this result underlines the importance of an appropriate choice of the size of the computational domain.

With a point wise difference not exceeding 5% for accelerations and 2% for displacements the time step $\Delta t = 0.002s$ is sufficiently small to ensure stable and accurate results.

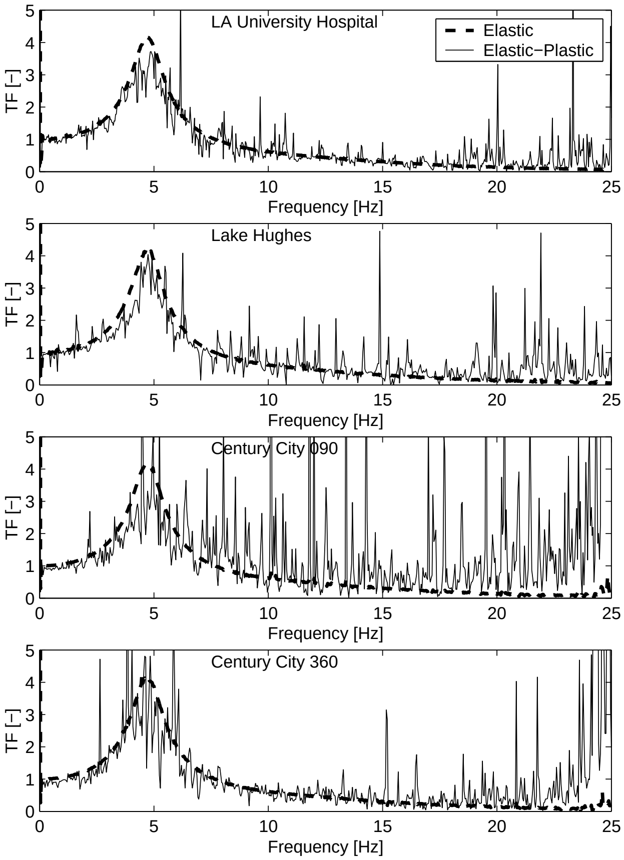

Figure 311.80: Transfer functions between acceleration at the soil surface and the base

311.7.1.5 2d Model

A 2d-model is proposed as a simplification of the full 3d-model. Representing a cross section of the full model it is expected to provide insight into its dynamic behavior while requiring considerably less computational resources. The 2d-model consists of one slice of eight-node brick elements as shown in Figure 311.83. The nodes of the two lateral faces are constrained to move together in x- and z-direction, the out-of-plane displacement in y-direction is fixed. The model approximates a plane strain situation.

The earthquake motion is applied to the model by the DRM method.

311.7.1.6 Input Motions

As input for the 2d model the motion from the Northridge earthquake recorded at LA University Hotel (Figure 311.75) is used. The acceleration time history is scaled to a peak ground acceleration of 1 g. Motion is applied in x-direction only, that is, this is a 1–D wave propagation.

Acceleration time histories at all the nodes of the boundary layer are obtained by vertically propagating

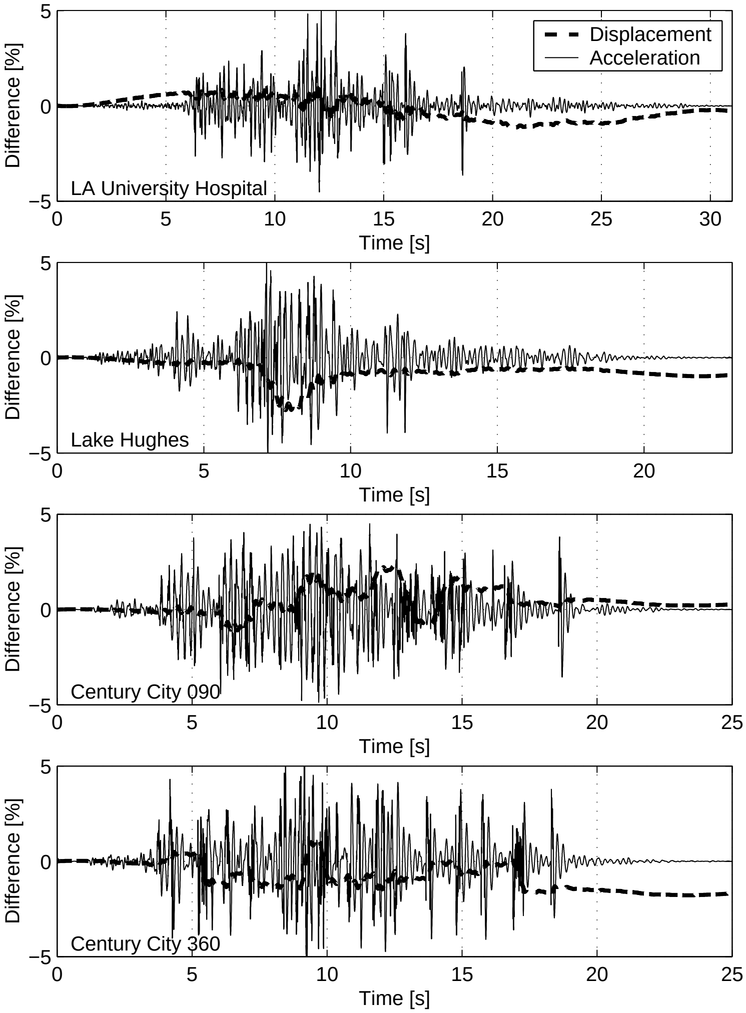

Figure 311.81: Difference between results of analysis with different time steps, in percent of the maximum value

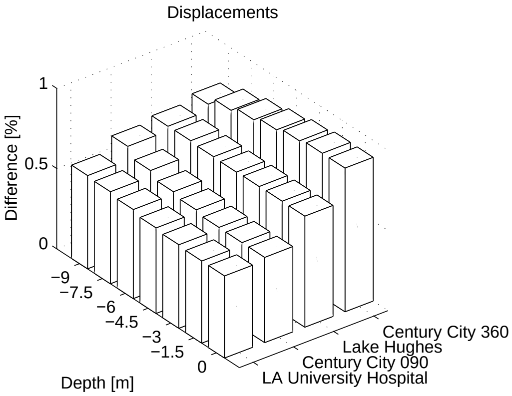
a plane wave using the program SHAKE91 (Idriss and Sun, 1992). Because the free-field model has to match the properties of the free field as represented by the finite element model for the reduced domain, only linear elastic material without strain dependent reduction of shear modulus and a constant amount of hysteretic material damping is used in the SHAKE91-analysis. The earthquake motion obtained in this way corresponds to a shear wave propagating upward through a homogeneous linearly elastic half space.

The acceleration time histories from the SHAKE91-analysis are then integrated twice to obtain displacements. Before integration the acceleration and velocity time histories are transformed into Fourier space, multiplied with a high pass filter and transformed back into time domain. Then a simple parabolic baseline correction is performed in order to obtain zero initial, final and mean values.



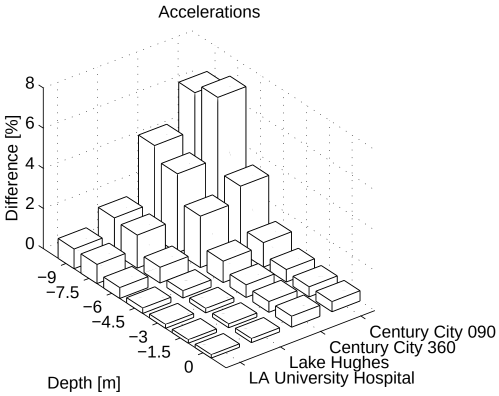


Figure 311.82: Averaged differences between results of analysis with different time steps

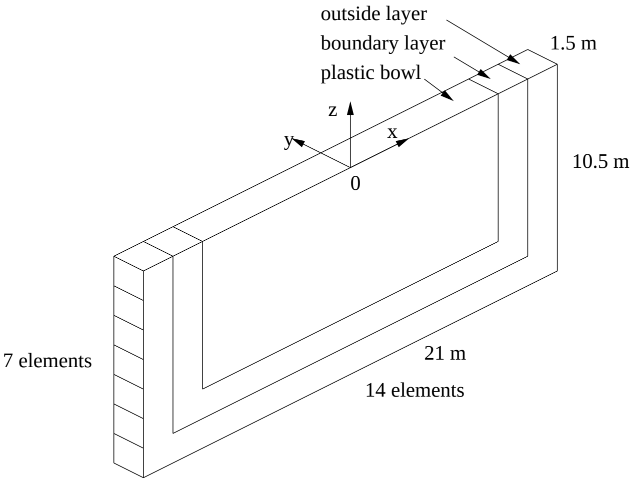

Figure 311.83: Two-dimensional quasi-plane-strain model

311.7.1.7 Boundary Conditions

Different boundary conditions are tested on the free-field model. First all outside boundary nodes are fully fixed as shown in Figure 311.84 a). Then they are released and attached to dash pots that are both perpendicular and tangential to the boundary (schematically shown in Figure 311.84 b)). The dash pots perpendicular to the boundary are specified to absorb p-waves, those tangential to the boundary to absorb s-waves. Because in this configuration no displacement constraint is imposed to the model on the faces at $x = \pm 10.5$ meter the horizontal at-rest soil pressure has to be applied to the corresponding nodes manually. This is done by recording the reaction forces in the model with fixed boundaries and applying them with opposite sign to the model with absorbing boundaries. The horizontal displacements after applying self weight should be very small.

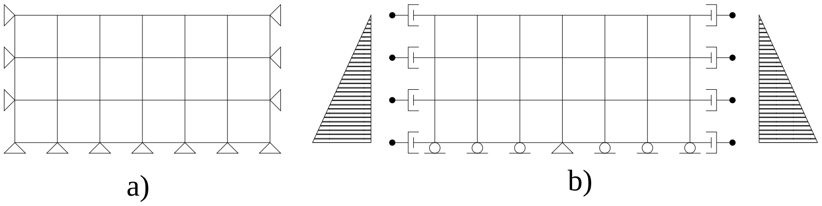

Figure 311.84: The boundary conditions of the 2d model

This configuration of boundary conditions has no fixed point in x-direction. Because the dash pots only provide resistance to high velocity motions the model is very sensitive to low frequency components of the motion. The slightest imbalance in acceleration causes the entire model to move as a rigid body in x-direction. To avoid this to happen the node at the center of the base (x = 0.0 m, z = -10.5 m) is fully fixed in the following analysis.

Figure 311.85 shows results from a free-field analysis on a homogeneous elastic model. Displacements on an exterior boundary node as well as transfer functions between a point at the surface and a point on the exterior boundary of the plastic bowl are presented for the two configurations of boundary conditions shown in Figure 311.84. It can be seen that the displacements outside the plastic bowl in the model using absorbing boundary conditions are much larger compared to the model with fixed boundaries. This result is as expected considering the immediate proximity of the boundary. It also gives an idea about the constraints the fixed boundary imposes on the motions. The transfer function in Figure 311.85 b) is defined as the ratio between the Fourier amplitude spectra of a point at the surface and a point on the exterior boundary:

$$TF(\omega) = \frac{A_1(\omega)}{A_2(\omega)} \tag{311.21}$$

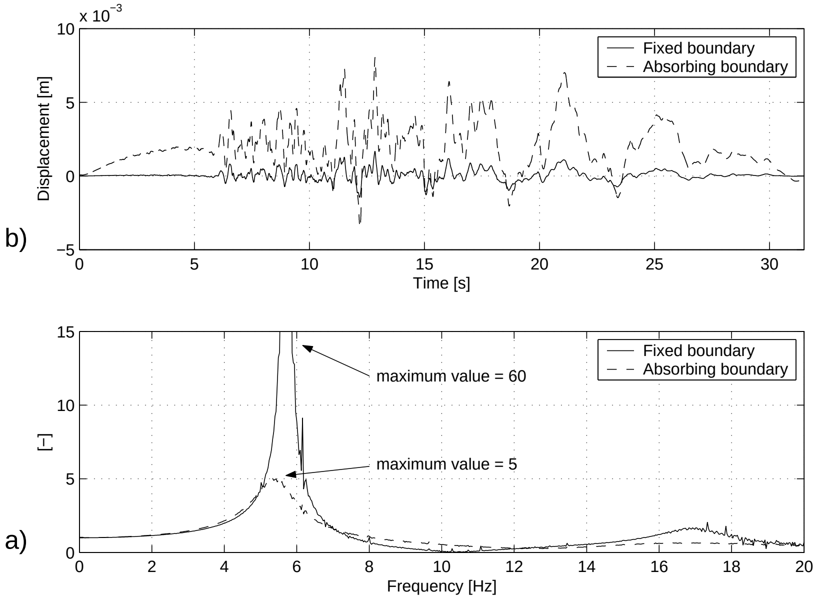

Figure 311.85: Elastic homogeneous free-field model: a) Displacements of an exterior boundary node (x,z) = (9.0,0.0) m, b) Acceleration transfer function between surface and depth $\frac{A(\omega)_1}{A(\omega)_2}$

where $A_1(\omega)$ is the Fourier amplitude spectrum of the acceleration time history at the point (x,z) = (0,0)m and $A_2(\omega)$ the corresponding spectrum at the point (x,z) = (9.0,-7.5)m. The figure shows that the large peak representing the first natural frequency of the system, corresponding to a standing shear wave in a soil layer of 10.5 meter depth, gets reduced considerably by the absorbing boundary. An energy build-up in the model due to reflection of waves on the model boundaries can be reduced effectively with the configuration of boundary conditions shown in Figure 311.84 b). By releasing the fixed node at (x,z) = (0,-10.5)m the resonance peak could be reduced by another 10% approximately, however at the cost of remaining permanent displacements at the end of the analysis.

Alternatively to imposing a rigid constraint to a single node at the base the model can be prevented to move horizontally as a rigid body through uniaxial springs. This gives the possibility to adjust the frequency of the eigenmode that corresponds to a vertically propagating plane shear wave. By appropriately choosing the spring constants the model can therefore be adjusted in such a way that it represents the natural frequency of a soil deposit on bedrock.

311.7.1.8 Structure

Four very simple structures are chosen to illustrate the effects of dynamic SFSI. A beam-column element of length L and moment of inertia I_y is fixed to a footing. A lumped mass of $M = 100,000$ kg is added to

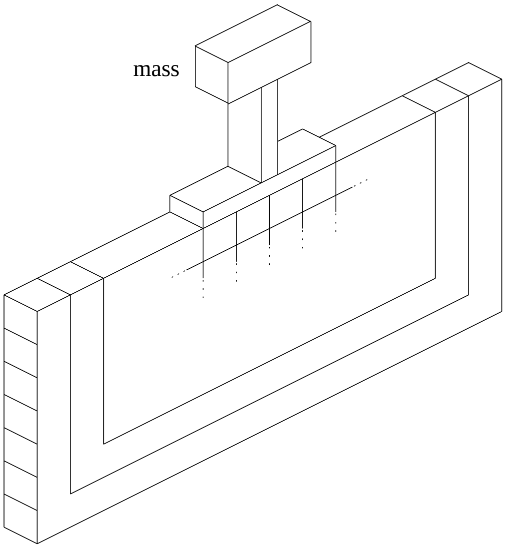

Figure 311.86: The 2d SFSI-model

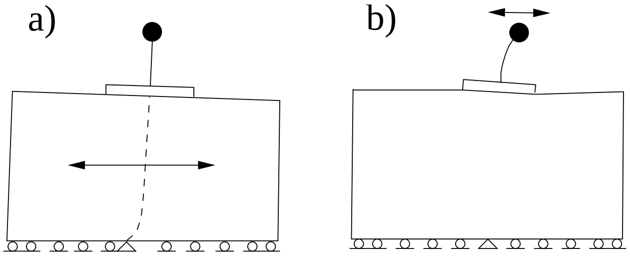

Figure 311.87: a) First eigenmode, b) second eigenmode of SFSI-system

the translational degrees of freedom of the top of the structure. The footing is 0.5 m deep, spans over four soil elements and is rigidly connected to the adjacent soil nodes. Its Young's modulus is chosen large enough so that the footing can be considered rigid. The mass density of the footing is $\rho = 2400\,\text{kg/m}^3$, the column is considered massless. The moment connection between the nodes of the footing, having 3 (translational) degrees of freedom, and the 6 degrees of freedom of the nodes of the column is assured by a very stiff beam element that is connected to a node at the bottom and a node at the top of the footing. The column is then simply connected to the upper node of this auxiliary beam element.

The parameters of the four columns are chosen such that the second natural frequency, that is the natural frequency attributed to bending of the column (Figure 311.87 b)), is evenly distributed over the frequency range of the input motion (Figure 311.88). Structure 4 is designed such that it's second natural frequency matches the largest spike in the input motion. Table 311.2 lists the properties of the structures used in the analysis. For the nonlinear columns a strain hardening material is chosen

Structure	Length [m]	Stiffness $E\,I_y$ $[MN\,m^2]$	Mass [kg]	Yield Moment [kNm]
1	5.5	1680	100,000	800
2	3.5	5670	100,000	1,800
3	2.5	13440	100,000	320
4	5.0	5670	100,000	1,800

Table 311.2: Properties of the analyzed structures

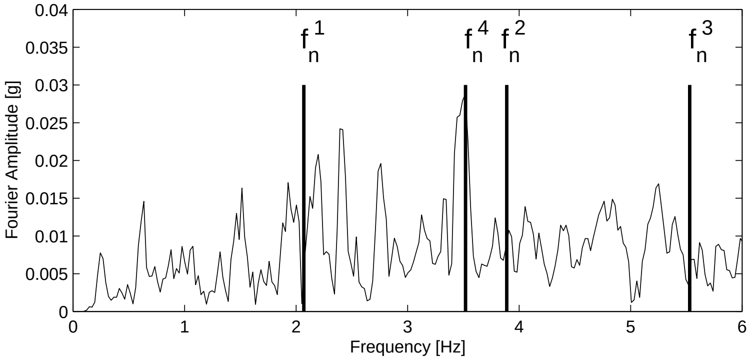

Figure 311.88: Fourier amplitude spectrum of input motion with second natural frequencies of the 4 SFSI-systems

that consists of an initial elastic branch with tangent modulus E and a post-yield branch with tangent modulus $0.2\,E$. The Young's modulus for all four structures is $E = 210$ GPa. The yield stress f_y for structures 1, 2 and 4 is 20 MPa and for structure 3 it is 2 MPa.

311.7.1.9 Structure with Fixed Base

To begin with a parametric study of a series of structures with varying stiffnesses is analyzed. The stiffness is varied by changing the width of the column section. The different structures are expected to respond specifically to the frequency range of the input motion that is in the neighborhood of the natural frequency of the column. The input motion that is applied at the base of the structure has been recorded in a previous free-field analysis of the 2d-model.

The results of this parametric study are shown in Figures 311.89 and 311.90 for linear and nonlinear structures, respectively. The Fourier amplitudes spectra's of the acceleration at the top of the structure are plotted for 15 structures with variable natural frequency f_n. A line of equal frequency is also provided. The input motion is plotted in the background of the figure. It can be seen that the maxima of the

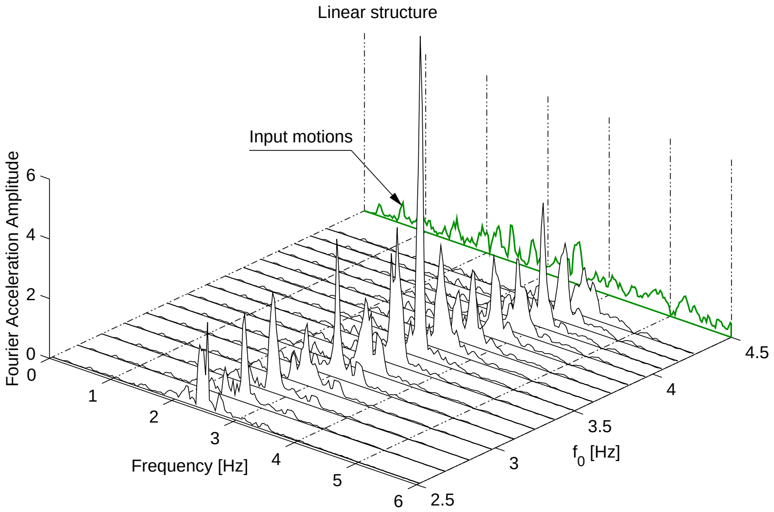

Figure 311.89: Parametric study of 15 *linear* structures with varying natural frequency.

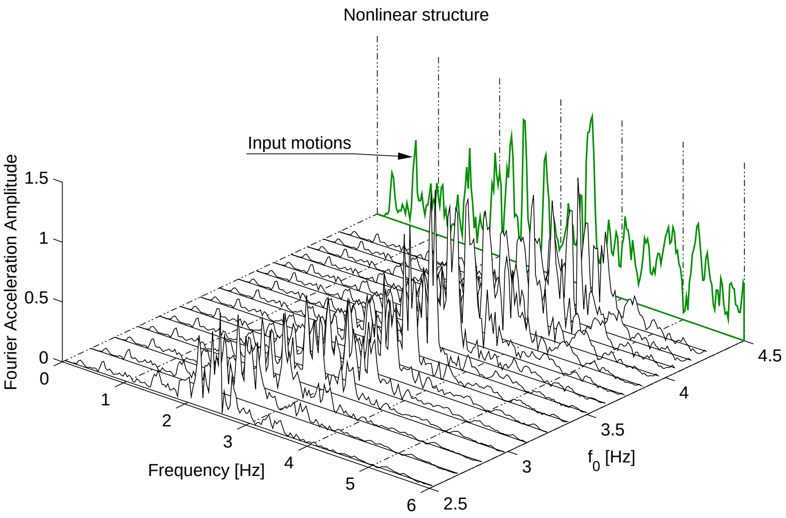

Figure 311.90: Parametric study of 15 *nonlinear* structures with varying natural frequency

frequency spectra's are almost perfectly aligned along the line of equal frequency. This is even more obvious in the case of a linear structure. In that case the responses of the structures are very narrow banded. As the structure remains elastic the top of the structure oscillates mainly in its initial natural frequency. Lower and higher frequencies are eliminated to a great extent.

In the case of the inelastic structure there is clearly more damping and reduction of the responses at some (most) frequencies. The nonlinearity in structure is producing a longer effective period for the structure, and that effective period changes during shaking. This in turn widens the frequency range of structural response. That is, the response is lower, but the frequency characteristic is (much) wider.

A series of fixed-base analysis is also performed on the four structures mentioned in Section 311.7.1.8. The first natural frequencies of the four structures with its base fixed, corresponding to the second mode of vibration of the SFSI-model, are given in Table 311.3. It can be seen that the influence of the soil on the natural frequency of the SFSI-system increases as the overall stiffness of the structure increases.

Structure	1^{st} natural frequency of fixed-base system [Hz]	2^{nd} natural frequency of SFSI-system [Hz]
1	2.71	2.07
2	9.82	3.89
3	25.1	5.53
4	5.75	3.52

Table 311.3: Eigenfrequencies of the analyzed models

311.7.1.10 Results

The results of the SFSI- as well as the fixed-base analysis are presented in the following. The displacements at the top of the nonlinear structures are recorded and plotted in Figure 311.91. It can be seen that the results from the SFSI- and the fixed-base-model differ considerably in terms of maximum as well as permanent displacement. In contrast to this the displacements at the base of the column are almost identical for the two models (results not plotted). Figure 311.92 displays the displacements at the top of structures 1 and 2 for all the combinations of linear and nonlinear soil and structures that have been analyzed. Due to the low yield moment the permanent displacement for structure 1 is relatively large in the analysis involving nonlinear columns. The results involving nonlinear columns on linear and on nonlinear soil are very similar in their overall shape, however permanent deformations are very different. It seems that the forces that trigger plastic deformations in the column strongly depend on the behavior of the soil beneath the foundation.

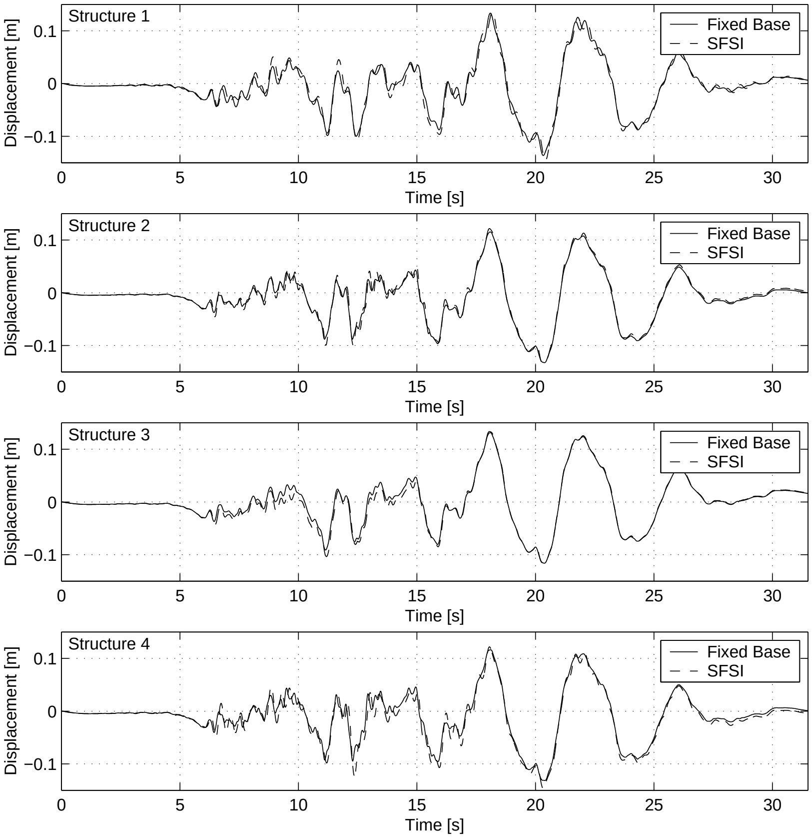

Figure 311.91: Displacements in x-direction at the top of the *nonlinear* structures

In order to investigate the forces causing plastic deformations in the structures we look at the base moments between foundation and column. In Figure 311.93 the moments at the base of the linear structures are plotted.

For structures 1 and 4 the moments for the fixed-base model are higher than for the SFSI-model. This means that in this case neglecting the effects of SFSI leads to a conservative design. Structures 2 and 3 however have to resist higher moments when SFSI is taken into account. Because the SFSI-system is more flexible than the fixed-base structure its modes of vibration are excited by a different range of frequencies contained in the input motion. For a particular motion this can lead to resonance of the SFSI-system. This result is in contradiction with current engineering practice suggesting that neglecting SFSI in general leads to a more conservative design.

Figure 311.94 shows the moments at the base of structures 1 to 4, this time for the analysis involving nonlinear column elements. The evolution of the second natural frequency of the SFSI-system is also provided as a qualitative indication for when plastic deformations occur. The base moments for structures 1 and 3 in the fixed-base- and the SFSI-analysis are very similar. Due to the low yield moment of the

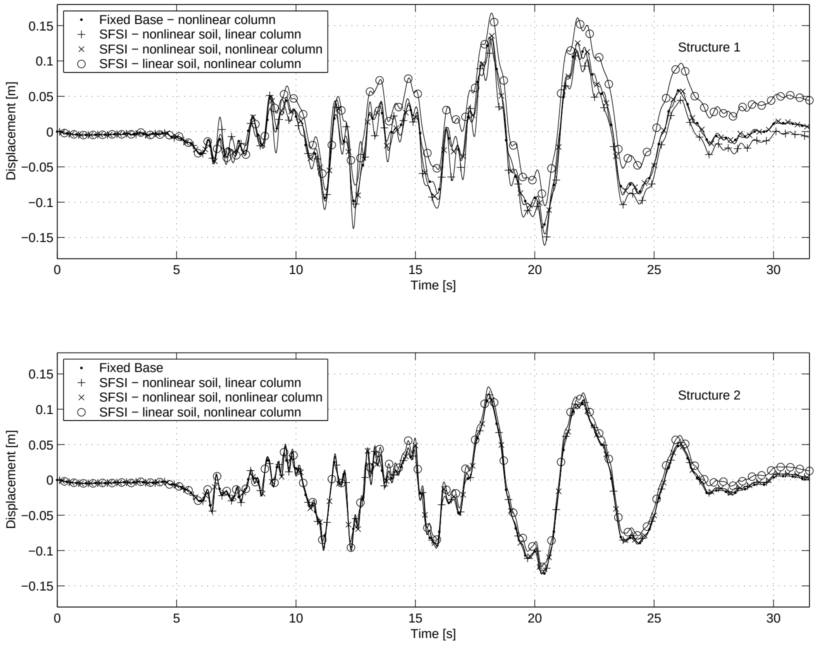

Figure 311.92: Displacements in x-direction at the top of structures 1 and 2

structure no resonance with the input motion occurs as a lot of energy is dissipated through plastic deformation.

Figure 311.95 shows an interesting aspect of nonlinear SFSI. In the analysis involving elastic-plastic soil the Fourier amplitudes of the moment at the base of the structure are reduced in the neighborhood of the natural frequency of the system. This is most likely due to dissipation of energy caused by elastic-plastic deformations in the soil that, in their turn, are a result of large loads provoked by resonance between the SFSI-system and the input motion.

As a measure of the plastic strain occurring beneath the footing the equivalent plastic strains averaged over all the Gauss points are calculated. The results are given at $t = 12$ s and at $t = 14$ s, that is shortly before and after the largest plastic deformation occurs (Figures 311.96 and 311.97).

Plastic strains are larger in the analysis involving an elastic structure. This reflects the fact that elastic structures don't dissipate any energy by themselves. For structure 2 no significant difference can be observed because of its high yield moment. Structure 4 is characterized by the same yield moment, its slightly smaller natural frequency however causes resonance with the input motion which leads to larger plastic strains beneath the footing. The largest plastic strains develop in the layer of elements adjacent to the boundary layer. This can be due to an input motion that isn't fully compatible with the elastic properties of the DRM-model. It should be possible to reduce these undesired plastic strains by either increasing the size of the soil model or by selecting a method to obtain the free-field motions that

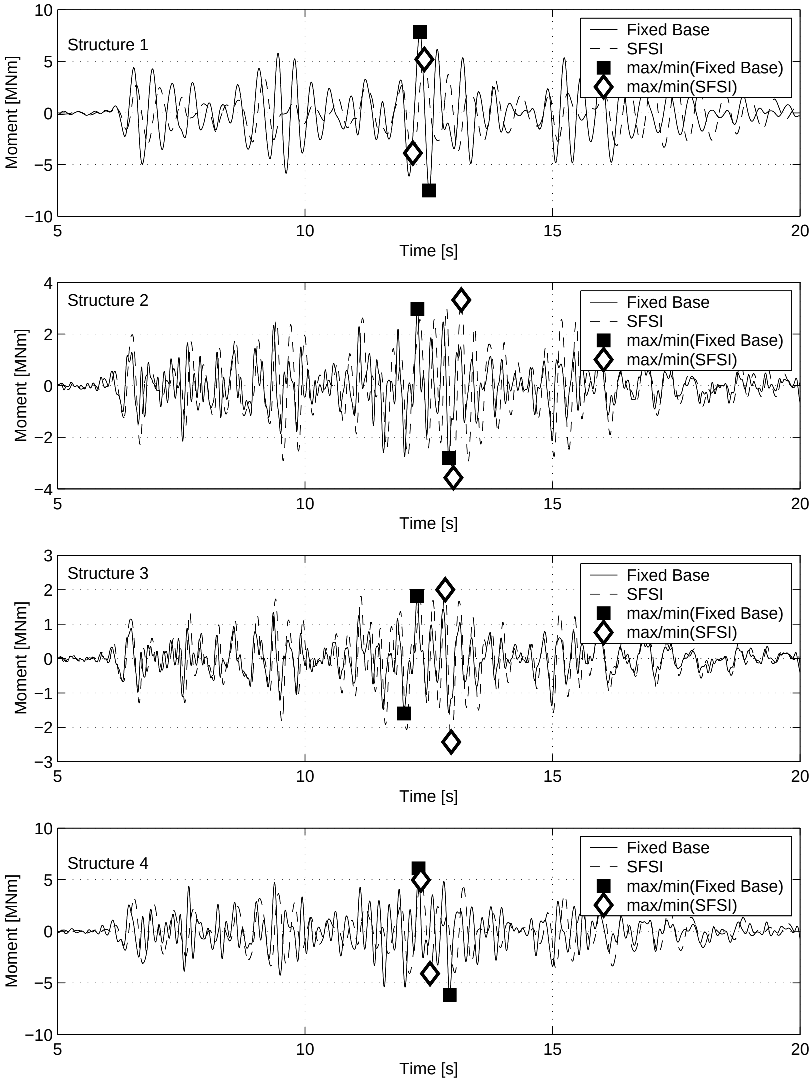

Figure 311.93: Moments at the base of the *linear* column

represents the soil properties of the DRM-model more closely.

311.7.2 Full nonlinear 3d Model

The 2d SFSI-model presented in the previous section is extended to a 3d model in the following. The goal is to show that the considerations for accuracy and stability of the numerical method obtained from the 1d-model remain valid for the 3d-model. Even if the simplicity of the analyzed problem doesn't necessarily justify the additional computational effort it is important to show that it is possible to obtain reliable results for a problem that involves the following elements:

- 3d model with about 700 elements, 960 nodes and 2700 equations

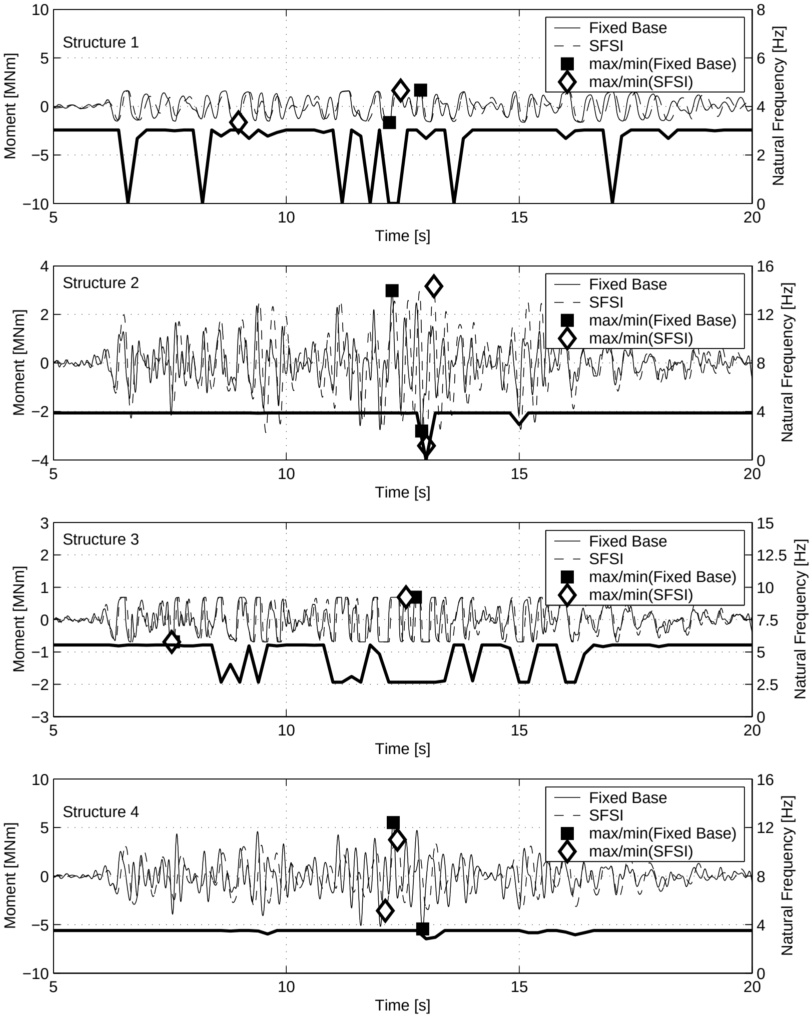

Figure 311.94: Moments at the base of the *nonlinear* column

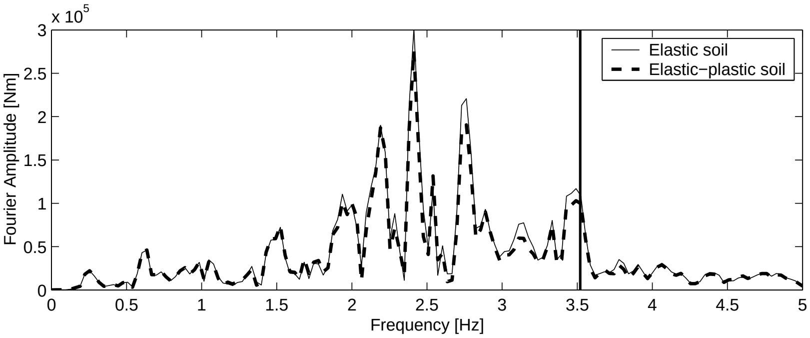

Figure 311.95: Fourier amplitude spectra of moments at the base of *nonlinear* column, SFSI-analysis

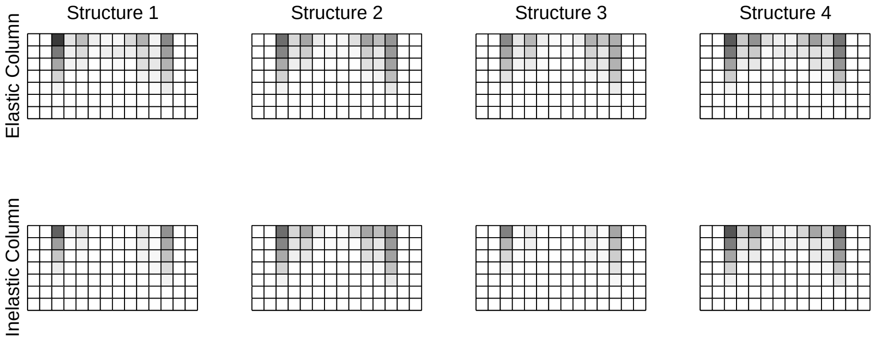

Figure 311.96: Average equivalent plastic strain at time t = 12 s

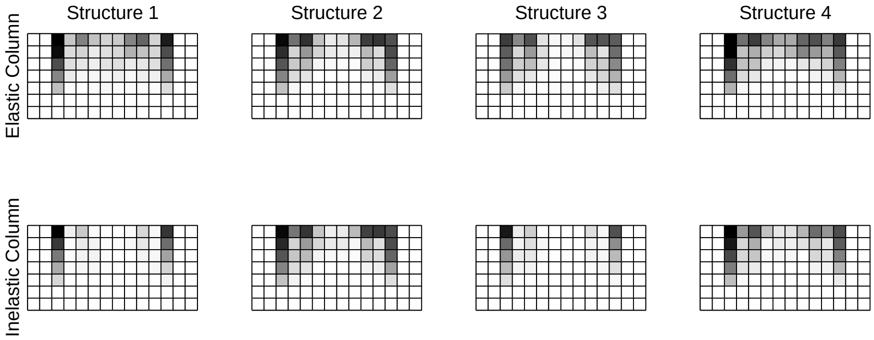

Figure 311.97: Average equivalent plastic strain at time t = 14 s

- Elastic-plastic soil (Drucker-Prager with kinematic hardening)
- Nonlinear structure (bilinear material model)
- Ground motion applied through the Domain Reduction Method (DRM)
- Absorbing boundary of Lysmer type

311.7.2.1 Description of Model

The 3d model is based on the 2d model shown in Figure 311.86. In y-direction 6 more slices of 7 x 14 elements are added (Figure 311.98). The x-z plane at y = 0 represents a plane of symmetry. Lysmer boundaries are attached to all outside boundaries with the exception of the plane of symmetry and the soil surface. The main difference to the 2d model is that 3d wave propagation is possible which leads to higher radiation damping.

The structure was chosen to have the same geometric and material properties as Structure 4 in the previous section.

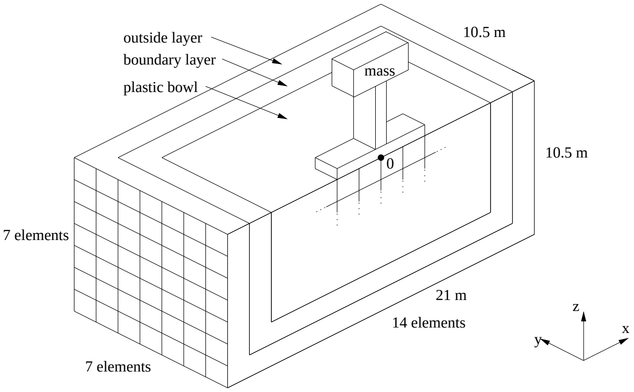

Figure 311.98: The full 3d-model

311.7.2.2 Results

Some results of the 3d-analysis together with the corresponding data of the 2d analysis are presented in Figure 311.99. Due to limited memory only the first 20 seconds of the time history were processed. A more efficient implementation of the application of effective forces for the DRM-method inside the finite element code should solve this problem. The analysis took 66 hours to finish.

The displacements obtained at the top of the structure as well as the moments at its base are very close to the results of the 2d-analysis. This shows that the analysis provides reliable results for a full 3d nonlinear SFSI problem. The amplitude of the base moment is at several instances larger for the 3d-model than for the 2d-model. This can be explained with the fact that more energy is present in the 3d-model whereas the energy the structure can absorb is the same as in the 2d-model. Also it is obvious that the natural frequencies of the 3d-model are not exactly the same as for the 2d-model and therefore changes the dynamic behavior in a way that is almost impossible to predict beforehand.

Because of the simple geometry of the problem the 2d-model is absolutely sufficient for analyzing the forces acting on the structure. If one is interested in the stress history in the soil surrounding the footing then the 3d-model can provide valuable additional information.

Chapter 313

Verification and Validation for Dynamic Solid-Fluid Interaction

(2017-2018-2019-2020-2021-)

(In collaboration with Dr. Hexiang Wang)

313.1 Chapter Summary and Highlights

313.2 V&V Examples

313.2.1 Box sloshing

A numerical example of earthquake-driven box sloshing is provided here. The initial configuration is shown in figure 313.1. The length of the box is 30 meters and the height is 10 meters. The thickness is 3 meters filled with 8-meter-deep water. The box is shaken by a uniform 1D horizontal excitation plotted in figure 313.2. The box is modeled with elastic material with $E = 12GPa, \mu = 0.2$.

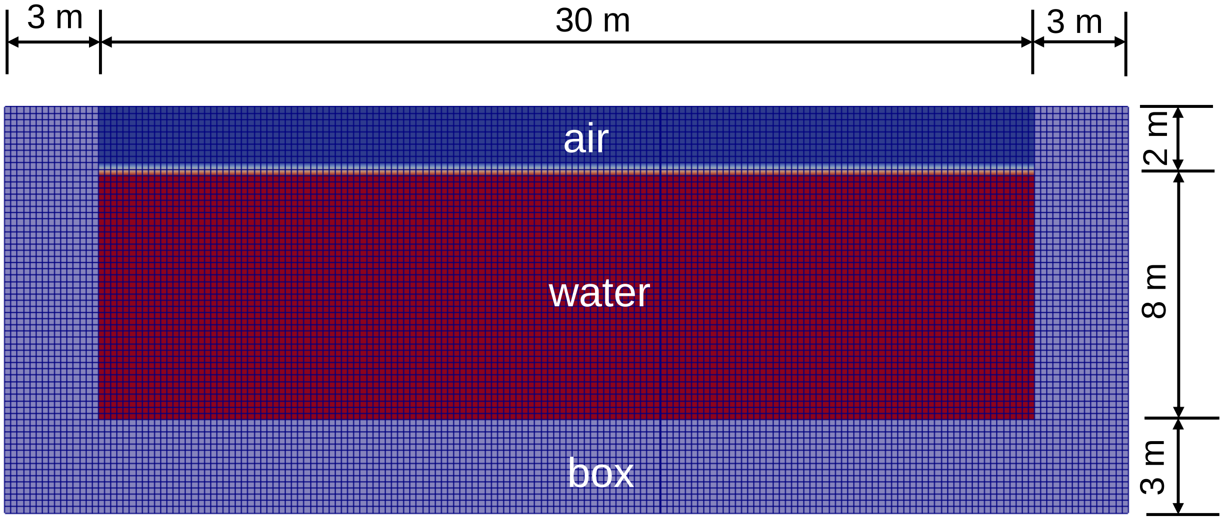

Figure 313.1: Model configuration of 2D sloshing box

The simulation result can be seen in figure 313.3. Clearly, elevations of free water surface can be observed under the excitation.

Another sloshing box example is driven by falling water flow. Figure 313.4(a) shows the result where solid domain and fluid domain has totally compatible mesh size (mesh size ratio 1:1). As mentioned before, VOF method has high requirement for the mesh size. In order to get accurate enough result with limited computation resources, refined mesh in the fluid domain is usually required for soil-structure-fluid interaction analysis. Analysis of model with discontinuous mesh is supported here through generalized interpolation scheme. Figure 313.4(b) shows the result of refined finite volume mesh in fluid domain (mesh size ratio 1:3).

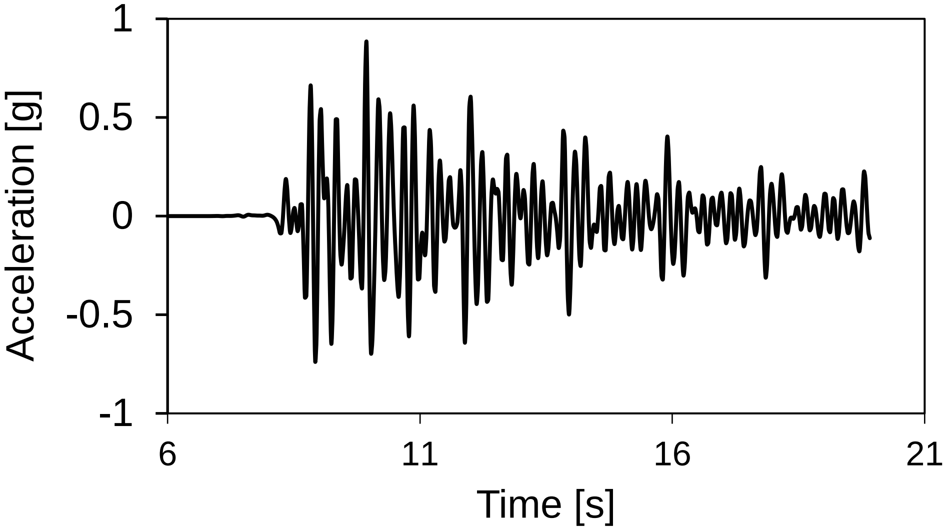

Figure 313.2: Time history of 1D excitation

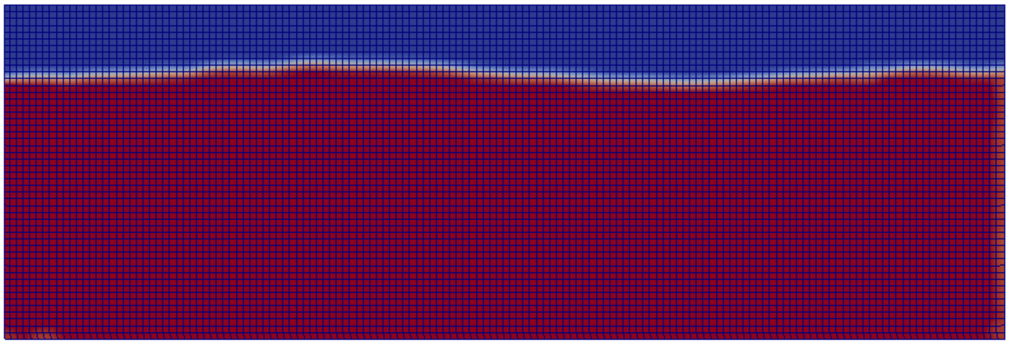

Figure 313.3: Simulation result of 2D sloshing box

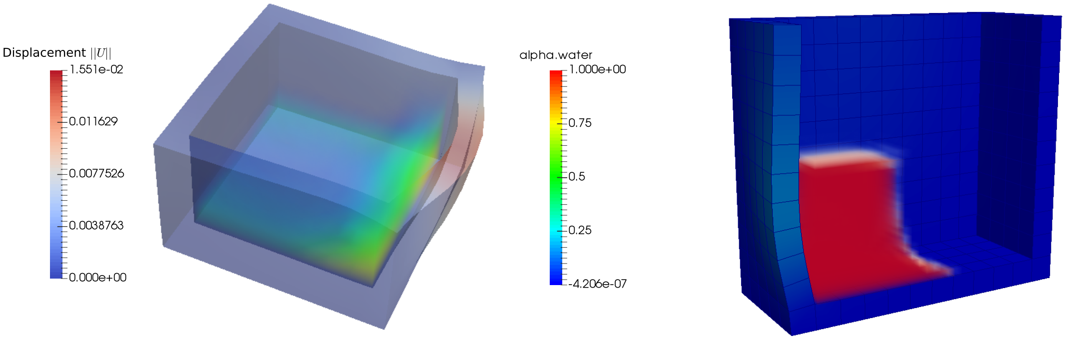

Figure 313.4: Box sloshing under falling water

313.2.2 Dam Break

313.3 Verification & Validation

Verification and validation is crucially important to guarantee the accuracy of simulation result. Verification and validation (V & V) procedure of SFI problem involve three aspects: V & V for response of solid domain (i.e. V & V for RealESSI as a solver for solid mechanics), V & V for response of fluid domain (i.e. V & V for OpenFOAM as a solver for free surface flow) and V & V for SFI (i.e. V & V for interaction between solid domain and fluid domain).

Since RealESSI developed by Jeremić et al. (1988-2025) has rigorous V & V procedure, the focus here is on V & V of OpenFOAM and SFI.

313.3.1 Free Surface Flow validation

The functionality of OpenFOAM as a solver for free surface flow is validated in this section. A numerical validation test is conducted based on the experiments reported by Martin and Moyce (1952).

A rectangular column of water, in hydrostatic equilibrium, is confined between two vertical walls, as shown in figure 313.5. The water column is 1 unit wide and 2 unit high. At the beginning of the calculation, the right wall (dam) is removed and water is allowed to flow out along a dry horizontal floor.

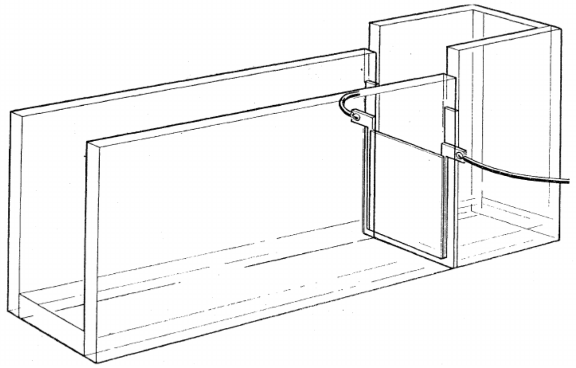

Figure 313.5: Experiment set up by]Martin and Moyce (1952)

The real-time position of the leading edge of the water is recorded during the experiment. This is a good test problem because it has simple boundary conditions and a simple initial configuration. 2D numerical models with two different types of mesh size ($\Delta x = 0.1m$ and $\Delta x = 0.05m$) are built (figure 313.6).

The comparison result between numerical solution, experiment result and benchmark solution by Hirt and Nichols (1981) is presented in figure 313.7.

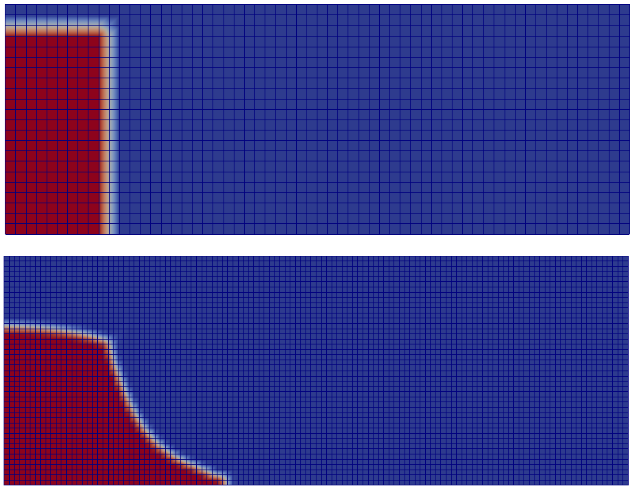

Figure 313.6: Numerical model for validation of free surface flow

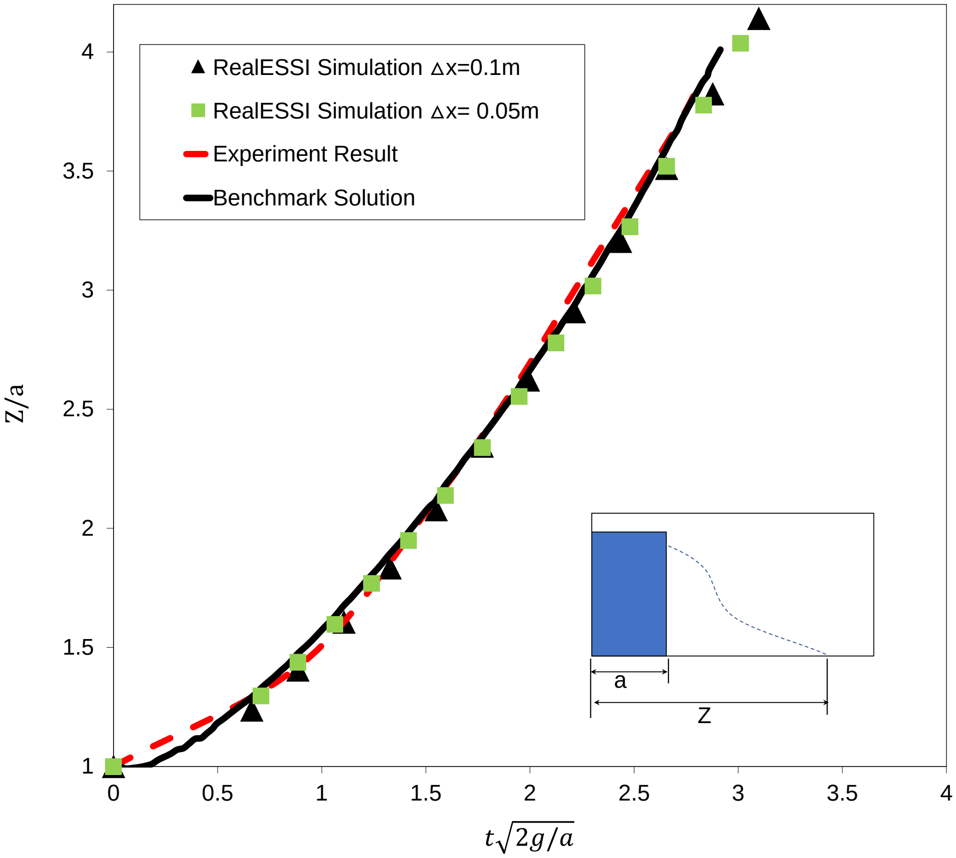

Figure 313.7: Validation result of free surface flow

It can be seen that numerical simulation matches well with both experiment result and benchmark solution. OpenFOAM, as a finite volume solver for free surface flow based on VOF method, is reliable.

313.3.2 Mass conservation verification

As mentioned in section 111.4.6, for a closed fluid system, mass conservation should be strictly satisfied. The total volume of fluid in the system can be calculated with equation 313.1.

$$V_{total} = \sum_{i=1}^{n} \alpha_i V_i \tag{313.1}$$

The time history record of total volume in the numerical example (section 313.2.1) is given in figure 313.8. It can be seen that the total volume remains almost constant during the simulation of SFI. In this example, after 400 time steps, the relative mass change is only 0.25%, which demonstrates that our coupling program has excellent performance regardng mass conservation.

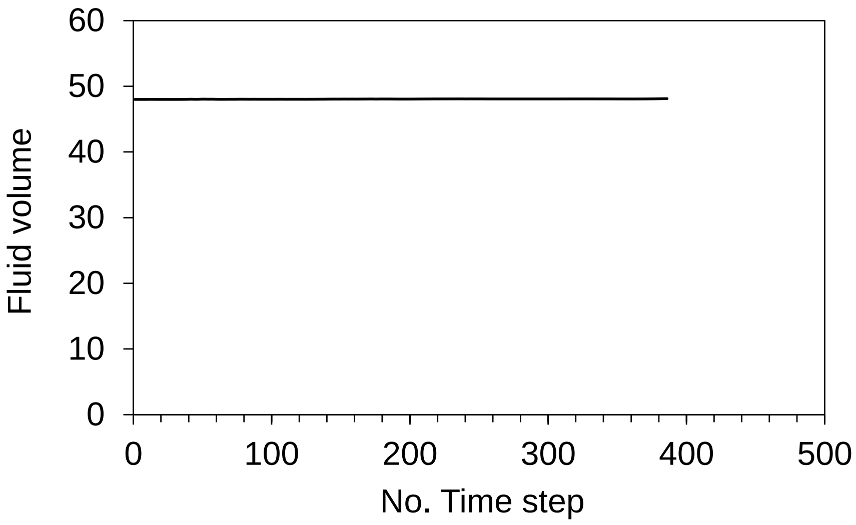

Figure 313.8: Time history record of total fluid volume

313.3.3 SFI Verification & Validation

A box sloshing numerical experiment (rectangular tank under sway oscillations $X(t) = Asin(wt)$) is taken as the verification and validation test for solid fluid interaction. The box is 1.0 m long (L) and 0.8 m height (H). The depth (D) of submerged water is 0.5 m. The natural frequency of the tank can be calculated according to Lamb (1932):

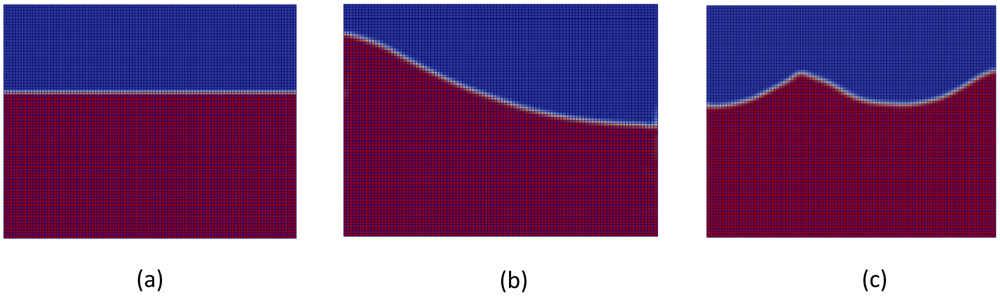
$$\omega_i = \sqrt{g\frac{\pi i}{L}tanh(\frac{\pi i}{L}D)} \quad i = 1, 2, 3, ... \tag{313.2}$$

where ω_i is the natural frequency, and g is gravitational acceleration. The lowest linear mode ω_i is of primary importance for the tank sloshing phenomenon.

Based on the original analytical solution of Linton and McIver (2001), Jin et al. (2014) gives the equation for non-dimensional free surface elevation η_{max}/A as shown in equation 313.3, where $b = L/2, \mu_m = (m + 0.5)\pi/b, K_m = \mu_m tanh \lambda_m D, K = \omega^2/g$.

$$\frac{\eta_{max}}{A} = \frac{\omega}{gA}|A\omega b + \sum_{m=0}^{\infty}|\frac{2K}{\mu_m^2 b(K_m - K)}| \tag{313.3}$$

Jin et al. (2014) also conducted a 2D sloshing experiment and report detailed response of free surface elevation under different excitation magnitude A and frequency ω. Here A is fixed as 2.5 mm and different frequency values ($\omega/\omega_1 = 0.5 \sim 2$) are adopted to implement verification and validation numerical test. The initial setup of numerical experiment can be seen in figure 313.9(a). Figure 313.9(b) and figure 313.9(c) are the sloshing response under excitation of first-mode ($\omega/\omega_1 = 1$) and third-mode ($\omega/\omega_3 = 1.793$) resonance frequency.



(a) (b) (c)

Figure 313.9: Numerical experiment of solid fluid interaction: (a) Initial setup (b) Sloshing response under first-mode resonance excitation (c) Sloshing response under third-mode resonance excitation

Compared with experiment record (figure 313.10) by Jin et al. (2014), it can be seen that the mode shape from our numerical simulation is same as the experimental observations.

The numerical results of η_{max}/A are also plotted into the same figure as theoretical predication and experiment record, as shown in figure 313.11. Very good agreement can be observed, especially between numerical simulation and experiment result. This manifests that suitable mathematical equations about SFI has been numerically solved in a correct way. The SFI coupling implementation in RealESSI is reliable.

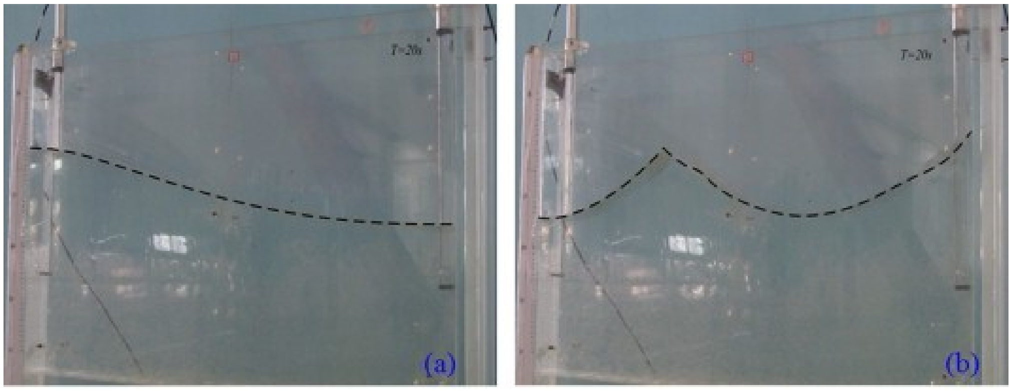


Figure 313.10: Resonant wave shape: (a) First-order mode (b) Third-order mode reproduced from Jin et al. (2014)

Chapter 314

Quality Management System

(2002-2005-2018-2019-2020-2021-)

314.1 Chapter Summary and Highlights

314.2 Reasoning Behind this Activity

Quality assurance for a numerical modeling system is of highest importance. A good, sound Quality Management System is therefor very important. This section provides details of quality management system used for the development and quality assurance (QA) for the Real-ESSI Simulator system (Jeremić et al., 1988-2025).

314.3 Real-ESSI Simulator System Quality Management System, based on ISO/IEC/IEEE 90003 Standard

This section is based on ISO/IEC/IEEE 90003 Developers et al. (2018). ISO/IEC/IEEE 9003 is a standard developed by the International Organization for Standardization (ISO), International Electrotechnical Commission (IEC), and Institute of Electrical and Electronics Engineers (IEEE), as a guidance for the application of ISO 9001:2015 standard to the acquisition, supply, development, operation and maintenance of computer software and related support services.

314.3.1 Real-ESSI Simulator Developer Organization

314.3.1.1 Internal Issues

Internal issues that are relevant to the Real-ESSI Simulator quality management system:

- legal
- Technological
- Competitive
- Market
- Cultural
- Social
- Economic environment, local, national, international

314.3.1.2 Internal Issues

External issues that are relevant to the Real-ESSI Simulator quality management system:

- Values
- Culture
- Knowledge
- Performance

314.3.1.3 External and Internal Issues for the Real-ESSI Simulator

External and Internal issues for the Real-ESSI Simulator can include:

- Use of "cloud" services, that is beneficial for ease of access and business continuity, however needs research to ensure lowering all beneficial effects. The Real-ESSI Simulator is fully deployed on Amazon Web Services (AWS), and is tightly managed by development group as well as ESSI Consultants. AWS was chosen after in depth examining other cloud services, namely Google cloud, that actually provided no dedicated tightly parallel computers as of 2018, Microsoft Azure, that was fast but very expensive, and local parallel cloud, Real-ESSI Parallel Computer, that works well for developers, but requires much management for outside users.
- Use of personal computers, laptops, can create a problem in managing safety and security of Real-ESSI Simulator sources. Developers are aware of this issue and have agree do tight safety and security and have signed a licensing agreement that commits them to managing such safety and security.
- Risk of external attack on developers computers and network and on Real-ESSI Simulator deployed computers is controlled by regular, up to date Linux and AWS security.
- Delivery of the Real-ESSI Simulator is mostly handled through AWS, while there are a number of example of remote deployment, whereby remote users commit fully utilizing and following the Real-ESSI Simulator quality management system.
- Legal and operational issues for Real-ESSI Simulator use in contgext of safety, security and mission assurance.

314.3.1.4 Needs and expectations of Interested Parties

Interested parties that are relevant to Quality Management System and their requirements

- Customers, professional practice companies, require working system, that is efficient, easy to use and that can provide more optimal, more economic and more safe designs than what is currently available.
- Partners, collaborators, require in depth knowledge of the system, possibility to influence changes and additions to the Real-ESSI Simulator
- Staff, require stable and nourishing research and development environment

- DOE, not sure anymore?
- NRC, not sure anymore?
- UN-IAEA, ...
- Professional Practice: development of the system that improves design and assessment process, while maintaining practicality, achieving highly efficient, minimally disrupting training for use Real-ESSI
- Research Community: Contributions to modeling and simulations, and use of Real-ESSI to investigate new behavior of ESSI systems.
- Developers form the Real-ESSI Simulator group:
- Competitors:
  - SimCenter ?
  - French project?
  - Linear Elastic community, SASSI,
  - nonlinear FEM programs, LS-Dyna...

314.3.2 Scope of the Real-ESSI Simulator Quality Management System

Plan-do-Check-Act (PDCA) cycle

Risk-based thinking

Quality Management Principles

314.4 Real-ESSI Simulator System Quality Management System, based on ASME NQA-1 Standard

ASME Nuclear Quality Assurance (NQA-1) is a standard developed by the American Society of Mechanical Engineers (ASME) that provides quality assurance guidance and certification for organizations supplying items and services which provide a safety function for nuclear installations.

314.4.1 ASME NQA-1 for the Real-ESSI Simulator System

Chapter 315

Comparison with Other Programs

(2016-2017-2020-2021-)

(In collaboration with Dr. Nima Tafazzoli, and Dr. Yuan Feng)

315.1 Chapter Summary and Highlights

315.1.1 Reasoning Behind this Activity

I personally do not like or approve code to code comparison. If results between two codes are the same, this does not prove that any tested code is right. If results between two codes are different, which code is right?

However, a number of professionals and industry in general feel very comfortable with some usually used codes/programs. In this sense, we provide code comparison with select widely used codes, to satisfy professionals. If results turn out to be the same (impossible to have exactly same results, but say very close) that is good for all codes involved, as we have a full verification suit and guaranty our accuracy to within limits of verification tests we used. If results are different, we still claim accuracy, as we have full verification suit and guaranty our accuracy to within limits of verification tests we used.

Part 400

Education, Training and Modeling, Simulation Examples

Chapter 401

Ten Section Course on Nonlinear Finite Element Methods for Realistic Modeling and Simulation of Earthquakes, and Soils, and Structures, and their Interaction, Real-ESSI

(1998-2021-)

401.1 Delivery

Instructor: Boris Jeremić, email: `Jeremic@ucdavis.edu`

Class meeting: two hour lecture/meetings, twice a week, flipped classroom method

Office hours: two hours, twice a week

Course delivery: live and recorded lectures, and live discussions

Course WWW: `http://sokocalo.engr.ucdavis.edu/~jeremic/Classes/ECI280A/`

401.2 Objectives

This course will provide students with state of the art finite element methods, numerical analysis tools and models for solving elastic–plastic problems in geotechnical and structural engineering. Focus is on analysis of Soils, Structures and their Interaction (SSI). Presented will be computational formulation, numerical techniques and models for static, nonlinear, elastic-plastic finite element methods that are used in professional practice and research. Both sequential and parallel computational approaches will be presented and used.

During this course students will:

- Learn about linear and nonlinear finite element modeling and simulation
- Select and calibrate nonlinear, elastic-plastic models for soil, rock, concrete, steel and interfaces
- Perform linear elastic and nonlinear, elastic-plastic analysis of solids and structures made of soil, rock, concrete, steel and their interfaces
- Perform elastic and nonlinear, inelastic analysis of soils-structure systems
- Become proficient in performing nonlinear analysis for soils, structures, interfaces, using different levels of sophistication, from simplified models to high fidelity elastic-plastic models of soil structure systems on sequential and parallel computers.

Who Should Attend?

Students and practicing engineers who want to learn about and expand their knowledge of modeling and simulation for nonlinear/inelastic material behavior, for soils, rock, and structures,

401.3 Additional Information

Lecture Notes: `http://sokocalo.engr.ucdavis.edu/~jeremic/LectureNotes/`.

Recorded Lectures: `http://sokocalo.engr.ucdavis.edu/~jeremic/Online-Education/`.

Computers: Most of the problems in this course will require numerical simulations. A finite element modeling system called Real-ESSI Simulator (`http://real-essi.us`) is available for computers running Windows (through WSL), MacOS, Linux. Please refer to `http://real-essi.us` to find out how to use Real-ESSI on local computers or on AWS computers. Other programs can be used as well, as long as they provide modeling and simulation capabilities that are required for assignments, example problems and term project. Both sequential and parallel computers will be used.

Problems: Assigned weekly, students are expected to attempt to develop solutions. You are encouraged to discuss the approach to problem solutions with other students in the course as well as with the instructor.

Examples: Model development, finite element models, finite element mesh, boundary conditions, material models, loads, model verification process, linear and nonlinear elastic FEM with solids and structural elements,

There are a large number of examples available at the Real-ESSI Simulator web site:
`http://real-essi.info/`, or `http://real-essi.us/`, in these documents:

- Real-ESSI Simulator Examples Collection
- Real-ESSI Simulator Short Course Examples Collection

Term Project: Term project will involve work related to developing or using numerical models for numerically simulating elastic–plastic problem of your choice, related to your interests. Term projects will be presented at the end of quarter.

Grading: TBD

Examination: TBD

401.4 Teaching Plan, Topics

401.4.1 Section I, Introduction

Introduction: Course objectives, methodology, computer modeling and simulation

Modeling and Simulation System Setup: Introduction to the Real-ESSI Simulator system. Computational Mechanics field of study, kinematics of deformation, strain, stress, linear and nonlinear elasticity, equilibrium relations, finite element method review, nonlinear analysis cycles; Introduction to sequential and parallel computers.

Lectures, recordings and slides:

- Introduction to Modeling and Simulation: PDF slides, MP4 recording
- Introduction to Modeling Simplifications, Epistemic Uncertainty: PDF slides, MP4 recording
- Introduction to Parametric, Aleatory Uncertainty: PDF slides, MP4 recording

Reading: Lecture Notes: 101, 201, 205; Papers/Reports: CM988, CM2714, CM2715, CM3170

Examples: Model development, finite element models, finite element mesh, boundary conditions, material models, loads, model verification process, linear and nonlinear elastic FEM with solids and structural elements. see examples collection at `http://real-essi.info/` or `http://real-essi.us/`,

Problems:

1. Model a $0.1m \times 0.1m \times 1.0m$ linear elastic cantilever beam, with transversal end forcing, using:
    - Single and ten Bernoulli beam elements
    - Single and ten Timoshenko beam elements
    - 1 $(1 \times 1 \times 1)$; 10 $(1 \times 1 \times 10)$; 24 node solid brick elements
2. Model a $0.1m \times 0.1m \times 1.0m$ simple shear linear elastic test using
    - 1 $(1 \times 1 \times 1)$ and 32 $(4 \times 4 \times 4)$ 8 node solid brick elements
    - 1 $(1 \times 1 \times 1)$ and 32 $(4 \times 4 \times 4)$ 24 node solid brick elements
3. Model a $0.1m \times 0.1m \times 1.0m$ pure shear (no rotations) linear elastic test using
    - 1 $(1 \times 1 \times 1)$ and 32 $(4 \times 4 \times 4)$ 8 node solid brick elements
    - 1 $(1 \times 1 \times 1)$ and 32 $(4 \times 4 \times 4)$ 24 node solid brick elements

401.4.2 Section II, Inelastic Finite Elements

Theory: Expanding the matrix deformation method, linear elastic truss element, Beams (Bernoulli, Timoshenko), solids, plates, walls (plane stress), shells, stiffness, forces, displacements, interpolating functions for displacements. Local and global equilibrium. Internal and external forces,

Lectures, recordings and slides:

- Introduction to the Finite Element Method (FEM): PDF slides, MP4 recording
- Derivation of FEM equations of motions for single phase, dry material: PDF slides, MP4 recording
- Derivation of FEM equations of motions for coupled, two phase, fully and partially saturated material, u-p-U formulation: PDF slides, MP4 recording

Reading: Lecture Notes: 101, 102; Papers/Reports: CM81, CM125, CM1835, CM2714, CM3155, CM3155

Examples: Truss, beam, solid bricks. external forces. internal forces (sectional forces, stresses). Generalized nodal displacements and internal deformation (curvature, axial, shear, volumetric, general strains),

Problems:

1. Develop a set of simple, single element examples using truss, beam and brick finite elements with simple static loads, and extract sectional forces, stress, strain and strain energy from results.

401.4.3 Section III, Micromechanics of Elasto-Plasticity

Theory: Micro-mechanical origins of elasto-plasticity, particles in contact, friction, Hertz, Mindlin-Deresiewicz contact/interface

Lectures, recordings and slides:

- Micromechanical origins of elasto-plasticity:
- Lectures by Prof. Stein Sture (University of Colorado, Boulder) on micromechanical origins of elasto-plasticity are available HERE,

Reading: Lecture Notes: 103; Papers/Reports: CM1000, CM1830, CM1831,

Examples: Particle contact problems.

Problems:

1. Develop a simple, 2D, plane-strain model of two particles in contact and apply normal and then shear forces,
2. For the above model, vary normal and shear forces. Comment on results.

401.4.4 Section IV, Incremental Elastic-Plastic Theory

Theory: Incremental, continuum elasto-plasticity, Material Models, perfectly plastic, hardening and softening. Explicit, forward Euler and Implicit, backward Euler, constitutive integrations,
Lectures, recordings and slides:

- Introduction to the incremental theory of elasto-plasticity: PDF slides, MP4 recording, YouTube video
- Explicit solution to the constitutive elastic-plastic problem: PDF slides, MP4 recording, YouTube video
- Implicit solution to the constitutive elastic-plastic problem: PDF slides, MP4 recording, YouTube video

Reading: Lecture Notes: 104; Papers/Reports: CM3199
Examples: Constitutive integrations, explicit and implicit computations: single element response using select elastic-plastic material models: von Mises, Drucker-Prager, Cam Clay. Perfectly plastic, isotropic hardening, kinematic hardening models and cyclic response. Inelastic, fiber (1D) and 3D structural models for concrete and steel.
Problems:

1. Develop a constitutive only linear elastic example. with monotonic loading and vary elastic modulus and Poisson's ratio. Comment on results
2. Develop a constitutive only elastic-perfectly plastic von-Mises example, for monotonic loading, and vary elastic properties, yield strength. Comment on results.
3. For the above developed example, develop results using explicit and implicit constitutive integrations. Vary step size, integration algorithm, tolerances. Comment on results.
4. For the above developed examples, use two cycles of cyclic loading. Comment on Results.

401.4.5 Section V, Inelastic, Elasto-Plastic Solids Modeling

Theory: Continuation: Incremental elasto-plasticity. Material modeling for practical applications. Advanced topics in constitutive elasto–plasticity, stability and accuracy, errors in constitutive integrations, problematic incremental steps, energy dissipation, sub-incrementation, line search, model calibrations.

Lectures, recordings and slides:

- Choice of elastic-plastic material models for soils and interfaces/contacts/joints: PDF slides, MP4 recording YouTube video
- Calibration of elastic-plastic material models for sand: PDF slides, MP4 recording YouTube video
- Calibration of elastic-plastic material models for clay: PDF slides, MP4 recording YouTube video

Reading: Lecture Notes: 104, 402, 403, 512; Papers/Reports:

Examples: Errors in constitutive modeling, sub-increments. Material model calibration, Constitutive modeling of soil, rock, concrete, steel: von Mises, Drucker-Prager, Cam Clay, SaniSand, rounded Mohr-Coulomb, Pisano. Modeling G/G_{max} and damping response. Nonlinear, elastic-plastic structural models for concrete and steel (1D, 3D).

Problems:

1. Develop a single element, 8 and 24 node brick, linear elastic example. with monotonic loading and vary elastic modulus and Poisson's ratio. Comment on results
2. Develop a single element elastic-perfectly plastic von-Mises example, for monotonic loading, and vary elastic properties, yield strength. Vary number of integration, Gauss points. Comment on results.
3. For the above developed example, develop results using explicit and implicit constitutive integrations. Vary step size, integration algorithm, tolerances. Comment on results.
4. For the above developed examples, use two cycles of cyclic loading. Comment on Results. Use both axial loading and shear loading.

401.4.6 Section VI, Inelastic, Elastic-Plastic Interfaces, Joints, Contacts Modeling

Theory: Interface/Joint/Contact modeling: Hard contact, Soft contact. Axial contact stiffness, shear contact stiffness. Interface gap opening and closing. Saturated contacts, effective stress and buoyant forces on foundations.

Lectures, recordings and slides:

- Choice of elastic-plastic material models for soils and interfaces/contacts/joints: PDF slides, MP4 recording YouTube video
- Calibration of elastic-plastic material models for interfaces/contacts/joints: PDF slides, MP4 recording YouTube video

Reading: Lecture Notes: 104, 403, 512; Papers/Reports:

Examples: Interface: concrete to soil and rock, steel to soil and rock. Gap opening, closing. Shear interface, slip, no slip.

Problems:

1. Develop a two solid element example that are connected using force based interface elements.
2. Develop a two solid element example that are connected using stress based interface elements.
3. For the above developed example, use normal loading and vary load step size. Comment on results.
4. For the above developed example, use normal and then shear loading and vary load step size. Comment on results.
5. For the above developed example, vary interface properties, use interface/contact/joint properties for soil on concrete, soil on steel, concrete on concrete, &c. Comment on results.

401.4.7 Section VII, Inelastic, Elastic-Plastic Structural Modeling

Theory: Inelastic structural models, beams, plates, walls and shells.

Lectures, recordings and slides:

- Choice of elastic-plastic material models for structural elements, beams and walls/plates/shells: PDF slides, MP4 recording, YouTube video
- Calibration of elastic-plastic material models for concrete, in reinforced beams and walls/plates/shells: PDF slides, MP4 recording YouTube video
- Calibration of elastic-plastic material models for steel, in reinforced beams and walls/beams/shells: PDF slides, MP4 recording YouTube video

Reading: Lecture Notes: 102, 403, 512; Papers/Reports:

Examples: Nonlinear analysis of structures. Steel Frames. Reinforces concrete frames, walls, plates, shells.

Problems:

1. Develop a nonlinear truss model, and load it using monotonic and cyclic loading up to yielding and past yielding. Comment on results.
2. Develop a nonlinear beam model, and load it in bending using monotonic and cyclic loading up to yielding and past yielding. Comment on results.
3. Develop a two solid element example that are connected using stress based interface elements. Comment on results.

401.4.8 Section VIII, Nonlinear Analysis Progress

Theory: Analysis Progress. Stages, increments, iterations, elastic–plastic stiffness matrix, pure incremental methods, force residuals, Newton iterative algorithm for finite element level iterations, constraints to the global (force residual) system of equations, equilibrium iterations, convergence, load control, displacement control, arc-length, hyper-spherical constraint, convergence criteria, automatic step size control, line search, stability and accuracy. Sequential and parallel computations for inelastic, nonlinear solids and structures.

Lectures, recordings and slides:

-

Reading: Lecture Notes: 102, 107, 403; Papers/Reports:

Examples: Nonlinear analysis of structures and solids, elastic plastic solids, structures and contacts. Staged analysis steps, incremental only analysis with no equilibrium enforcement, incremental-iterative analysis, with equilibrium enforcement, convergence criteria (force, displacement), convergence tolerances, step size control.

Problems:

1. Develop a nonlinear analysis, using all of previous examples, that will feature explicit, no equilibrium check simulation. Comment on results.
2. Develop a nonlinear analysis, using all of previous examples, that will feature implicit, equilibrium check simulation. Comment on results.

401.4.9 Section IX, Verification and Validation

Theory: Verification, Validation and Prediction, basic theory, solution verification, manufactured solutions, validation experiments, prediction under uncertainty,

Lectures, recordings and slides:

-

Reading: Lecture Notes: 301, 302, 303..., 313, 314...; Papers/Reports:

Examples: Solution verification examples for elements, material models, constitutive integration algorithms, solution advancement algorithms.

Problems:

1. Choose a model of your interest, and develop a list of verification examples for all components of your model.
2. For the above model, develop a list of validation examples.

401.4.10 Section X, Practical Considerations for Nonlinear Analysis

Theory: Elastic–plastic FEM modeling (practical recommendations for development and analysis of nonlinear (elastic-plastic) finite element models, phased development of general FEM (and ESSI in particular) models. Core Functionality for inelastic/nonlinear modeling, Energy dissipation. Notes on sequential and parallel computing.

Lectures, recordings and slides:

-

Reading: Lecture Notes: 510, 512; Papers/Reports:

Examples: Illustrations of algorithms and models described above, benefits and detriments of different algorithms and models.

Problems:

1. Develop a realistic nonlinear analysis model of your choice, perhaps the one developed in previous section and experiment with all/most above models and algorithms. Comment on results.

Chapter 402

Ten Section Course on Dynamic Finite Element Methods for Realistic Modeling and Simulation of Earthquakes, and Soils, and Structures, and their Interaction, Real-ESSI

(1998-2021-)

402.1 Delivery

Instructor: Boris Jeremić, email: `Jeremic@ucdavis.edu`

Class meeting: two hour lecture/meetings, twice a week, flipped classroom approach

Office hours: two hours, twice a week

Course delivery: live and recorded lectures, and live discussions

Course WWW: `http://sokocalo.engr.ucdavis.edu/~jeremic/Classes/ECI280B/`

402.2 Objectives

This course will provide students with state of the art finite element methods, numerical analysis tools and models for solving dynamic problems in geotechnical and structural engineering, Focus is on analysis of Earthquakes, Soils, Structures and their Interaction (ESSI). Presented will be computational formulation, numerical techniques and models for dynamic, nonlinear, elastic-plastic finite element methods that are used in professional practice and research. In addition, sequential and parallel computing approaches will be explained, and used.

During this course, students will:

- Learn about dynamic finite element modeling and simulation
- Develop dynamic modeling and simulations for linear and nonlinear soils and structures
- Perform dynamic, linear and nonlinear analysis of solids and structures made of soil, rock, concrete, steel and their interfaces, joints and contacts
- Develop and use of one compoinent (1C), 3×1C and 3C seismic motions from given earthquake records and from analytic wave solutions
- Perform dynamic, nonlinear/inelastic earthquake soil structure interaction (ESSI) analysis
- Become proficient in performing nonlinear ESSI analysis using different levels of sophistication, from simplified models to high fidelity elastic-plastic ESSI models on sequential and parallel computers

Who Should Attend?

Students and practicing engineers who want to learn about and expand their knowledge of modeling and simulation for dynamic, nonlinear/inelastic material behavior, for soils, rock, and structures,

402.3 Additional Information

Lecture Notes: `http://sokocalo.engr.ucdavis.edu/~jeremic/LectureNotes/`.

Recorded Lectures: `http://sokocalo.engr.ucdavis.edu/~jeremic/Online-Education/`.

Computers: Most of the problems in this course will require numerical simulations. A finite element modeling system called Real-ESSI Simulator (`http://real-essi.us`) is available for computers running Windows (through WSL), MacOS, Linux. Please refer to `http://real-essi.us` to find out how to use Real-ESSI on local computers or on AWS computers. Other programs can be used as well, as long as they provide modeling and simulation capabilities that are required for assignments, example problems and term project.

Problems: Assigned for each section, students are expected to attempt to develop solutions. You are encouraged to discuss the approach to problem solutions with other students in the course as well as with the instructor.

Term Project: Term project will involve work related to developing or using numerical models for numerically simulating elastic–plastic problem of your choice, related to your interests. Term projects will be presented at the end of quarter.

Grading: TBD

Examination: TBD

402.4 Teaching Plan, Topics

402.4.1 Section I, Introduction

Introduction: Course objectives, methodology, computer modeling and simulation; Dynamics of nonlinear structures and soils during earthquakes, examples Preliminary theory, terminology, issues to be addressed: Deformation, kinematics of moving systems, elasticity, dynamic equilibrium relations, d'Alembert's principle, forces in dynamic equilibrium, mass, damping, stiffness, external force, single degree of freedom systems,

Modeling and Simulation System Setup: Introduction to the Real-ESSI Simulator system. Computational Mechanics field of study, kinematics of deformation, strain, stress, linear and nonlinear elasticity, equilibrium relations, finite element method review, nonlinear analysis cycles;

Lectures: Recorded lectures covering topics for this section can be found in Section 404.1.1 on Page 1937 in Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 101, 102; Papers/Reports:

Examples: Model Development, simple models vs sophisticated models, pre-processing, post-processing, results visualization.

Problems:

1.
2.
3.

402.4.2 Section II, Dynamic FEM

Dynamic FEM Theory: Dynamic finite element method (FEM) equations, virtual work method in dynamics, nonlinear dynamic equations of motion, consistent and lumped mass, velocity and displacement proportional damping/energy dissipation, Rayleigh and Caughey viscous damping, linear and nonlinear material behavior.

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.3 on Page 1939 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 102; Papers/Reports:

Examples: Structural and solid elements and models, dynamic excitations, resonance, linear and nonlinear (elastic and inelastic/elastic-plastic) material models, viscous damping, consistent and lumped mass matrix.

Problems:

1.

2.

3.

402.4.3 Section III, Nonlinear FEM

Nonlinear FEM: Elasto-plasticity, material models for dynamics of soils and structures, material parameter calibration, uncertainty in material parameters, explicit and implicit constitutive integrations. Sequential and parallel computations

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.3 on Page 1939 and Section 404.1.4 on Page 1940 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 103, 104; Papers/Reports:

Examples: Elastic plastic solids, beams and shells, material energy dissipation, material damping

Problems:

1.

2.

3.

402.4.4 Section IV, Time Domain Nonlinear Dynamic FEM

Time Domain Nonlinear Dynamic FEM: Direct, time marching solution for dynamics of nonlinear, inelastic systems, general Newmark family of methods, stability and accuracy, nonlinear resonance, numerical damping, explicit and implicit algorithms, unconditionally and conditionally stable Newmark and Hilber–Hughes–Taylor α–method, stability and accuracy, examples)

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.3 on Page 1939 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 108; Papers/Reports:

Examples: Nonlinear solid and structural models direct time integration, step size, damping (material, viscous, numerical), stable and unstable computations.

Problems:

1.

2.

3.

402.4.5 Section V, Earthquake Soil Structure Interaction (ESSI)

Earthquake Soil Structure Interaction (ESSI): Background, problem definition, seismic motions, seismic body and surface wave field, seismic energy propagation, free field motions, beneficial and detrimental effects, balancing input and dissipated energy.

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.8 on Page 1946 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 502; Papers/Reports:

Examples: Analytic development of ground motions, 3D vs 1D motions, seismic energy calculations.

Problems:

1.

2.

3.

402.4.6 Section VI, Seismic Motions

Seismic Motions: Free field vs ESSI motions, incoherent motions, Domain Reduction Method, boundary conditions, radiation damping, 3D inclined wave fields vs 1D vertical motions, nonlinear wave propagation simulations, time step size, element size, earthquake modeling.

Free field motions development, 1D motions, 3D/6D motions, regional scale models, Geophysical models,

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.7 on Page 1945 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 502, 511, 705, 706; Papers/Reports:

Examples: Real ESSI and analytic wave field models for free field and local (DRM) motions, element and time step size and propagation of (required) frequencies. Vertical and inclined waves development, and input into SSI models

Problems:

1.

2.

3.

402.4.7 Section VII, Coupling with Internal and External Fluids

Dynamics of Coupling with Pore Fluids and External Fluids: Fully coupled, porous solid – pore fluid systems formulation, discretization, basic system of DOFs, coupling damping forces, specialization to slow (consolidation) and fast phenomena (ESSI, liquefaction), boundary conditions, initial conditions, stability and accuracy of various algorithms. Coupling with external fluids, pools, reservoirs.

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.3 on Page 1939 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 102, 505; Papers/Reports:

Examples: 1D and 3D coupled examples, consolidation, liquefaction and de-liquefaction waves, piles in liquefied soil... Coupling with external fluids, using OpenFOAM...

Problems:

1.

2.

3.

402.4.8 Section VIII, Dynamic Stochastic Elastic-Plastic FEM (SEPFEM)

Stochastic Elastic-Plastic Dynamic FEM:

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.6 on Page 1943 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: Papers/Reports:

Examples:

Problems:

1.

2.

3.

402.4.9 Section IX, Verification and Validation

Verification and Validation: Definition, procedures, code verification, solution verification, validation experiments, model verification

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.9 on Page 1947 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 301-314; Papers/Reports:

Examples: modeling verification examples, verification for algorithms, elements. Availability of validation data.

Problems:

1.

2.

3.

402.4.10 Section X, ESSI Modeling and Simulation Synthesis

ESSI Modeling and Simulation Synthesis: Example building structure (boundary conditions, initial conditions, nonlinear interface/contact (gap/slip), nonlinear soil/rock, 1D vs 3D seismic motions development, buoyant forces at foundation level, etc.). Use of sequential and parallel computers for analysis.

Lectures: Recorded lectures covering topics for this week can be found in Section 404.1.11 on Page 1949 in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Reading: Lecture notes: 503, 504, 509 510, 512; Papers/Reports:

Examples: Real ESSI illustrative examples

Problems:

1.

2.

3.

Chapter 403

Nonlinear ESSI for Professional Practice, A Short Course

(2017-2022-)

403.1 Short Course Delivery

Instructor: Boris Jeremić, email: `Jeremic00@gmail.com`; `Jeremic@ucdavis.edu`

Short Course Meeting: Two hour lectures, twice a week, online, using zoom; live and recorded lectures and discussions.

403.2 Objectives

The nonlinear analysis of Earthquakes, Soils, Structures, and their Interaction (ESSI) is crucial in ensuring the safety and efficiency of various structures, such as bridges, dams, buildings, tunnels, nuclear facilities, and other parts of the built environment. This analysis involves a deep understanding of statics and dynamics in soil mechanics, structural mechanics, and numerical modeling in order to accurately analyze ESSI systems' nonlinear behavior under static and dynamic loads.

This online course provides training on nonlinear, inelastic analysis for soil-structure systems, specifically focusing on earthquake soil-structure interaction (ESSI). The course is designed for practicing engineers, consultants, managers, and regulators and covers practical aspects of nonlinear analysis for ESSI systems. The main advantages and disadvantages of using nonlinear analysis for ESSI systems will also be discussed.

Who Should Attend: This short online course is designed for practicing engineers, consultants, managers, and regulators who want to reinforce and expand their knowledge of nonlinear, inelastic analysis for soil-structure systems. If you are looking to improve your understanding of the nonlinear behavior of ESSI systems and become proficient in performing nonlinear ESSI analysis, this course is will help you to achieve your goals.

What will you learn? Upon completion of this course, the participants will be able to:

1. Plan, develop, and verify different levels of sophistication ESSI models,
2. Select and calibrate elastic and elastic-plastic material models for soil, interfaces/contacts, and structural components such as beams and plates/shells,
3. Develop one component (1C), 3×1C, and 3C seismic motions from chosen earthquake records and/or stress test motions,
4. Choose numerical simulation parameters, convergence tolerances, and efficient solvers for high-performance sequential and parallel computing,
5. Identify and explain the limitations of nonlinear, inelastic finite element analysis,

6. Perform nonlinear ESSI analysis with proficiency, ranging from simplified models to high- fidelity elastic-plastic models of soil-structure systems.

Course Delivery: Online course and online office hours will use zoom platform.

Lecture Notes: `http://sokocalo.engr.ucdavis.edu/~jeremic/LectureNotes/`.

Computers: Course will rely on use of analysis system called the Real-ESSI Simulator (`http://real-essi.us`). The Real-ESSI Simulator program is available for computers running Windows (through WSL), MacOS and Linux, Please refer to `http://real-essi.us` to find out how to use Real-ESSI on local computers through Docker. The system is also available in the cloud, on Amazon Web Services (AWS) computers.

Short Course Program:

- Part I: Introduction to Nonlinear Finite Element Analysis
  - Brief overview of static and dynamic finite elements method (FEM)
  - Brief overview of linear and material nonlinear FEM
  - Nonlinear FEM analysis: stages, increments and iterations
  - Quality assurance: verification and validation (V&V) procedures
  - Introduction to the Real ESSI Simulator system, documentation, examples
- Part II: Nonlinear Material Models. Participants will learn about and use nonlinear, inelastic, elastic-plastic models:
  - Nonlinear material models for soil and rock
  - Nonlinear material models for concrete
  - Nonlinear material models for steel
  - Fiber section Nonlinear material models for concrete and steel, for beams and walls,
  - 3D soil-foundation interface/contact nonlinear material models,
- Part III: Nonlinear Finite Element Analysis. Participants will learn about and perform nonlinear finite element analysis:
  - Develop stages-increments-iterations cycles
  - Develop and perform purely incremental nonlinear analysis
  - Develop and perform iterative incremental nonlinear analysis
  - Liquefaction analysis, fully coupled, saturated, porous solid – pore fluid,
  - Energy dissipation during elasto-plastic deformation.
- Part IV: Hands on elasto-plastic example exercise. Participants will develop and use elastic-plastic models for nonlinear material analysis:
  - Calibration of nonlinear/inelastic elastic-plastic models for
    soil,
    rock,
    concrete,
    steel,
    interface/contact,
    base isolators and dissipators
  - Use of best practices for nonlinear, inelastic model development and calibration.

- Part V: Introduction to Seismic Ground Motions. Participants will learn about and develop seismic ground motions from:
    - Ground motions from given surface motions, in 1C, 3×1C, and 3C
    - Analytic, stress test ground motions, in 1C, 3×1C, and 3C
    - Ground motions from small and regional scale models

- Part VI: Ground Motions for ESSI Modeling. Participants will learn about, apply and propagate ground motions through the free field and soil-structure systems:
    - Input ground motion into FEM model
    - Application of free field and ESSI ground motions
    - Ground motions using Domain Reduction Method (DRM)
    - Control ground motion frequency content

- Part VII: Hands on ESSI Ground Motion Exercise. Participants will analyze soil-structure systems using developed ground motions:
    - Develop hierarchy of input ground motions: 1C, 3×1C and 3C.
    - Free field analysis with 1C, 3×1C and 3C motions.
    - ESSI analysis with 1C, 3×1C and 3C motions.
    - Use of best practice for ground motion ESSI modeling

- Part VIII: Hands on nonlinear ESSI examples exercise. Participants will analyze nonlinear ESSI FEM models:
    - Hierarchy of sound engineering judgement ESSI model development steps
    - Nonlinear Finite Element, elastic-plastic examples for: soils, structures, interfaces,
    - Energy dissipation in dynamic ESSI analysis: viscous, plastic, algorithmic...
    - Nonlinear finite element models for ESSI using solids, structural elements, interfaces,
    - Use of best practices for nonlinear/inelastic ESSI modeling

Chapter 404

Online Education and Training

(2019-2020-2021-)

(In collaboration with Prof. Han Yang and Dr. Hexiang Wang)

404.1 Real-ESSI Simulator Online Education and Training

This chapter was created to present online material for the theory for modeling and simulation of earthquakes, soils, structures and their interaction, as well practical examples using the Real-ESSI Simulator, `http://real-essi.us/`.

It is worth noting that some early recorded material for use of the Real-ESSI Simulator on Amazon Web Services was created in 2019, however, majority of presented, recorded material was created during Corona-Virus (COVID-19) pandemic and quarantine from March through June of 2020, in Zürich Switzerland, where Boris Jeremić was locked-up, and in Davis, California, where Han Yang and Hexiang Wang were locked-up... Internet worked very good across the Atlantic ocean, zoom.us worked really well as well. Development of online educational material continued with all three contributors now in Davis, California during Summer and Fall 2020, Winter and Spring 2021, still during partial/full lock-down, shelter in place, still using zoom.us, and still keeping physical distance, wearing face masks, etc.

In addition to organizing slides and vide lectures through this document, a youtube video channel for the Real-ESSI is available here: Real-ESSI youtube channel.

It is hoped that this material will be helpful to students and engineers that work in the area of modeling and simulation of earthquakes, soils, structures and their interaction.

404.1.1 Modeling and Simulations for ESSI

The following recorded lectures modeling and simulation approaches for Earthquakes, Soils, Structures and their Interaction are available:

404.1.1.1 Introduction to Modeling and Simulation

PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.1.2 Introduction to Modeling Simplifications, Epistemic Uncertainty

PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.1.3 Introduction to Parametric, Aleatory Uncertainty

PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.2 Real-ESSI Simulator Modeling and Simulation System

The following recorded lectures about the Real-ESSI Simulator modeling and simulation system are available:

1. The Real-ESSI Simulator, Introduction:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. The Real-ESSI Simulator, Modeling Features:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. The Real-ESSI Simulator, Domain Specific Language:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. The Real-ESSI Simulator, Model Development:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
5. The Real-ESSI Simulator, Results Post Processing:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
6. The Real-ESSI Simulator, Quick Analysis Startup Guide, how to run simple example models:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.3 Finite Element Method

The following recorded lectures on the finite element method are available:

404.1.3.1 Backgound

1. Introduction to the Finite Element Method (FEM):
   PDF slides, MP4 recording
2. Derivation of FEM equations of motions for single phase, dry material:
   PDF slides, MP4 recording
3. Derivation of FEM equations of motions for coupled, two phase, fully and partially saturated material, u-p-U formulation:
   PDF slides, MP4 recording

404.1.3.2 Nonlinear, Inelastic FEM

4. Nonlinear, Inelastic FEM, residual equations:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
5. Solution of nonlinear, inelastic FEM equations:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.3.3 Dynamic FEM

6. Dynamic FEM equations:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
7. Time marching algorithms for dynamic FEM equations:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.4 Deterministic Elasto-Plasticity

404.1.4.1 Introduction to Modeling and Simulation

PDF slides, and a direct MP4 recording and/or alternatively YouTube video

The following recorded lectures on deterministic elasto-plasticity are available:

404.1.4.2 Theory Backgound

1. Micromechanical origins of elasto-plasticity:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. Introduction to the incremental theory of elasto-plasticity:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. Explicit solution to the constitutive elastic-plastic problem:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. Implicit solution to the constitutive elastic-plastic problem:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.4.3 Elastic-Plastic Material Model Choices

5. Choice of elastic-plastic material models for soils and interfaces/contacts/joints:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
6. Choice of elastic-plastic material models for structural elements, beams and walls/plates/shells:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.4.4 Calibrating Elastic-Plastic Material Models

7. Calibration of elastic-plastic material models for sand:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
8. Calibration of elastic-plastic material models for clay:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
9. Calibration of elastic-plastic material models for interfaces/contacts/joints:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

10. Calibration of elastic-plastic material models for concrete, in reinforced beams and walls/plates/shells: PDF slides, and a direct MP4 recording and/or alternatively YouTube video

11. Calibration of elastic-plastic material models for steel, in reinforced beams and walls/beams/shells: PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.5 Seismic Energy Dissipation

The following recorded lectures on energy dissipation are available:

404.1.5.1 Theory Background

1. Energy dissipation introduction:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. Energy dissipation in solids:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. Energy dissipation in fiber beams:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. Energy dissipation in interfaces/joints/contacts:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
5. Energy dissipation due to viscous effects:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
6. Energy dissipation due to time integration, algorithmic, numerical effects:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.5.2 Illustrative Examples

7. Energy dissipation examples:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.6 Probabilistic Elasto-Plasticity and Stochastic Elastic-Plastic Finite Element Method

404.1.6.1 Theory Background

1. Introduction to the Polynomial Chaos (PC) expansion:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. Introduction to the Karhunen-Loève (KL) expansion:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. Introduction to the Stochastic Elastic-Plastic Finite Element Method (SEPFEM)
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. Introduction to Sensitivity Analysis
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.6.2 Choice and Calibration of Probabilistic Material Models and Probabilistic Seismic Loads

5. Choice, analysis and calibration of probabilistic elastic material parameters:
   PDF slides, and a direct MP4 recording and/or alternatively; YouTube video
6. Choice, analysis and calibration of probabilistic elastic-plastic, nonlinear, inelastic material parameters:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
7. Choice, analysis and calibration of probabilistic seismic motions:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.6.3 Simple Probabilistic Examples

8. SEPFEM, Two Examples:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
9. SEPFEM, Seismic Risk Analysis Example:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.6.4 Probabilistic Wave Propagation Examples

10. Analysis of one component (1C) seismic wave propagation with uncertain motions and uncertain elastic material parameters:

PDF slides, and a direct MP4 recording and/or alternatively YouTube video

11. Analysis of one component (1C) seismic wave propagation with uncertain motions and uncertain elastic-plastic, nonlinear, inelastic material parameters:
    PDF slides, and a direct MP4 recording and/or alternatively YouTube video
12. Sensitivity analysis for uncertain motions and uncertain elastic material parameters:
    PDF slides, and a direct MP4 recording and/or alternatively YouTube video
13. Sensitivity analysis for uncertain motions and uncertain elastic-plastic, nonlinear, inelastic material parameters:
    PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.7 Seismic Motions

The following recorded lectures on seismic motions are available:

1. On earthquakes:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. On six component (6C) seismic motions:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. On the Domain Reduction Method (DRM):
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. Development of DRM motions from surface records, 1C, 2×1C, and 3×1C:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
5. Development of DRM motions from inclined, 3C seismic waves:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.8 Earthquake Soil Structure Interaction

The following recorded lectures on Earthquake Soil Structure Interaction (ESSI) are available:

1. On ESSI:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.9 Verification and Validation

Basic theory of Verification and Validation (V&V), as well as V&V examples for the Real ESSI Simulator are shown in recorded lectures below:

1. Verification and Validation introduction:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. Real ESSI Simulator Verification and Validation system:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. Real ESSI Simulator Verification examples:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
4. Real ESSI Simulator Validation examples:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.10 High Performance Computing

High Performance Computing (HPC) is helping with analysis of sophisticated models efficiently on sequential and parallel computers.

404.1.10.1 HPC Introduction

1. HPC, an Introduction:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
2. Fine grainded HPC:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
3. Coarse grainded HPC, a Distributed Memory Parallel (DMP) Introduction:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.10.2 HPC and Real-ESSI

1. Real-ESSI Simulator HPC Approach:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.10.3 Real-ESSI Parallel Computing Examples

1. Real-ESSI Simulator Parallel Examples:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

404.1.11 Real-ESSI Simulator Examples

Select Real-ESSI examples are shown in recorded lectures below:

1. How to run already installed Real-ESSI program on a simple example:
   MP4 recording and/or alternatively YouTube video
2. Running Real-ESSI program for a frame model:
   MP4 recording and/or alternatively YouTube video
3. Running Real-ESSI program for a elastic-plastic solids model:
   MP4 recording and/or alternatively YouTube video
4. Running Real-ESSI program for a solids, beams and shells model:
   MP4 recording and/or alternatively YouTube video
5. Post-processing Real-ESSI results using Paraview for frame model:
   MP4 recording and/or alternatively YouTube video
6. Post-processing Real-ESSI results using Paraview for a solids, beams and shells model:
   MP4 recording and/or alternatively YouTube video
7. Developing a DRM SSI model, solids and beams:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video
8. Running a DRM SSI model, solids and beams:
   PDF slides, and a direct MP4 recording and/or alternatively YouTube video

Chapter 405

Constitutive, Material Behaviour Examples

(2016-2017-2019-2023-)

(In collaboration with Dr. Yuan Feng and Dr. Han Yang)

405.1 Chapter Summary and Highlights

In this Chapter constitutive behavior of elastic-plastic material is illustrated through a number of examples.

All the examples described here, and many more, organized in sub-directories, for constitutive behavior, static and dynamic behavior can be directly downloaded from a repository at: `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_Examples/education_examples`. These examples can then be tried, analyzed using Real-ESSI Simulator that is available on Amazon Web Services (AWS) computers around the word. Login to AWS market place and search for Real-ESSI...

405.2 Elastic Solid Constitutive Examples

405.2.1 Linear Elastic Constitutive Examples

405.2.1.1 Pure Shear, Monotonic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type linear_elastic_isotropic_3d
   mass_density = 2E3 * kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio= 0.0 ;
simulate constitutive testing strain control pure shear monotonic loading use ↩
    material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   number_of_increment = 100;
bye;
```

Material Response:

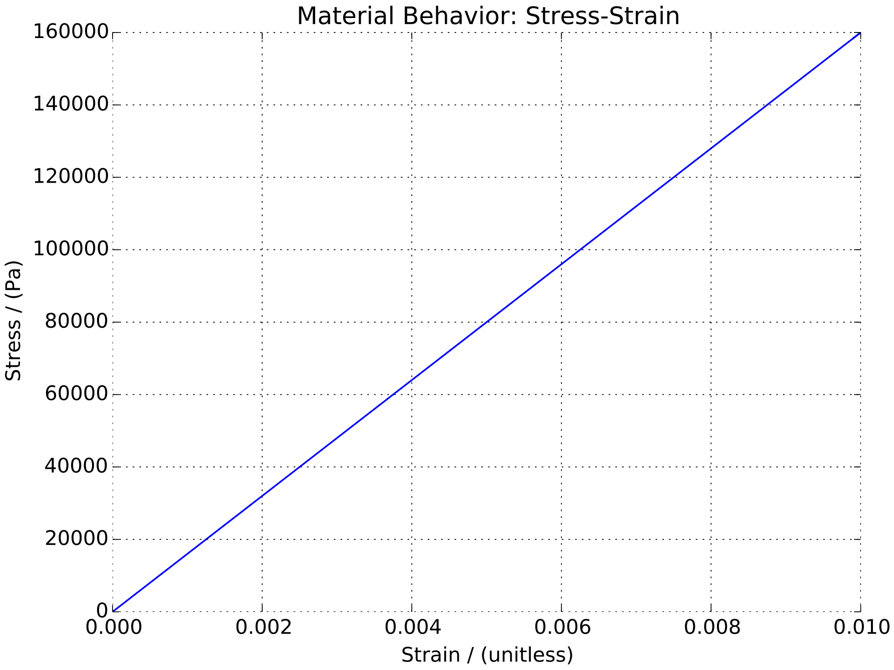

Figure 405.1: Linear Elastic Pure Shear Monotonic Loading

405.2.1.2 Pure Shear, Cyclic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type linear_elastic_isotropic_3d
   mass_density = 2E3 * kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio= 0.25 ;
simulate constitutive testing strain control pure shear cyclic loading use ↩
    material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   maximum_strain = 0.01
   number_of_cycles = 1;
bye;
```

Material Response:

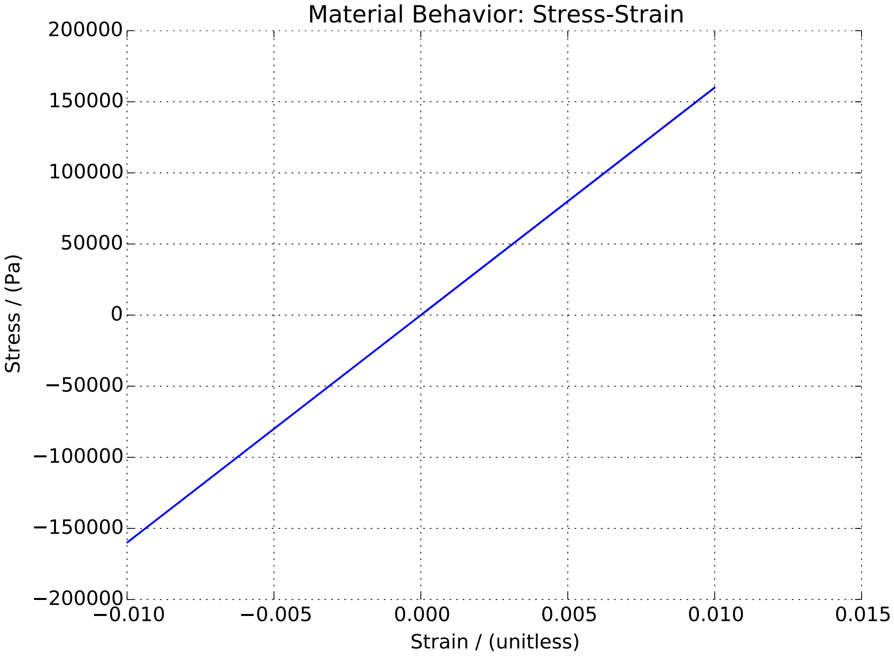

Figure 405.2: Linear Elastic Pure Shear Cyclic Loading.

405.2.1.3 Uniaxial Strain, Monotonic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type linear_elastic_isotropic_3d
   mass_density = 2E3 * kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio= 0.0 ;
simulate constitutive testing strain control uniaxial monotonic loading use ↩
    material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   number_of_increment = 100;
bye;
```

Material Response:

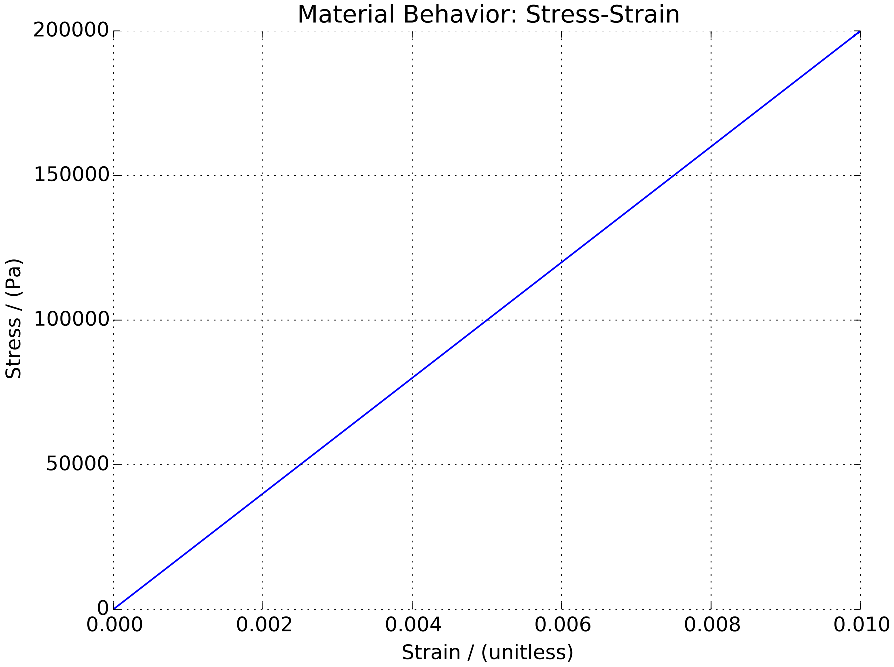

Figure 405.3: Linear Elastic Uniaxial Monotonic Loading

405.2.1.4 Uniaxial Strain, Cyclic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type linear_elastic_isotropic_3d
   mass_density = 2E3 * kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio= 0.25 ;
simulate constitutive testing strain control pure shear cyclic loading use ↩
    material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   maximum_strain = 0.01
   number_of_cycles = 1;
bye;
```

Material Response:

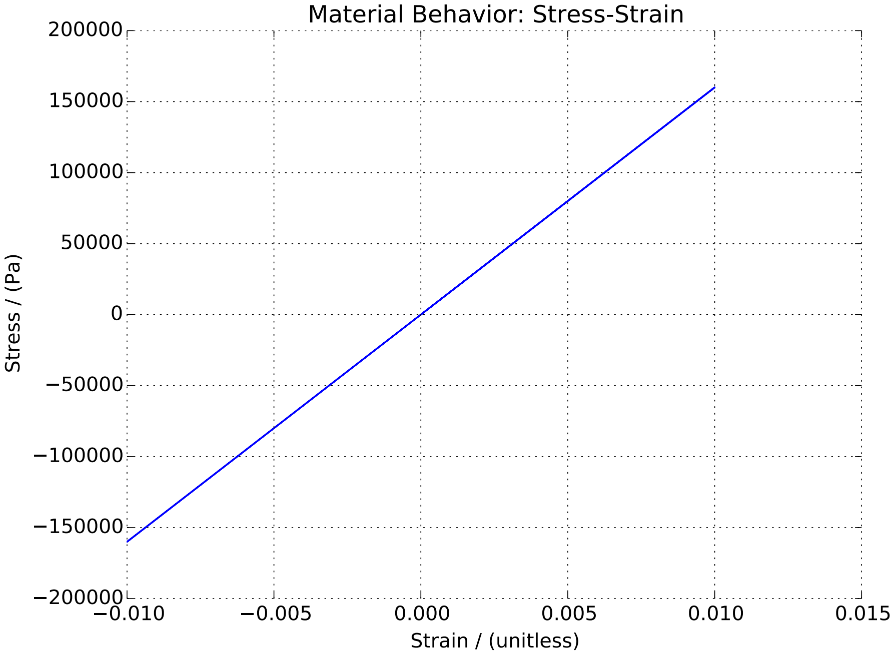

Figure 405.4: Linear Elastic Uniaxial Cyclic Loading

405.2.2 Nonlinear Elastic Constitutive Examples

405.2.2.1 Triaxial Uniform Pressure, Monotonic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The Duncan-Chang nonlinear elastic materials:

$$E = K p_a \left(\frac{\sigma_3}{p_a}\right)^n \tag{405.1}$$

where K and n are material constants. And pressure p_a is atmospheric pressure. And stress σ_3 is the minor principal stress.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type Duncan_Chang_nonlinear_elastic_isotropic_3d_LT
    mass_density = 2E3 * kg/m^3
    initial_elastic_modulus = 3E5 * Pa
    poisson_ratio= 0.15
    DuncanChang_K = 1E3
    DuncanChang_pa = 1E5 * Pa
    DuncanChang_n = 0.5 ;
simulate constitutive testing strain control triaxial confinement loading use ↩
    material # 1
    strain_increment_size = 0.00001
    maximum_strain = 0.01
    number_of_increment = 2000;
bye;
```

Material Response:

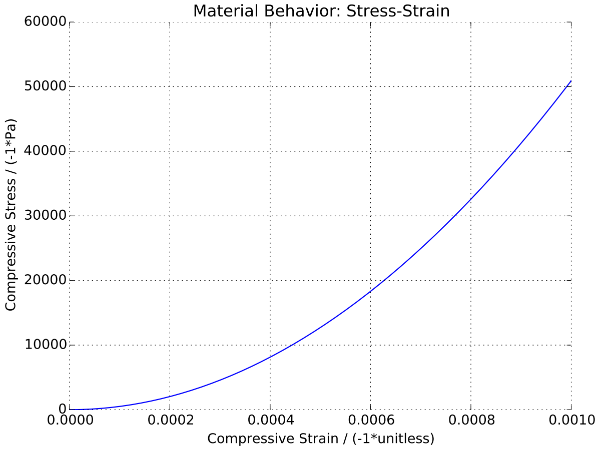

Figure 405.5: Results of Duncan-Chang Nonlinear Elastic Monotonic Loading

405.3 Elastic Plastic Solid Constitutive Examples

405.3.1 Elastic Perfectly Plastic Constitutive Examples

405.3.1.1 Pure Shear

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type VonMises
   mass_density = 2E3*kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio=0.25
   von_mises_radius = 1E5*Pa
   kinematic_hardening_rate = 0.0 *Pa
   isotropic_hardening_rate = 0.0*Pa ;
define NDMaterial constitutive integration algorithm Backward_Euler
   yield_function_relative_tolerance = 1E-2
   stress_relative_tolerance = 1E-3
   maximum_iterations = 30;
simulate constitutive testing strain control pure shear cyclic loading use ↩
    material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   maximum_strain = 0.01
   number_of_cycles = 1;
bye;
```

Material Response:

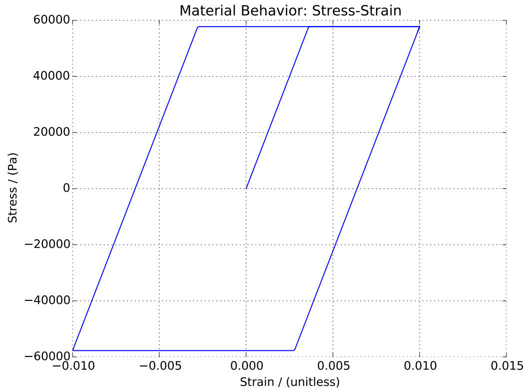

Figure 405.6: Perfectly Plastic Pure Shear Cyclic Loading.

405.3.1.2 Uniaxial Strain

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type VonMises
   mass_density = 2E3*kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio=0.25
   von_mises_radius = 1E5*Pa
   kinematic_hardening_rate = 0.0 *Pa
   isotropic_hardening_rate = 0.0*Pa ;
define NDMaterial constitutive integration algorithm Backward_Euler
   yield_function_relative_tolerance = 1E-2
   stress_relative_tolerance = 1E-3
   maximum_iterations = 30;
simulate constitutive testing strain control uniaxial cyclic loading use material # 1
   confinement_strain = 0.001
   strain_increment_size = 0.0001
   maximum_strain = 0.01
   number_of_cycles = 1;
bye;
```

Material Response:

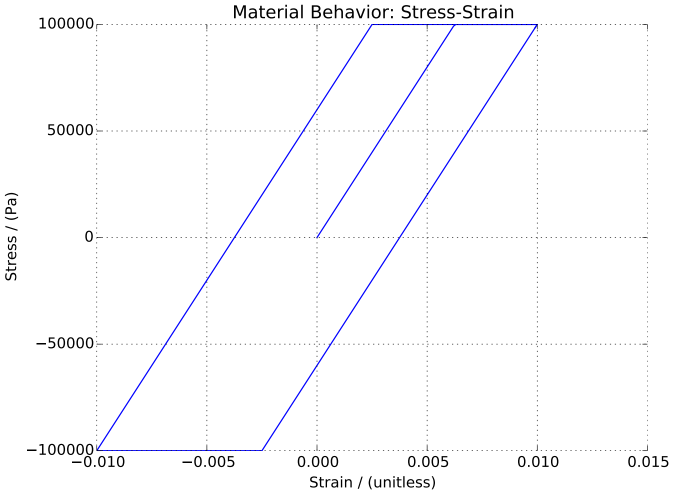

Figure 405.7: Perfectly Plastic Uniaxial Cyclic Loading

405.3.2 Elastic Plastic, Isotropic Hardening, Constitutive Examples

405.3.2.1 Pure Shear, Monotonic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Material properties in Real-ESSI input:

```
model name "test";
add material # 1 type VonMises
   mass_density = 2E3*kg/m^3
   elastic_modulus = 2E7 * Pa
   poisson_ratio=0.25
   von_mises_radius = 1E5*Pa
   kinematic_hardening_rate = 0.0*Pa
   isotropic_hardening_rate = 2E6 *Pa ;
define NDMaterial constitutive integration algorithm Backward_Euler
   yield_function_relative_tolerance = 1E-2
   stress_relative_tolerance = 1E-3
   maximum_iterations = 30;
simulate constitutive testing strain control pure shear monotonic loading use ↩

405.3.6 Elastic Plastic, SaniSAND, Constitutive Examples

405.3.6.1 Bardet Constraint Examples

The compressed package of Real-ESSI input files and postprocessing scripts and results for this example is available HERE. Material Response is shown in Figure 405.18

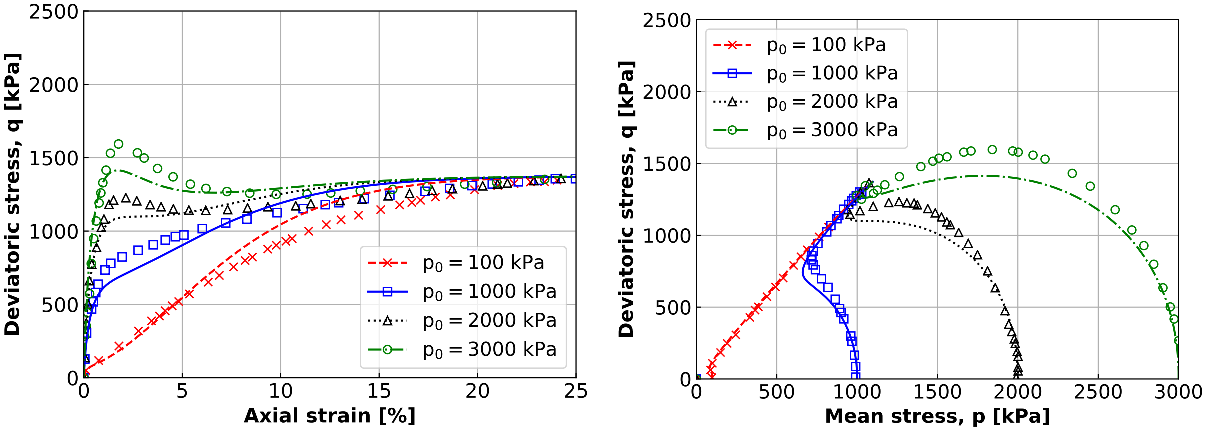

Figure 405.18: SaniSAND response.

405.4 Stiffness Reduction and Damping Curves Modeling

405.4.1 Multi-yield-surface von-Mises

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

405.4.1.1 Model description

This model illustrates the G/Gmax input to multi-yield-surface von-Mises material. This example is based on one Gauss-point with multi-yield-surface von-Mises material. The G/Gmax is converted to material modeling parameters (yield-surface size and hardening parameter) inside the DSL.

405.4.1.2 Real-ESSI input file

```
model name "test";
add material # 1 type vonMisesMultipleYieldSurfaceGoverGmax
   mass_density = 0.0*kg/m^3
   initial_shear_modulus = 3E8 * Pa
   poisson_ratio = 0.0
   total_number_of_shear_modulus = 9
   GoverGmax =
   "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
   ShearStrainGamma =
   "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01"
   ;
define NDMaterial constitutive integration algorithm Backward_Euler
    yield_function_relative_tolerance = 1E-6
    stress_relative_tolerance = 1E-6
    maximum_iterations = 30
    ;
incr_size = 0.000001 ;
max_strain= 0.005 ;
num_of_increm = max_strain/incr_size -1 ;
simulate constitutive testing strain control pure shear use material # 1
   confinement_strain = 0.0
   strain_increment_size = incr_size
   maximum_strain = max_strain
   number_of_increment = num_of_increm;
bye;
```

Material Response at Gauss Point:

Computed G/Gmax curve exactly matches the one used for input at control points.

The difference in G/Gmax between control points can be reduced by using more than just 9 control points as in this example.

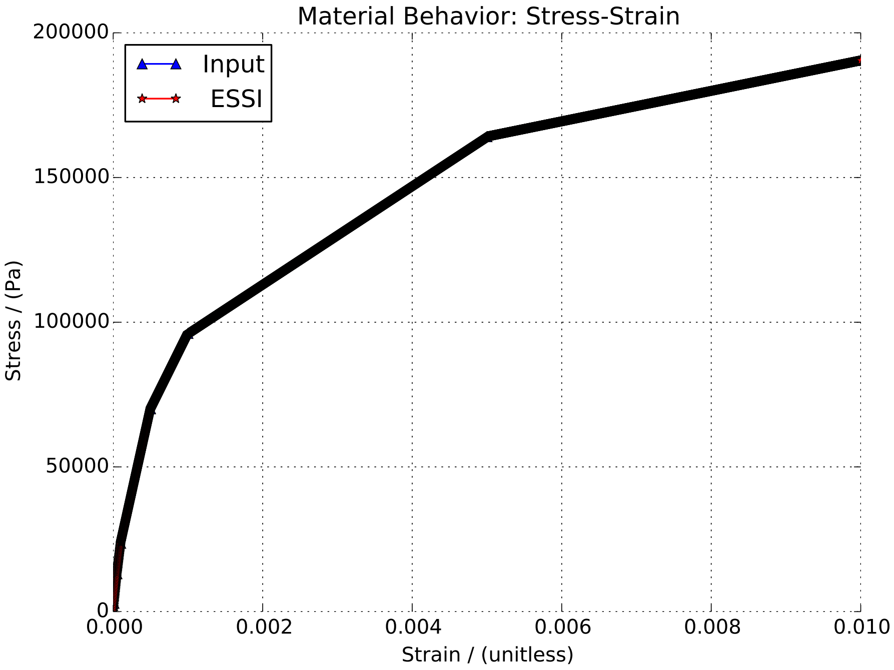

Figure 405.19: Stress-Strain Relationship

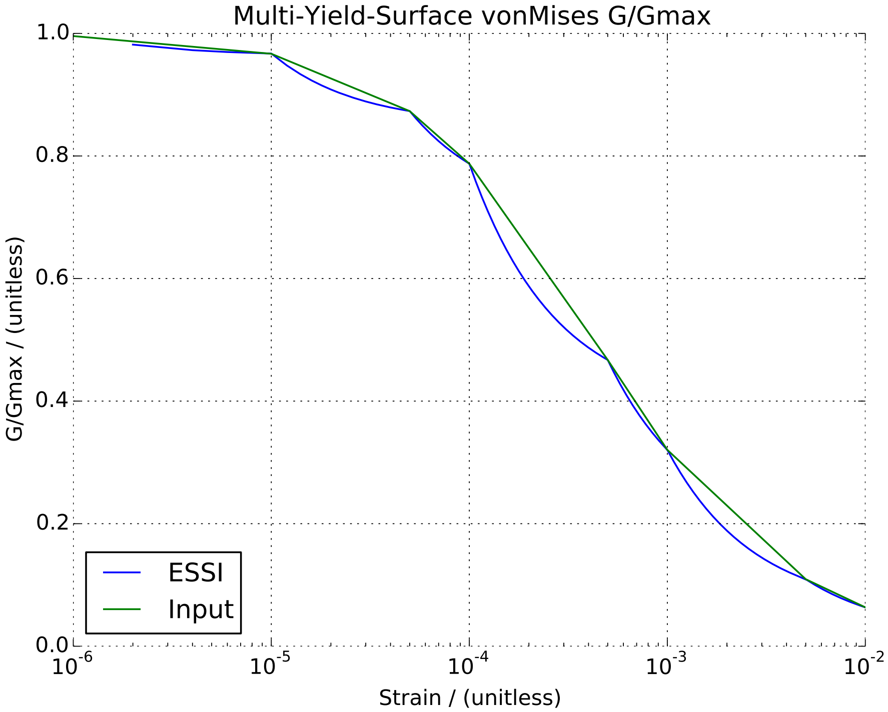

Figure 405.20: The G/Gmax results.

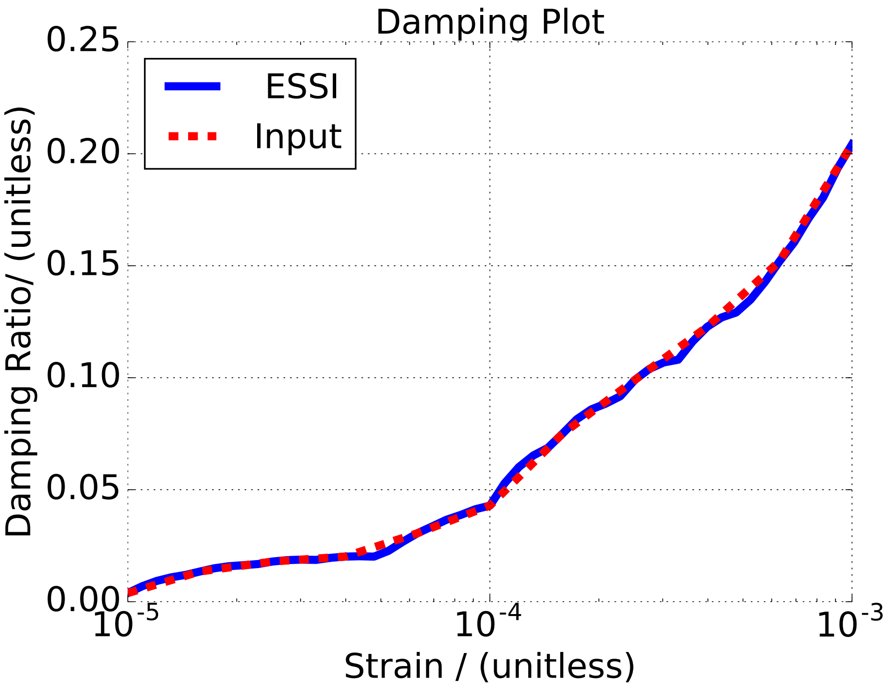

Figure 405.21: Damping Ratio Plot

405.4.2 Multi-yield-surface Drucker-Prager

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

405.4.2.1 Problem description

This model illustrates the G/Gmax input to multi-yield-surface Drucker-Prager material. Purely deviatoric plastic flow is used in this material, which means that the parameter dilation_scale is set to zero. If user wants to model change of volume (dilation or compression) for this material, then G/Gmax curve need to be iterated upon manually by changing yield surface size directly, which is done using different DruckerPragerMultipleYieldSurface command. This example is based on one Gauss-point which use multi-yield-surface Drucker-Prager material. The G/Gmax is converted to the yield-surface size and hardening parameter inside the DSL.

405.4.2.2 Real-ESSI input file:

```
model name "test";

add material # 1 type DruckerPragerMultipleYieldSurfaceGoverGmax
   mass_density = 0.0*kg/m^3
   initial_shear_modulus = 3E8 * Pa
   poisson_ratio = 0.0
   initial_confining_stress = 1E5 * Pa
   reference_pressure = 1E5 * Pa
   pressure_exponential_n = 0.5
   cohesion = 0. * Pa
   dilation_angle_eta =1.0
   dilation_scale = 0.0
   total_number_of_shear_modulus = 9
   GoverGmax =
   "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
   ShearStrainGamma =
   "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01"
   ;
define NDMaterial constitutive integration algorithm Backward_Euler
   yield_function_relative_tolerance = 1E-6
   stress_relative_tolerance = 1E-6
   maximum_iterations = 30;
simulate constitutive testing strain control pure shear use material # 1
   confinement_strain = 0.0
   strain_increment_size = 0.000001
   maximum_strain = 0.005
   number_of_increment = 0.005 / 0.000001 -1 ;
bye;
```

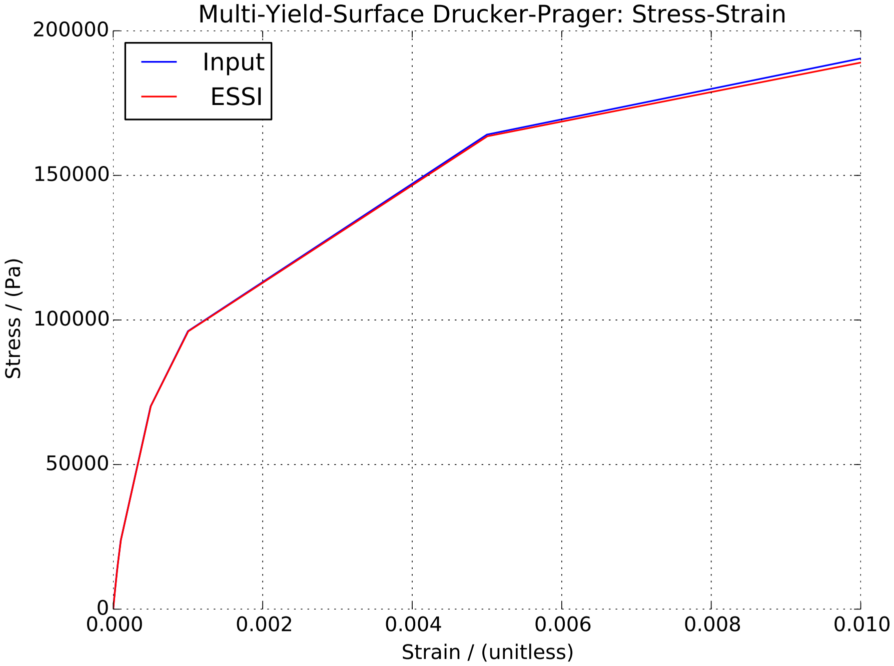

Figure 405.22: Nested-Yield-Surface Drucker-Prager Stress-Strain Relationship

Inside the DSL, the yield surface radius is calculated as $\sqrt{3}\sigma_y$, where σ_y is the yield stress of the corresponding yield surface. Then, the radius is divided by the confinement to obtain the slope (opening angle).

The hardening parameter is calculated as

$$\frac{1}{H_i'} = \frac{1}{H_i} - \frac{1}{2G} \tag{405.2}$$

where H_i' is the current hardening parameter corresponding to yield surface i. H_i is the current tangent shear modulus to surface i, namely, $H_i = 2(\tau_{i+1} - \tau_i)/(\gamma_{i+1} - \gamma_i)$. And G is the initial shear modulus.

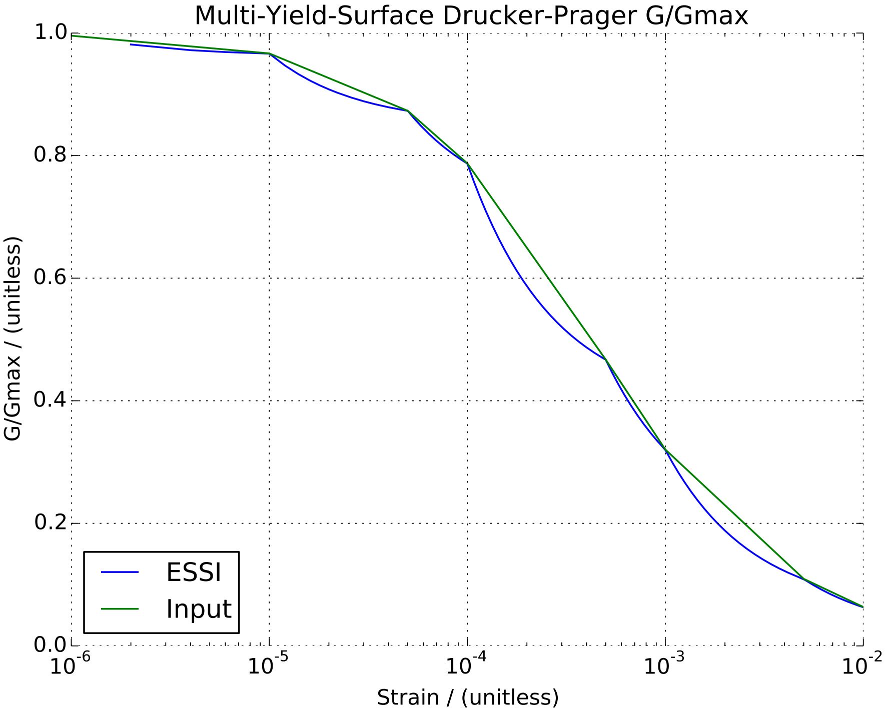

Figure 405.23: Nested-Yield-Surface Drucker-Prager G/Gmax results

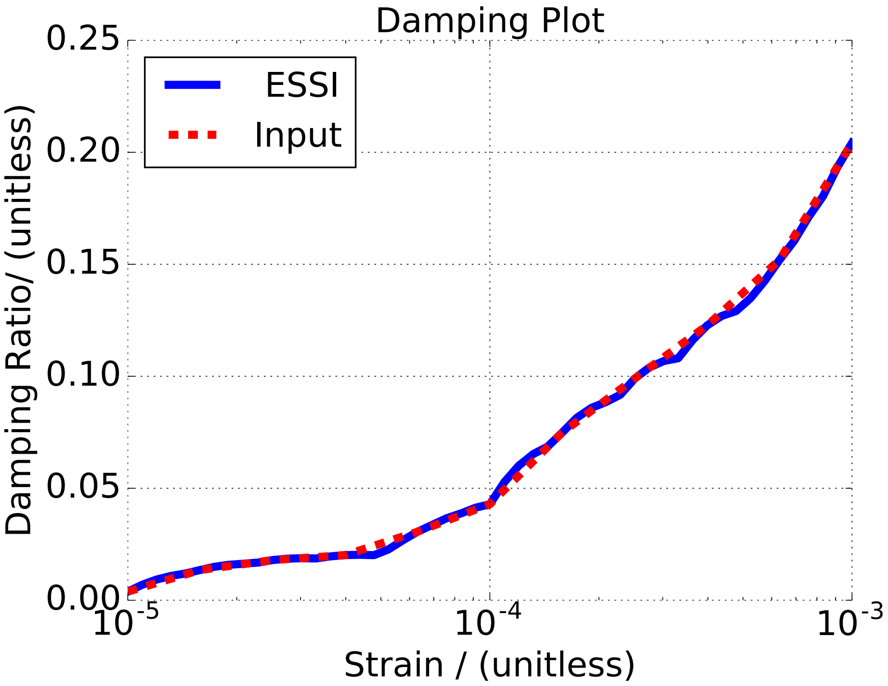

Figure 405.24: Damping Ratio Plot

405.4.3 Simulate Stiffness Reduction using von-Mises Armstrong-Frederick

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

405.4.3.1 Model description

This model illustrates the simulation of stiffness reduction using von-Mises Armstrong-Frederick. This example is based on one Gauss-point.

405.4.3.2 Real-ESSI input file:

```
model name "test";

add material # 1 type vonMisesArmstrongFrederick
    mass_density = 2500.0*kg/m^3
    elastic_modulus = 3E7*N/m^2
    poisson_ratio = 0.2
    von_mises_radius = 300 * Pa
    armstrong_frederick_ha = 5*3E7*N/m^2
    armstrong_frederick_cr = 25000
    isotropic_hardening_rate = 0*Pa
    ;
define NDMaterial constitutive integration algorithm Backward_Euler
    yield_function_relative_tolerance = 1E-6
    stress_relative_tolerance = 1E-6
    maximum_iterations = 30
    ;
incr_size = 0.000001 ;
max_strain= 0.005 ;
num_of_increm = max_strain/incr_size -1 ;
simulate constitutive testing strain control pure shear use material # 1
 confinement_strain = 0.0
 strain_increment_size = incr_size
 maximum_strain = max_strain
 number_of_increment = num_of_increm;
bye;
```

The von-Mises Armstrong-Frederick material behavior matches the stiffness reduction curve.

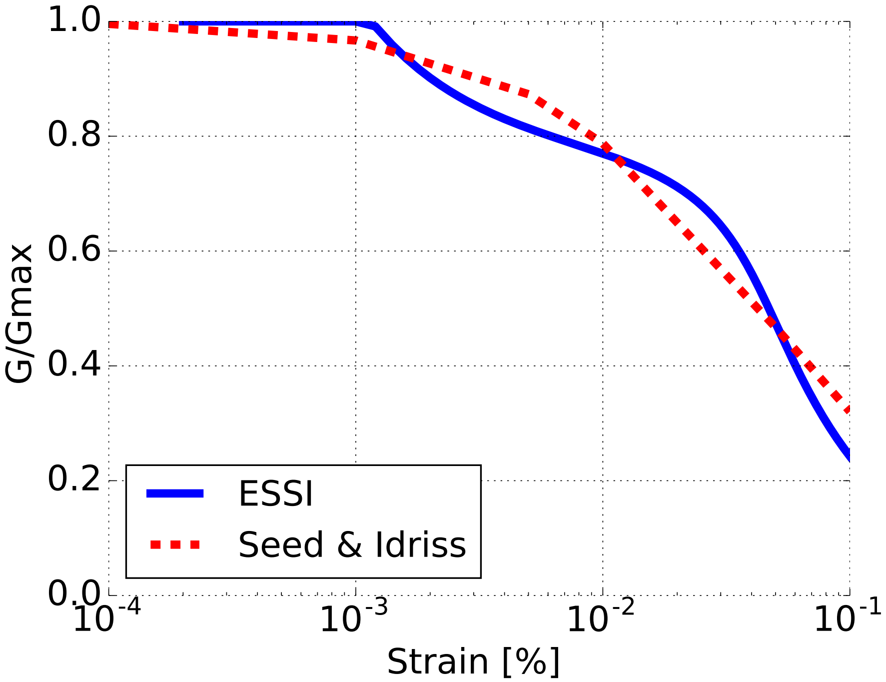

Figure 405.25: The stiffness reduction results.

Chapter 406

Static Examples

(2016-2017-2019-2021-)

(In collaboration with Prof. José Abell, Dr. Yuan Feng, Mr. Sumeet Kumar Sinha, and Dr. Han Yang)

406.1 Chapter Summary and Highlights

In this Chapter static modeling and simulation of solids and structures is illustrated through a number of examples.

All the examples described here, and many more, organized in sub-directories, for constitutive behavior, static and dynamic behavior can be directly downloaded from a repository at: `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_Examples/education_examples`. These examples can then be tried, analyzed using Real-ESSI Simulator that is available on Amazon Web Services (AWS) computers around the word. Login to AWS market place and search for Real-ESSI...

406.2 Static Elastic Solid Examples

406.2.1 Statics, Bricks, with Nodal Forces

406.2.1.1 Statics, 8 Node Brick, with Nodal Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with a nodal force at the tip. Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (406.1).

The mesh is generated with elastic 8 node brick.

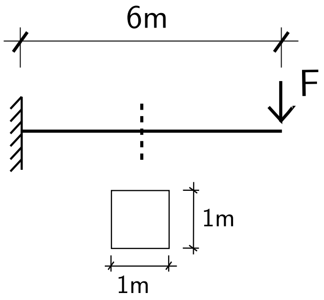

Figure 406.1: Problem description for cantilever beams.

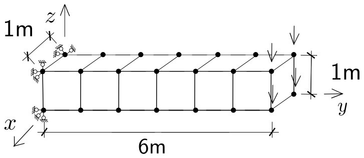

Figure 406.2: Six 8NodeBrick elements.

406.2.1.2 Statics, 27 Node Brick, with Nodal Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with a nodal force at the tip. Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (406.3).

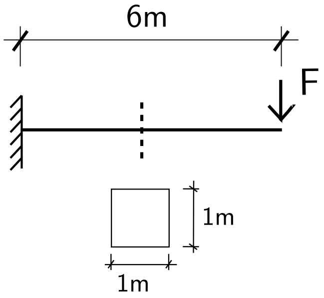

Figure 406.3: Problem description for cantilever beams.

The mesh is generated with elastic 27 node brick.

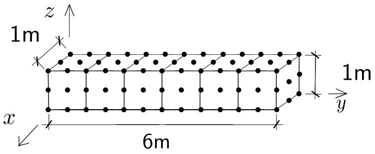

Figure 406.4: Six 27NodeBrick elements.

406.2.1.3 Statics, 8-27 Node Brick, with Nodal Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with a nodal force at the tip. Length=2m, Width=2m, Height=2m, $\nu = 0.0$. The force direction was shown in Figure (406.5).

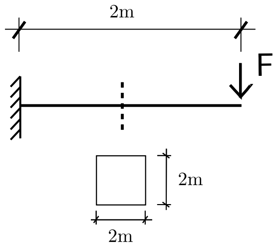

Figure 406.5: Problem description for cantilever beams.

The mesh is generated with an elastic 8-27 node brick. As shown in the Figure 406.16, some of the nodes are missing on purpose. The variable node brick element is usually used as the transition mesh between 8 node brick and 27 node brick.

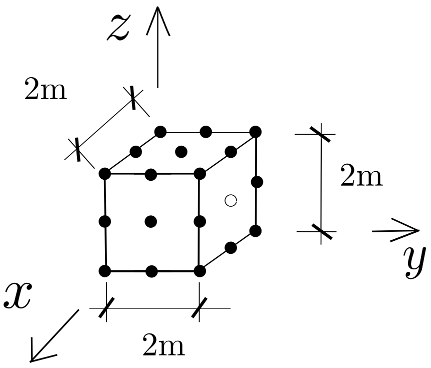

Figure 406.6: One 8-27 Node elements.

406.2.2 Statics, Bricks, with Surface Loads

406.2.2.1 Statics, 8 Node Brick, with Surface Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with the load on one surface. Length=2m, Width=2m, Height=2m, $\nu = 0.0$. The force distribution was shown in Figure (406.7).

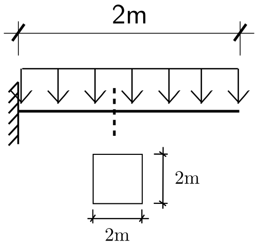

Figure 406.7: Problem description for cantilever beams.

The mesh is generated with an elastic 8 node brick.

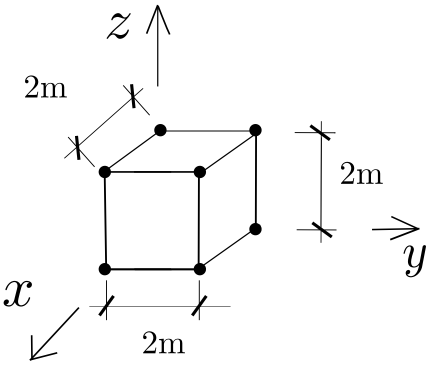

Figure 406.8: One element with surface load.

406.2.2.2 Statics, 27 Node Brick, with Surface Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with the load on one surface. Length=2m, Width=2m, Height=2m. The force distribution was shown in Figure (406.9).

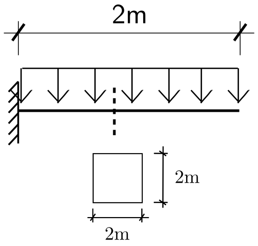

Figure 406.9: Problem description for cantilever beams.

The mesh is generated with an elastic 27 node brick.

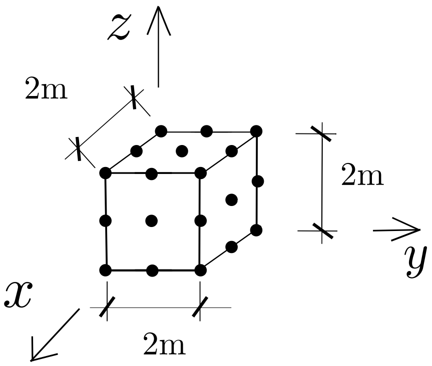

Figure 406.10: One element with surface load.

406.2.3 Statics, Bricks, with Body Forces

406.2.3.1 Statics, 8 Node Brick, with Body Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with self weight on the whole element. Length=6m, Width=1m, Height=1m, $\nu = 0.3$. The force direction was shown in Figure (406.11).

The mesh is generated with an elastic 8 node brick.

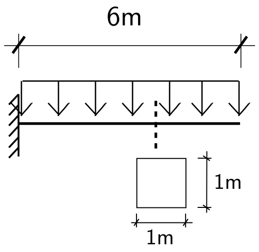

Figure 406.11: Problem description for cantilever beams.

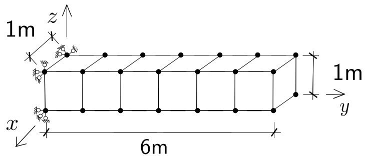

Figure 406.12: Six 8NodeBrick elements.

406.2.3.2 Statics, 27 Node Brick, with Body Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with self weight on the whole element. Length=6m, Width=1m, Height=1m, $\nu = 0.3$. The force direction was shown in Figure (406.13).

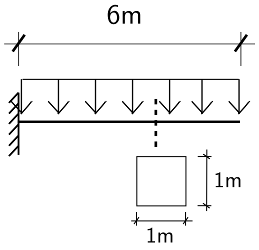

Figure 406.13: Problem description for cantilever beams.

The mesh is generated with an elastic 27 node brick.

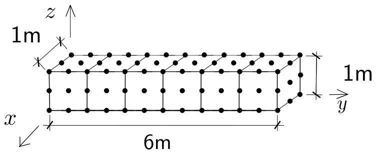

Figure 406.14: Six 27NodeBrick elements.

406.2.3.3 Statics, 8-27 Node Brick, with Body Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with self weight on the whole element. Length=2m, Width=2m, Height=2m, $\nu = 0.3$. The force direction was shown in Figure (406.15).

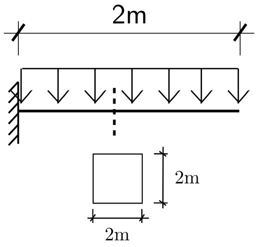

Figure 406.15: Problem description for cantilever beams.

The mesh is generated with an elastic 8-27 node brick. As shown in the Figure 406.16, some of the nodes are missing on purpose. The variable node brick element is usually used as the transition mesh between 8 node brick and 27 node brick.

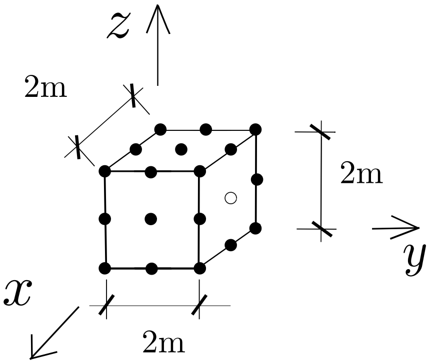

Figure 406.16: One variable Node Brick elements.

406.3 Static Elastic Structural Examples

406.3.1 Statics, Truss, with Nodal Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with the nodal load on the tip. Length=1m, Cross Section=$1m^2$. The cross section shape is not necessarily a square. The force direction was shown in Figure (406.17). Truss only takes axial force.

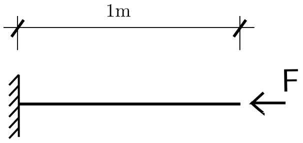

Figure 406.17: Problem description for a cantilever.

406.3.2 Statics, Elastic Beam, with Nodal Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with nodal load on the tip. Length=1m, Width=1m, Height=1m, E=1Pa. The force direction was shown in Figure (406.18).

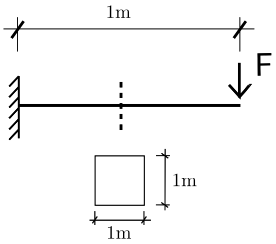

Figure 406.18: Problem description for cantilever beams.

406.3.3 Statics, Elastic Beam, with Body Forces

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with self weight. Length=1m, Width=1m, and Height=1m. The force direction was shown in Figure (406.19).

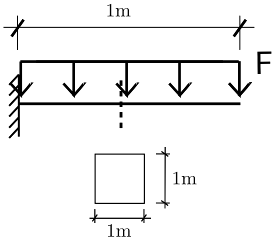

Figure 406.19: Problem description for cantilever beams.

406.3.4 Statics, ShearBeam Element

406.3.4.1 Problem description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

In the element type "ShearBeam", only one Gauss point exists. ShearBeam element was used here to test the von Mises Armstrong-Frederickó material model. Vertical force F_z was used to apply confinement to the element. Then, cyclic force F_x is used to load. Usually, pressure-dependent materials, like Drucker-Prager, require the confinement. The pressure-independent materials, like von Mises, do not require the confinement.

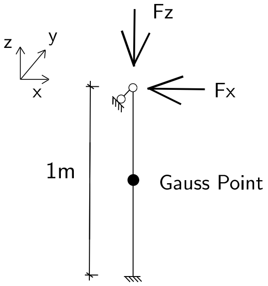

Figure 406.20: ShearBeam element.

406.3.4.2 Results

Resulting stress-strain relationship is shown in Fig.(707.51).

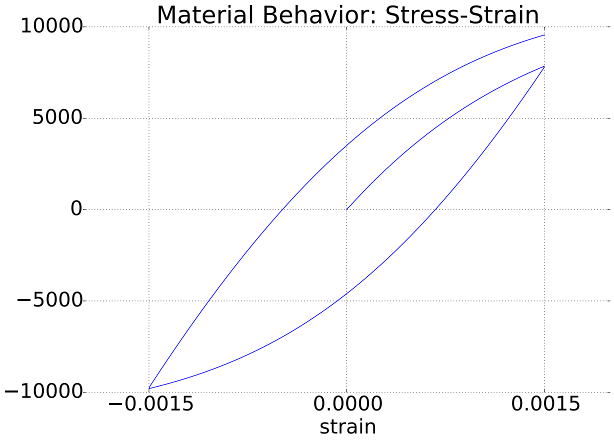

Figure 406.21: Shear stress-strain response.

406.3.5 Statics, Elastic Shell, with Nodal Forces

406.3.5.1 ANDES Shell, out of Plane Force

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$.

The force direction was shown in Figure (406.22).

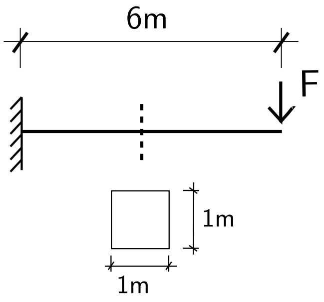

Figure 406.22: Problem description for cantilever beams.

406.3.5.2 ANDES Shell, Perpendicular to Plane, bending

The mesh and the out-of-plane force is shown in Fig. 406.23.

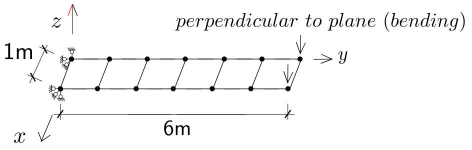

Figure 406.23: Six 4NodeANDES elements.

406.3.5.3 ANDES Shell, In-plane Force

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with a nodal force at the tip. Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (406.24).

The mesh and the inplane force is shown in Fig. 406.25.

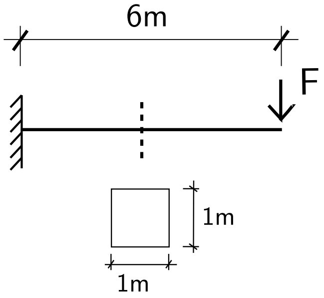

Figure 406.24: Problem description for cantilever beams.

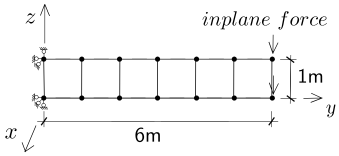

Figure 406.25: Six 4NodeANDES elements.

406.3.6 Statics, Elastic Shell, with Body Forces

406.3.6.1 ANDES shell under the out-of-Plane Body Force

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (406.26).

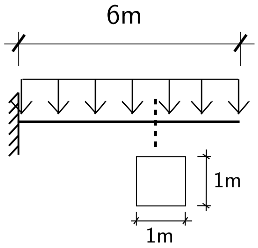

Figure 406.26: Problem description for cantilever beams.

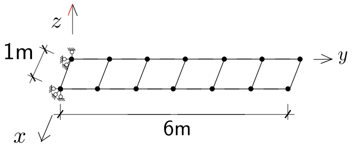

Figure 406.27: Six 4NodeANDES elements.

406.3.6.2 ANDES Shell, In-plane Body Force

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Problem description: a cantilever with a nodal force at the tip. Length=6m, Width=1m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.0$. The force direction was shown in Figure (406.28).

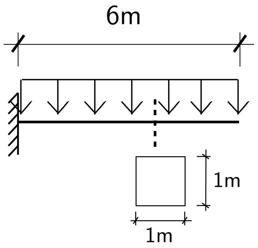

Figure 406.28: Problem description for cantilever beams.

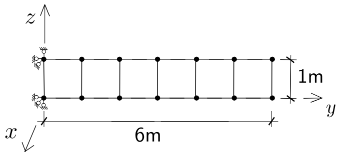

Figure 406.29: Six 4NodeANDES elements.

406.4 Statics, Interface/Contact Elements

406.4.1 Statics, Two Bar Normal Interface/Contact Problem Under Monotonic Loading.

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

This is an example of normal monotonic loading on a 1-D contact/interface between two bars separated by an initial gap of 0.1 unit. An illustrative diagram of the problem statement is shown below.

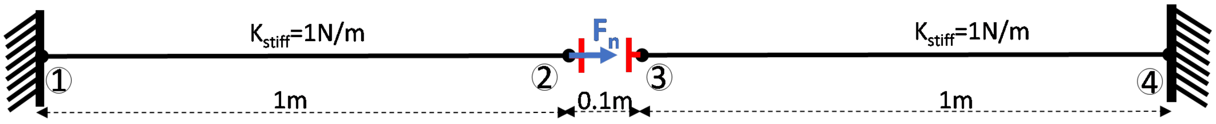

Figure 406.30: Illustration of Two Bar Normal Interface/Contact Problem under monotonic loading with initial gap.

The displacement output of *Node 2 and Node 3* are shown below.

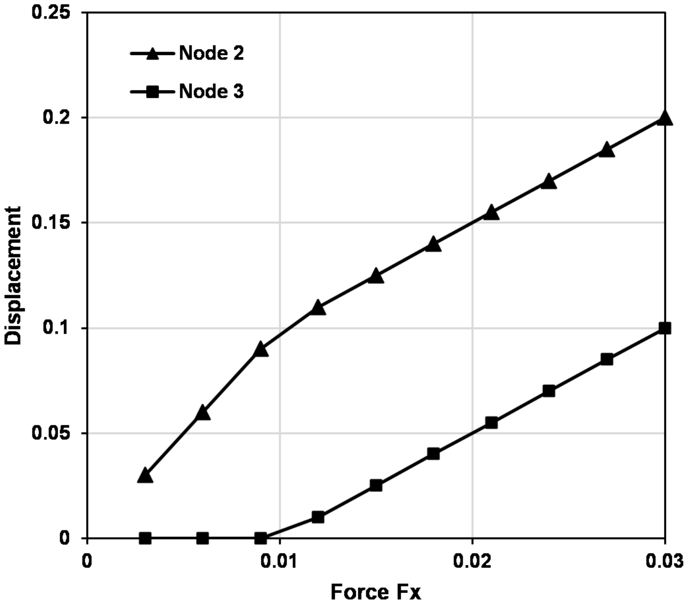

Figure 406.31: Displacement of Nodes 2 and 3.

406.4.2 Statics, Four Bar Interface/Contact Problem With Normal and Shear Force Under Monotonic Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

This is an example to show the normal and tangential behavior (stick and slip case) of contacts using four bars in 2-D plane. The bars in x-directions are in contact/interface (initial gap=0).

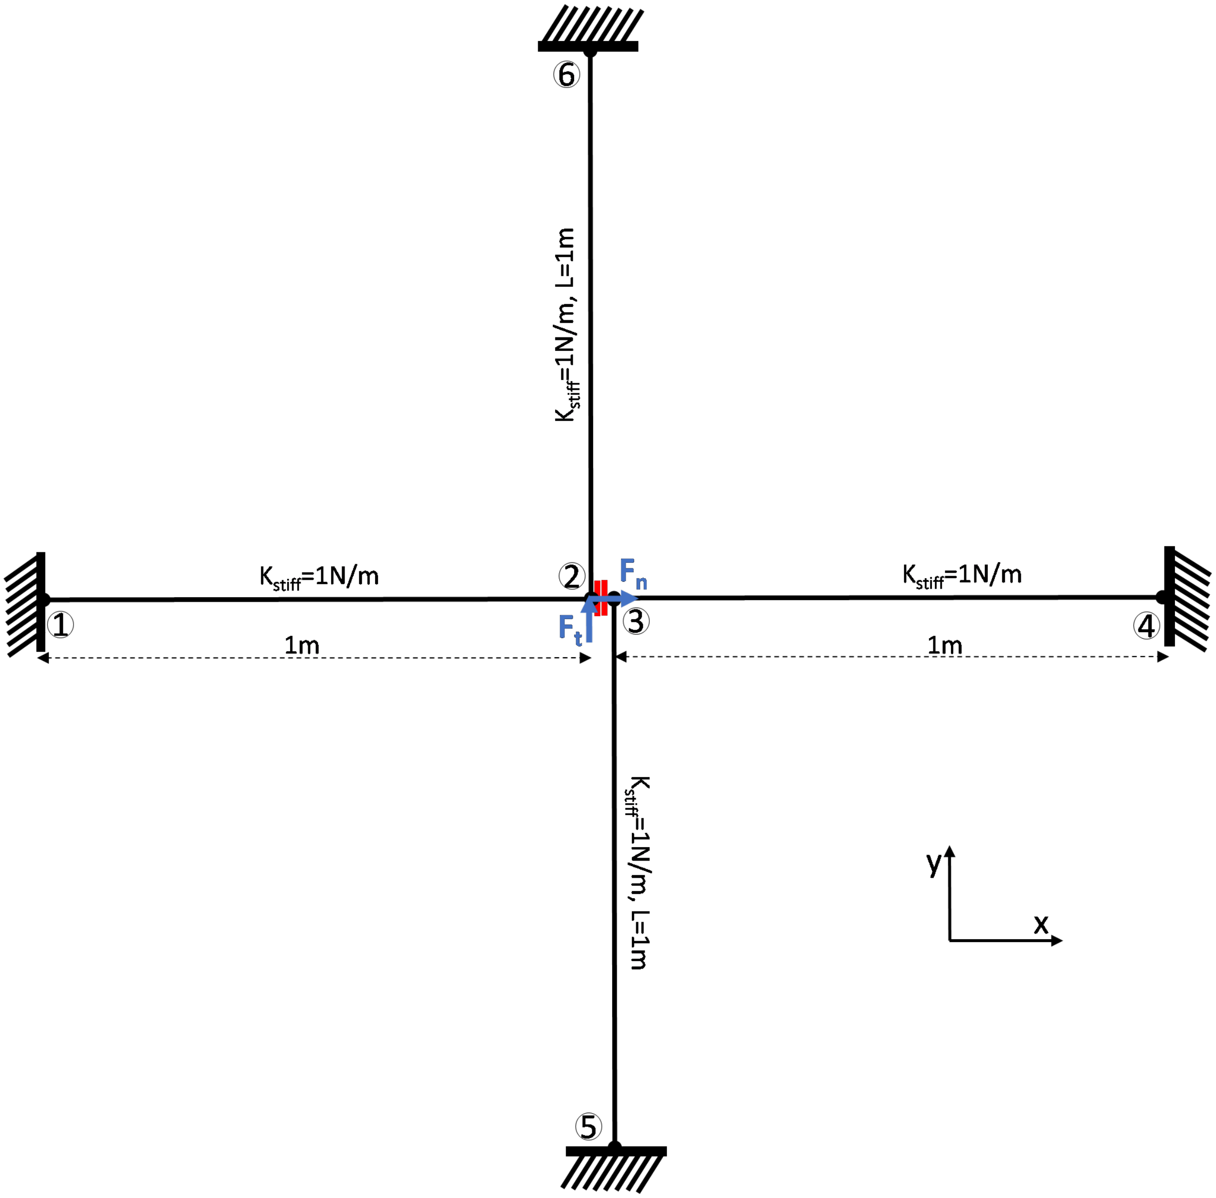

Figure 406.32: Illustration of Four Bar Normal Interface/Contact Problem With Normal and Shear Force Under Monotonic Loading with no initial gap.

The displacement output of *Node 2 and Node 3* are shown below.

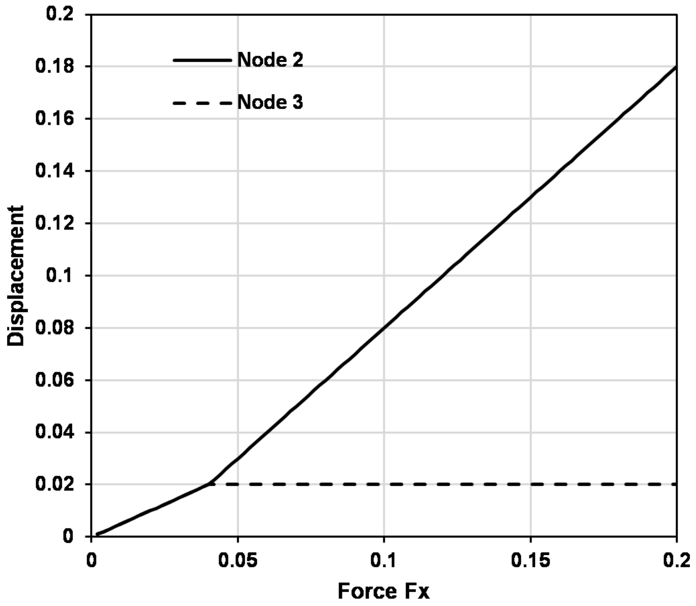

Figure 406.33: Displacement of Nodes 2 and 3 along y direction.

406.4.3 Statics, 3-D Truss example with normal confinement and Shear Loading

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

A simple 3-D truss example with Normal confinement in z-direction of $F_N = 0.5N$, friction coefficient $\mu = 0.2$ and shear loading of magnitude $F_s = 0.5N$. Figure 707.57 below, shows the description of the problem.

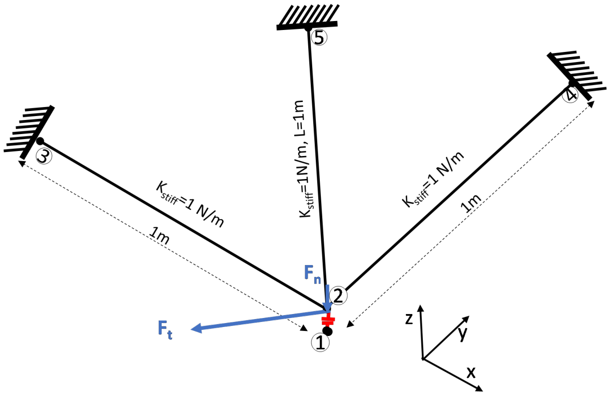

Figure 406.34: Illustration of 3-D Truss Problem with confinement loading in z-direction of 0.5N and then shear loading of 0.5N in x-y plane.

The generalized displacement response of the tangential loading stage is shown below.

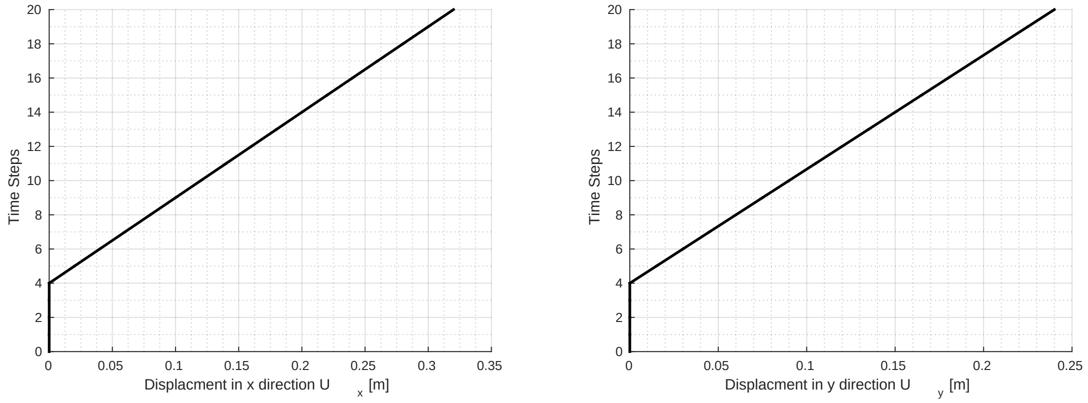

Figure 406.35: Displacements of Node 2 with applied shear tangential load step.

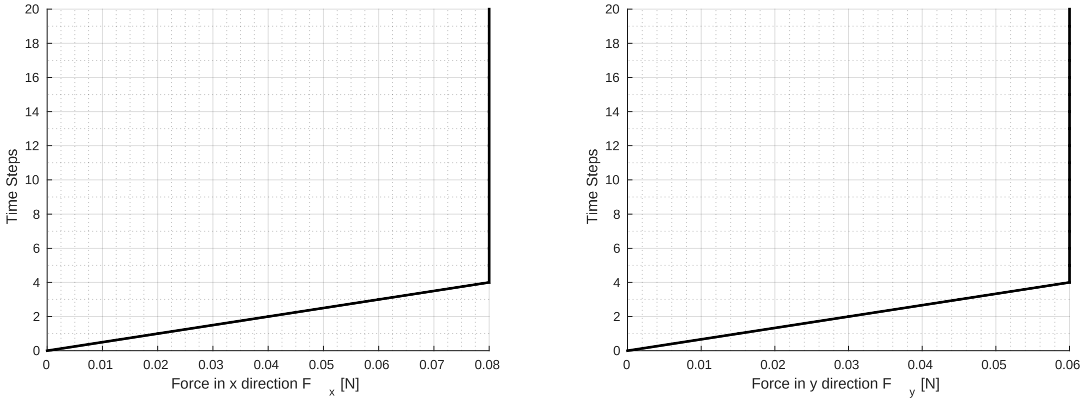

Figure 406.36: Resisting force by the contact/interface element with applied shear tangential load step.

406.4.4 Statics, Six Solid Blocks Example With Interface/Contact

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

This is a 3-D solid block example with initial normal and then tangential load on different surfaces as shown below.

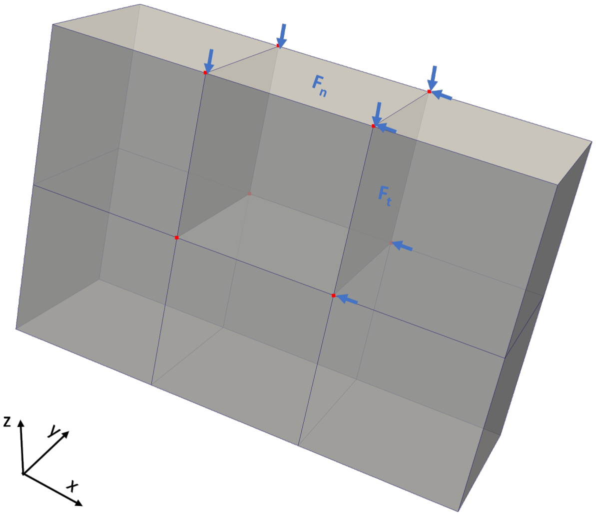

Figure 406.37: Illustration of Six Solid Blocks Example with Interface/Contact with first normal and then tangential loading stages.

The generalized displacement field of the two loading stages `normal loading` and *tangential loading* is shown below..

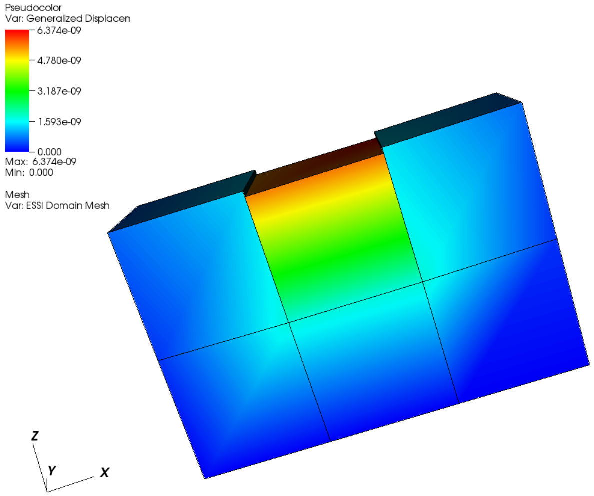

Figure 406.38: Generalized displacement magnitude visualization of normal loading.

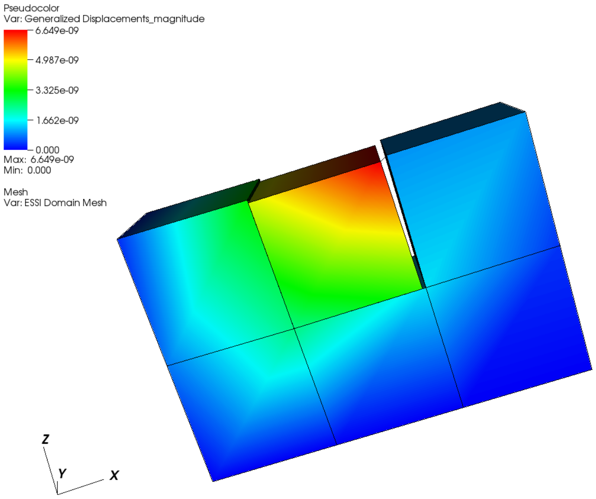

Figure 406.39: Generalized displacement magnitude visualization of tangential loading.

406.5 Static Inelastic Solid Examples

406.5.1 Statics, Bricks, Elastic-Plastic, von Mises, with Nodal Forces

406.14.2 Statics, 4NodeANDES Square Plate, Four Edges Clamped

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

406.14.2.1 Problem description

Length=20m, Width=20m, Height=1m, Force=100N, E=1E8Pa, $\nu = 0.3$.

The four edges are clamped.

The load is a self weight.

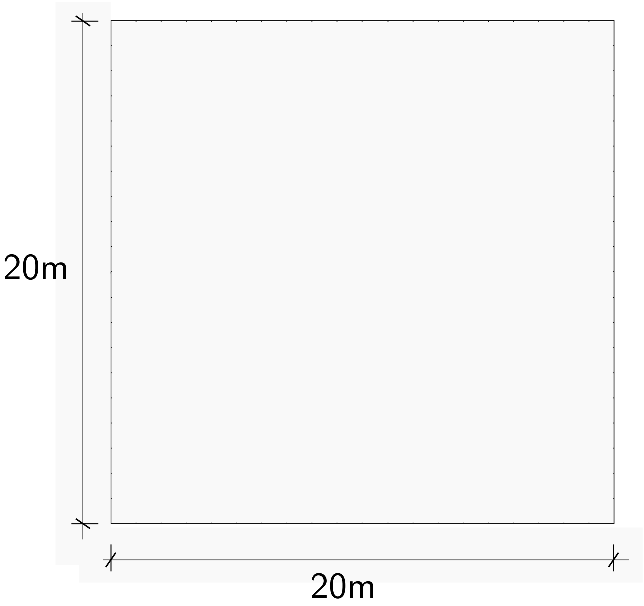

Figure 406.101: Square plate with four edges clamped.

406.14.2.2 Numerical model

The element side length is 1 meter.

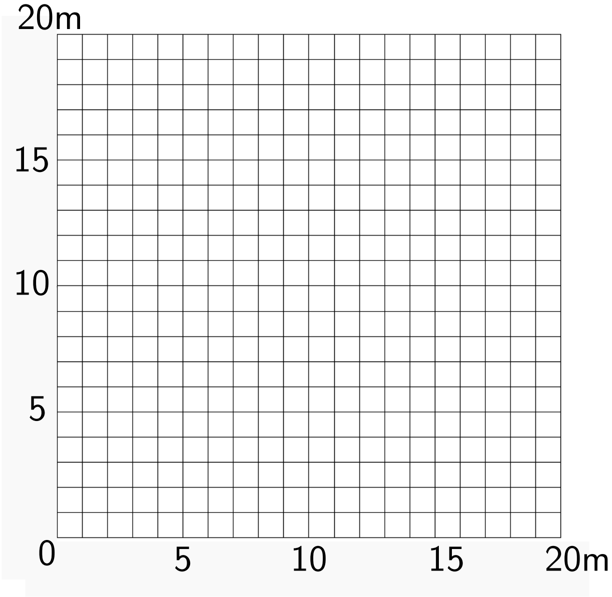

Figure 406.102: 4NodeANDES edge clamped square plate with element side length 1m.

406.14.3 Statics, Six Solid Blocks Example With Interface/Contact

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

This is a 3-D solid block example with initial normal and then tangential load on different surfaces as shown below.

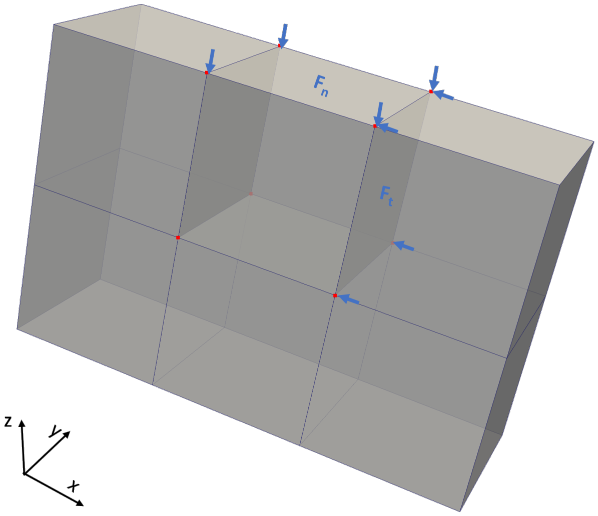

Figure 406.103: Illustration of Six Solid Blocks Example with Interface/Contact with first normal and then tangential loading stages.

The generalized displacement field of the two loading stages normal loading and tangential loading is shown below..

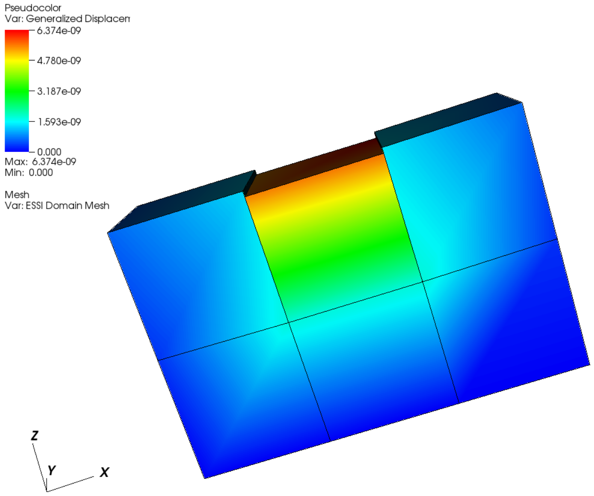

Figure 406.104: Generalized displacement magnitude visualization of normal loading.

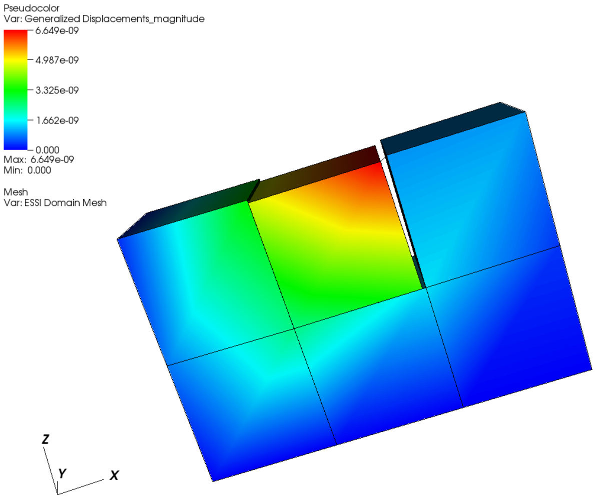

Figure 406.105: Generalized displacement magnitude visualization of tangential loading.

Chapter 407

Dynamic Examples

(2016-2017-2018-2019-2021-)

(In collaboration with Prof. José Abell, Dr. Yuan Feng, Mr. Sumeet Kumar Sinha, Dr. Hexiang Wang, and Dr. Han Yang)

407.1 Chapter Summary and Highlights

In this Chapter dynamic/transient modeling and simulation of solids and structures is illustrated through a number of examples.

All the examples described here, and many more, organized in sub-directories, for constitutive behavior, static and dynamic behavior can be directly downloaded from a repository at: `http://sokocalo.engr.ucdavis.edu/~jeremic/lecture_notes_online_material/Real-ESSI_Examples/education_examples`. These examples can then be tried, analyzed using Real-ESSI Simulator that is available on Amazon Web Services (AWS) computers around the word. Login to AWS market place and search for Real-ESSI...

407.2 Dynamic Solution Advancement (in Time)

407.2.1 Dynamics: Newmark Method

407.2.1.1 Newmark Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at one side. Second, the model starts free vibration.

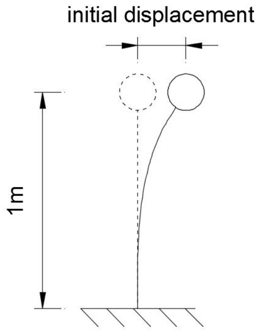

Figure 407.1: Problem Description for Newmark Method

407.2.1.2 Newmark Results

With damping, the displacement peak is smaller and smaller. The displacement at the top is

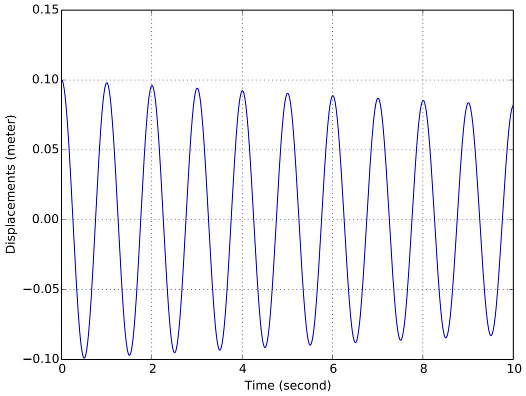

Figure 407.2: Results for Newmark Method

407.2.2 Dynamics: Hilber-Hughes-Taylor (α) Method

407.2.2.1 HHT Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at one side. Second, the model starts free vibration.

407.2.2.2 HHT Results

With NO damping, the displacement peak keeps the same. The displacement at the top is

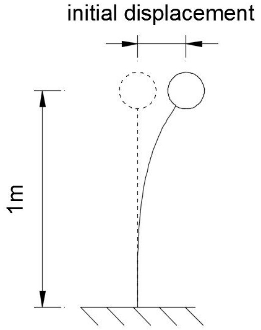

Figure 407.3: Problem Description for HHT Method

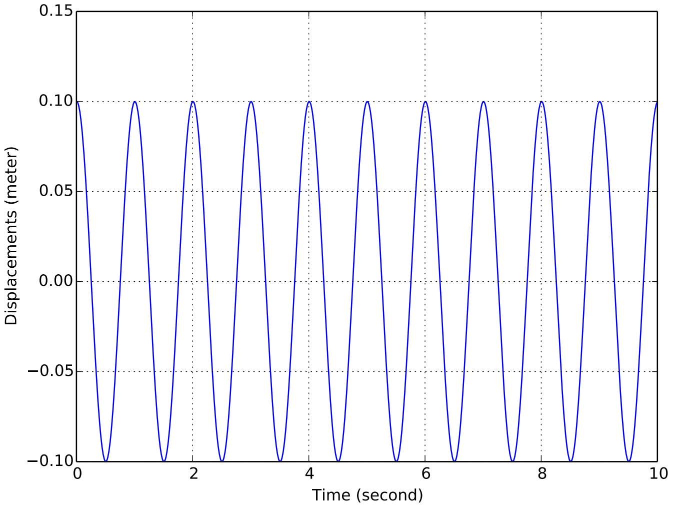

Figure 407.4: Results for HHT Method

407.3 Dynamics: Solution Advancement: Time Step Size

407.3.1 Dynamics: Solution Advancement: Equal Time Step

407.3.1.1 Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is given an earthquake input motion at the bottom with equal time step. After the wave propagation, the motion at the top is recorded.

407.3.1.2 Results

The input motion is on the left, while the output motion is on the right.

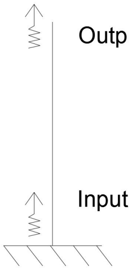

Figure 407.5: Problem Description for Solution Advancement

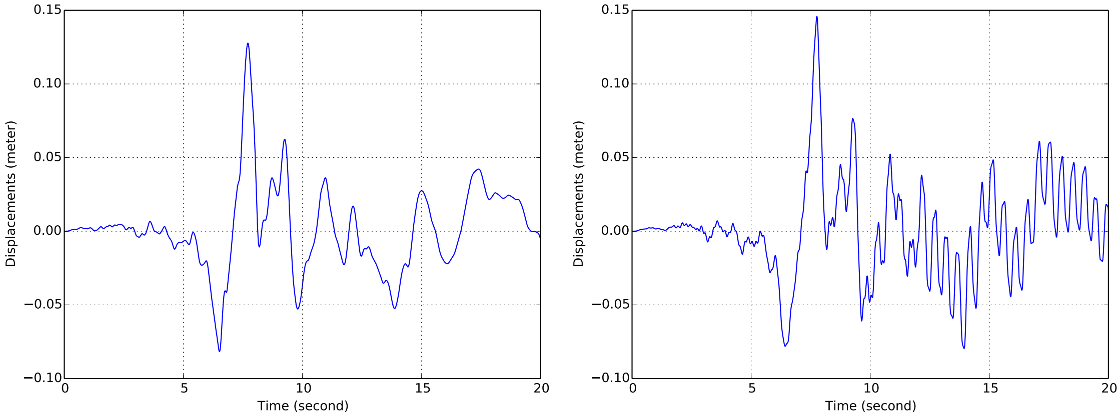

Figure 407.6: Input Motion (Left) And Output Motion (Right)

407.3.2 Dynamics Solution Advancement: Variable Time Step

407.3.2.1 Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is given an earthquake input motion at the bottom with variable time step. After the wave propagation, the motion at the top is recorded.

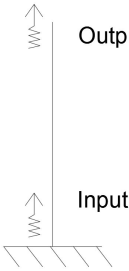

Figure 407.7: Problem Description for Newmark Method

407.3.2.2 Results

The input motion is on the left, while the output motion is on the right. The input motion is in variable time step. As shown in Fig 407.8, from time 10-11 second, the input motion is a straight line (a big time step) without the small time steps.

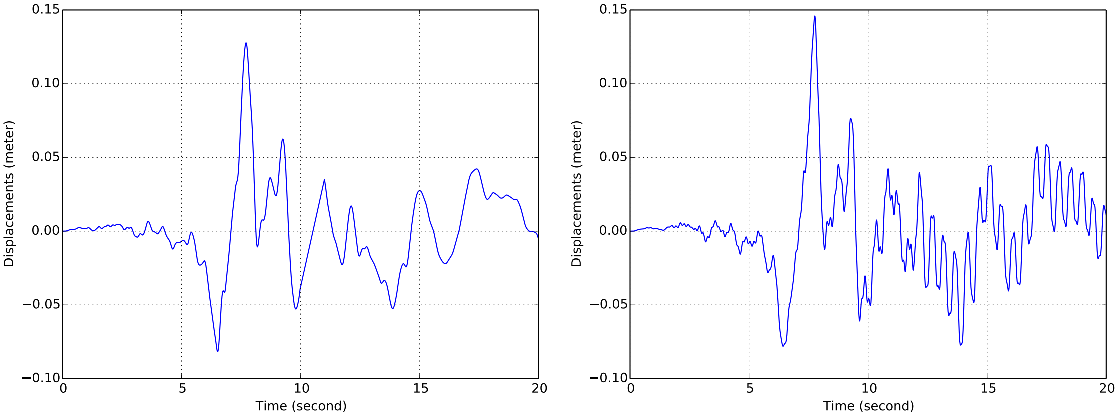

Figure 407.8: Input Motion (Left) And Output Motion (Right)

407.4 Dynamics: Energy Dissipation, Damping

407.4.1 Dynamics: Energy Dissipation: Viscous Damping

407.4.1.1 Dynamics: Energy Dissipation, Viscous Damping: Rayleigh Damping

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at the top from 0 to 1 second. Second, after the time 1 second, the model starts free vibration.

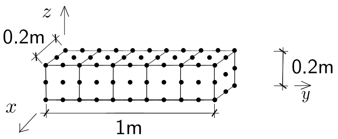

Figure 407.9: Problem Description for Newmark Method

Results This model employs Rayleigh damping. The displacement at the top is

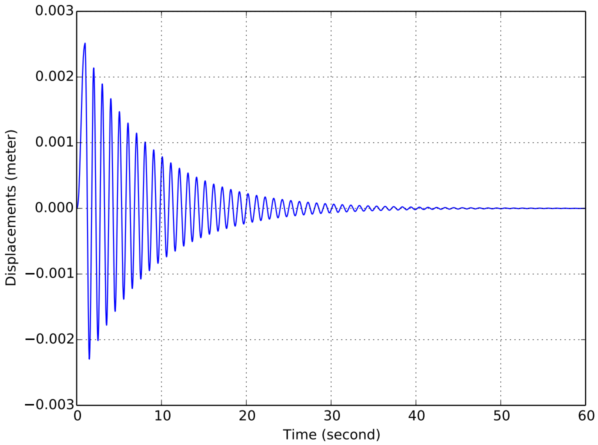

Figure 407.10: Results for Newmark Method

407.4.1.2 Dynamics: Energy Dissipation, Viscous Damping: Caughey Damping

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at the top from 0 to 1 second. Second, after the time 1 second, the model starts free vibration.

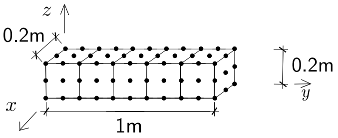

Figure 407.11: Problem Description for Newmark Method

Results This model employs Caughey damping. The displacement at the top is

407.4.2 Dynamics: Energy Dissipation: Material (Elastic-Plastic, Hysteretic) Damping

407.4.2.1 Dynamics: Energy Dissipation, Material Damping: Elastic Perfectly Plastic Models

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is a one-element solid brick example with perfectly plastic materials.

Results The Hysteretic loop at the Gauss point is

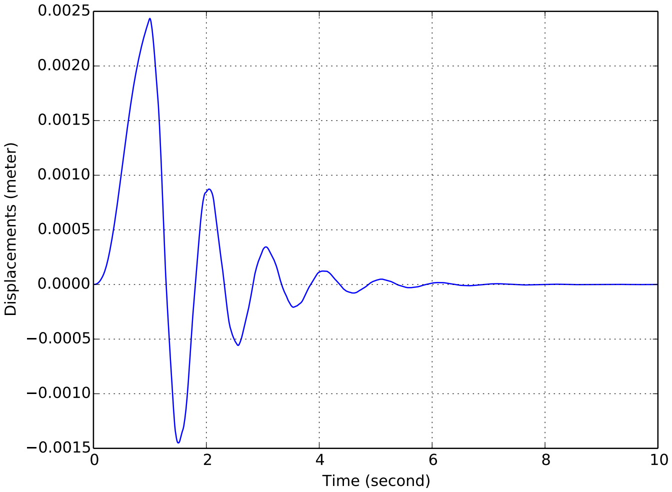

Figure 407.12: Results for Newmark Method

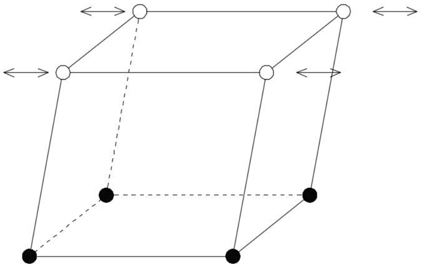

Figure 407.13: Problem Description for Newmark Method

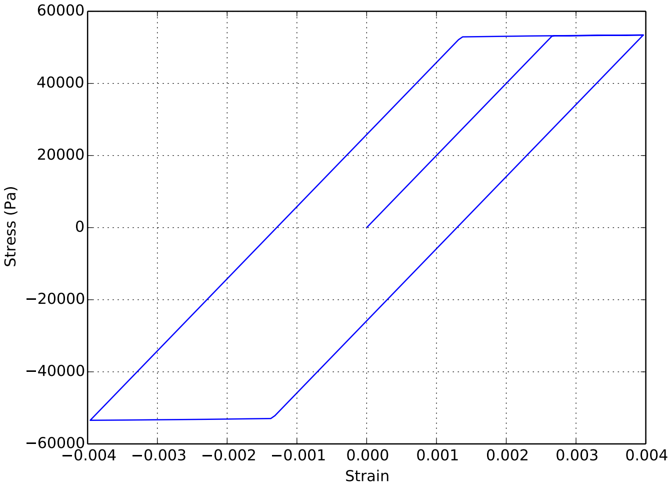

Figure 407.14: Results for Newmark Method

407.4.2.2 Dynamics: Energy Dissipation, Material/Hysteretic Damping: Elastic Plastic Isotropic Hardening Models

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is a one-element solid brick example with isotropic hardening materials.

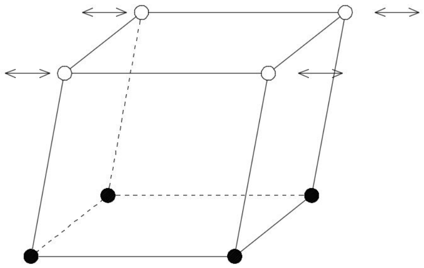

Figure 407.15: Problem Description for Newmark Method

Results The Hysteretic loop at the Gauss point is

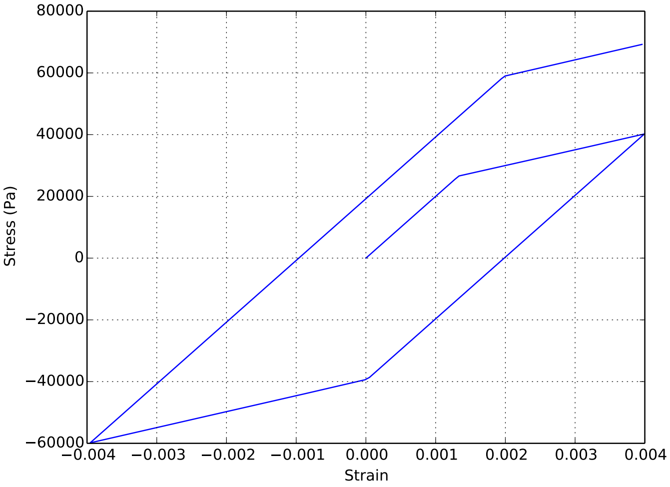

Figure 407.16: Results for Newmark Method

407.4.2.3 Dynamics: Energy Dissipation, Material/Hysteretic Damping: Elastic Plastic Kinematic Hardening Models

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is a one-element solid brick example with kinematic hardening materials.

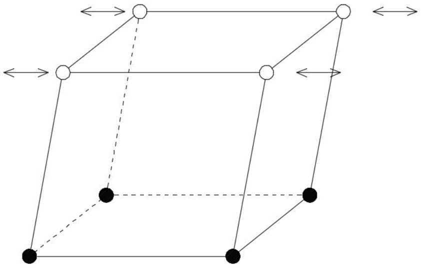

Figure 407.17: Problem Description for Newmark Method

Results The Hysteretic loop at the Gauss point is

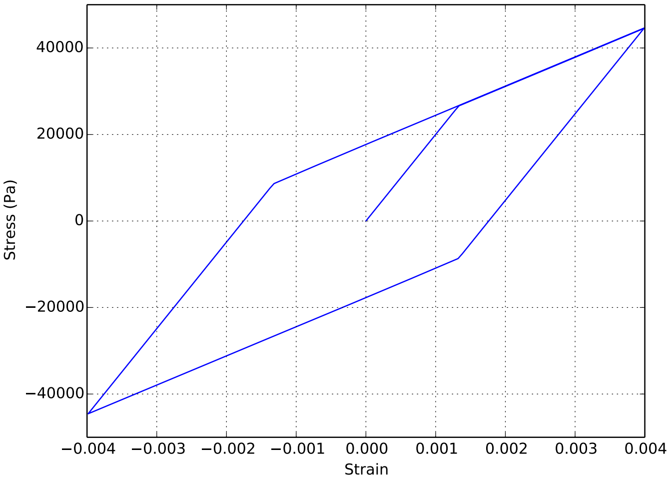

Figure 407.18: Results for Newmark Method

407.4.2.4 Dynamics: Energy Dissipation, Material/Hysteretic Damping: Elastic Plastic Armstrong-Frederick Models

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The model is a one-element solid brick example with materials with nonlinear hardening Armstrong-Frederick.

Results The Hysteretic loop at the Gauss point is

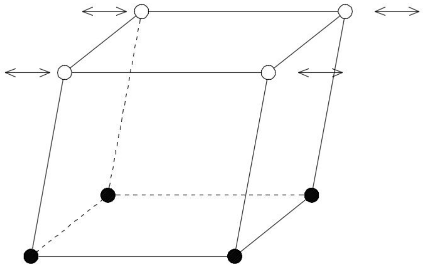

Figure 407.19: Problem Description for Newmark Method

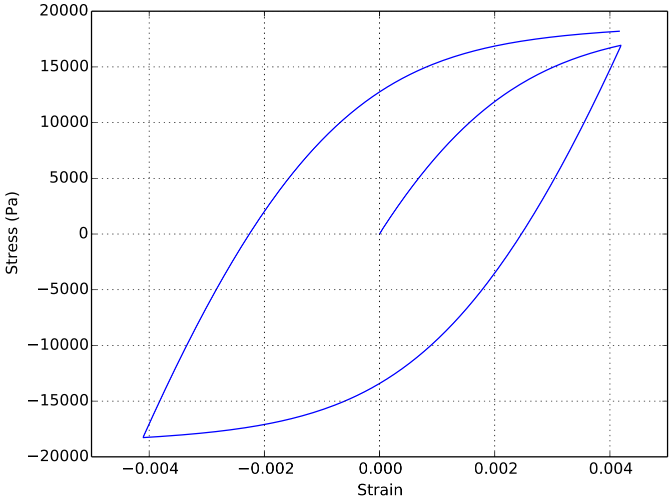

Figure 407.20: Results for Material Armstrong-Frederick

407.4.3 Dynamics: Energy Dissipation: Numerical Damping

407.4.3.1 Energy Dissipation, Numerical Damping: Newmark Method

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement in the first loading stage. In the second loading stage, the model starts free vibration.

Results This model employs Newmark numerical damping. The displacement at the top in the second loading stage is

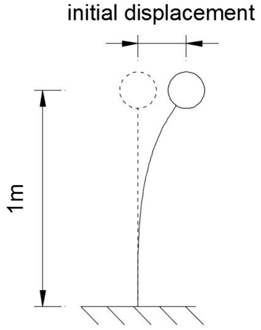

Figure 407.21: Problem Description for Newmark Method

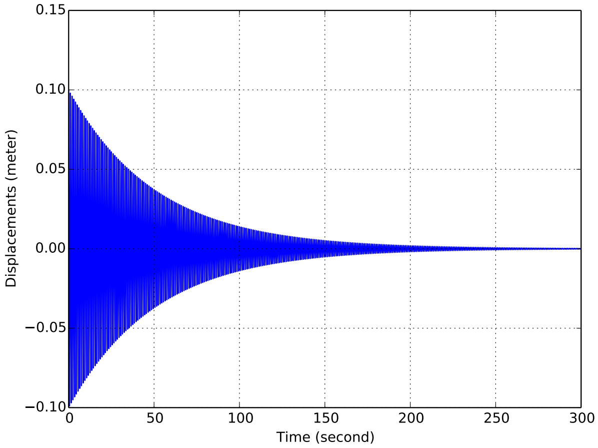

Figure 407.22: Results for Newmark Method

407.4.3.2 Dynamics: Energy Dissipation, Numerical Damping: Hilber-Hughes-Taylor (α) Method

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement in the first loading stage. In the second loading stage, the model starts free vibration.

Results This model employs HHT numerical damping. The displacement at the top in the second loading stage is

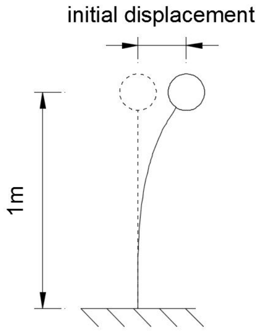

Figure 407.23: Problem Description

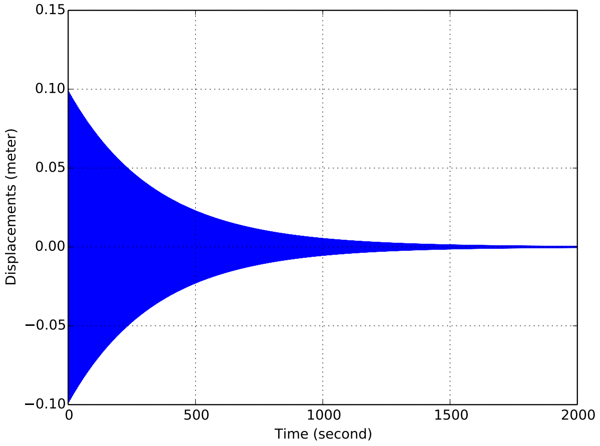

Figure 407.24: Results for HHT Method

407.5 Dynamics: Elastic Solid Dynamic Examples

407.5.1 Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at the top from 0 to 1 second. Second, after the time 1 second, the model starts free vibration.

407.5.2 Results

This model employs Caughey damping. The displacement at the top is

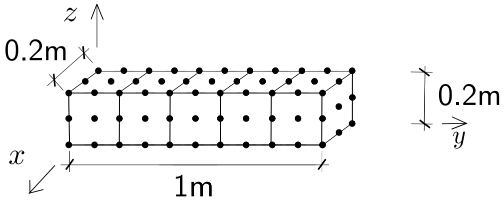

Figure 407.25: Problem Description for Newmark Method

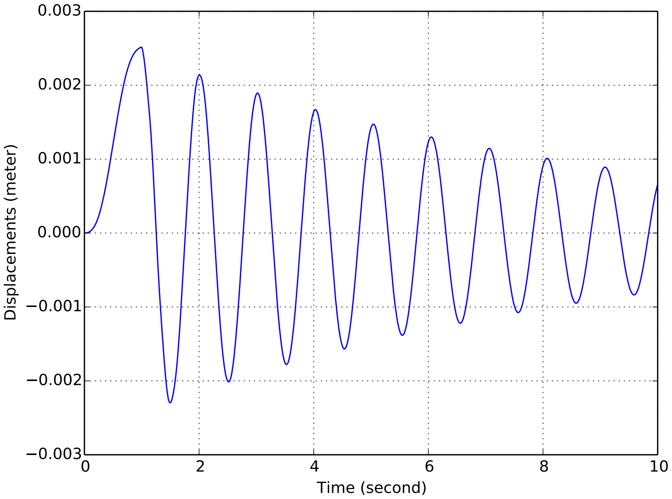

Figure 407.26: Results for Newmark Method

407.6 Dynamics: Elastic Structural Dynamic Examples

407.6.1 Model Description

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement in the first loading stage. In the second loading stage, the model starts free vibration.

407.6.2 Results

With NO damping, the displacement peak keeps the same. The displacement at the top is

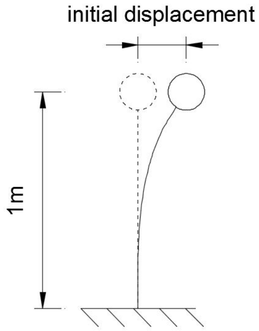

Figure 407.27: Problem Description for Newmark Method

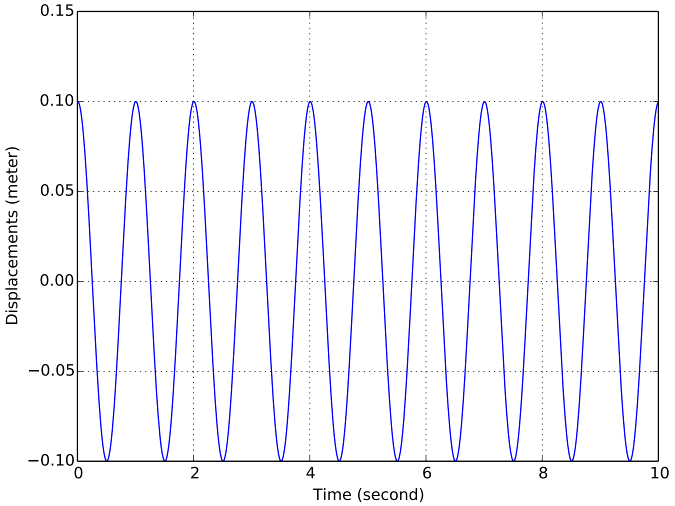

Figure 407.28: Results for Newmark Method

407.7 Dynamics: Interface/Contact Elements

407.7.1 Dynamics: Hard Interface/Contact: One Bar Normal Interface/Contact Dynamics

407.7.1.1 Model Description

This is an example of a ball, bouncing on a solid flat surface. There is only normal contact/interface between the ball and the floor. An upward force is first applied to the concentrated mass lifting it up by $0.1m$ and then the force is removed, resulting in free vibration of the ball. An illustrative diagram of the problem is shown below.

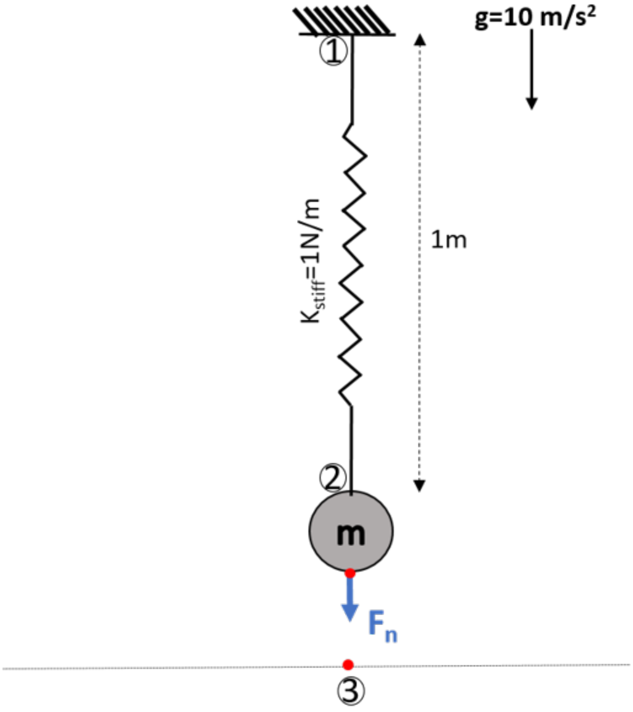

Figure 407.29: Illustration of one bar normal contact/interface dynamics.

The same example can be modeled with different contact/interface and simulation parameters as shown below. For all the different cases shown below, no numerical damping is applied. Only the contact parameters are changed to expose their functionality. The response of node 2 is plotted for all the cases.

407.7.1.2 Dynamics: No Viscous Damping

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results Here, no viscous damping between the contact/interface pair nodes is applied. The displacement output of *Node 2* is shown below.

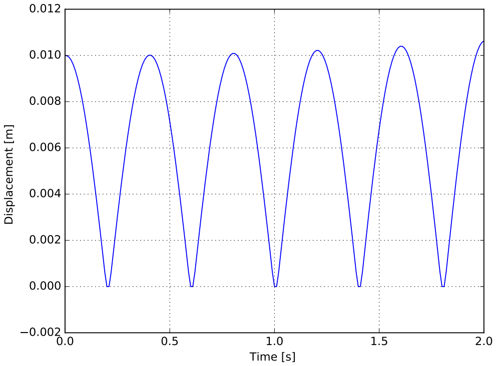

Figure 407.30: Displacement of Node 2

407.7.1.3 Dynamics: Normal Viscous Damping Between Interface/Contact Node Pairs

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results Viscous damping between the contact/interface pair nodes is applied in normal contact/interface direction. The displacement output of *Node 2* is shown below.

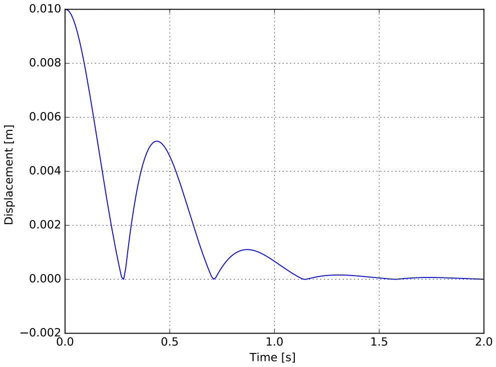

Figure 407.31: Displacement of Node 2

407.7.1.4 Dynamics: Explicit Simulation

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results With no viscous damping, the analysis is run explicitly without any convergence check. The displacement output of *Node 2* is shown below.

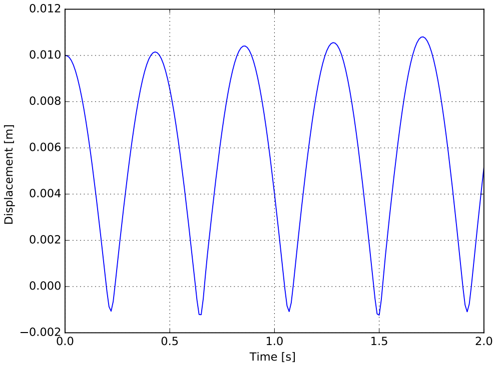

Figure 407.32: Displacement of Node 2

407.7.2 Dynamics: Hard Interface/Contact: Frictional Single Degree of Freedom Problem

Model Description This is an example of a block on a rough surface under gravity. It has been attached to a spring at one end. At the other end a tangential load is applied greater than the coulomb friction and is then removed. The block oscillates back and forth with continuously loosing energy because of frictional force and then stops, with some permanent deformation. This kind of damping is called frictional damping which is linear as compared to exponential in case of viscous damping. An illustrative diagram of the problem is shown below.

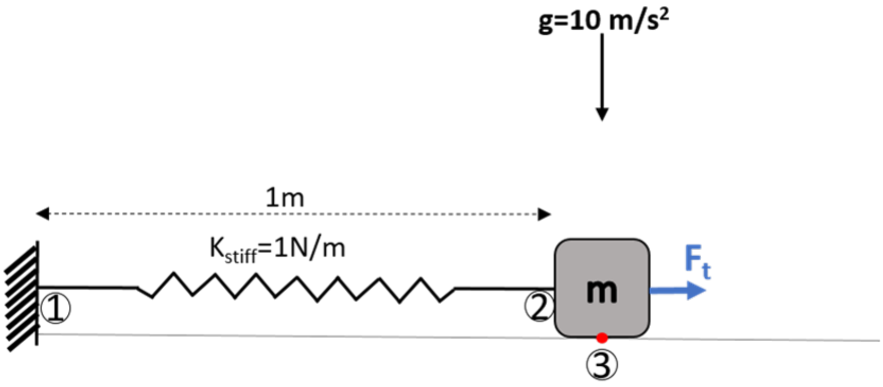

Figure 407.33: Illustration of frictional single degree of freedom problem

The same example can be modeled with different contact/interface and simulation parameters as shown below. For all the different cases shown below, no numerical damping is applied. Only the contact/interface parameters are changed to expose their functionality. The response of node 2 is plotted for all the cases.

407.7.2.1 Dynamics: No Viscous Damping

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results In this examples, no viscous damping between the contact/interface pair nodes is applied. The displacement output of *Node 2* is shown below.

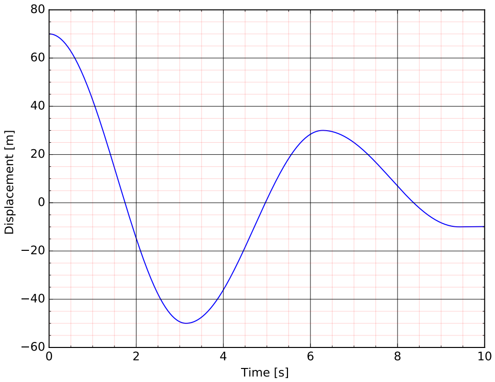

Figure 407.34: Displacement of Node 2

407.7.2.2 Dynamics: Tangential Viscous Damping Between Interface/Contact Node Pairs

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results Viscous damping between the contact/interface pair nodes is applied in tangential contact/interface direction. The displacement output of *Node 2* is shown below.

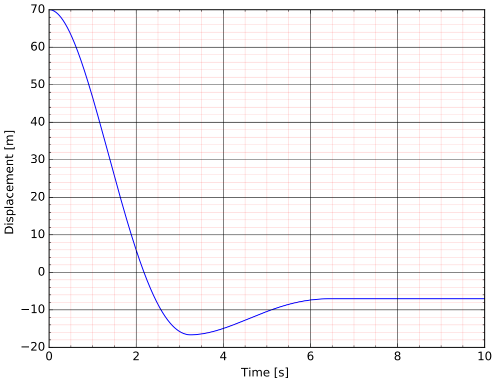

Figure 407.35: Displacement of Node 2

407.7.2.3 Dynamics: Explicit Simulation

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results With no viscous damping, the analysis is run explicitly without any convergence check. The displacement output of *Node 2* is shown below.

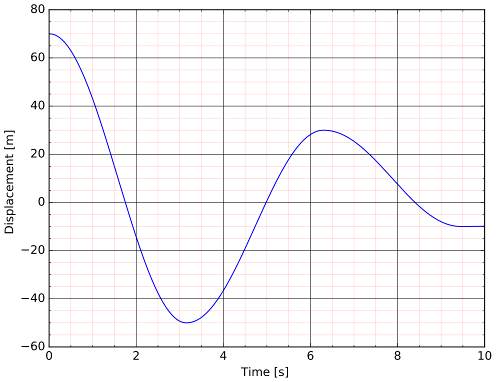

Figure 407.36: Displacement of Node 2

407.7.3 Dynamics: Soft Interface/Contact: One Bar Normal Interface/Contact Dynamics

Model Description This is an example of a ball, bouncing on a solid flat surface. There is only normal contact/interface between the ball and the floor. An upward force is first applied to the concentrated mass lifting it up by $0.1m$ and then the force is removed, resulting in free vibration of the ball. An illustrative diagram of the problem is shown below.

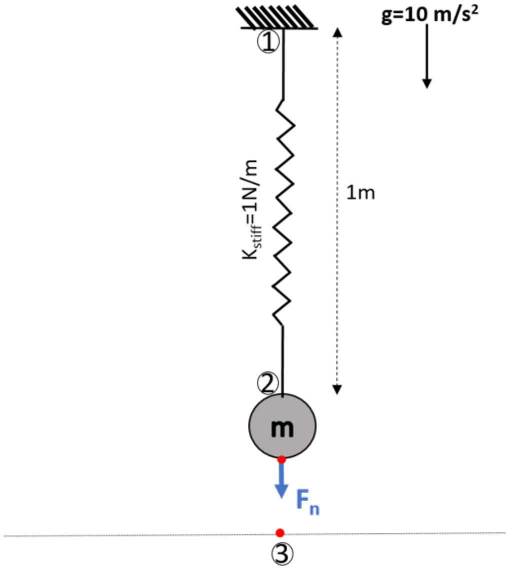

Figure 407.37: Illustration of one bar normal contact/interface dynamics

The same example can be modeled with different contact/interface and simulation parameters as shown below. For all the different cases shown below, no numerical damping is applied. Only the contact/interface parameters are changed to expose their functionality. The response of node 2 is plotted for all the cases.

407.7.3.1 Dynamics: No Viscous Damping

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results In this example, no viscous damping between the contact/interface pair nodes is applied. The displacement output of *Node 2* is shown below.

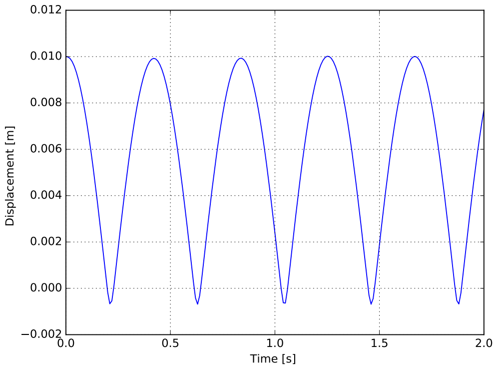

Figure 407.38: Displacement of Node 2

407.7.3.2 Dynamics: With Normal Viscous Damping Between Interface/Contact Node Pairs

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results Viscous damping between the contact/interface pair nodes is applied in normal contact/interface direction. The displacement output of *Node 2* is shown below.

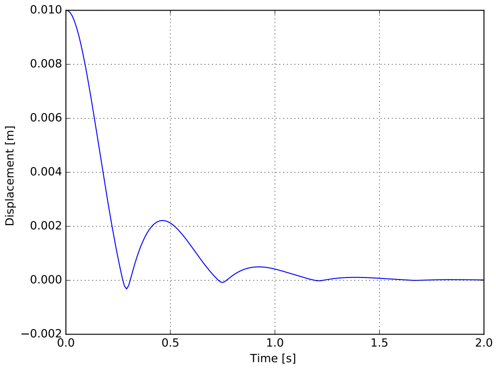

Figure 407.39: Displacement of Node 2

407.7.3.3 Dynamics: Explicit Simulation

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results With no viscous damping, the analysis is run explicitly without any convergence check. The displacement output of *Node 2* is shown below.

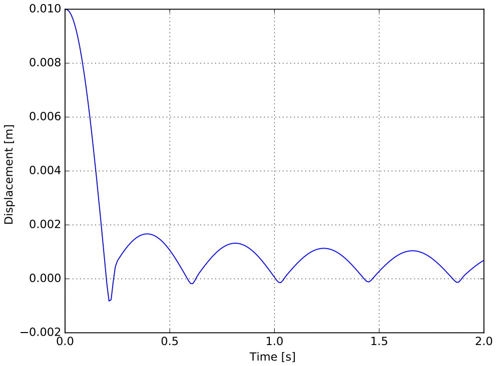

Figure 407.40: Displacement of Node 2

407.7.4 Dynamics: Soft Interface/Contact: Frictional Single Degree of Freedom Problem

Model Description This is an example of a block on a rough surface under gravity. It has been attached to a spring at one end. At the other end a tangential load is applied greater than the coulomb friction and is then removed. The block oscillates back and forth with continuously loosing energy because of frictional force and then stops, with some permanent deformation. This kind of damping is called frictional damping which is linear as compared to exponential in case of viscous damping. An illustrative diagram of the problem is shown below.

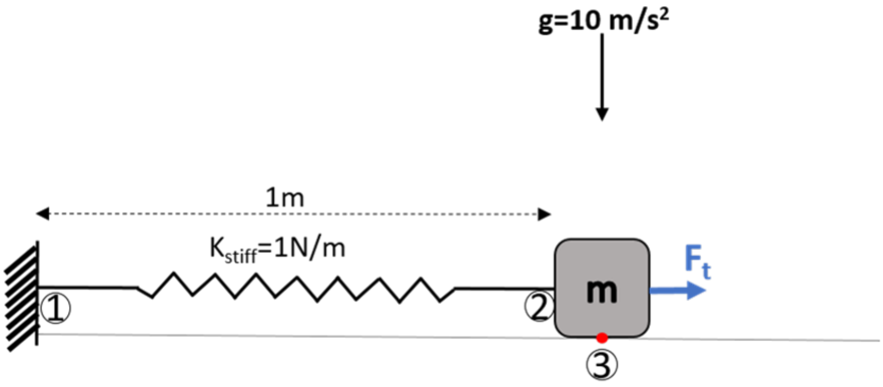

Figure 407.41: Illustration of frictional single degree of freedom problem

The same example can be modeled with different contact/interface and simulation parameters as shown below. For all the different cases shown below, no numerical damping is applied. Only the contact/interface parameters are changed to expose their functionality. The response of node 2 is plotted for all the cases.

407.7.4.1 Dynamics: No Viscous Damping

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results In this example, no viscous damping between the contact/interface pair nodes is applied. The displacement output of *Node 2* is shown below.

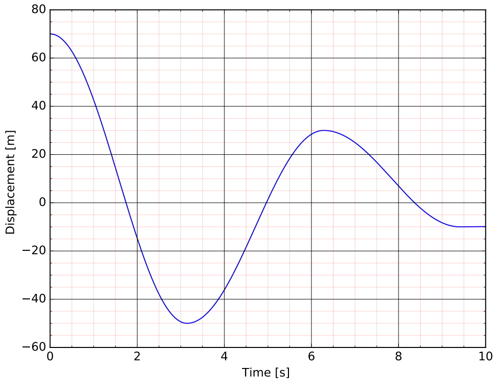

Figure 407.42: Displacement of Node 2

407.7.4.2 Dynamics: Tangential Viscous Damping Between Interface/Contact Node Pairs

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results Viscous damping between the contact/interface pair nodes is applied in tangential contact/interface direction. The displacement output of *Node 2* is shown below.

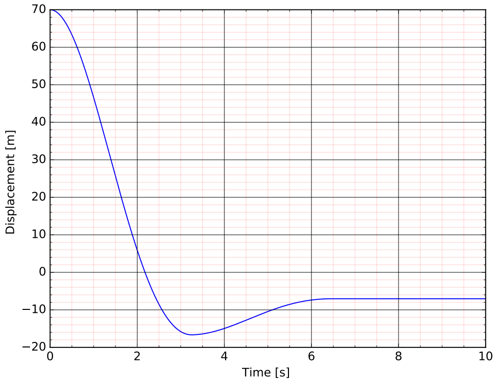

Figure 407.43: Displacement of Node 2

407.7.4.3 Dynamics: Explicit Simulation

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Results With no viscous damping, the analysis is run explicitly without any convergence check. The displacement output of *Node 2* is shown below.

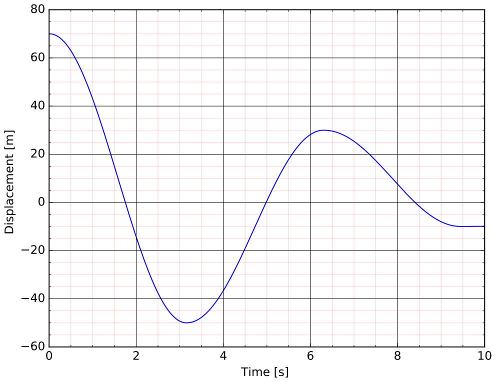

Figure 407.44: Displacement of Node 2

407.7.5 Dynamics: Split Beam

407.7.5.1 Model Description

In this example, a normal beam is split into two halves along its depth. A uniform surface load of 50 Pa is applied to the top half of the beam, pulling it away from its lower part. Then, the load is removed, to allow free vibration between the split beams. An illustrative diagram of the problem is shown below.

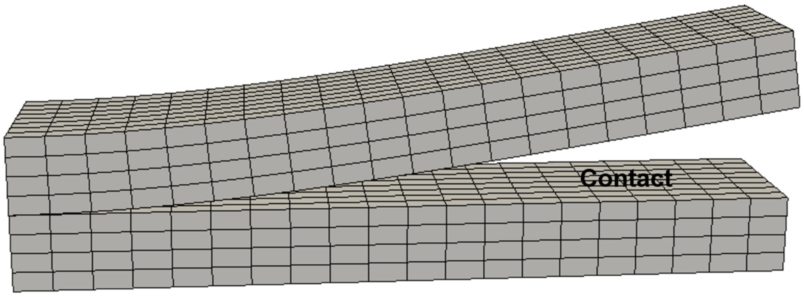

Figure 407.45: Illustration of Split Beam Analysis

The same example was modelled with soft and hard contact/interface. Numerical as well as viscous damping between contact/interface pair nodes was applied. The displacement response of the extreme right mid node of top half beam is plotted.

407.7.5.2 Dynamics: Split Beam With Hard Interface/Contact

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

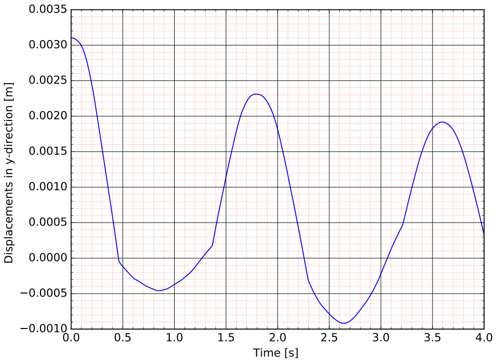

Figure 407.46: Displacement response of extreme mid node of top half beam

407.7.5.3 Dynamics: Split Beam With Soft Interface/Contact

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

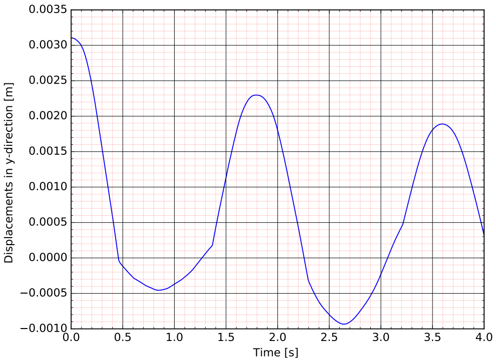

Figure 407.47: Displacement response of extreme mid node of top half beam

407.7.6 Dynamics: Block on Soil ESSI

Model Description The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

A solid block is placed in the soil. There is contact/interface between the interface of solid and the soil. First, self-weight and then a uniform acceleration in x-direction is applied to the whole model. This analysis would provide relative displacement, velocity and acceleration response for the given shaking. An illustrative diagram of the problem is shown below.

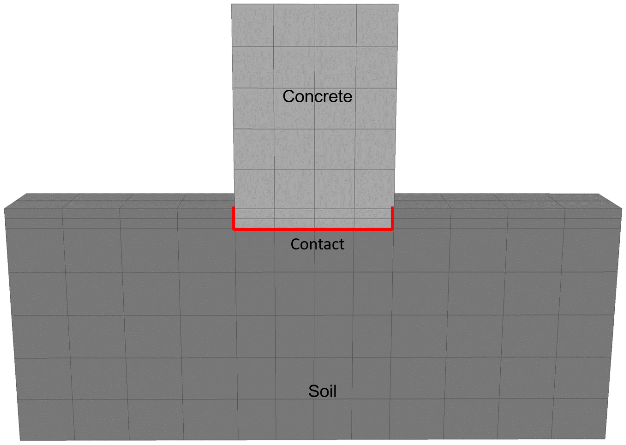

Figure 407.48: Illustration of frictional single degree of freedom problem

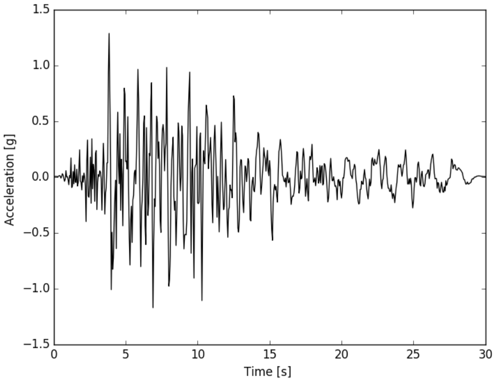

Figure 407.49: Applied Motion

Results Displacement response of the top of the solid block is shown below. Numerical Damping, Raleigh damming and viscous damping between contact/interface node pairs are applied.

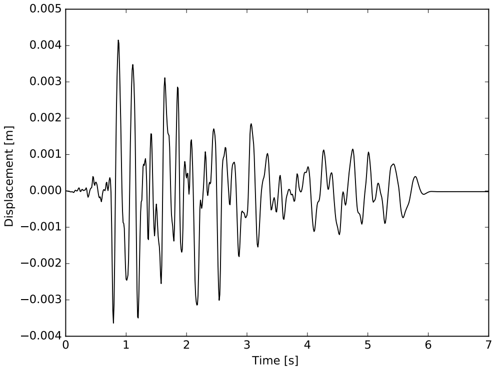

Figure 407.50: Displacement response at the top of the block

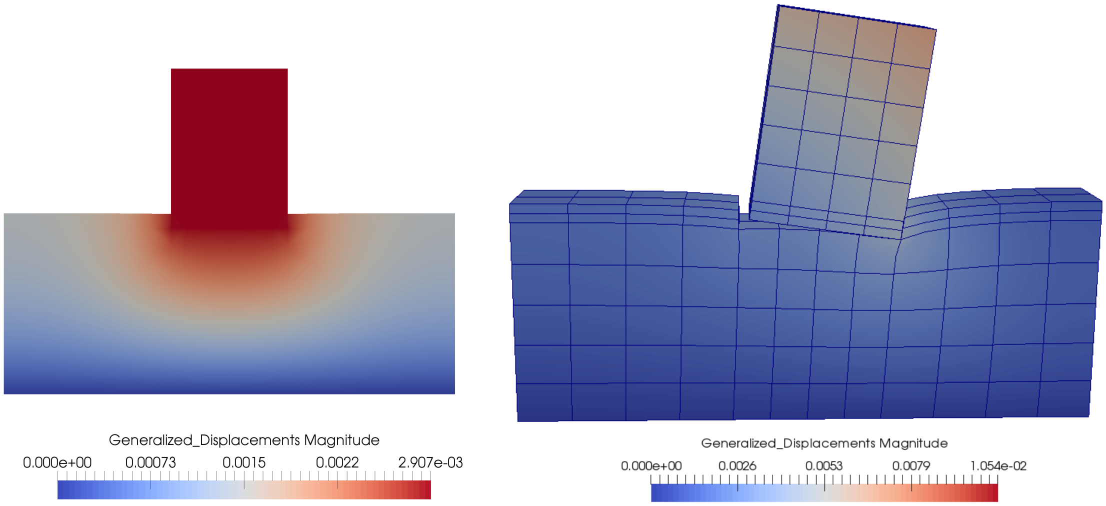

(a) Self Wight Stage

(b) Uniform Acceleration Stage at 0.85 sec

Figure 407.51: Simulation results visualization

407.8 Dynamics: Inelastic Solid Examples

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Firstly, the model is given an initial displacement at the top from 0 to 1 second. Second, after the time 1 second, the model starts free vibration.

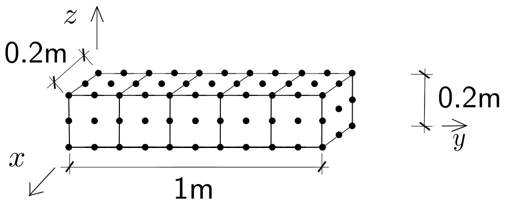

Figure 407.52: Problem Description for Newmark Method

Results This model has material damping. The displacement at the top is

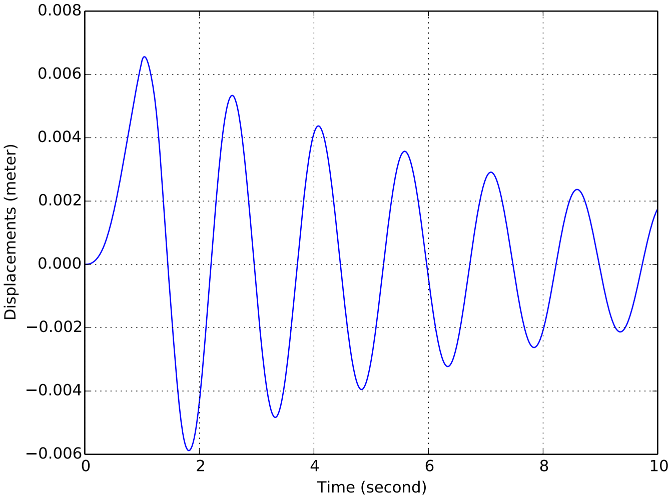

Figure 407.53: Results for Newmark Method

407.9 Dynamics: Inelastic Structural Examples

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

The column beam is represented by the fiber section. This example is under the dynamic load of ground motion.

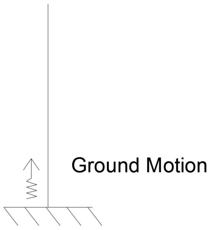

Figure 407.54: Ground motion on the Fiber Beam with Column Section

The fiber represents the rebar. The section of all fibers represents the cross section properties of the inelastic beam.

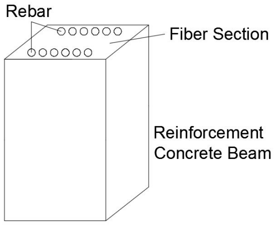

Figure 407.55: Diagram of the Fiber Beam with Column Section

407.10 Dynamics: Domain Reduction Method (DRM)

407.10.1 Dynamics: DRM One Dimensional (1D) Model

The Real-ESSI input files with 8NodeBrick for this example are available

HERE.

The same model for this example with 27NodeBrick is available

HERE.

A simple 1D DRM model is shown in Fig.(707.44). The "DRM element", "Exterior node" and "Boundary node" are required to be designated in the DRM HDF5 input. The format and script for the HDF5 input is available in DSL/input manual.

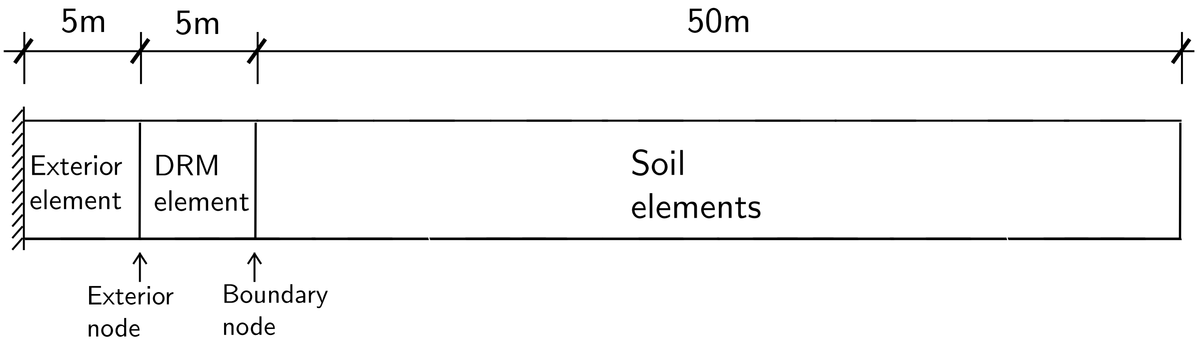

Figure 407.56: 1D DRM model.

Numerical model

Long 1D DRM model 1000:1 The Real-ESSI input files for this example are available

HERE.

The results can also be seen from this

ANIMATION.

To show the wave propagation explicitly, a long 1D model (1000:1) similar to the 1D DRM model above was made in this section.

The model description is same to Fig.(707.44) except this model use far more soil elements.

The general view is shown in Fig.(707.46) below.

There is still now outgoing waves at the exterior layers, which is shown in Fig(707.47).

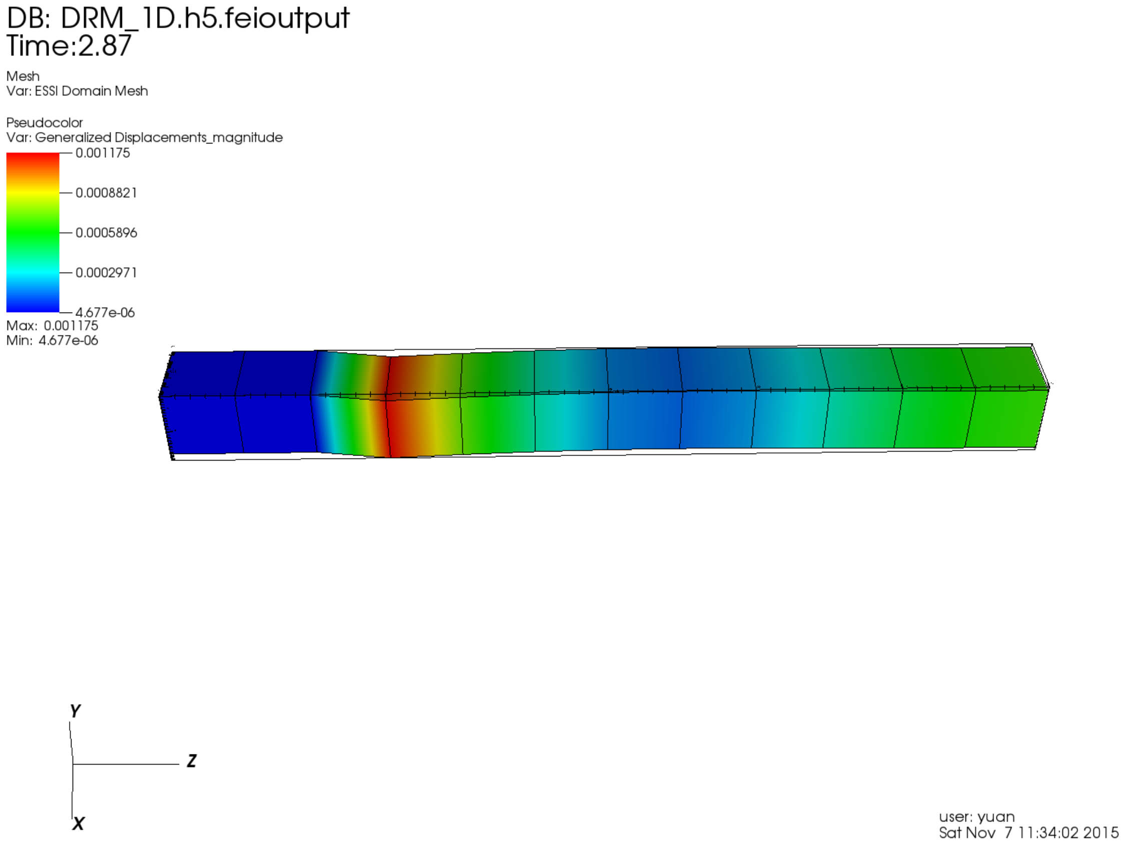

Figure 407.57: 1D DRM model.

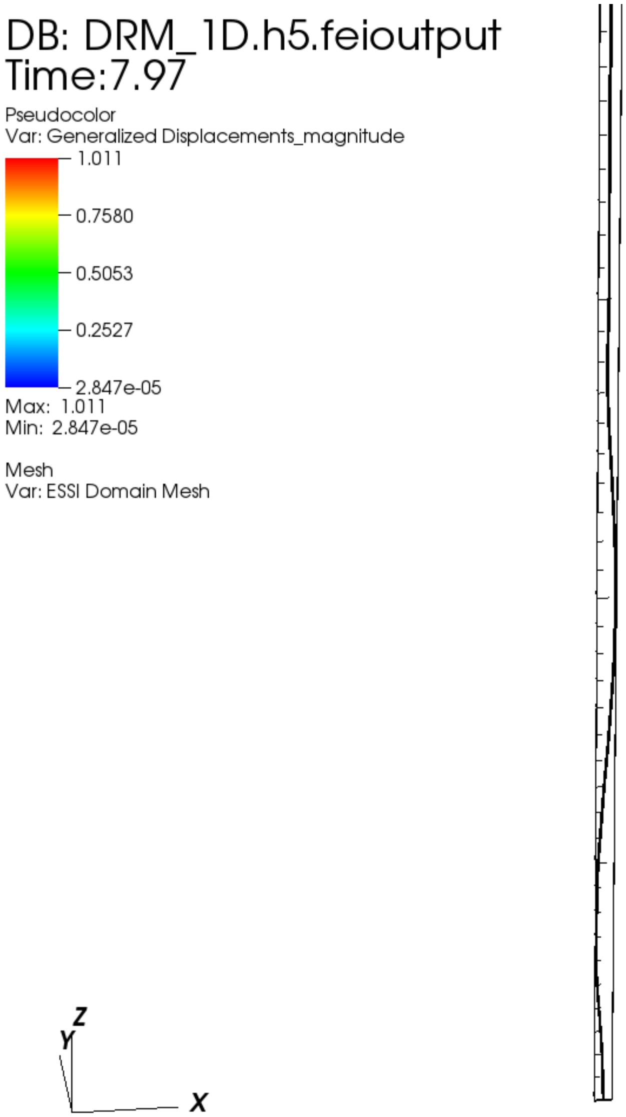

Figure 407.58: Long 1D DRM model

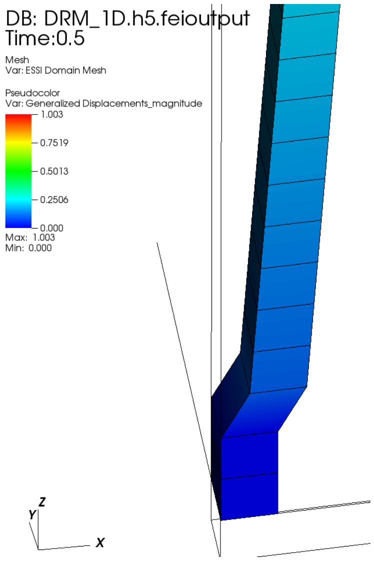

Figure 407.59: Long 1D DRM model: exterior layer

407.10.2 Dynamics: Three Dimensional (3D) DRM Model

The Real-ESSI input files with 8NodeBrick for this example are available

HERE.

The same model for this example with 27NodeBrick is available

HERE.

As shown in Fig.(707.48), the DRM layer is used to add the earthquake motion.

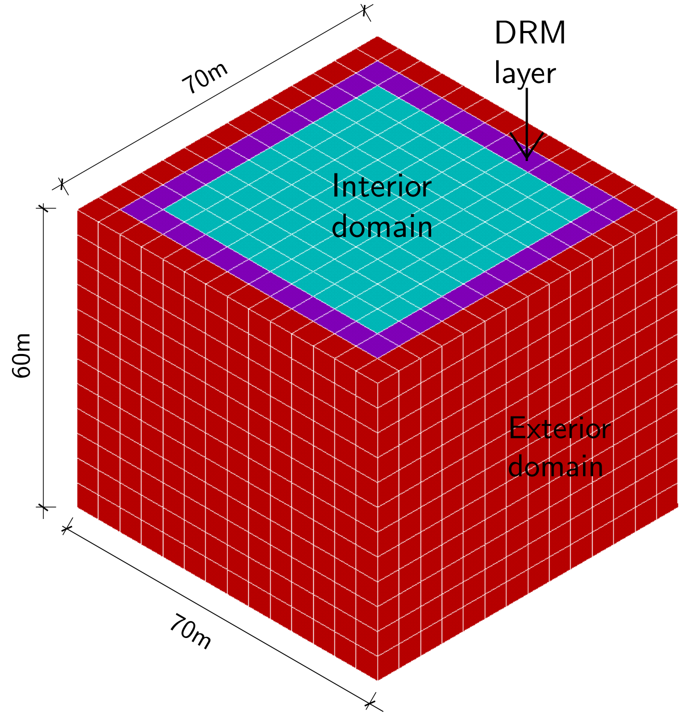

Figure 407.60: The diagram for 3D Domain Reduction Method example.

Numerical result

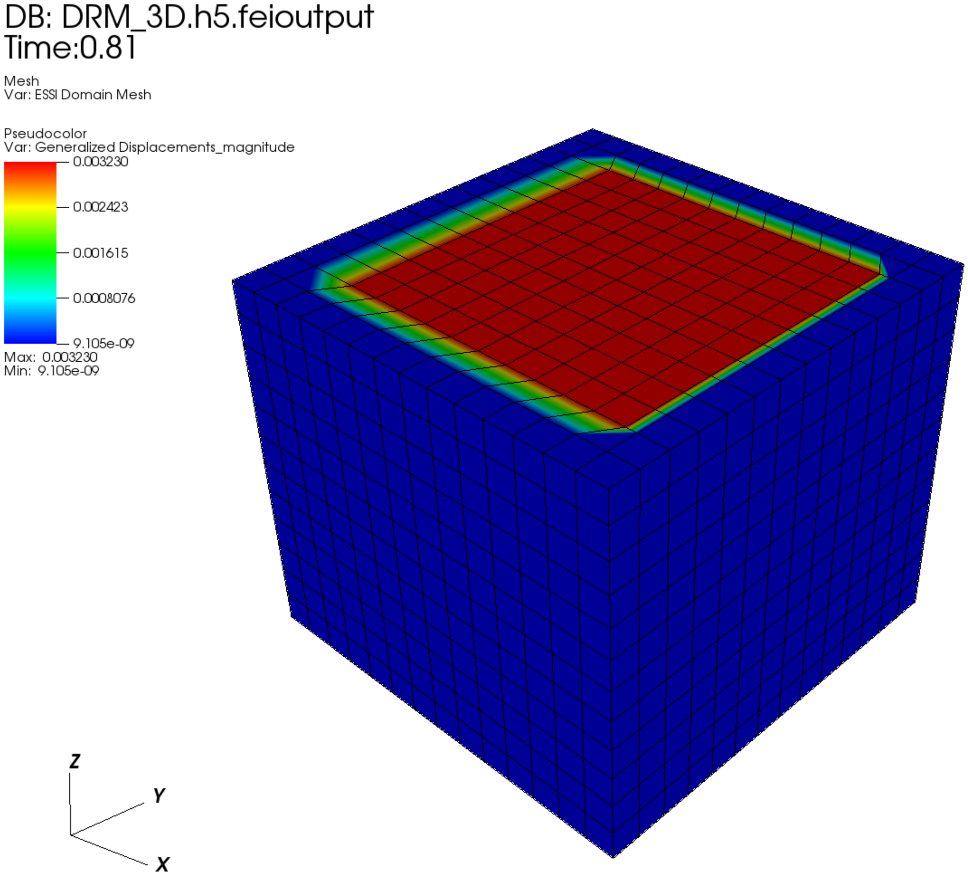

Figure 407.61: Diagram for the 3D DRM model.

407.10.3 Dynamics: DRM Model with Structure

Problem description The Real-ESSI input files for this example are available HERE.

The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

As shown in Fig.(407.62), the structure is placed in the middle. Five different materials are assigned to structure, contact/interface zones, soil, DRM layer, and damping layers, respectively.

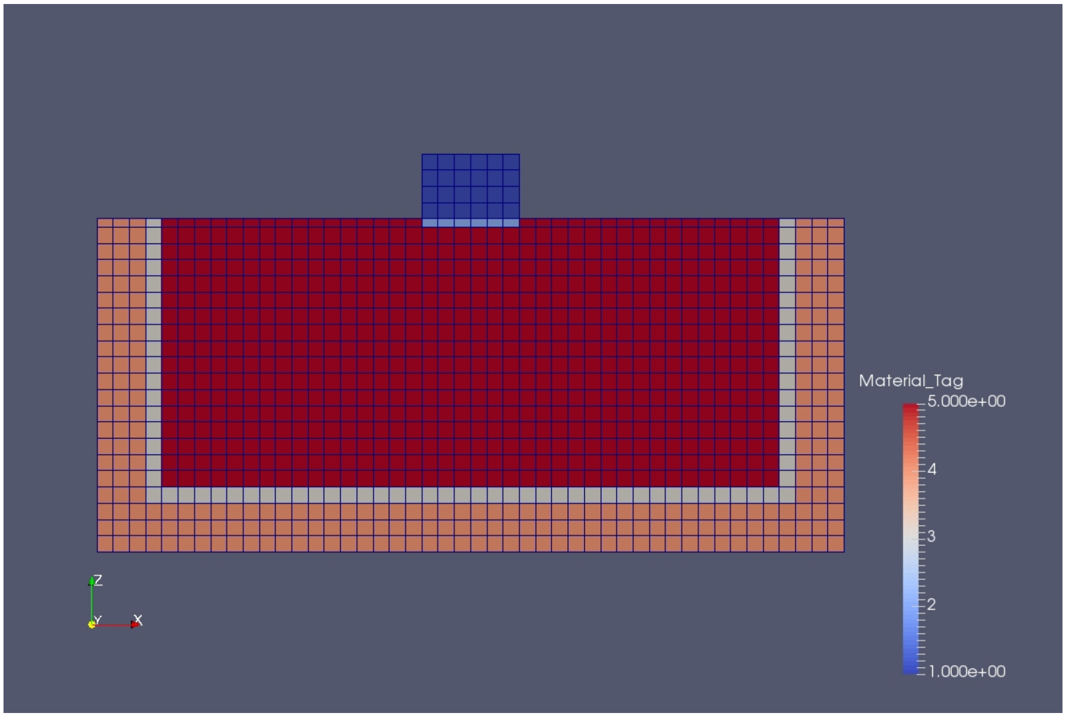

Figure 407.62: A Domain Reduction Method example with a Simple Structure.

407.11 Dynamics: Eigen Analysis

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files and postprocessing results for this example is available HERE.

Model is a brick beam with distributed mass.

407.12 Dynamics: Fully Coupled u-p-U and u-p Elements

The Real-ESSI input files for coupled example are available HERE.

407.13 Dynamics: Partially Saturated / Unsaturated u-p-U Element (example in development)

407.14 Dynamics: Coupled Interface/Contact Element (example in development)

407.15 Dynamics: Buoyant Forces (example in development)

407.16 Chapter Summary and Highlights

In this Chapter stochastic/probabilistic modeling and simulation is illustrated through a number of examples. These examples can then be analyzed using Real-ESSI Simulator that is available for Linux, Windows (through ESL) or MacOS, and on Amazon Web Services (AWS) computers. Please refer to the Real-ESSI web site `real-essi.us`, for more information on how to install Real-ESSI on your computer (Linux, Windows, MacOS...).

Chapter 408

Stochastic Examples

(2018-2019-2020-2021-)

(In collaboration with Dr. Hexiang Wang)

408.1 Probabilistic Constitutive Modeling

408.1.1 Probabilistic Constitutive Modeling: Linear Elastic

The model description:

The Real-ESSI input files for this example are available in a zip archive HERE.

A stochastic uniaxial elastic material with lognormal distributed random elastic modulus, mean 155 MPa and coefficient of variation 30%.

Results:

The probabilistic stress strain response of the stochastic uniaxial elastic material is shown in Figure 408.1.

408.1.2 Probabilistic Constitutive Modeling: Elasto-Plastic

The model description:

The Real-ESSI input files for this example are available in a zip archive HERE.

A stochastic uniaxial elastoplastic material with vanishing elastic region and nonlinear Armstrong-Frederick kinematic hardening rule is modeled. The model parameters are: Armstrong-Frederick pa-

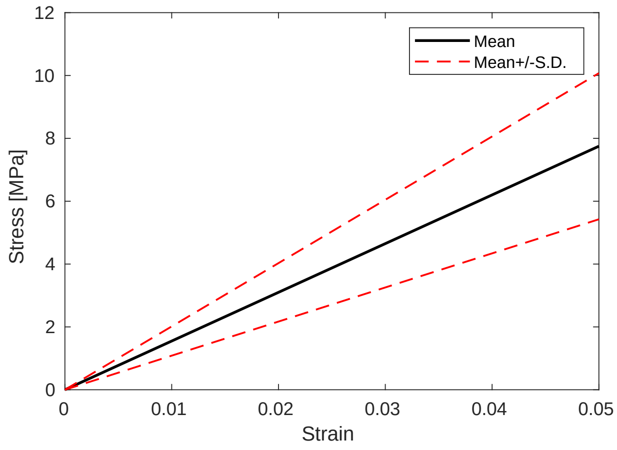

Figure 408.1: Constitutive behavior of stochastic uniaxial elastic material.

rameter H_a follows lognormal distribution with marginal mean 12 MPa and coefficient of variation 20%. Armstrong-Frederick parameter C_r follows lognormal distribution with marginal mean 200 and coefficient of variation (CV) 20%.

Results:

The probabilistic stress strain response of the stochastic uniaxial elastic material is shown in Figure 408.2.

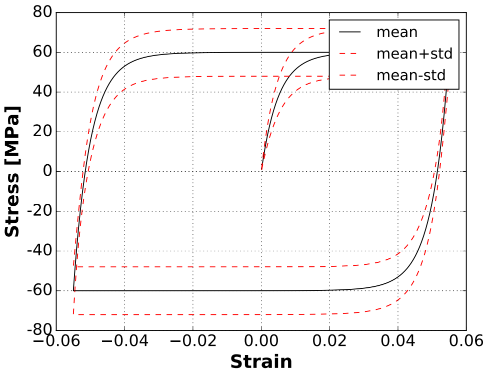

Figure 408.2: Constitutive behavior of stochastic uniaxial elastoplastic material.

408.2 Probabilistic Characterization of Seismic Motions

The model description:

The Real-ESSI input files for this example are available in a zip archive HERE.

For stochastic analysis with uncertain seismic excitations, it is important to characterize input uncertain motions as a non-stationary random process. The random process can be quantified through marginal mean, marginal standard deviation and correlation structure, and can be represented as Hermite polynomial chaos (PC). This example presents such a random process of seismic motions with marginal mean, marginal standard deviation and correlation structure defined through plain text files. It is noted that this random process is used as input bedrock excitations in the subsequent stochastic wave propagation analysis.

Results:

It is important to check that the statistics synthesized from PC representation matches well with the input. Figures 408.3 and 408.2 compare the marginal statistics and correlation structure synthesized from PC representation with the target input.

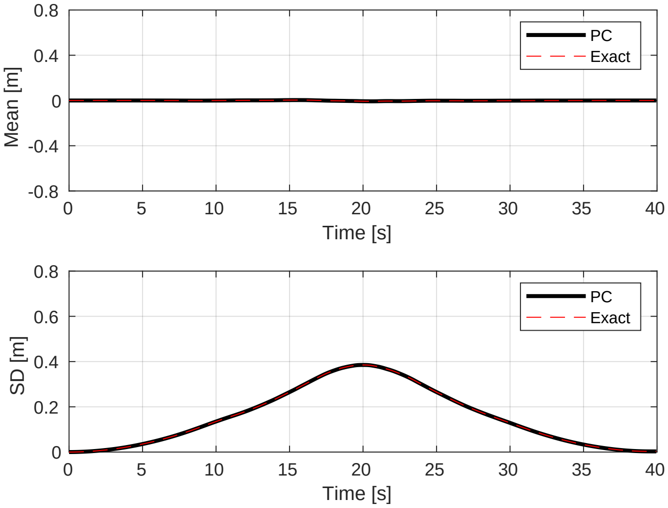

Figure 408.3: Verification of marginal statistics of random process motions.

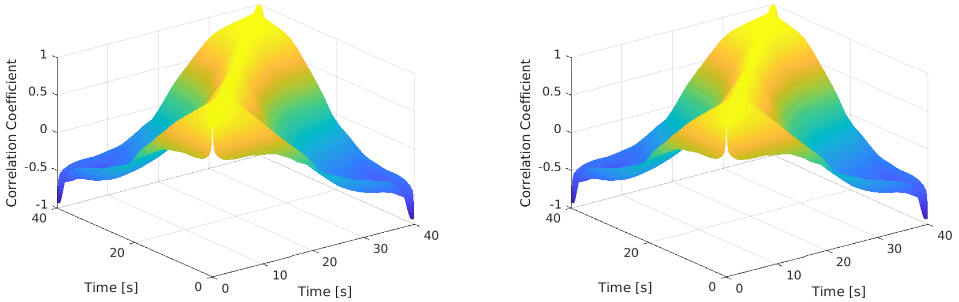

Figure 408.4: Input correlation structure (Left) and PC-synthesized correlation structure (Right).

408.3 1D Stochastic Seismic Wave Propagation

408.3.1 1D Stochastic Seismic Wave Propagation: Linear Elastic

The model description:

The Real-ESSI input files for this example are available in a zip archive HERE.

Presented is 1D stochastic seismic wave propagation through uncertain linear elastic, layered ground. The uncertain motions characterized in section 408.2 is adopted as bedrock input. The ground is 10m thick with three layers and discretized with 10 stochastic shear beam elements as shown in Figure 408.5.

- Layer #1: Thickness 3m, uncertain elastic modulus follows lognormal distribution with marginal mean 120 MPa and 20% coefficient of variation.
- Layer #2: Thickness 3m, uncertain elastic modulus follows lognormal distribution with marginal mean 150 MPa and 25% coefficient of variation.
- Layer #3: Thickness 4m, uncertain elastic modulus follows lognormal distribution with marginal mean 180 MPa and 25% coefficient of variation.

The correlation structure of the uncertain elastic modulus random field follows exponential correlation with correlation length as 10m.

Results:

Time evolving marginal mean and marginal standard deviation of surface probabilistic displacement and acceleration response are shown in Figure 408.6 and 408.7.

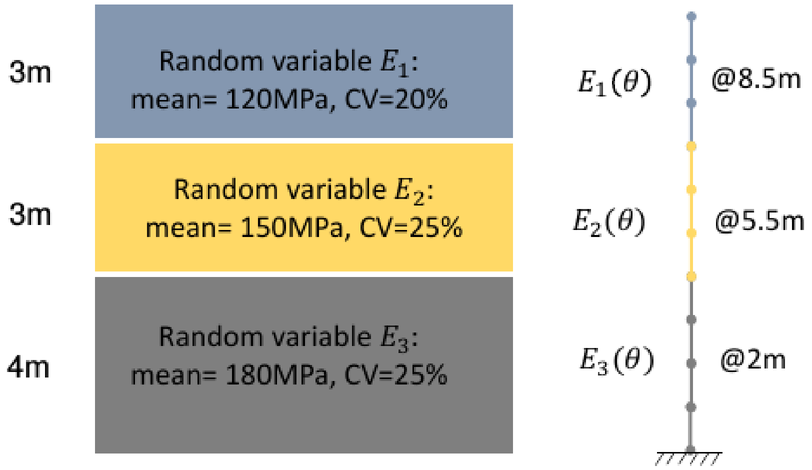

Figure 408.5: 1D layered ground and stochastic shear beam FEM model.

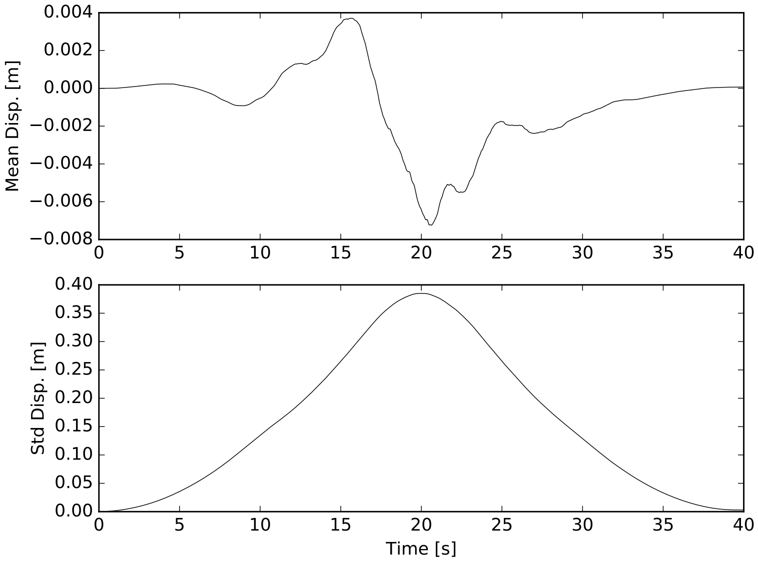

Figure 408.6: Probabilistic displacement response of ground surface.

408.3.2 1D Stochastic Seismic Wave Propagation: Elasto-Plastic

The model description:

The Real-ESSI input files for this example are available in a zip archive HERE.

The model geometry and input seismic excitations are identical to the example in section 408.3.1. The only difference is the constitutive model of soil. In this example, probabilistic elastoplastic soil model with vanishing elastic region and Armstrong-Frederick kinematic hardening is adopted.

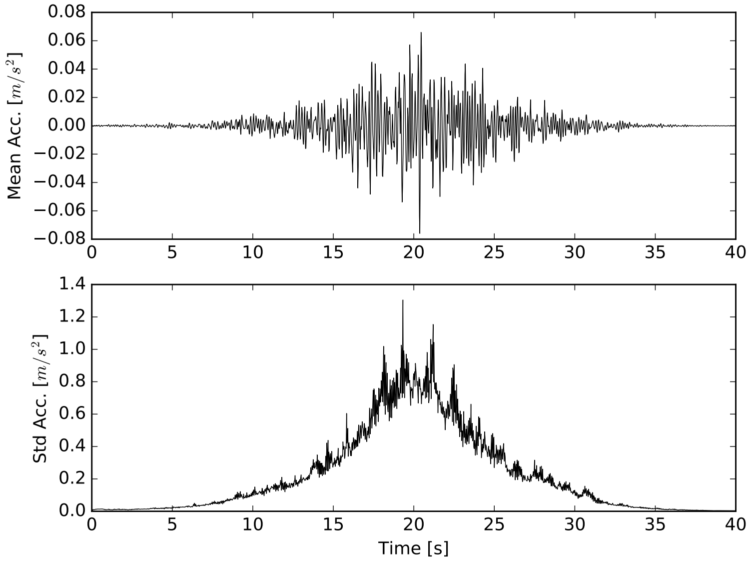

Figure 408.7: Probabilistic acceleration response of ground surface.

Results:

Time evolving marginal mean and marginal standard deviation of surface probabilistic displacement and acceleration response are shown in Figure 408.8 and 408.9.

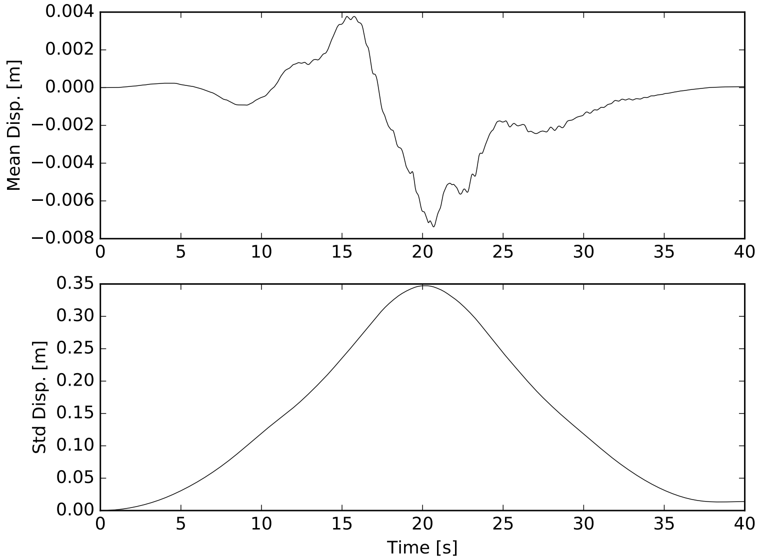

Figure 408.8: Probabilistic displacement response of ground surface.

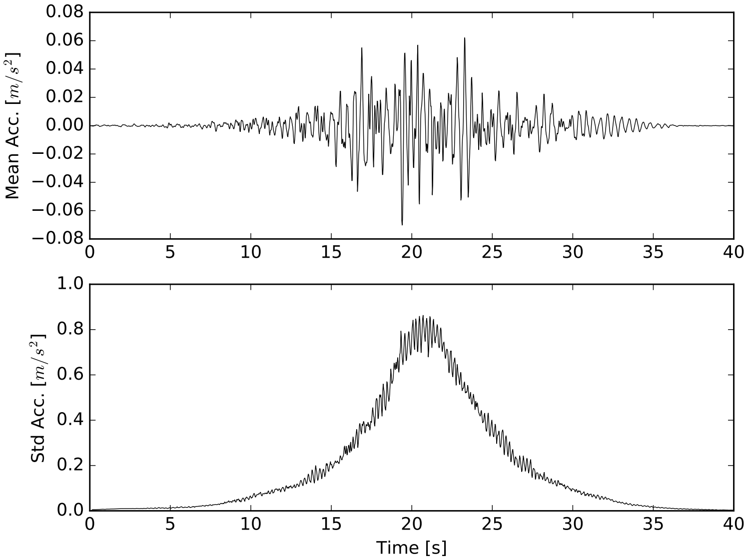

Figure 408.9: Probabilistic acceleration response of ground surface.

408.4 1D Stochastic Seismic Wave Propagation: Sobol Sensitivity Analysis

The Real-ESSI input files for this example are available in a zip archive HERE.

Sobol sensitivity analysis is performed for the stochastic wave propagation example in section 408.3.1. From the sensitivity analysis results for probabilistic response at ground surface, it is shown that for this specific case most of the variance comes from the uncertain input motions.

Chapter 409

Large Scale, Realistic Examples

(2016-2018-)

(In collaboration with Dr. Yuan Feng, Mr. Sumeet Kumar Sinha, Dr. Han Yang, and Dr. Hexiang Wang)

Full scale, realistic examples of statics and dynamics of bridges, dams, buildings and nuclear power plants are presented in part 500 on page 2189 in Jeremić et al. (1989-2025).

Chapter 410

Short Course Examples

(2017-2023-)

(In collaboration with Dr. Yuan Feng and Dr. Han Yang)

410.1 Nonlinear Analysis Steps

410.1.1 Free Field 1C

Elastic Material. The Real-ESSI input files for elastic example are available HERE.

The modeling parameters are listed below:

- Elastic Material Properties
  - Mass Density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

Elastoplastic Material, von Mises with Armstrong-Frederick Kinematic Hardening The Real-ESSI input files for elastoplastic material example are available HERE.

The modeling parameters are listed below

- von-Mises nonlinear hardening material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - von Mises radius, k, 60 kPa
  - Nonlinear kinematic hardening, H_a, 30 MPa
  - Nonlinear kinematic hardening, C_r, 60
  - Shear strength ($\approx \sqrt{2/3}\, H_a/C_r$), S_u, 408 kPa
  - Isotropic hardening rate, K_{iso}, 0 Pa

Results of the simulation are shown in Fig. 410.1.

The time series of simulation results is shown in Fig. 410.3.

The response spectrum of motion is shown in Fig. 410.4.

Figure 410.1: Simulation model.

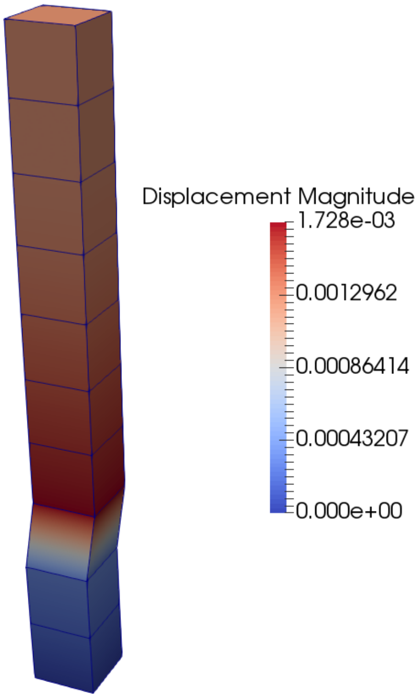

Figure 410.2: Simulation model.

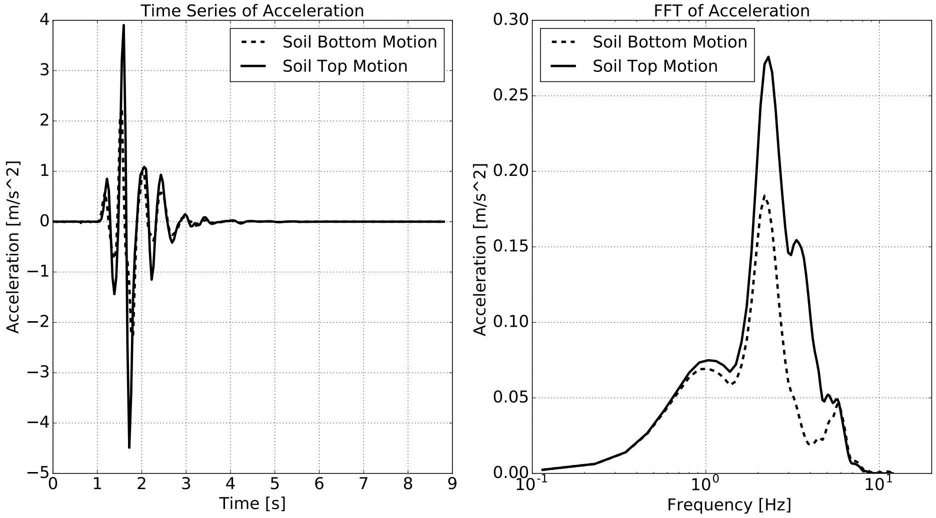

Figure 410.3: Simulation results: acceleration time series.

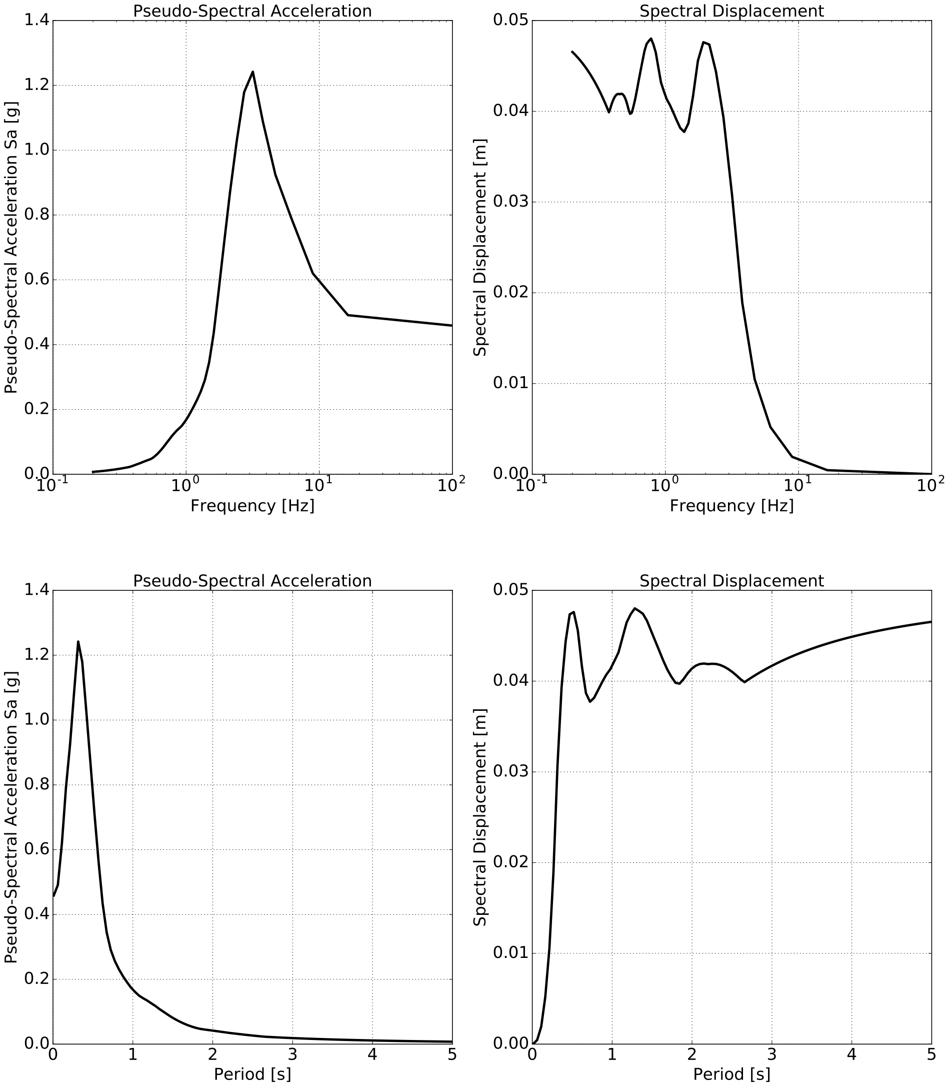

Figure 410.4: Simulation results: response spectrum at soil top.

410.1.2 Free Field 3C

Elastic Material. The compressed package of input files for this example is HERE.

The Modeling parameters are listed below:

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 5 minutes.

von-Mises Armstrong-Frederick Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- von-Mises nonlinear hardening material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - von Mises radius, k, 60 kPa
  - Nonlinear kinematic hardening, H_a, 30 MPa
  - Nonlinear kinematic hardening, C_r, 60
  - Shear strength ($\approx \sqrt{2/3}\ H_a/C_r$), S_u, 408 kPa
  - Isotropic hardening rate, K_{iso}, 0 Pa

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 17 minutes.

von-Mises G/Gmax Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- von-Mises G/Gmax material model

  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - Total number of shear modulus 9
  - G over Gmax, 1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063
  - Shear strain gamma, 0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 565 minutes.

Drucker-Prager G/Gmax Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- Drucker-Prager G/Gmax material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - Initial confining stress, p_0, 100 kPa
  - Reference pressure, p_{refer}, 100 kPa
  - Pressure exponential, n, 0.5
  - Cohesion, n, 1 kPa
  - Total number of Shear Modulus 9
  - G over Gmax, 1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063
  - Shear strain gamma, 0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 565 minutes.

Results are shown in Fig. 410.56.

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 871 minutes.

The time series of simulation results is shown in Fig. 410.7.

The response spectrum of motion is shown in Fig. 410.8.

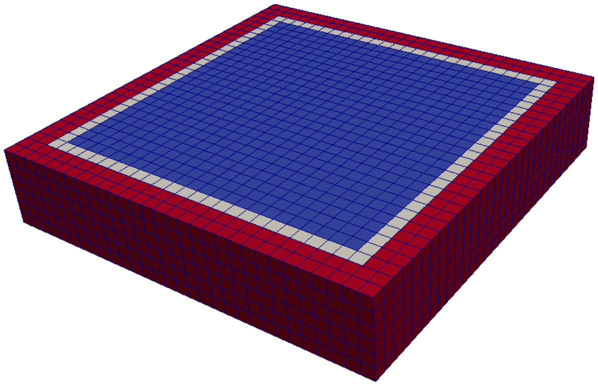

Figure 410.5: Simulation model.

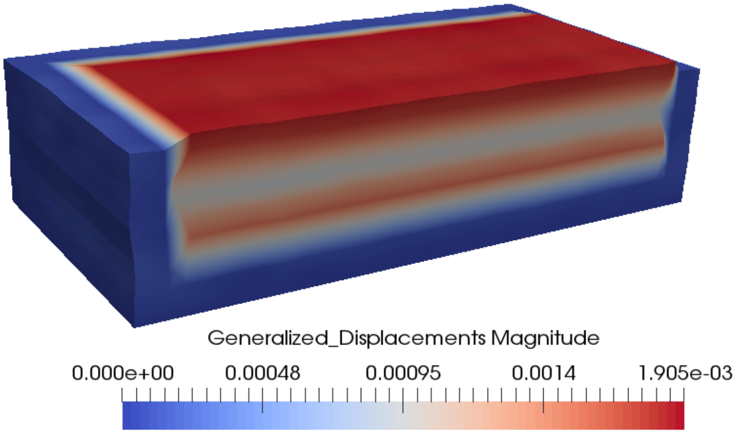

Figure 410.6: Simulation model.

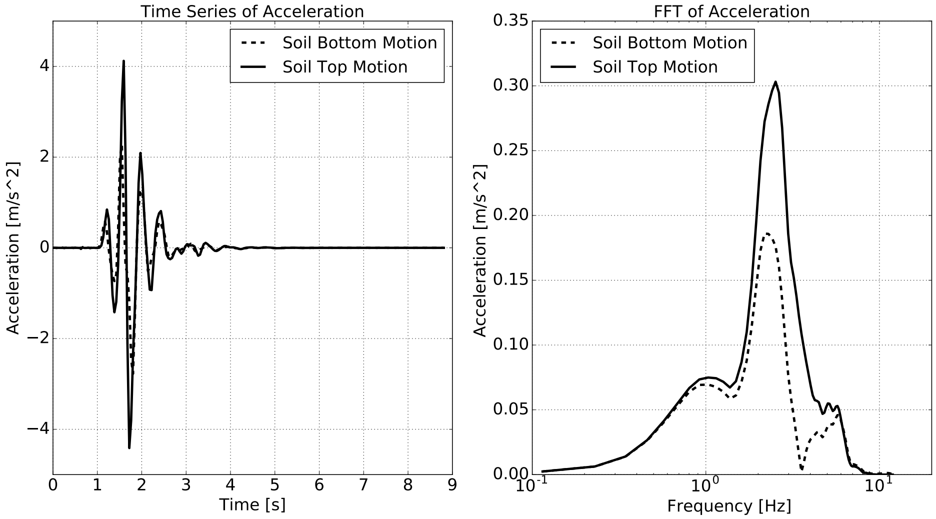

Figure 410.7: Simulation results: acceleration time series.

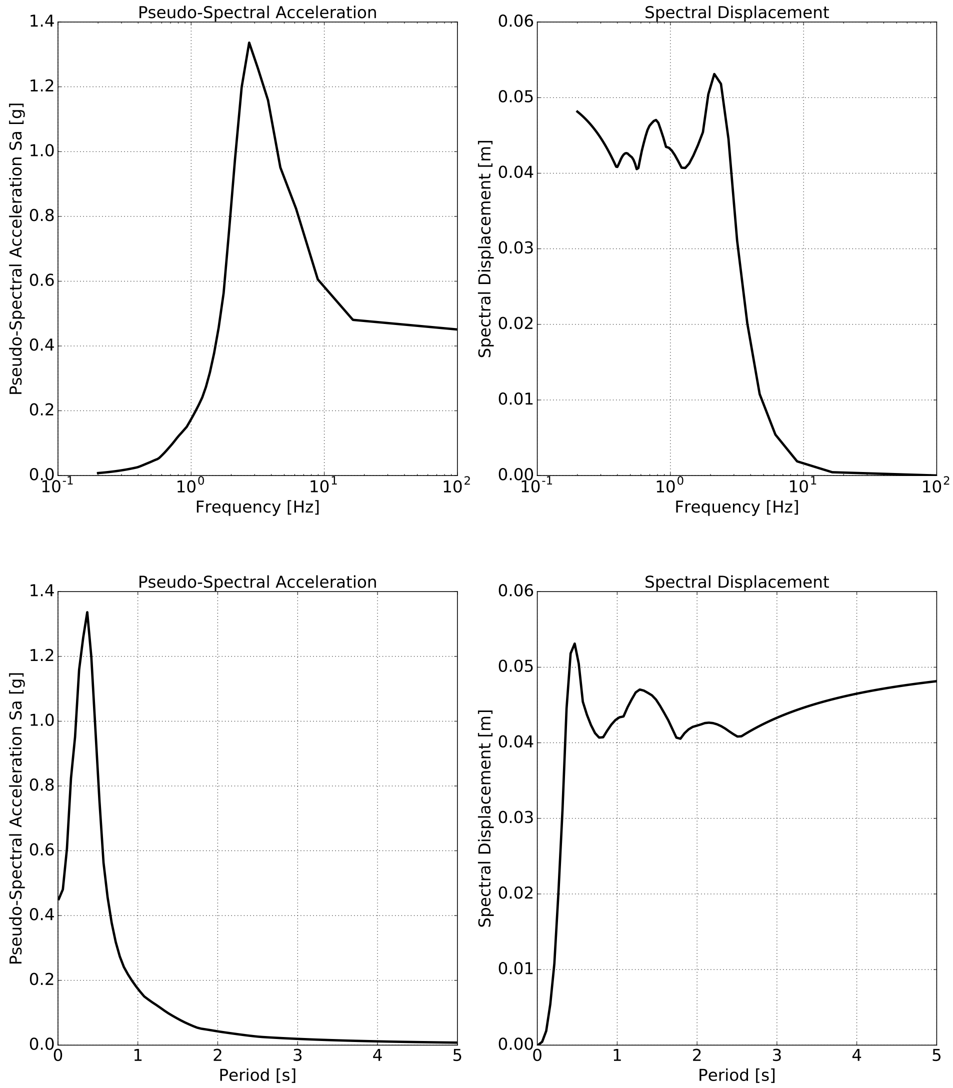

Figure 410.8: Simulation results: response spectrum at soil top.

410.1.3 Soil-Foundation Interaction 3D

Elastic Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 13 minutes.

von-Mises Armstrong-Frederick Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- von-Mises nonlinear hardening material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - von Mises radius, k, 60 kPa
  - Nonlinear kinematic hardening, H_a, 30 MPa
  - Nonlinear kinematic hardening, C_r, 60
  - Shear strength ($\approx \sqrt{2/3}\ H_a/C_r$), S_u, 408 kPa
  - Isotropic hardening rate, K_{iso}, 0 Pa

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 36 minutes.

von-Mises G/Gmax Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- von-Mises G/Gmax material model

  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - Total number of shear modulus 9
  - G over Gmax, 1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063
  - Shear strain gamma, 0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 726 minutes.

Drucker-Prager G/Gmax Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- Drucker-Prager G/Gmax material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - Initial confining stress, p_0, 100 kPa
  - Reference pressure, p_{refer}, 100 kPa
  - Pressure exponential, n, 0.5
  - Cohesion, n, 1 kPa
  - Total number of Shear Modulus 9
  - G over Gmax, 1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063
  - Shear strain gamma, 0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 1252 minutes.

Contact/Interface/Joint Elements. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 24 minutes.

Both Elastoplastic Material and Contact/Interface/Joint Elements. The compressed package of input files is HERE.

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 41 minutes.

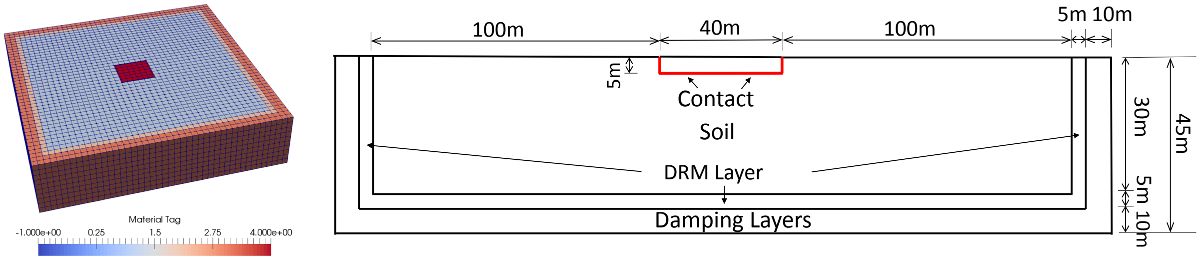

Figure 410.9: Simulation model.

Results of the simulation are shown in Fig. 410.12.

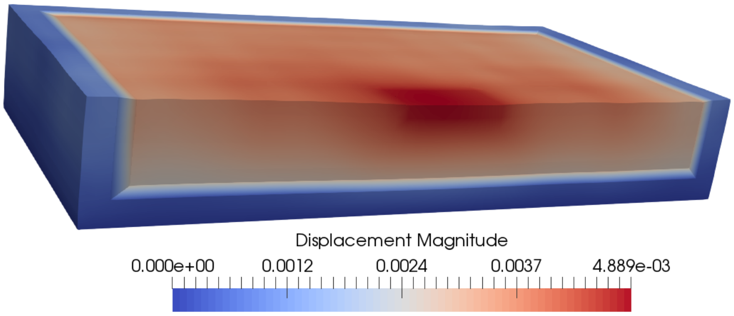

Figure 410.10: Soil foundation interaction results.

410.1.4 Soil-Structure Interaction 3D

Elastic Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 10 minutes.

von-Mises Armstrong-Frederick Material. The compressed package of input files is HERE.

The Modeling parameters are listed below:

- von-Mises nonlinear hardening material model
  - Mass density, ρ, 2000 kg/m^3
  - Shear wave velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
  - von Mises radius, k, 60 kPa
  - Nonlinear kinematic hardening, H_a, 30 MPa
  - Nonlinear kinematic hardening, C_r, 60
  - Shear strength ($\approx \sqrt{2/3}\ H_a/C_r$), S_u, 408 kPa
  - Isotropic hardening rate, K_{iso}, 0 Pa

SIMULATION TIME: With 8 cores on AWS EC2 c4.2xlarge instance, the running time for this example is 46 minutes.

von-Mises G/Gmax Material. The compressed package of input files is HERE.

410.1.5 Analysis of a Structure without Soil

410.1.5.1 Eigen Analysis

Eigen analysis of a fixed base structural model should provide a good check of the structural model, natural (eigen) frequencies, and natural (eigen) modes.

The compressed package of input files is HERE.

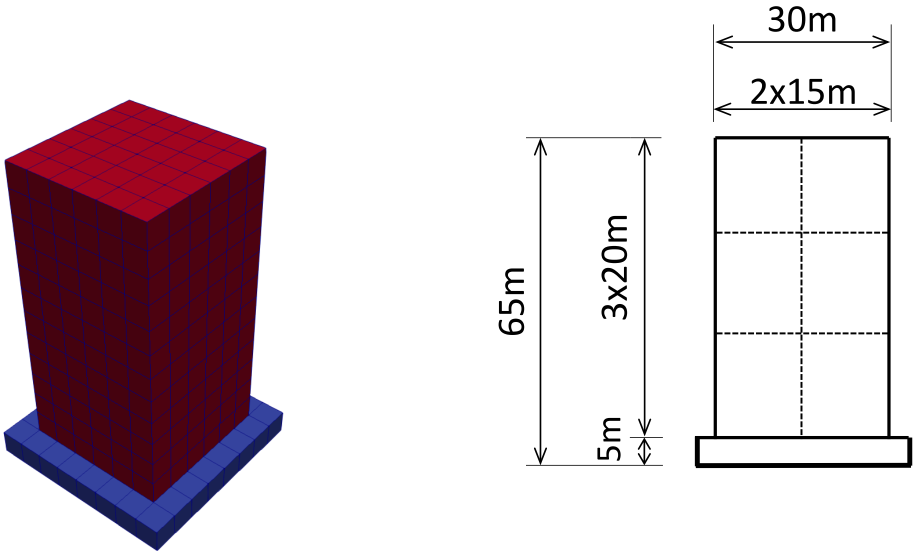

Figure 410.17: Structure on a fixed based simulation model.

For this particular example, eigen modes and frequencies are given in Figures 410.18 and 410.19

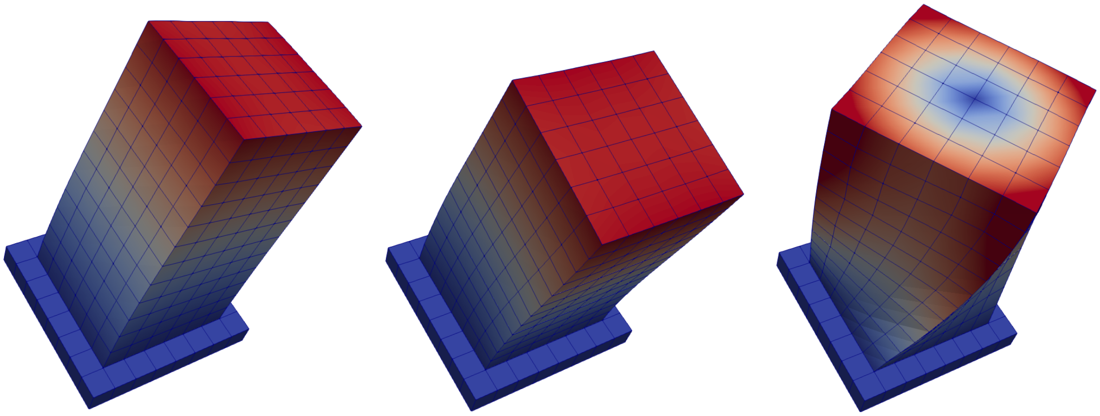

Figure 410.18: Eigen frequencies: f_1 = 3.47Hz f_2 = 3.47Hz f_3 = 6.88Hz (eigen mode 1 to 3 from left to right).

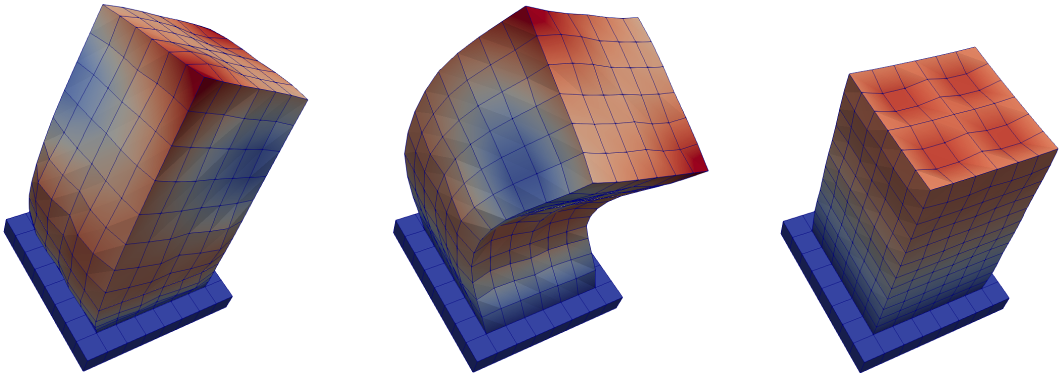

Figure 410.19: Eigen frequencies: $f_4 = 11.50\text{Hz}$ $f_5 = 11.50\text{Hz}$ $f_6 = 12.13\text{Hz}$ (eigen modes 4 to 6 from left to right).

Input files for eigen analysis of the fixed base structure are available at this LINK, and can be directly simulated using Real-ESSI Simulator, `http://real-essi.us/`, that is available on Amazon Web Services, `https://aws.amazon.com/`.

410.1.5.2 Imposed Motion

The Real-ESSI input files for this example are available HERE. The compressed package of input files is HERE.

In addition to eigen analysis, fixed base structural model is used to test response of a fixed base structure. This is important as it provides an opportunity to compare results between different finite element programs, some of which can only model dynamics of fixed base structures.l

The simulation model is shown below.

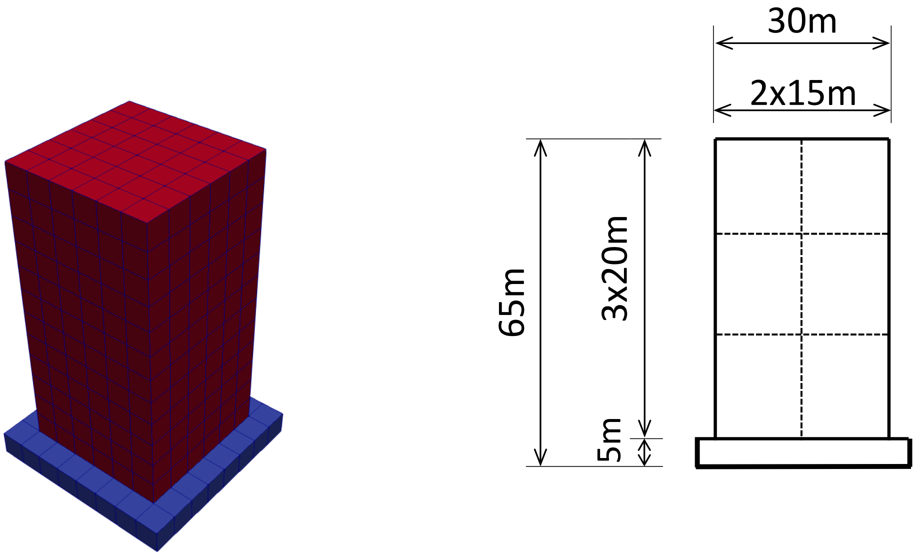

Figure 410.20: Simulation Model.

The simulation results:

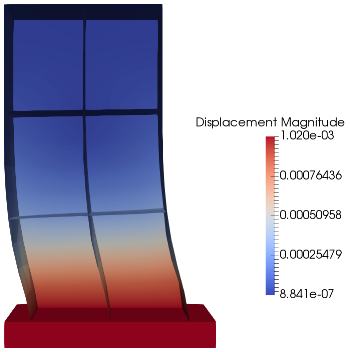

Figure 410.21: Simulation Results.

The time series of simulation results is shown in Fig. 410.22.

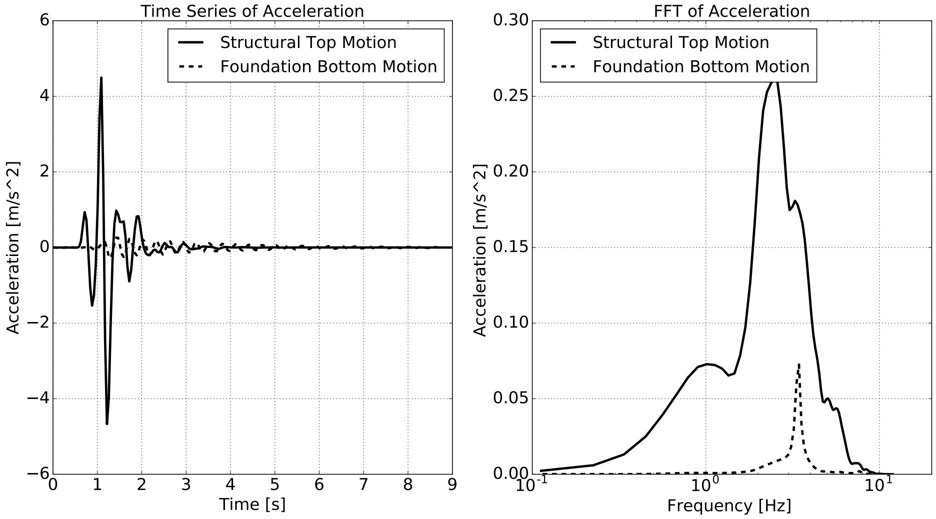

Figure 410.22: Simulation Results: Acceleration Time Series with 1C imposed motion.

The response spectrum of motion is shown in Fig. 410.23.

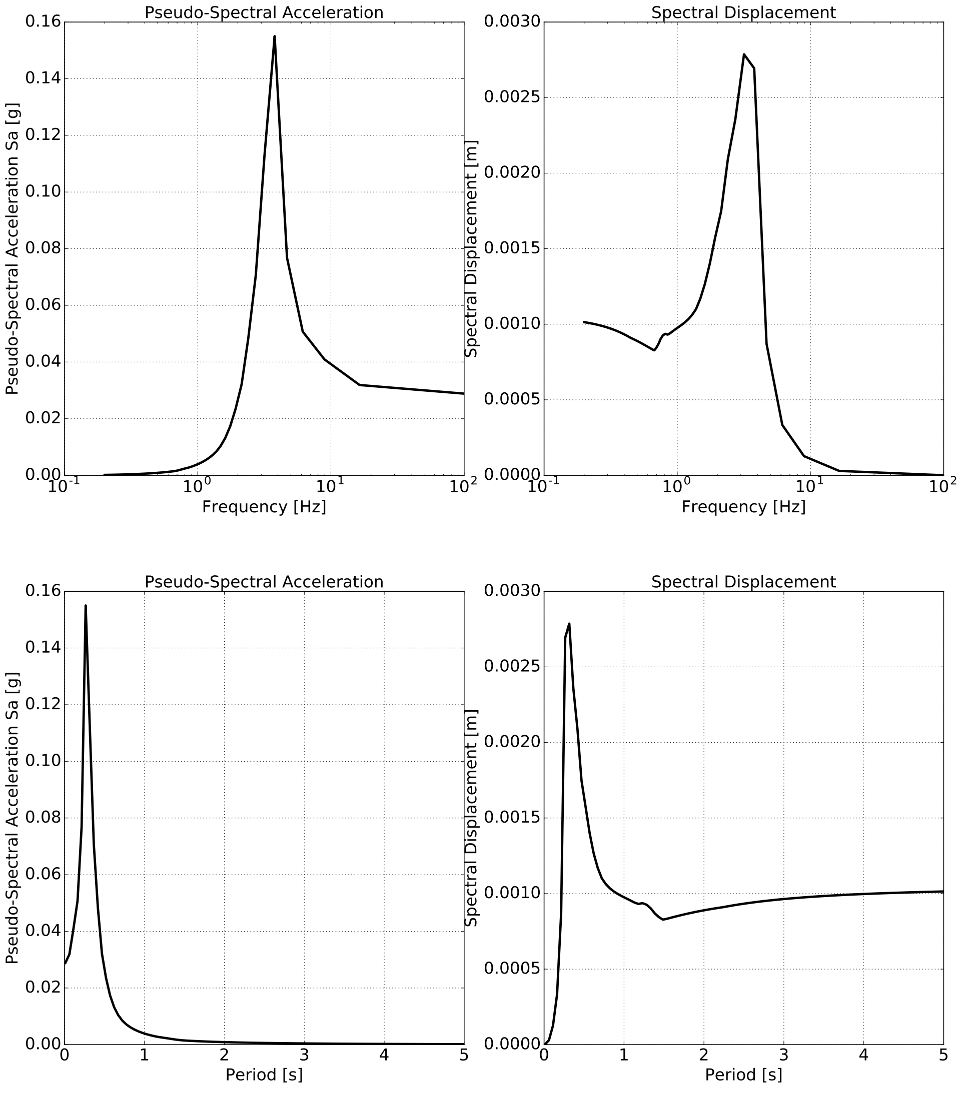

Figure 410.23: Simulation Results: Response Spectrum of Structure Top with 1C imposed motion.

410.2 Day 1: Overview

410.2.1 Nuclear Power Plant with 3C motions from SW4

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

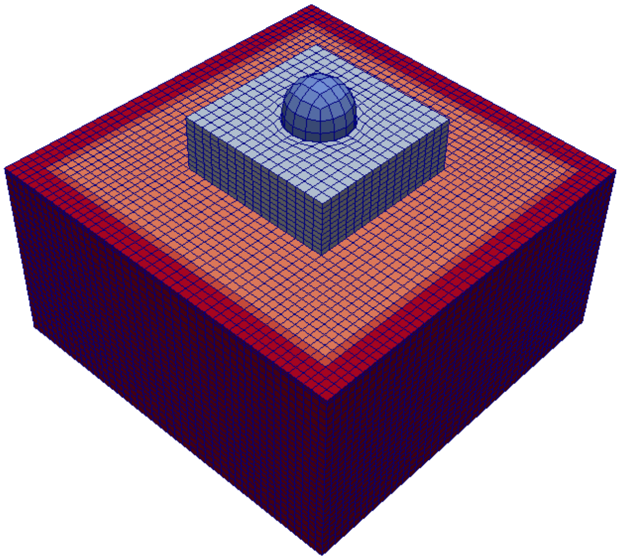

Figure 410.24: Simulation Model.

The Modeling parameters are listed below:

- Soil
  - Unit weight, γ, 21.4 kPa
  - Shear velocity, Vs, 500 m/s
  - Young's modulus, E, 1.3 GPa
  - Poisson's ratio, ν, 0.25
  - Shear strength, S_u, 650 kPa
  - von Mises radius, k, 60 kPa
  - kinematic hardening, H_a, 30 MPa
  - kinematic hardening, C_r, 25
- Structure
  - Unit weight, γ, 24 kPa

  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.21

The input motion at the bottom is a 3C wave from SW4.

SIMULATION TIME: With 32 cores on AWS EC2 c4.8xlarge instance, the running time for this example is 17 hours.

410.2.2 Nuclear Power Plant with 1C motions from Deconvolution

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

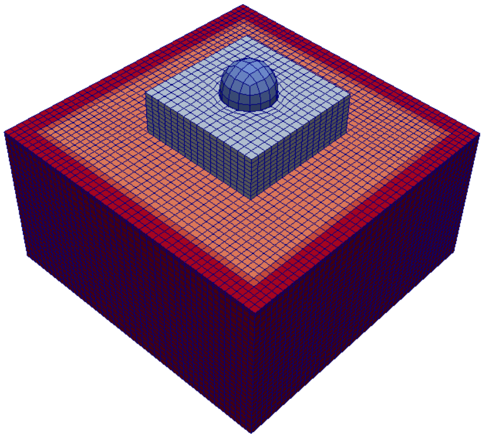

Figure 410.25: Simulation Model.

The input motion at the bottom is the deconvolution of the Northridge earthquake records.

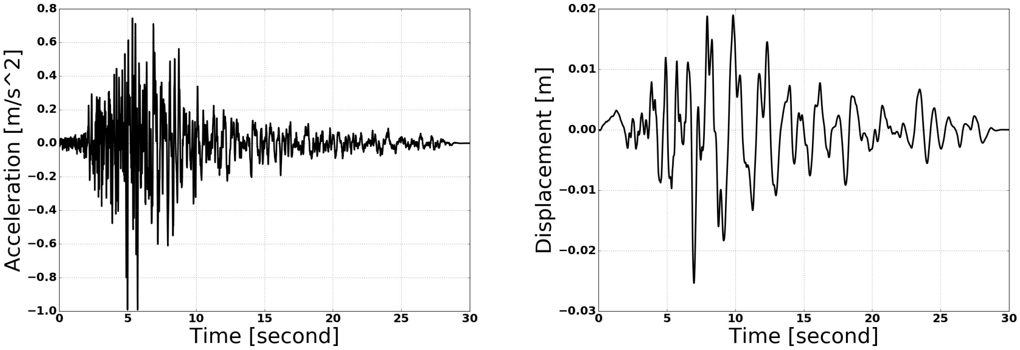

Figure 410.26: Motion Deconvolution.

The Modeling parameters are listed below:

- Soil
  - Unit weight, γ, 21.4 kPa
  - Shear velocity, Vs, 500 m/s
  - Young's modulus, E, 1.3 GPa
  - Poisson's ratio, ν, 0.25

  - Shear strength, S_u, 650 kPa
  - von Mises radius, k, 60 kPa
  - kinematic hardening, H_a, 30 MPa
  - kinematic hardening, C_r, 25

- Structure
  - Unit weight, γ, 24 kPa
  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.21

410.2.3 Nuclear Power Plant with 3×1C motions from Deconvolution

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

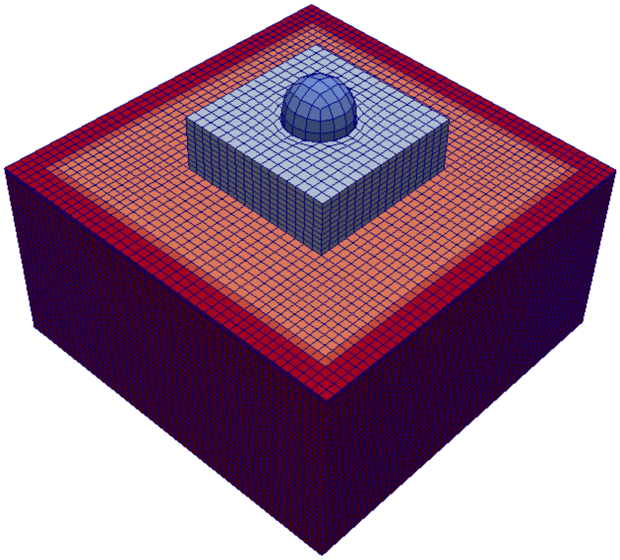

Figure 410.27: Simulation Model.

The input motion at the bottom is the deconvolution of the Northridge earthquake records.

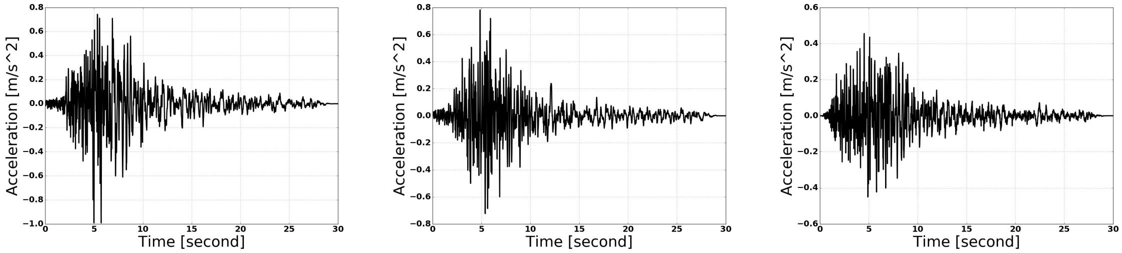

Figure 410.28: Acceleration Deconvolution, from left to right in x, y, z directions respectively. .

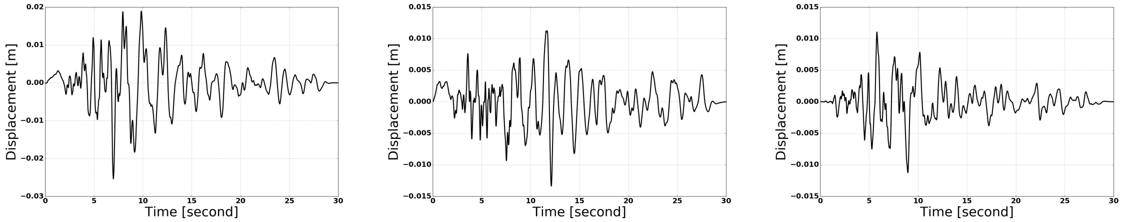

Figure 410.29: Displacement Deconvolution, from left to right in x, y, z directions respectively. .

The Modeling parameters are listed below:

- Soil
  - Unit weight, γ, 21.4 kPa
  - Shear velocity, Vs, 500 m/s
  - Young's modulus, E, 1.3 GPa
  - Poisson's ratio, ν, 0.25
  - Shear strength, S_u, 650 kPa
  - von Mises radius, k, 60 kPa
  - kinematic hardening, H_a, 30 MPa
  - kinematic hardening, C_r, 25
- Structure
  - Unit weight, γ, 24 kPa
  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.21

410.2.4 Single Element Models: Illustration of the Elastic-Plastic Behavior

The compressed package of Real-ESSI input files for this example with von-Mises material model are available HERE.

The compressed package of Real-ESSI input files for this example with Drucker-Prager material model are available HERE.

The Modeling parameters are listed below:

- von-Mises linear hardening material model
  - Mass Density, ρ, 0.0 kg/m^3
  - Young's modulus, E, 20 MPa
  - Poisson's ratio, ν, 0.0
  - von Mises radius, k, 100 kPa
  - kinematic hardening rate, K_{kine}, 2 MPa
  - isotropic hardening rate, K_{iso}, 0 Pa
- Drucker-Prager nonlinear hardening material model
  - Mass Density, ρ, 0.0 kg/m^3
  - Young's modulus, E, 20 MPa
  - Poisson's ratio, ν, 0.0
  - Drucker-Prager, k, 0.179527
  - nonlinear kinematic hardening, H_a, 20 MPa
  - nonlinear kinematic hardening, C_r, 100
  - isotropic hardening rate, K_{iso}, 0 Pa
  - initial confining stress, p_0, 1 Pa

Inelastic/nonlinear material behavior is shown in Fig. 410.31.

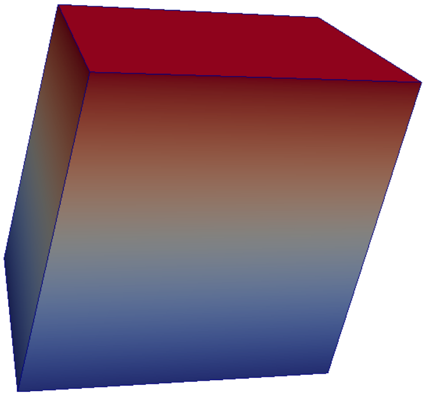

Figure 410.30: Simulation Model of Single Element.

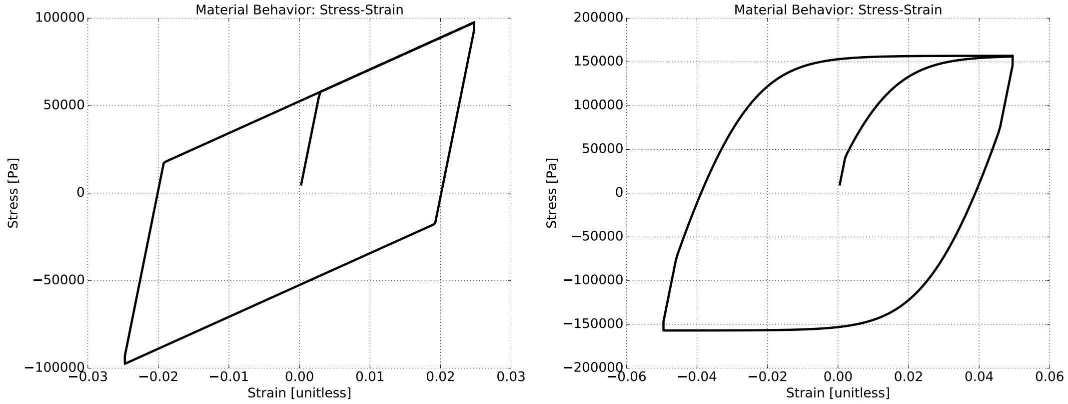

Figure 410.31: Inelastic/Nonlinear material behavior.

410.2.5 Pushover for Nonlinear Frame

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

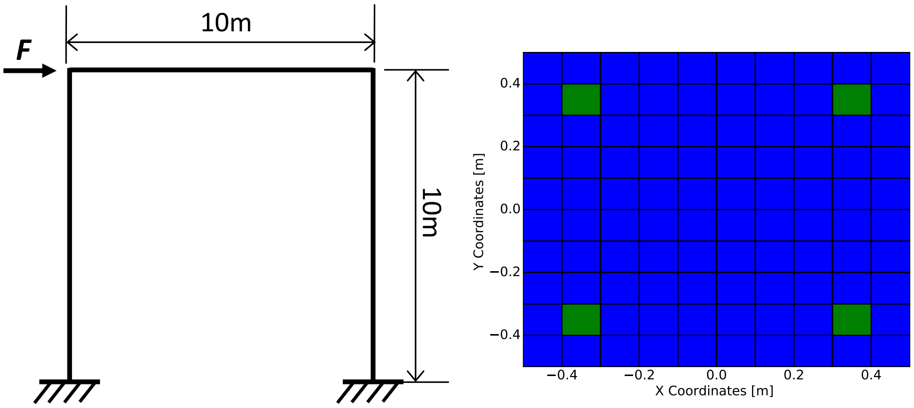

Figure 410.32: Model for pushover simulation and the cross section of fiber beam (concrete and reinforcement).

Result are shown in Fig. 410.33.

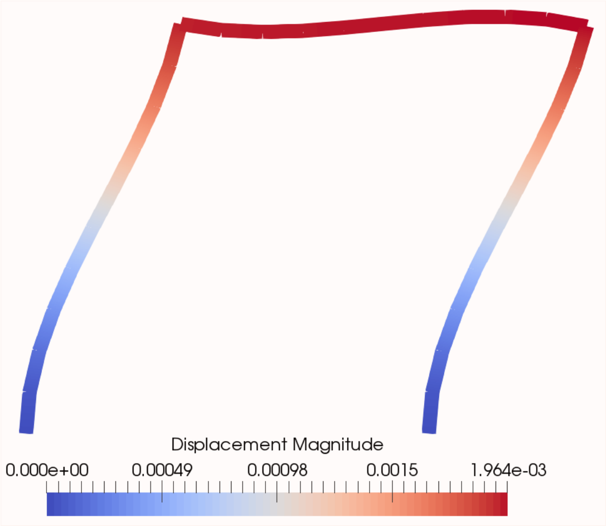

Figure 410.33: Results for fiber beam pushover.

The Modeling parameters are listed below:

- Uniaxial concrete
  - Compressive strength, 24 MPa
  - Strain at compressive strength, 0.001752

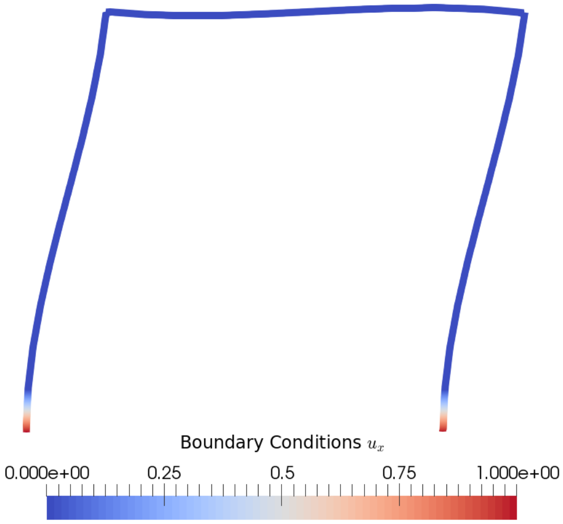

Figure 410.34: Boundary condition u_x for fiber beam pushover.

  - Crushing strength, 0.0 Pa
  - Strain at compressive strength, 0.003168
  - lambda, 0.5
  - Tensile strength, 0 Pa
  - Tension softening stiffness, 0 Pa

- Uniaxial steel
  - Yield strength, 413.8 MPa
  - Young's modulus, 200 GPa
  - Strain hardening ratio, 0.01
  - R0, 18.0
  - cR1, 0.925
  - cR2, 0.15
  - a1, 0.0
  - a2, 55.0
  - a3, 0.0
  - a4, 55.0

410.2.6 Pre-Processing examples with Gmsh

410.2.6.1 Cantilever Example

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

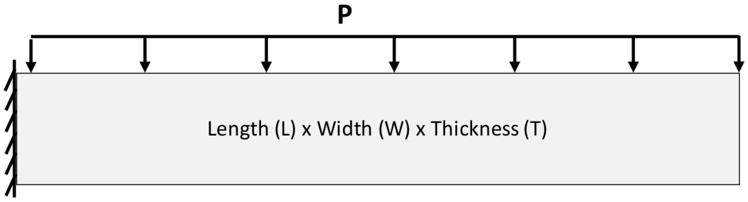

Figure 410.35: Simulation Model Cantilever.

Results are shown in Fig. 410.36.

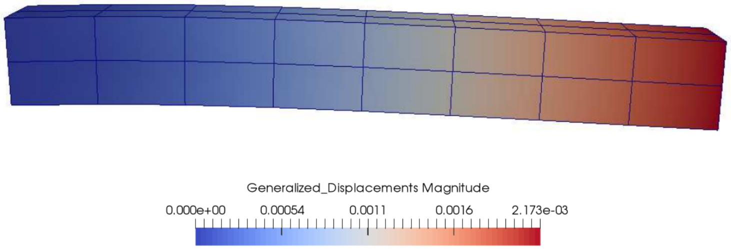

Figure 410.36: Simulation model. cantilever, results.

410.2.6.2 Brick-shell-beam Example

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

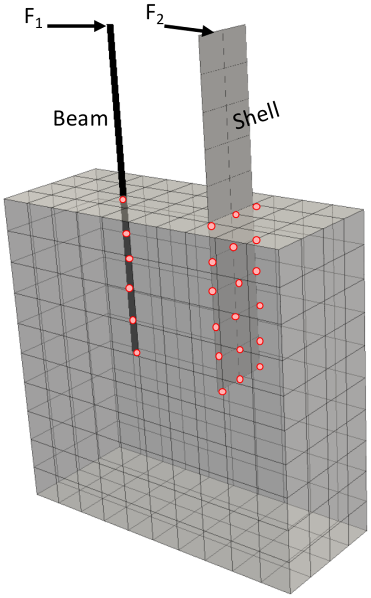

Figure 410.37: Simulation Model Brick-Shell-Beam.

Results are shown in Fig. 410.38.

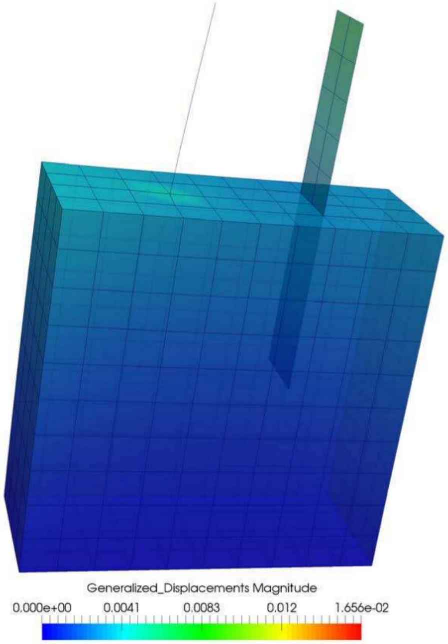

Figure 410.38: Brick-Shell-Beam, Results.

410.2.6.3 DRM 2D Example

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

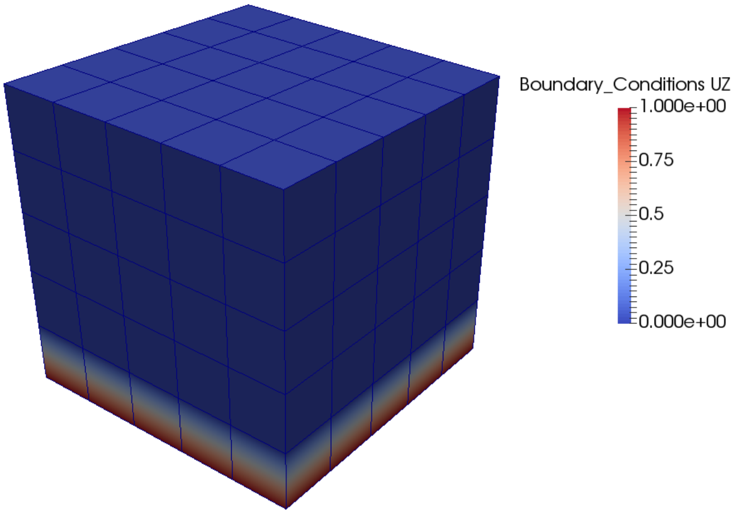

Figure 410.48: Partition Information Visualization with Paraview.

410.2.9 Restart Simulation

410.2.9.1 Restart in the next stage

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

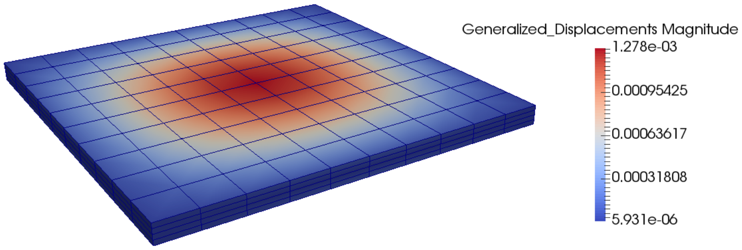

Figure 410.49: Restart Simulation.

This group of examples illustrates the restart functionality between loading stages. There are three test cases in this example. The two loading stages in the first test case is split into two test cases to show the restart feature.

- The first test case run through two loading stages.
- The second test case only run the first loading stage and saves model state at the end.
- The third test case restart the simulation from the saved model state of the second test case. Then, with the restart model state, the test case run the second loading stage only.

Results of the third test case are exactly the same to the first test case.

410.2.9.2 Restart inside the stage

For the case of lack of convergence, restart with the previous loading stage.

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

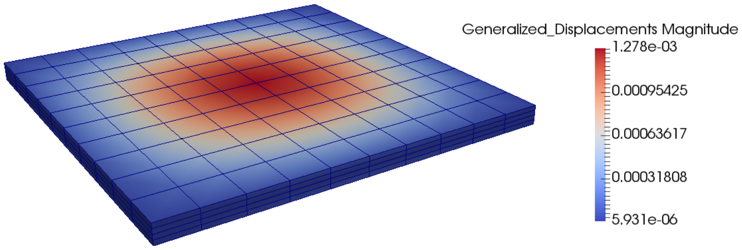

Figure 410.50: Restart Simulation.

This group of examples illustrate the restart functionality inside one loading stage when the simulation cannot converge in the nonlinear analysis. The nonlinear material model, von-Mises Armstrong-Frederick, is used in all test cases.

There are three test cases in this example.

- The first test case run through the whole simulation with a relatively big tolerance of the unbalanced force.
- The second test case failed in the middle of the simulation with a relatively small tolerance of the unbalanced force. When the second test failed, the model reverted to the last commit model state and saved model state.
- The third test case load the saved model state, increased the tolerance of the unbalanced force, and added the remaining load to the model to continue the simulation.

Results of the third test case are exactly the same to the first test case.

Note that in the third test case only the remaining load should be added to the model. Whenever the new loading stage is used, the previous loading are all finished, which means that the static loading becomes constant and the dynamic loading vanishes.

410.3 Day 2: Seismic Motions

410.3.1 Deconvolution and Propagation of 1C Motions, 1D Model

Various deconvolution and propagation 1D models for one component (1C) wave propagation are provided through links below.

Note: Please make sure that the input acceleration record is baseline corrected and the displacement record has no permanent deformation. Otherwise, the unrealistic high frequency components can be brought into the simulation results.

- Deconvolution of Ormsby wavelet, input files are available HERE.
- Deconvolution of Northridge earthquake, input files are available HERE.
- Deconvolution of and DRM propagation of Ormsby wavelet, input files are available HERE.
- Deconvolution of and DRM propagation of Northridge earthquake, input files are available HERE.

410.3.2 Convolution and Propagation of 1C Motions, 1D Model

Various convolution and propagation 1D models for one component (1C) wave propagation are provided through links below:

Note: Please make sure that the input acceleration record is baseline corrected and the displacement record has no permanent deformation. Otherwise, the unrealistic high frequency components can be brought into the simulation results.

- Convolution of Ormsby wavelet, input files are available HERE.
- Convolution of Northridge earthquake, input files are available HERE.
- Convolution of and DRM propagation of Ormsby wavelet, input files are available HERE.
- Convolution of and DRM propagation of Northridge earthquake, input files are available HERE.

410.3.3 Convolution, Deconvolution and Propagation of 1C Motions, 2D Model

Various convolution, deconvolution and propagation 2D models for one component (1C) wave propagation are provided through links below.

Note #1: Please make sure that the input acceleration record is baseline corrected and the displacement record has no permanent deformation. Otherwise, the unrealistic high frequency components can be brought into the simulation results.

Note #2: Please make sure that you develop seismic motions by doing deconvolution and then convolution before analyzing the actual model. File `run.sh` in examples directory has a proper sequence of commands, that is one should first run Real-ESSI on `Deconvolution_DRM_motion.fei` and then, when motions are developed, analyze model.

Examples are available through links below:

- Convolution/Deconvolution of and DRM propagation of Ormsby wavelet, input files are available HERE.
- Convolution/Deconvolution of and DRM propagation of Kobe earthquake records, input files are available HERE.

410.3.3.1 ESSI 3D building model, deconvolution 1C model, shell model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Elastic Soil Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear Wave Velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
- Elastic Structure Material Properties
  - Mass density, ρ, 2500 kg/m^3
  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.1

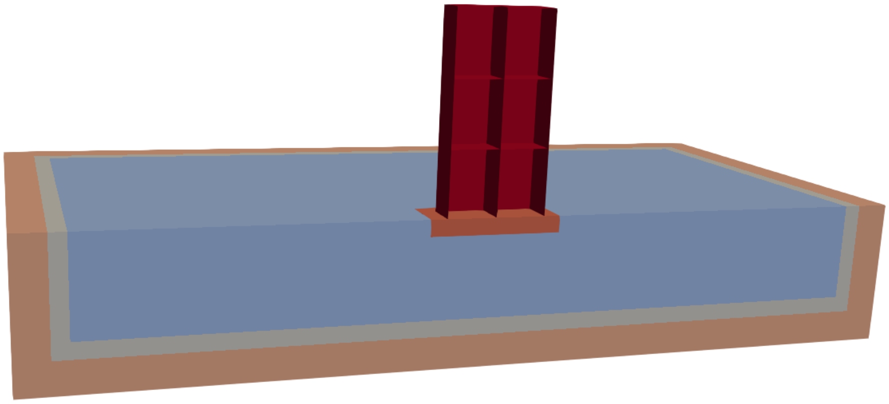

Figure 410.51: Simulation Model.

Results of DRM 3D shell Structure Model under 1C motion are shown in Fig. 410.52.

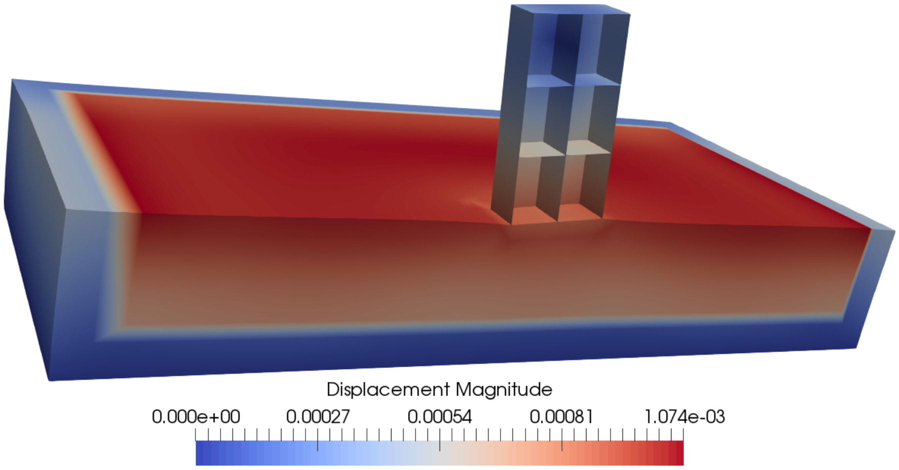

Figure 410.52: Simulation Model.

410.3.4 Deconvolution 3×1C Motions

410.3.4.1 Free field 1C model, deconvolution 3×1C motion, model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Elastic Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear Wave Velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

Figure 410.53: Simulation Model.

Results of the simulation are shown in Fig. 410.1.

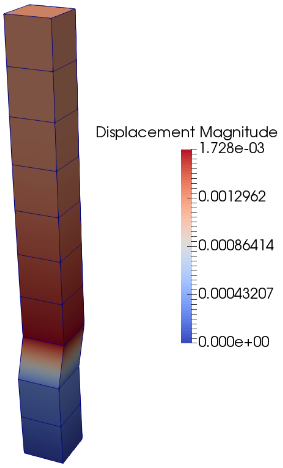

Figure 410.54: Simulation Model.

410.3.4.2 Free field 3D model, deconvolution 3×1C motion, model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Elastic Soil Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear Wave Velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1

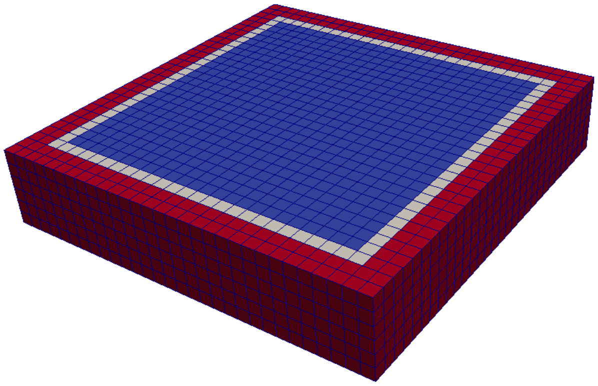

Figure 410.55: Simulation Model.

Results of the simulation are shown in Fig. 410.56.

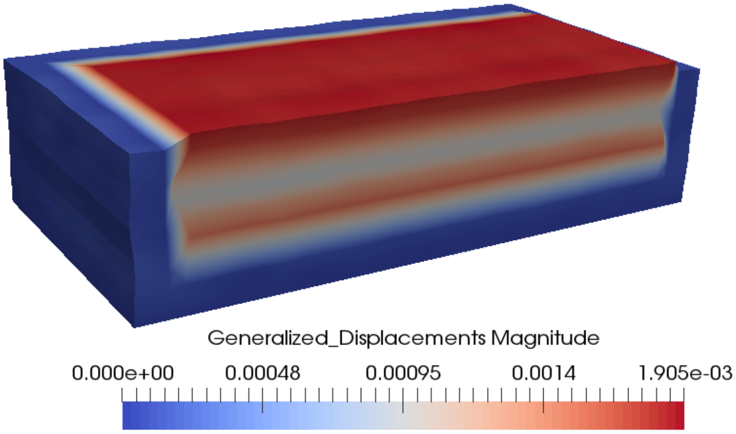

Figure 410.56: Simulation Model.

410.3.4.3 ESSI 3D building model, deconvolution 3×1C motion, shell model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Elastic Soil Material Properties
  - Mass density, ρ, 2000 kg/m^3
  - Shear Wave Velocity, V_s, 500 m/s
  - Young's modulus, E, 1.1 GPa
  - Poisson's ratio, ν, 0.1
- Elastic Structure Material Properties
  - Mass density, ρ, 2500 kg/m^3
  - Young's modulus, E, 20 GPa
  - Poisson's ratio, ν, 0.1

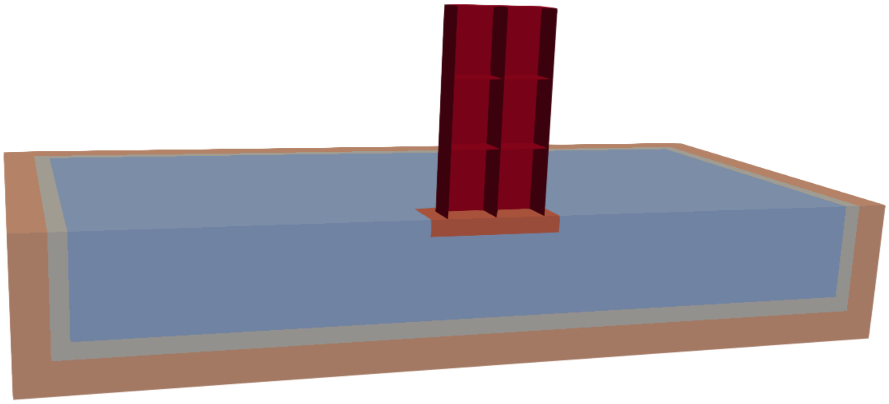

Figure 410.57: Simulation Model.

Results of DRM 3D shell Structure Model under 1C motion are shown in Fig. 410.58.

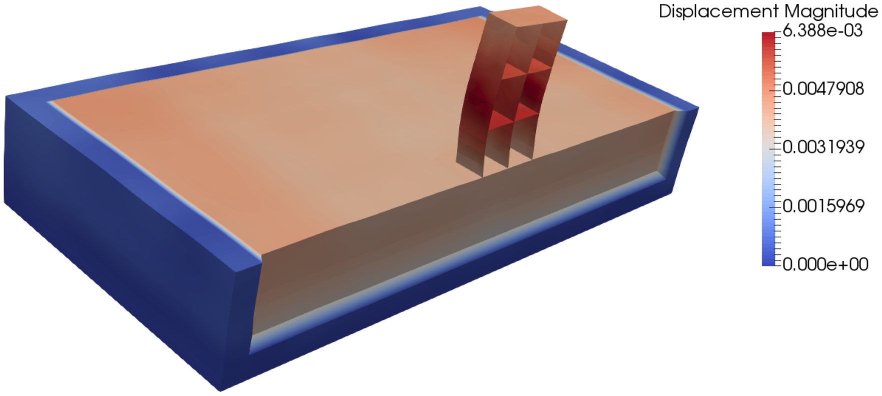

Figure 410.58: Simulation Model.

410.3.5 Mesh Dependence of Wave Propagation Frequencies

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

Show the mesh dependence of high frequency wave with Ormsby wavelet.

Figure 410.59: Simulation Model.

Results of mesh dependence are shown in Fig. 410.60.

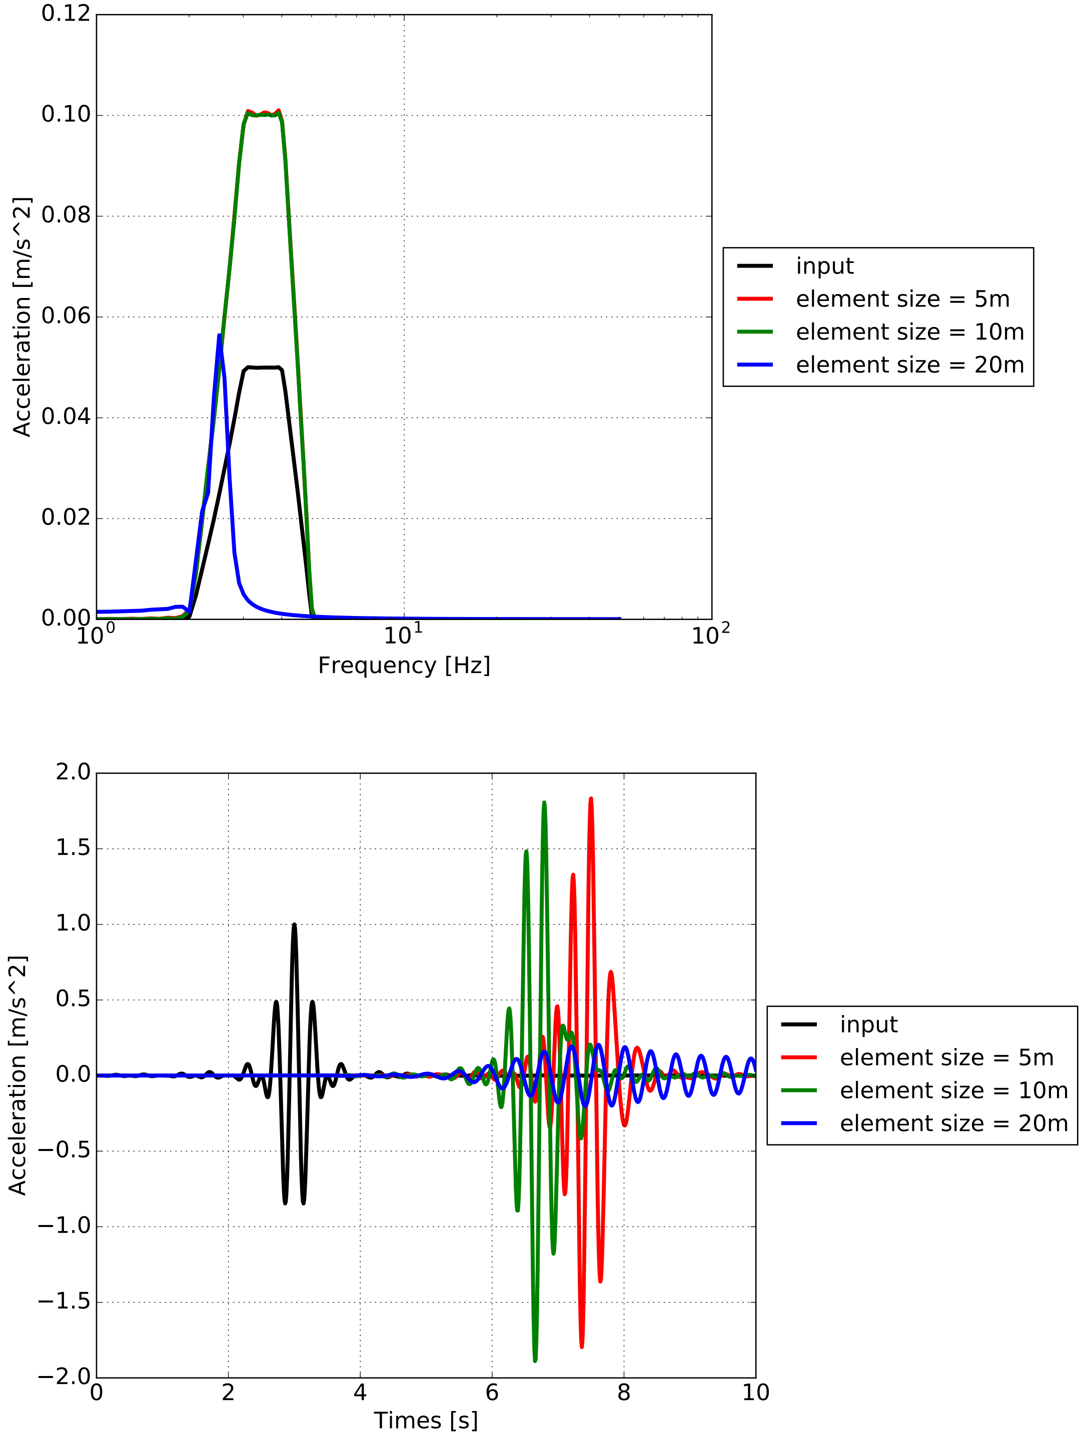

Figure 410.60: Convolution Results and Mesh Dependence.

410.3.6 Application of 3C Motions from SW4

410.3.6.1 3C Seismic Motion from SW4

A 3C seismic motion field has been developed by using SW4. The characteristic parameters of the seismic motion are given below:

- Geological model: length $3km$, width $3km$, height $1.7km$, grid size $50m$, width of super grid damping layer $30m$.
- Material model: Elastic material, First $1km$: $V_p = 4630.76m/s$, $V_s = 2437.56m/s$, $\rho = 2600kg/m^3$. $1km \sim 1.7km$: $V_p = 6000m/s$, $V_s = 3464m/s$, $\rho = 2700kg/m^3$
- Source type: point moment source, moment seismic moment $M_{xy} = 5e^{15} N \cdot m$, moment magnitude 4.5.
- Time function: Gaussian function, with dominant frequency $2.5Hz$ and maximum frequency $6.5Hz$.

The time series displacement and acceleration response at the center of the model is shown below in figure 410.61. And figure 410.62 gives corresponding FFT response.

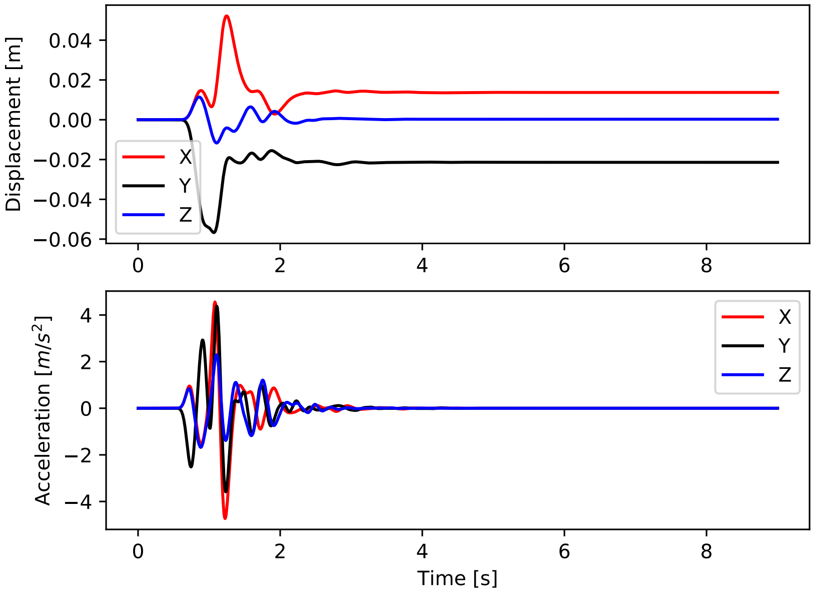

Figure 410.61: Time series response of 3C motion.

During the simulation of SW4, the time series motions at many ESSI nodes (basically are some pre-defined record stations) of an ESSI box ($300m \times 300m \times 100m$) are recorded and written into SAC

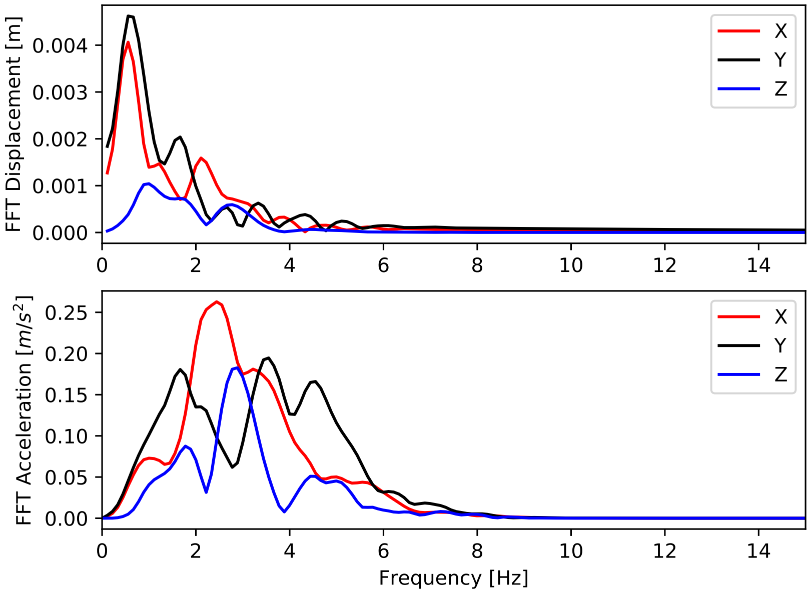

Figure 410.62: FFT response of 3C motion.

files. Then an transition program SW42ESSI has been developed to interpolate these motions to DRM nodes of localized ESSI model by specifying some geometric translational and rotational transformation, as shown in figure ??.

To launch SW42ESSI, following parameters are needed:

- DRM input: specify the name of DRM input files. This DRM file just contains the geometric information of DRM layer in ESSI model (e.g. DRM node IDs, nodal coordinates, etc).
- SW4 motion directory: specify the output directory of SW4, that contains SAC files.
- origin coordinates of ESSI box (x, y, z): the SW4 coordinates of the origin of ESSI box, i.e. the coordinates of ESSI nodes, whose station ID is (0, 0, 0).
- dimensions of ESSI Box (length, width, height): specify the dimension (length, width and height) of ESSI box.
- spacing of ESSI nodes: specify the grid spacing of ESSI nodes (i.e. motion recording stations)
- interval of time steps for sampling: specify the sampling frequency, if 1 is used here, ESSI simulation time step is the same as the simulation time step of SW4.

- reference point in ESSI model for translational transformation (x, y, z): specify the coordinate of reference point for translational transformation in ESSI model.
- reference point in SW4 model for translational transformation (x, y, z): specify the coordinate of reference point for translational transformation in SW4 model.
- conduct rotational transformation (yes/no): input yes and provide more rotational transformation parameters to enable rotational transformation. If input no, no more parameters are required.
- reference point in SW4 model for rotational transformation (x, y, z): specify the coordinate of reference point for rotational transformation in SW4 model.
- degrees of rotation along three axes (x, y, z): specify the degrees of rotation along three axes. The sign of rotation degrees follows right hand rule.

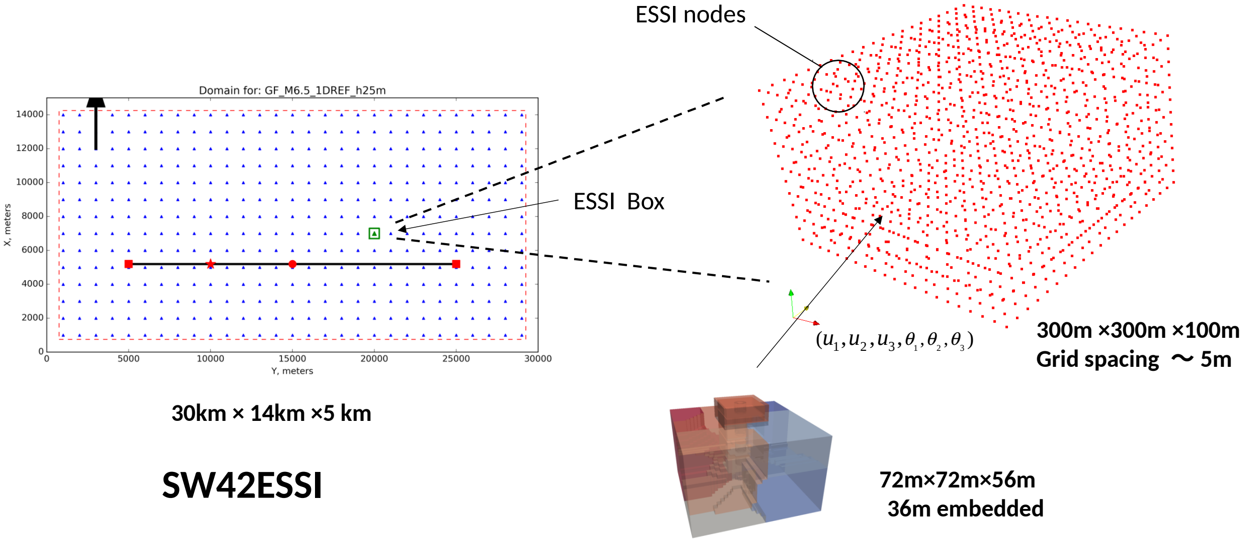

Figure 410.63: Illustration of transition from SW4 to Real-ESSI.

410.3.6.2 Free field 3D model, 3C motion, model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

Results of free field DRM 3D Model under 3C motion are shown in figure 410.65.

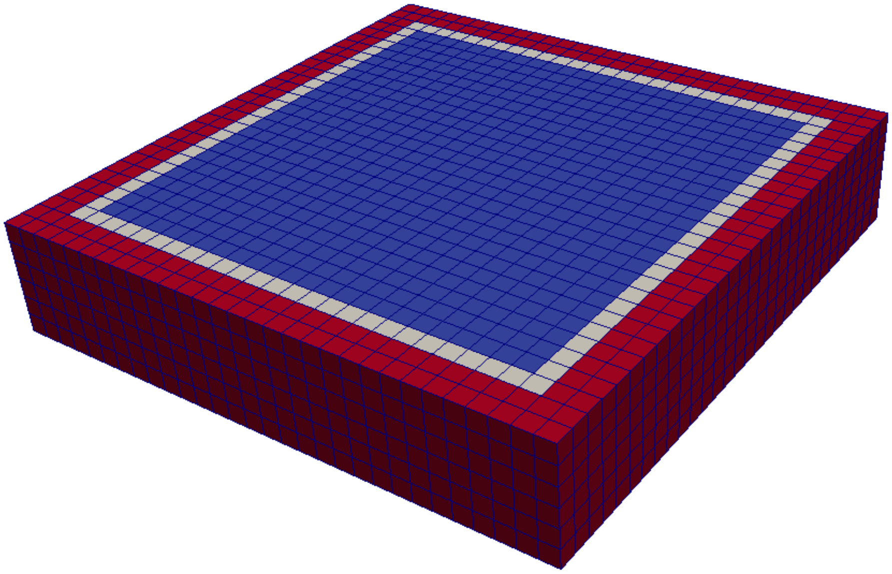

Figure 410.64: Simulation Model.

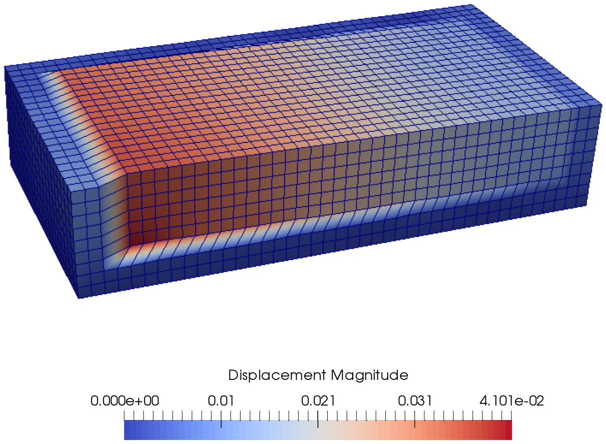

Figure 410.65: Simulation of 3D free field model under 3C seismic motion.

410.3.6.3 ESSI 3D building model, 3C motion, shell model with DRM

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

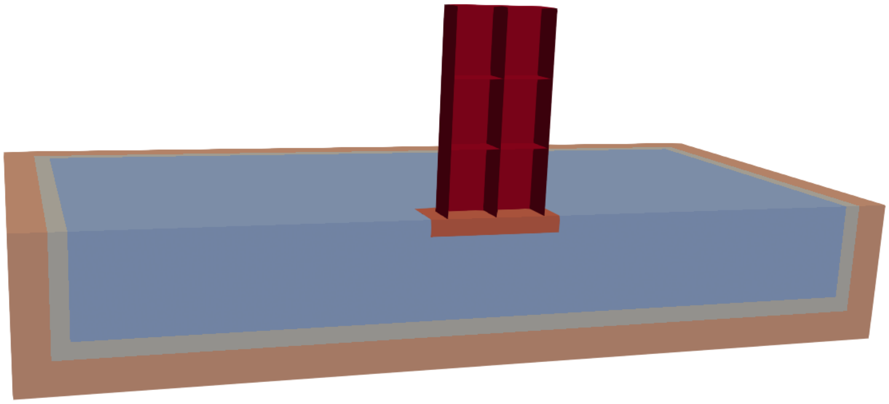

Figure 410.66: Simulation Model.

410.4 Day 3: Inelastic, Nonlinear Analysis

410.4.1 Single Element Models: Illustration of the Elastic-Plastic Behavior

410.4.1.1 von-Mises Perfectly Plastic Material Model.

The Real-ESSI input files for von-Mises perfectly plastic example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

410.4.1.2 von-Mises Armstrong-Frederick Material Model.

The Real-ESSI input files for von-Mises Armstrong-Frederick example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Left: von-Mises linear hardening material model
    - Mass Density, ρ, 0.0 kg/m^3
    - Young's modulus, E, 20 MPa
    - Poisson's ratio, ν, 0.0
    - von Mises radius, k, 100 kPa
    - kinematic hardening rate, K_{kine}, 2 MPa
    - isotropic hardening rate, K_{iso}, 0 Pa
- Right: Drucker-Prager nonlinear hardening material model
    - Mass Density, ρ, 0.0 kg/m^3
    - Young's modulus, E, 20 MPa
    - Poisson's ratio, ν, 0.0
    - Drucker-Prager, k, 0.179527
    - nonlinear kinematic hardening, H_a, 20 MPa
    - nonlinear kinematic hardening, C_r, 100
    - isotropic hardening rate, K_{iso}, 0 Pa
    - initial confining stress, p_0, 1 Pa

Results are shown in Fig. 410.68.

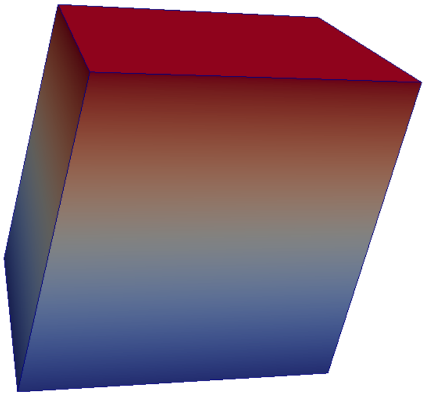

Figure 410.67: Simulation Model of Single Element.

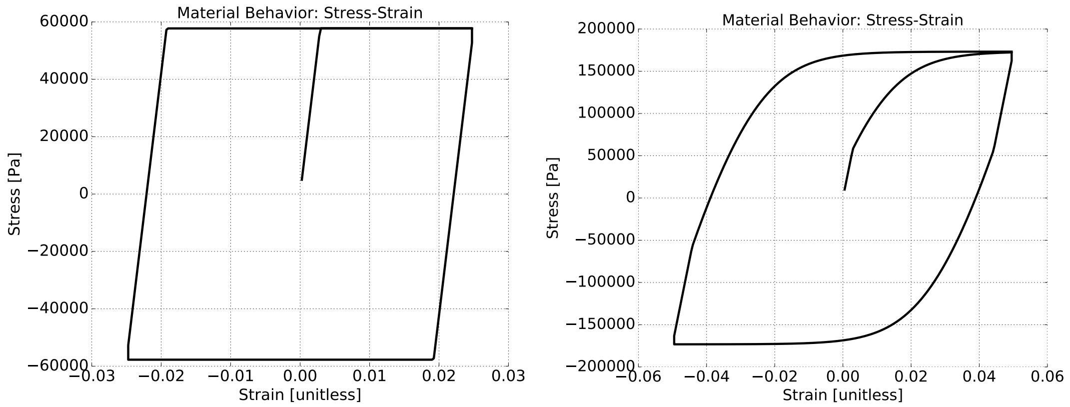

Figure 410.68: Simulation Results of Single Element.

410.4.1.3 von-Mises G/Gmax Material Model

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- von-Mises G/Gmax material model
  - Mass density, ρ, 2000 kg/m^3
  - Young's modulus, E, 200 MPa
  - Poisson's ratio, ν, 0.1
  - Total number of shear modulus 9
  - G over Gmax, 1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063
  - Shear strain gamma, 0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01

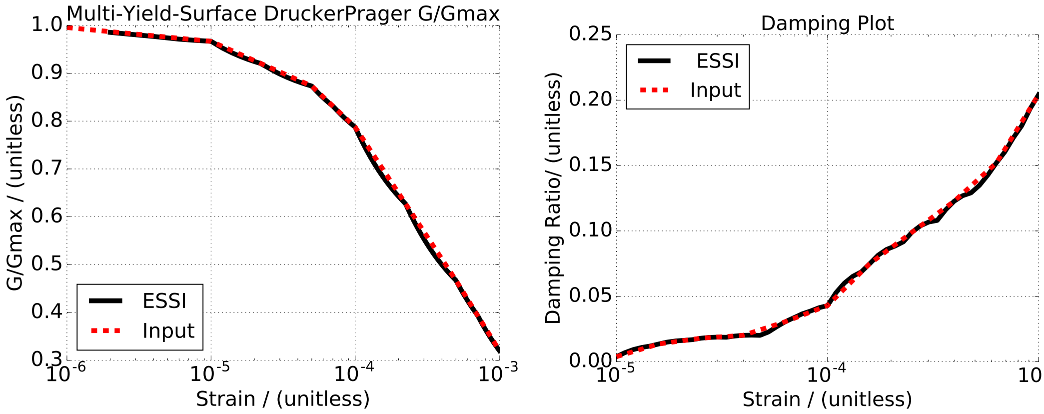

Figure 410.73: Simulation Results of Single Element.

410.4.2 Wave Propagation Through Elasto-plastic Soil

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

Figure 410.74: Wave Propagation through elastoplastic Soils.

The displacement series at the surface are plotted in time and frequency domain.

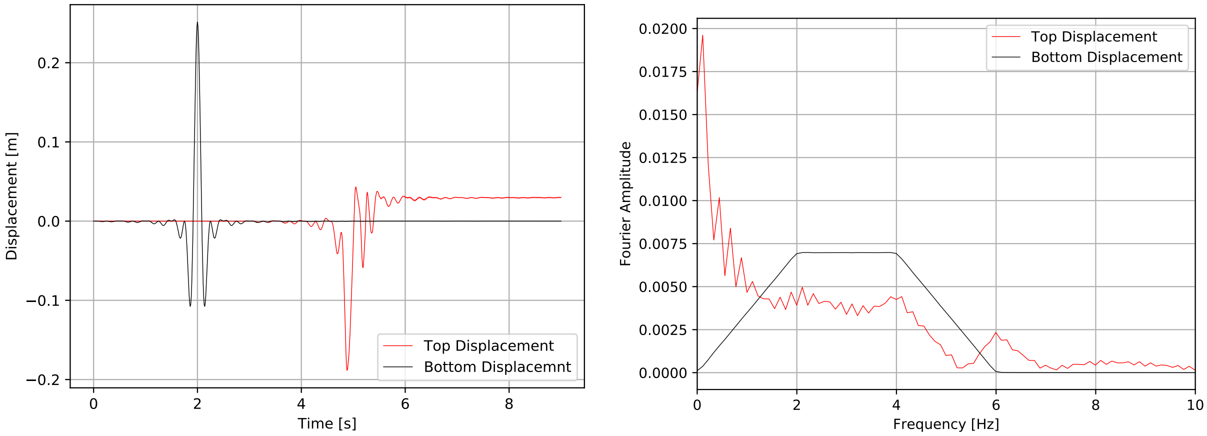

Figure 410.75: Simulation Results of Wave Propagation.

410.4.3 Contact/Interface/Joint Examples

410.4.3.1 Axial Behavior: Stress-Based Hard Contact/Interface/Joint Example

The Real-ESSI input files for hard contact/interface example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

410.4.3.2 Axial Behavior: Stress-Based Soft Contact/Interface/Joint Example

The Real-ESSI input files for soft contact/interface example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The axial behavior of hard contact/interface and soft contact/interface is illustrated in Fig. 410.76.

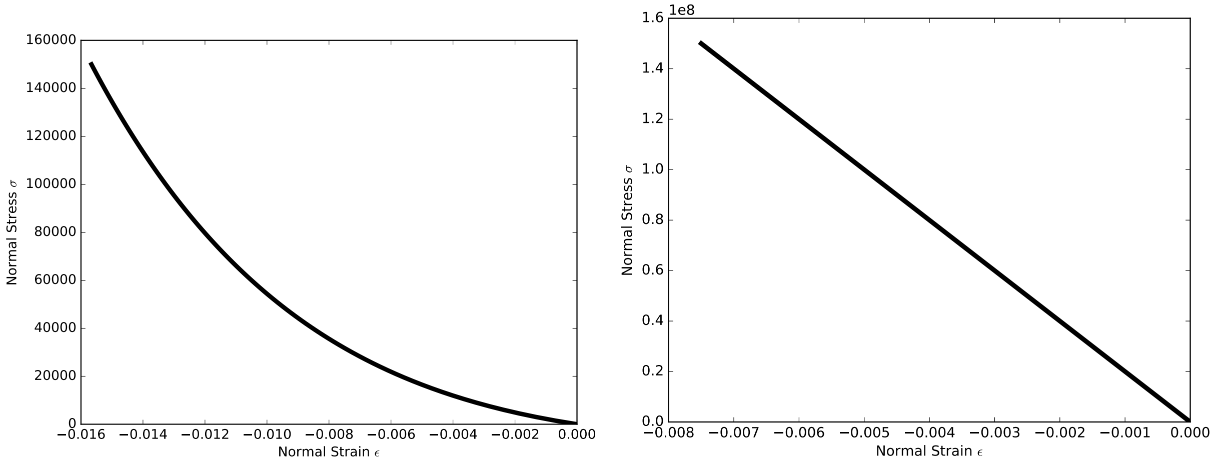

Figure 410.76: Simulation results for axial behavior of (left) soft contact/interface and (right) hard contact.

410.4.3.3 Shear behavior: Stress-Based Elastic Perfectly Plastic Contact/Interface/Joint

The Real-ESSI input files for the the elastic-perfectly plastic example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

410.4.3.4 Shear behavior: Stress-Based Elastic-Hardening Contact/Interface/Joint

The Real-ESSI input files for the elastic-hardening contact/interface example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

410.4.3.5 Shear behavior: Stress-Based Elastic-Hardening-Softening Contact/Interface/Joint

The Real-ESSI input files for the elastic-hardening-softening example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The shear behavior of elastic-perfectly plastic, elastic-hardening plastic, elastic and hardening and softening plastic is illustrated in Fig. 410.77.

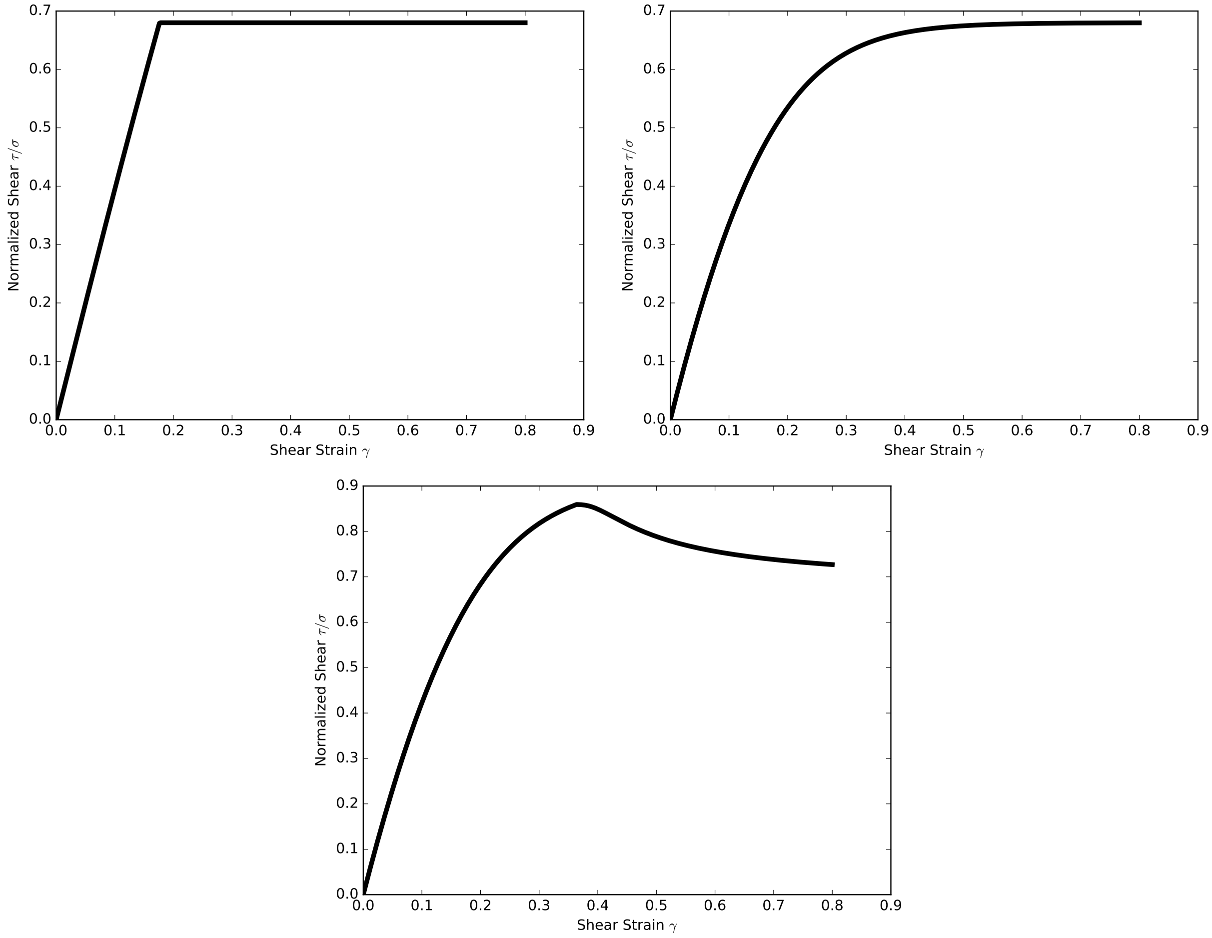

Figure 410.77: Simulation results for shear behavior for stress based contac.t elements: elastic-perfectly plastic, elastic-hardening plastic, elastic, hardening and softening plastic.

410.4.3.6 Force Based Contact/Interface/Joint Example: Base Isolator

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

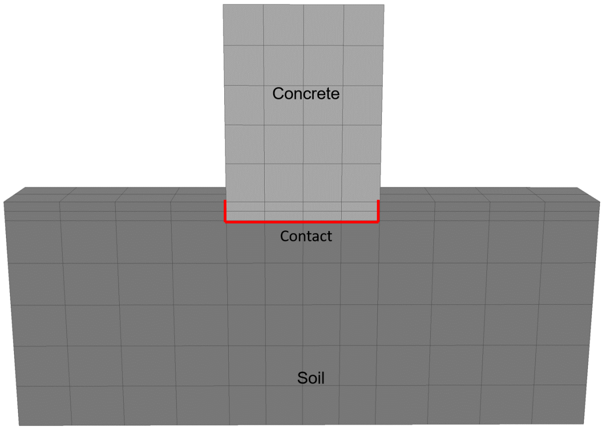

Figure 410.78: Simulation Model.

Results are show in Fig.410.79.

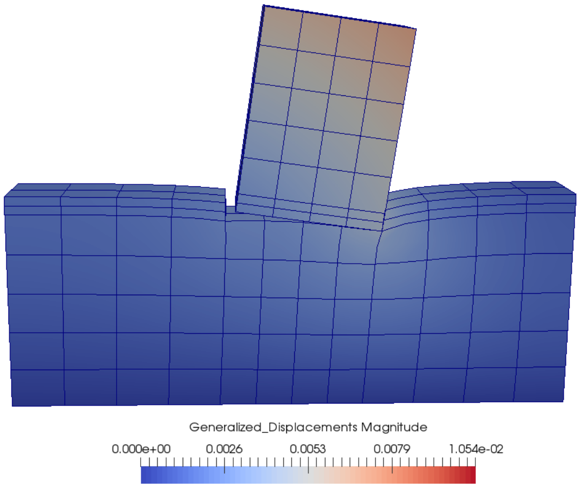

Figure 410.79: Simulation Results for Contact/Interface/Joint Examples.

410.4.4 Inelastic Frame Pushover

The Real-ESSI input files for this example are available HERE. The compressed package of Real-ESSI input files for this example is available HERE.

The Modeling parameters are listed below:

- Uniaxial concrete
    - Compressive strength, 24 MPa
    - Strain at compressive strength, 0.001752
    - Crushing strength, 0.0 Pa
    - Strain at compressive strength, 0.003168
    - lambda, 0.5
    - Tensile strength, 0 Pa
    - Tension softening stiffness, 0 Pa
- Uniaxial steel
    - Yield strength, 413.8 MPa
    - Young's modulus, 200 GPa
    - Strain hardening ratio, 0.01

The Real-ESSI building examples, models from FEMA-P-2091 report are available in Sections 509.2 (page 2676), 509.4 (page 2684), and 509.5 (page 2688), in Lecture Notes by Jeremić et al. (1989-2025) (Lecture Notes URL).

Part 500

Application to Practical Engineering Problems

Chapter 501

Static Soil-Pile and Soil-Pile Group Interaction in Single Phase Soils

(1999-2002-)

(In collaboration with Prof. Zhaohui Yang)

501.1 Chapter Summary and Highlights

501.2 Numerical Analysis of Pile Behavior under Lateral Loads in Layered Elastic–Plastic Soils

Material presented here has been previously published in our paper Yang and Jeremić (2005).

501.2.1 Introduction

The $p-y$ approach (Reese et al. Reese et al. (2000a)) has been widely used to design piles subjected to lateral loading. Based on the Winkler foundation theory, the method models the lateral soil-structure interaction with empirically derived nonlinear springs. The advancement of computer technology has made it possible to study this problem using more rigorous Finite Element Method (FEM).

Mentioned are a few representative finite element applications. Maqtadir and Desai Muqtadir and Desai (1986) studied the behavior of a pile-group using a three dimensional program with nonlinear elastic soil model. An axisymmetric model with elastic-perfectly plastic soil was used by Pressley and Poulos Pressley and Poulos (1986) to study group effects. Brown and Shie Brown and Shie (1990a) Brown and Shie (1990b) Brown and Shie (1991) and Trochanis Trochanis et al. (1991) conducted a series of 3D FEM studies on the behavior of single pile and pile group with elastic-plastic soil model. In particular, interface element was used to account for pile-soil separation and slippage. Moreover, Brown and Shie derived $p-y$ curves from FEM data, which provide some comparison of the FEM results with the empirical design procedures in use. A number of model tests of free- or fixed-headed pile groups under lateral loading has been simulated by Kimura et al. Kimura et al. (1995) and Wakai et al. Wakai et al. (1999) using 3D elasto-plastic FEM. A good correlation between the experiments and the analysis has been observed in these studies. All these results demonstrated that FEM can capture the essential aspects of the nonlinear problem. It is noted that there is not much literature reporting on FEM studies of pile behavior under lateral loading in layered soil system. In addition to that, there is a very small number of studies on the effects of layering system on the commonly used $p-y$ curve approach.

This paper describes four 3D finite element models of a laterally loaded pile embedded in uniform and layered soil profiles with the dimensions and soil parameters similar to those used in the centrifuge study by McVay et al. McVay et al. (1998) and Zhang et al. Zhang et al. (1999). The bending moments derived by integrating vertical stresses from FEM are numerically differentiated once and twice to compute the shear force and pressure diagrams, respectively. Particularly, $p-y$ curves are generated and cross compared to illustrate the effects of soft clay (sand) layer on the $p-y$ curves of the overlaid sand (soft clay) layer. The results from FEM are also compared with those from centrifuge test and LPILE.

In addition, a limited parametric study of pressure redistribution is conducted by changing the undrained shear strength of the soft clay layer and the friction angle of the sand layer to further investigate the layering effects. An early version of OpenSees OpenSees Development Team (Open Source Project) (2000-2006) finite element program was used in presented computations. Developed models are now available within our new framework FEI. Soil modeling was performed using Template Elastic–Plastic approach (Jeremić and Yang Jeremić and Yang (2002)).

501.2.2 Constitutive Models

Two simple models were used in this numerical study. Specifically, clay was modeled by a simple von Mises material model which is completely defined with the undrained shear strength. Sand was simulated by a Drucker–Prager material model with non-associated flow rule. The reason for using such simple models is that the experimental results used to compare our simulations against did specify only those two material properties for sands and clays. Figure 501.1 presents yield surfaces for both models. In both material models, the Young's moduli vary with confining pressure, as shown in Eqn. (501.1).

$$E = E_o \left(\frac{p}{p_a}\right)^a \tag{501.1}$$

where E_o is Young's Modulus at atmospheric pressure, p is the effective mean normal stresses, p_a is the atmospheric pressure, and a is constant for a given void ratio. In this work, 0.5 was used.

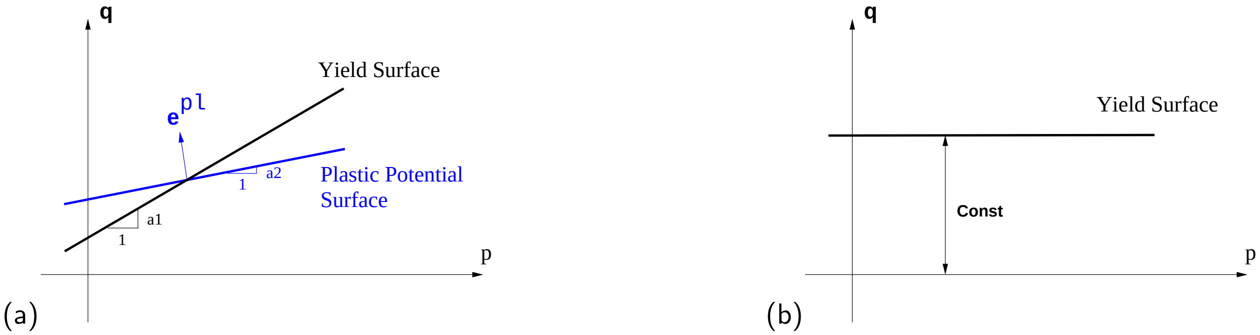

Figure 501.1: Elastic plastic models used in this study: (a) Drucker–Prager model specified with friction angle and dilation angle, and (b) von Mises model specified with undrained shear strength C_u.

The following parameters were used for medium dense sand: friction angle ϕ of 37.1^o, Shear modulus at a depth of 13.7 m of 8960 kPa (E_o = 17400 kPa), Poisson's ratio of 0.35 and unit weight of 14.50 kN/m^3. These parameters were given by Zhang et al. Zhang et al. (1999). A dilation angle of 0^o is used in this work (Brown and Shie Brown and Shie (1990a)). The undrained shear strength, Young's modulus, Poisson's ratio and unit weight of clay were chosen to be 21.7 kPa, 11000 kPa, 0.45, 13.7

kN/m^3, respectively. It should be noted that the above material models are available within the Template Elastic–Plastic Material Modeling paradigm (Jeremić and Yang Jeremić and Yang (2002)). It should also be noted that the use of simple Drucker–Prager model can over-predicted the friction angle to triaxial extension stress path. However this influence is limited to the zone behind the pile, within the interface zone and thus this drawback of the Drucker–Prager model was neglected.

501.2.3 Simulation Results

Presented in this subsection are representative results related to the behavior of piles in uniform and layered soil systems. Presented results are compared with those from the centrifuge study (McVay et al. McVay et al. (1998)), and with results obtained using LPILE program (Reese et al. Reese et al. (2000a,b).

501.2.3.1 Pile Models

A number of static pushover tests for single pile models were simulated using uniform soil and layered soil setups. Figure 501.2 shows the model setups. There are four main setups. Two of these are dealing with uniform sand and clay soils, while two others are featuring layered soils. In particular, the case # 1

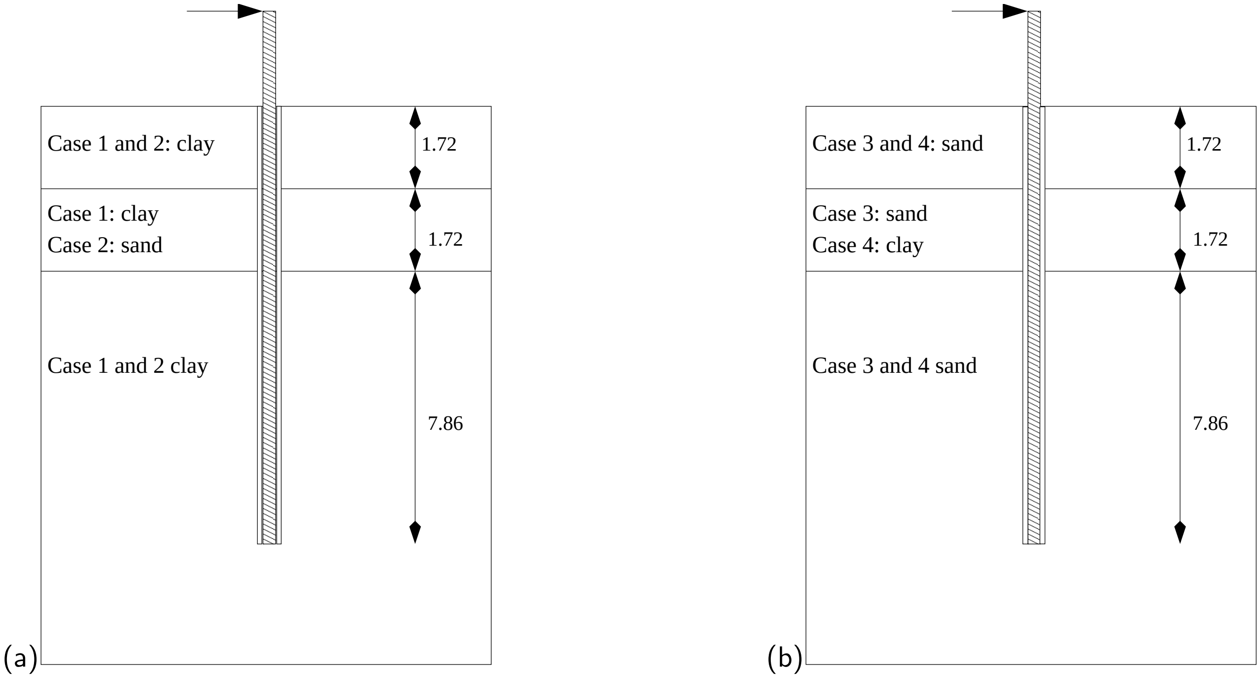

Figure 501.2: (a) Single pile models, dimensions and layers of case #1 and #2. (b) Single pile models, dimensions and layers of case #3 and #4.

is a uniform soft clay soil, case # 2 includes top and bottom layers of soft clay with an in–between layer of medium dense sand. On the other hand, case # 3 features uniform medium dense sand soil, while case # 4 features top and bottom layers of medium dense sand with an in–between layer of soft clay. Detailed layering setup is given in Figure 501.2.

Figure 501.3 shows the finite element mesh for all four cases. Based on symmetry, only half of the model is meshed. Twenty node brick elements are used for both soil, pile and interface. It should be noted that these quadratic elements exhibit high accuracy even for high aspect ratios and can model accurately bending of solid piles with two layers of elements. During mesh design stage, a study was performed to decide on appropriate (balanced) mesh size. That study showed that a much larger mesh, with many more elements (with lower aspect ratios) would account for a fairly small change in results, so it was decided that the current mesh is sufficient for our analysis.

The square pile, with a width of 0.429 m, consist of four elements (per cross subsection) with the elastic property of aluminum. The fine mesh in the upper part of the model is to provide data points for the computation of shear forces and $p-y$ curves of sufficient reliability as well as for the investigation of layering effects. The sides and bottom of the model are fixed with the exception of the symmetric boundary, which is only supported in Y direction. The interface layer between aluminum pile and surrounding soil is represented by one thin layer of elements. The purpose of this layer is to mimic the installation effects on piles (drilled or driven). It also serves a purpose of a simplified interface which allows for tension cut-off (gaping) and controlled, coupled horizontal and vertical stiffness. All interface elements were simulated by Drucker–Prager model with a friction angle of 25^o, and a dilation angle of 0^o.

501.2.3.2 Plastic Zones

The static pushover test were conducted using load control at pile head. The final plastic zones are depicted in Figures 501.4, 501.5. Plastic zones are actually presented by plastified Gauss points. In particular, Figure 501.4(a) shows developed plastic zones for the uniform clay soil (case # 1). It is interesting to note that the plastic zone propagates fairly deep while it does not extend far from the pile in clay. Moreover, compression side (right side) features much larger plastic zone while the plastic zone for the extension side (left side) is confined to the interface layer and a few Gauss points outside the interface layer. The case with clay and sand layer in–between is shown in Figure 501.4(b). The main difference is that the plastic zone is even smaller than for uniform clay layer. It is worth mentioning that this case, which includes sand layer, is stiffer than the uniform clay case, thus displacements are smaller in clay and the plastic zone does not propagate as much as in uniform clay soil.

Figure 501.5(a)(b) shows plastic zones at the end of loading process for sand and sand and clay soils.

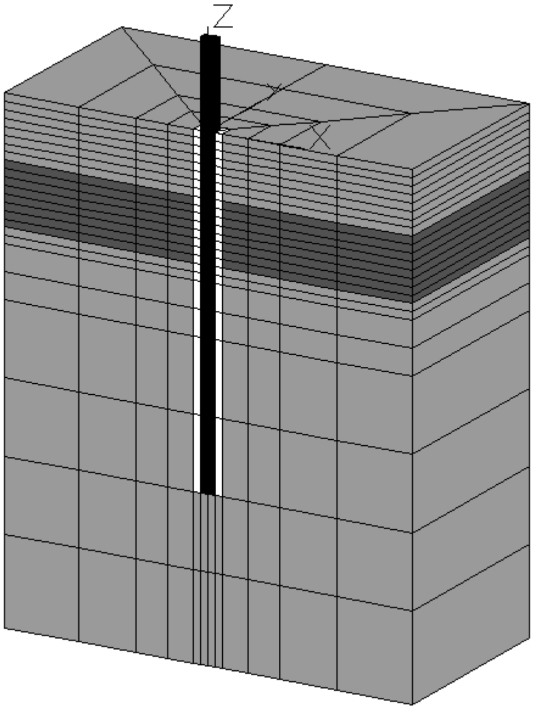

Figure 501.3: Mesh of single pile model, side view, top eight layers of finite elements are either clay or sand (depending on the cases), middle eight layers of finite elements are sand or clay (again depending on the cases) and the bottom is all uniform clay or sand, interface zone around the aluminum pile is also present.

In particular, Figure 501.5(a) shows the plastic zone for uniform sand. It is interesting to note that the plastic zone propagates toward the surface with the collapse mechanics similar to the active and passive failure. In this case of course the system is 3D and so the failure propagation angles do not match the active and passive failure angles, however the difference between active and passive zones propagation angles is almost exactly $\pi/2$. Figure 501.5(b) shows plastic zone for the case # 4 which includes a layer of clay between -1.72m and -3.44m (Z coordinate, origin is in the pile center at the ground surface) . It is noted that the plastic zone is deeper, but not as nicely defined as in the previous case.

501.2.3.3 $p-y$ Curves

Results from static pushover tests on piles were used to generate $p-y$ curves. The bending moments derived by integrating vertical stresses are numerically differentiated once and twice to compute the shear force and pressure diagrams, respectively. Direct integration of shear stresses was also performed to check results and it was found that shear forces were within 5% accuracy. The combination of calculated

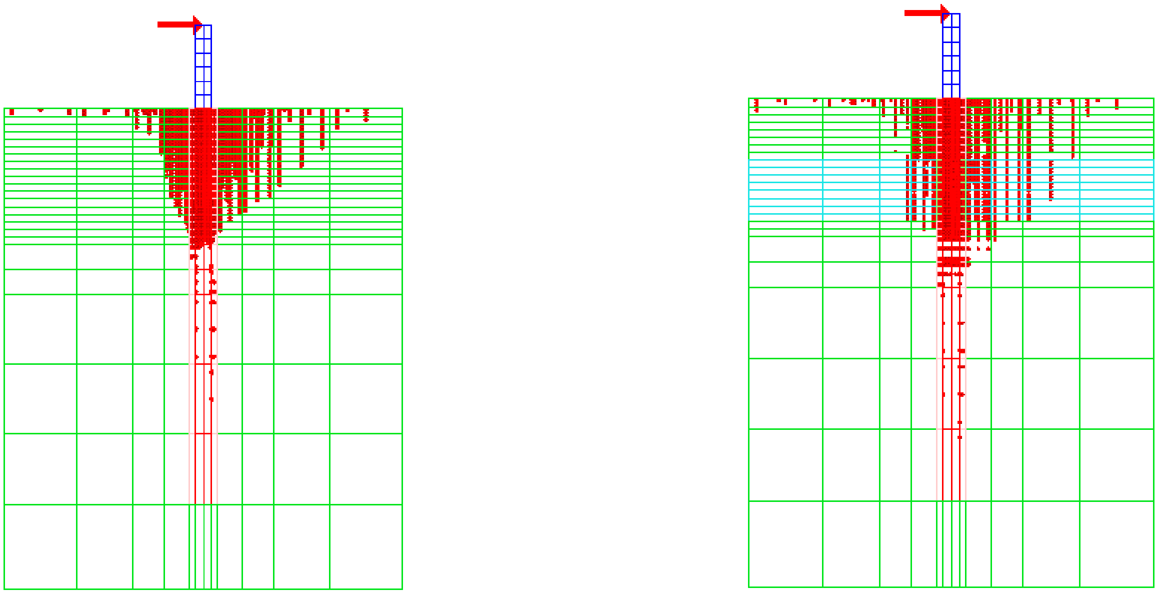
Figure 501.4: The plastic zones for (a) case # 1, and (b) case # 2 at lateral loading of 400kN.



a) b)

Figure 501.5: The plastic zones of case 3 and 4 at lateral loading of 400kN.

pressures (p) and displacements obtained from the finite element solution, allowed for generation of $p-y$ curves at various depths along the pile.

In what follows, presented are generated $p-y$ curves for both uniform soils (sand and clay) as well as for layered systems. It is noted that the graphical presentation of results for bending moments, shear forces and lateral pressures (load) on a pile beam are shown with 10 lines, each one representing results for one increment $(1/10)$ of the total load.

Uniform Clay Soil. Figure 501.6 shows bending moments, shear forces and pressures along the depth of a pile in clay soil. It should be noted that the maximum bending moment, as well as the switching of sign for shear force, moves quite a bit from the depth of approximately -1.7m all the way to the depth of -3.4m. Pressure distribution shows that the top layers are already at the ultimate values of pressures and thus the pressure diagram propagates downward. There is a slight fluctuation of pressures at the depths of $4-5$m, which is attributed to the small numerical problems while doing double differentiations.

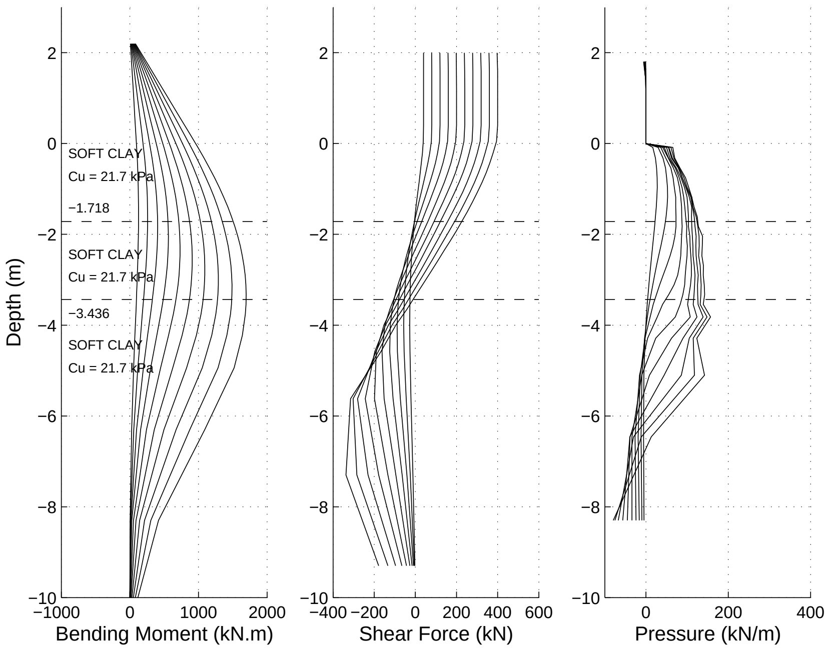


Figure 501.6: Bending moment, shear force and pressure distributions for the uniform clay profile.

Figure 501.7 shows generated $p-y$ curves for uniform clay layer. It is obvious that most of the clay (at least until the depth of -2.6m) has reached its peak resistance.

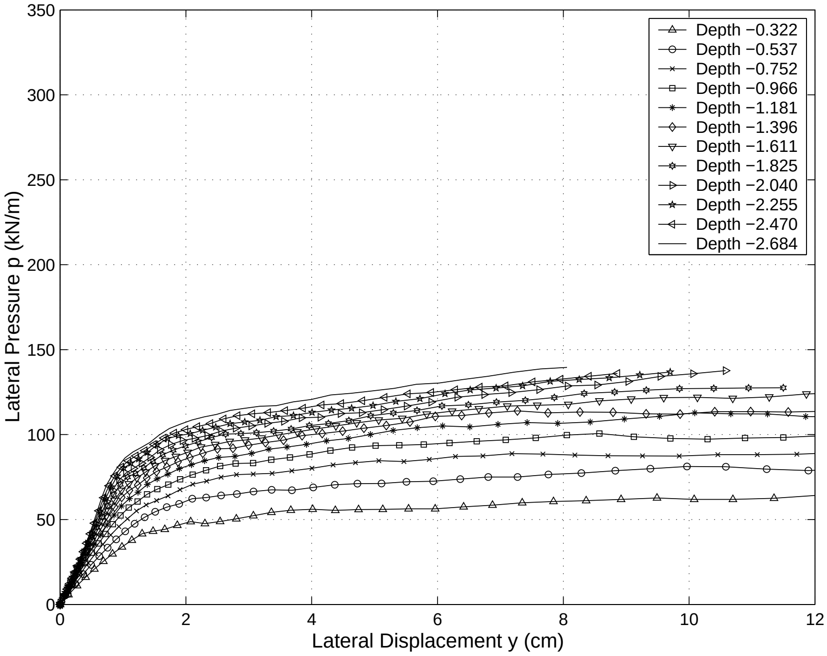

Figure 501.7: Calculated $p-y$ curves for the uniform clay profile.

Uniform Sand Soil. Figure 501.8 shows bending moments, shear forces and pressures for a pile in a uniform sand soil. In this case it is interesting to note that the maximum bending moment, as well as the change of sign for the shear force is moving only between the depths -1.8m and -2.0m. Moreover, the pressure diagram shows steady increase (with top layers reaching ultimate pressures) until the depth of -1.7m and then steadily decreases, and changes sign at greater depths (below -4.0m).

Figure 501.9 shows generated $p-y$ curves for the uniform sand case. It is interesting to note that only the top layer at the depth of about -0.3m will reach the ultimate pressure. All the other sand material is far away from corresponding ultimate pressures. It is also worth noting that the displacements in the case of uniform sand are much smaller (almost twice as small) than what has been observed in uniform clay case.

Clay Soil with a Layer of Sand. Figure 501.10 shows bending moments, shear forces and pressures for a layered soil case. In this case a layer of sand extends from $-1.72m$ to $-3.44m$. The rest of soil is soft clay. It is interesting to note a large jump in pressures for the sand layer (as expected) and that the pressures in the top clay layer (from the surface to $-1.7m$) reaches ultimate values. Small non–uniform distribution of the pressures at the interface of sand and clay at $-3.44m$ is attributed to the coarseness of the finite element mesh. In comparing Figure 501.10 with the results for uniform clay case (Figure 501.6) it is obvious that the sand layer arrests the propagation of deformation and forces in depth and

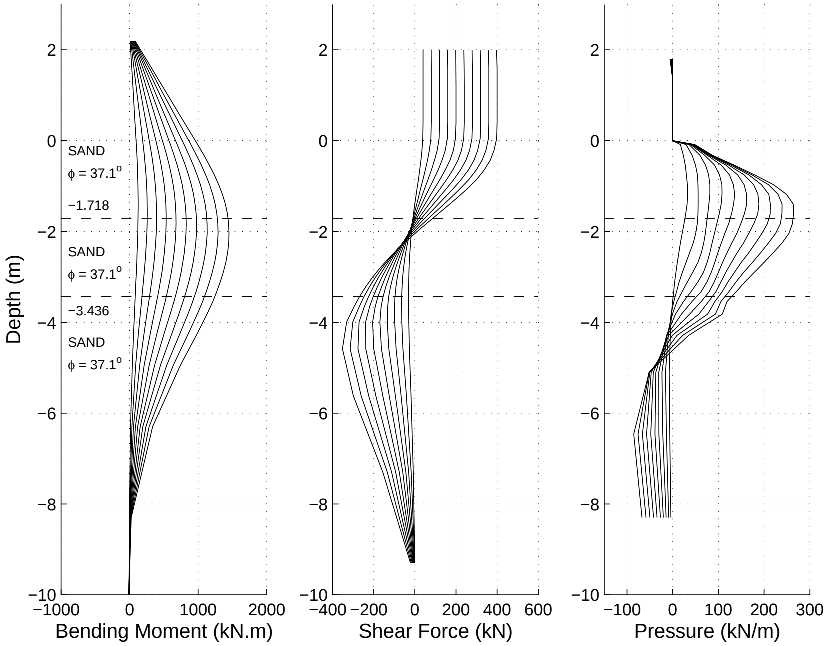

Figure 501.8: Bending moment, shear force and pressure distributions for the uniform sand profile.

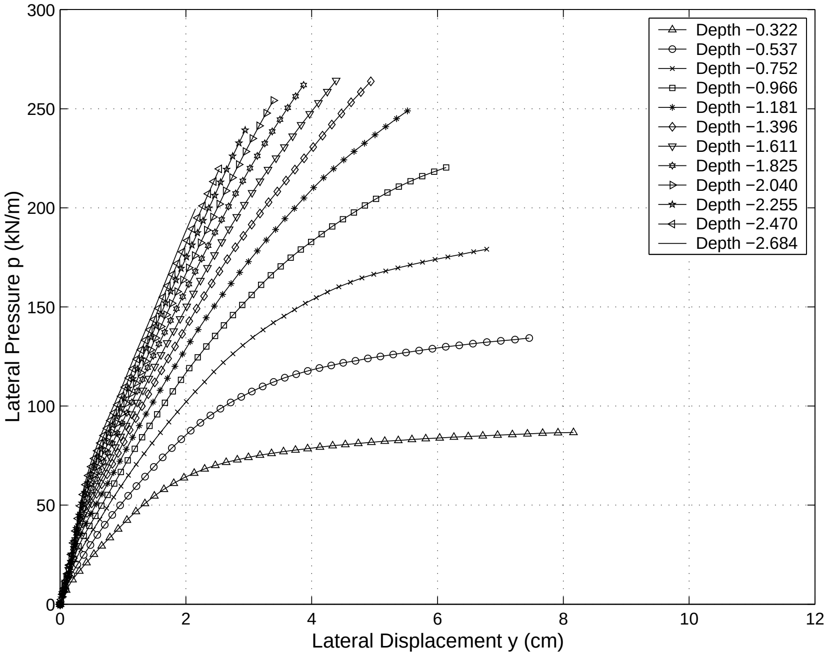

Figure 501.9: Calculated $p-y$ curves for the uniform sand profile.

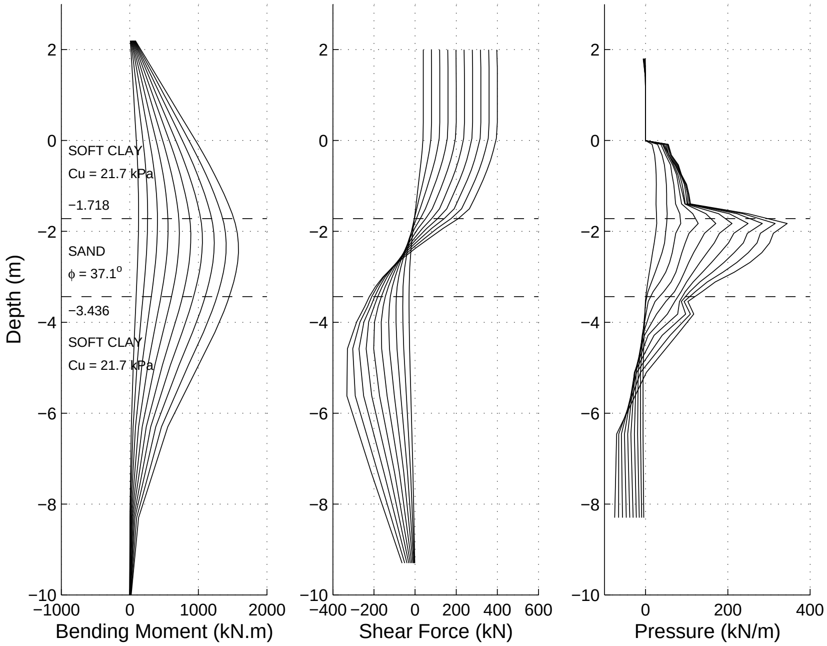

Figure 501.10: Bending moment, shear force and pressure distributions for the clay soil with a sand layer.

fixes the maximum moment to approx. $-2.1m$.

Figure 501.11 shows generated $p-y$ curves for the layered case (single layer of sand in clay). The $p-y$ curves were generated only for the top layer of clay and middle layer of sand, to the depth of $-2.7m$. It is interesting to note that the $p-y$ curve for clay at the depth of $-1.61m$ (close to the sand layer) exhibits strong hardening, unlike similar curve for the uniform clay soil, in Figure 501.7. The increase in pressure (transversal loading on the pile) between uniform clay (Fig. 501.7) and clay underlain by a medium dense sand layer (Fig. 501.11) at the displacement of $0.06m$ is more than two times.

Sand Soil with a Layer of Clay. Figure 501.12 shows bending moments, shear forces and transversal pressures for a case where a layer of soft clay is present within sand soil. Unlike the case of uniform sand soil (Figure 501.8) the presence of soft clay layer will change the depth of maximum moment by almost $1m$ (from $-2.0m$ to $-3.0m$). In addition to that, the distribution of pressures on a pile is changed significantly, as seen in the right plot of Figure 501.12. The reduction of pressures will extend into the sand layer and present significant influence of soft clay on pressures in sand.

Figure 501.13 shows generated $p-y$ curves for the case of sand with a soft clay layer. It is noted that the $p-y$ curves for sand that is some distance away from the interface with clay are much the same as for the uniform sand case (refer to Fig. 501.9 and Fig. 501.19(a)). However, the $p-y$ curves in sand

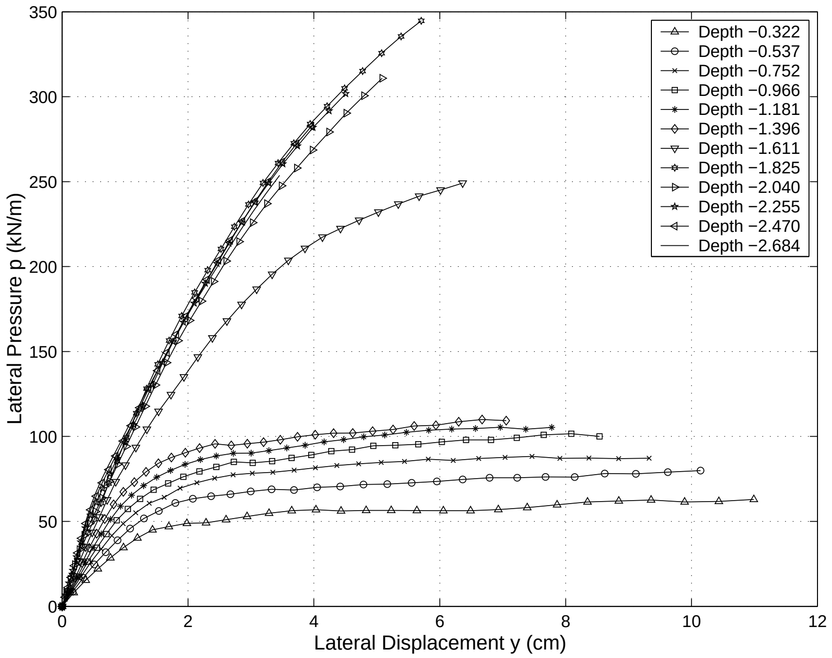

Figure 501.11: Calculated $p-y$ curves for the clay soil underlain by a medium dense sand layer.

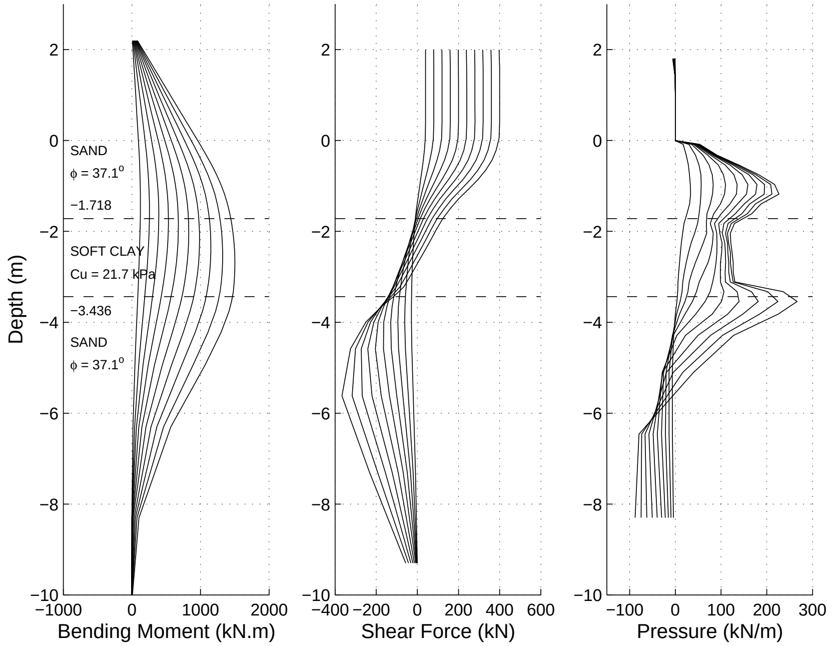

Figure 501.12: Bending moment, shear force and pressure distributions for the sand soil with a soft clay layer.

close to the interface are changed in some cases significantly. For example, the $p - y$ curve at depth of $-1.61m$ is showing pressure of approx. $p = 265kN/m$ at the displacement of $0.042m$ for the uniform sand case, while the same $p - y$ curve, still in sand, has a drop in pressure at the same displacement to $p = 140kN/m$. Similar trend is observed for other $p - y$ curves close to the interface of sand with clay.

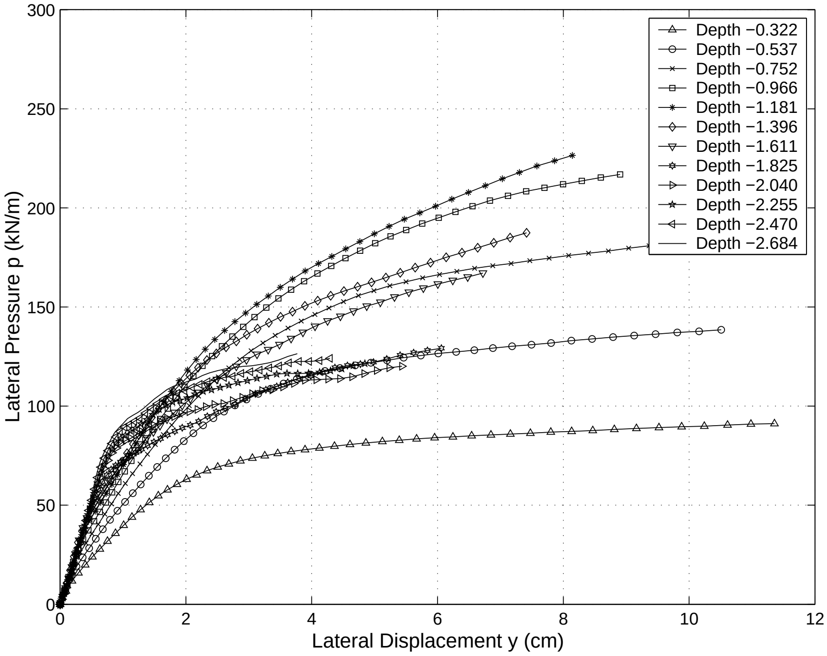

Figure 501.13: Calculated $p - y$ curves for the sand soil underlain by a soft clay layer.

501.2.3.4 Comparisons of Pile Behavior in Uniform and Layered Soils

Comparison of pile behavior in uniform and layered soils can also be performed by looking at the displacement and bending moment distributions. For example, Figure 501.14 compares the distributions of displacements for the uniform sand case with the sand and clay layer case. First observation is that the uniform sand layer allows smaller displacements of the pile head ($0.12m$) while the inclusion of clay layer raises those displacements to $0.22m$. Second observation is that the point of rotation for the pile (point which does not move as the loading is applied) is pushed deeper, from $5m$ to approximately $6m$. Moreover, the propagation of displacements along the depth of a pile is much greater for a layered case, the surface displacement is extended from $0.09m$ to almost $0.13m$.

Figure 501.15 shows similar results for uniform clay and clay with a layer of sand case. In this case, the inclusion of a sand layer will increase the stiffness of the pile (as expected) and will also reduce propagation of displacements with depth.

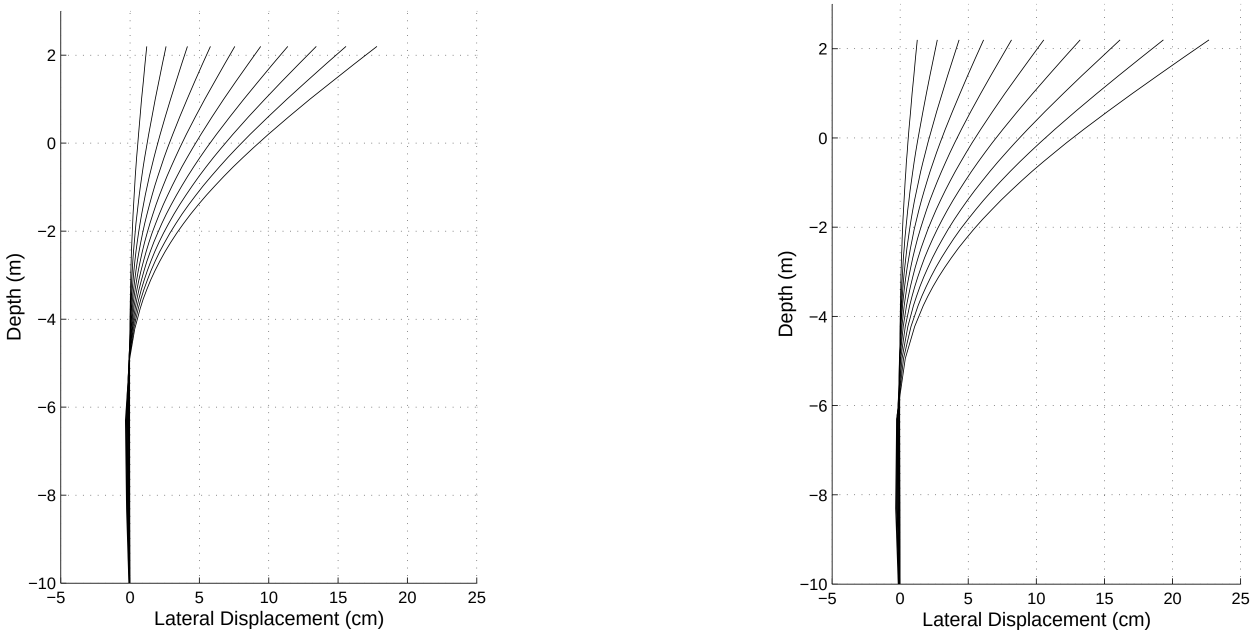

Figure 501.14: Pile displacement distributions along the depth in a uniform sand profile (left) and sand with clay layer profile (right).

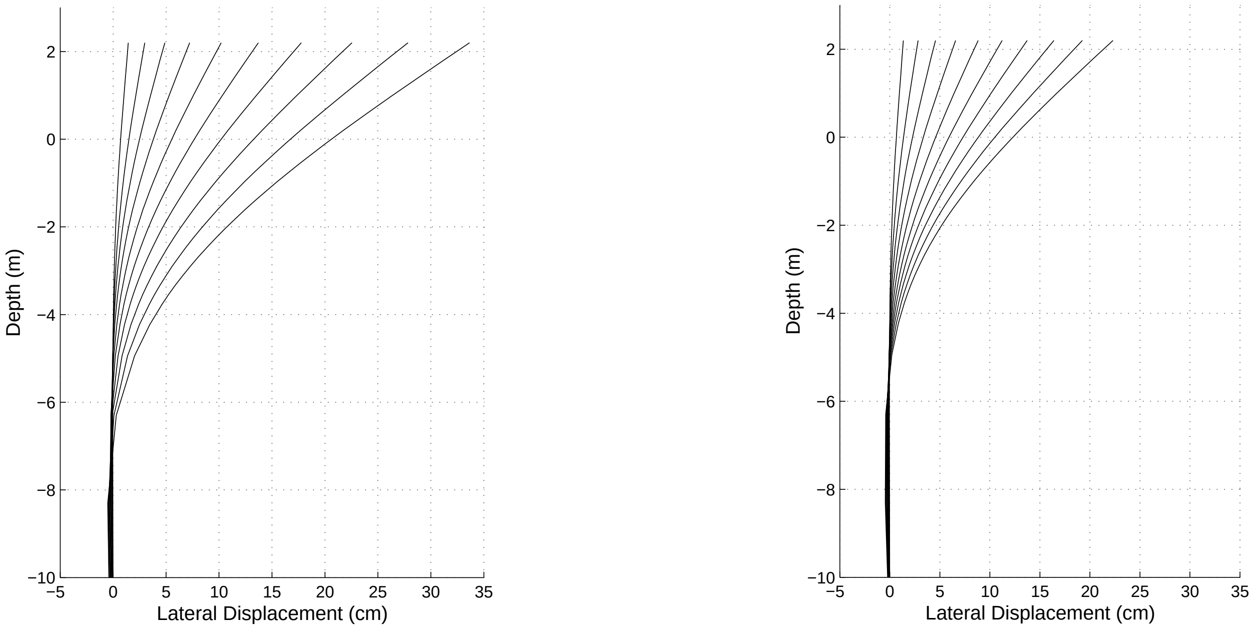

Figure 501.15: Pile displacement distributions along the depth in a uniform clay profile (left) and clay with sand layer profile (right).

Figure 501.16 shows comparison of pile head displacements for all four cases. It is noted that the two layered cases exhibit similar behavior in terms of displacements, both at the pile head and in terms of displacement profiles (compare right plot in Fig. 501.14 and left plot in Fig. 501.15).

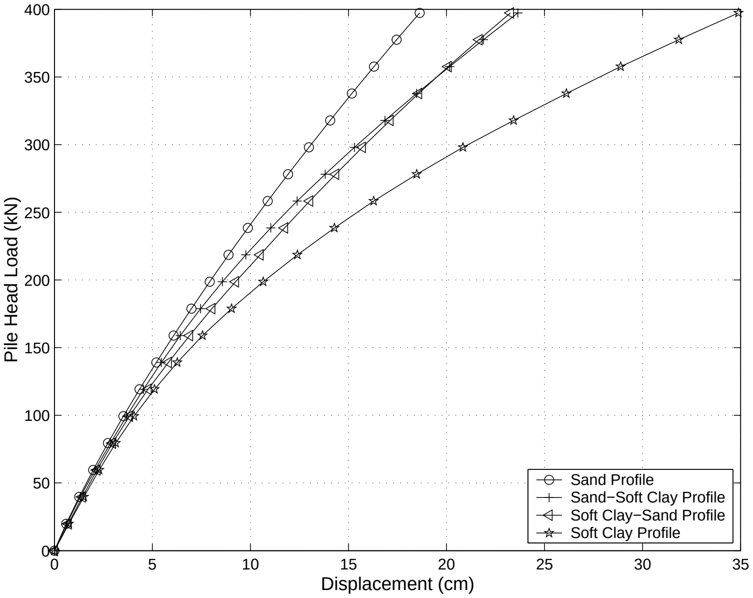

Figure 501.16: Pile head displacement comparison for all the four cases.

Figure 501.17 shows comparison of the maximum bending moment calculated for the pile for all four cases. It is interesting to note that the difference between the two uniform soil cases (uniform sand and uniform clay) is not that pronounced. Of course one has to remember that the material for pile was assumed to be linear elastic, no yielding was allowed for the aluminum pile.

The $p-y$ curves for uniform clay and clay with a layer of sand were plotted together in Figure 501.18 (a) for comparison. It can be seen that all the $p-y$ curves in clay except the one right next to the layer interface are almost identical. In order to measure the magnitude of the effects of sand layer on the pressure of soft clay layer, the ratio of pressures in clay layer for clay soils with a sand layer and uniform clay soils lateral displacement of 12%D, i.e. 5.15 cm, were computed and plotted against the distance in terms of times of pile width D in Figure 501.18. It is noted that the disturbance to the pressure field is much more confined to the immediate vicinity (within 0.75D) of the layer interface. In addition, the results from two more analysis of the same model with different sands (friction angles $\phi^{'} = 25^{o}, 30^{o}$ respectively, other parameters remain the same.) were included in Figure 501.18. It is shown that the lateral pressure ratio is affected considerably when sand friction angle increases from 25^{o} to 37^{o} (from 1.5 times to 2.2 times more pressure).

The $p-y$ curves for uniform sand and sand with a layer of soft clay were also plotted together for

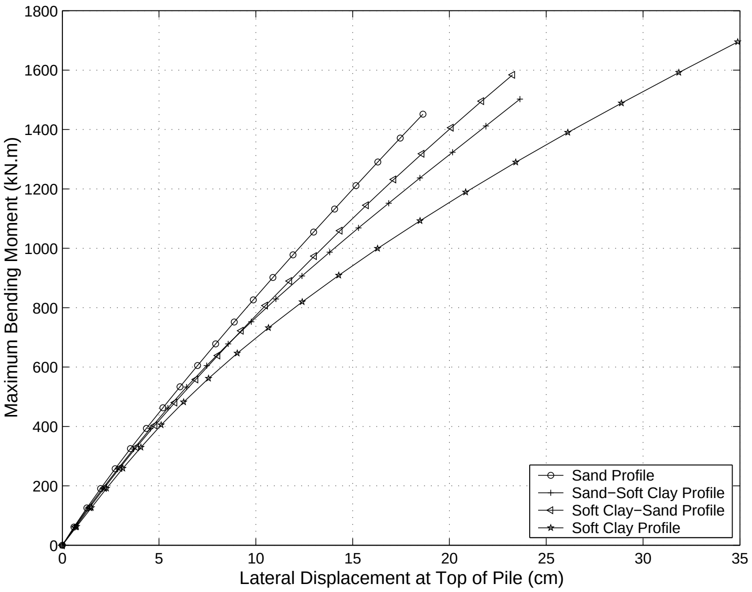

Figure 501.17: Maximum bending moment comparison for all the four cases.

comparison purposes. It was found that the effect of soft clay on the pressures in sand propagates far away from the layer interface. Therefore, three cases of an additional model with a thicker sand layer (2.4m in thickness) underlain by a soft clay layer were analyzed by varying the undrained shear strength ($C_u = 13.0\ kPa,\ 21.7\ kPa,\ 30.3\ kPa$) of the soft clay layer. Similarly, the pressure ratios at 6.5% D, i.e. 2.8 cm, were plotted in Figure 501.19. It is noted that the effects extends to as far as 4.75D from the layer interface and the reduction of pressures adjacent to the interface is about 0.6 in all three cases.

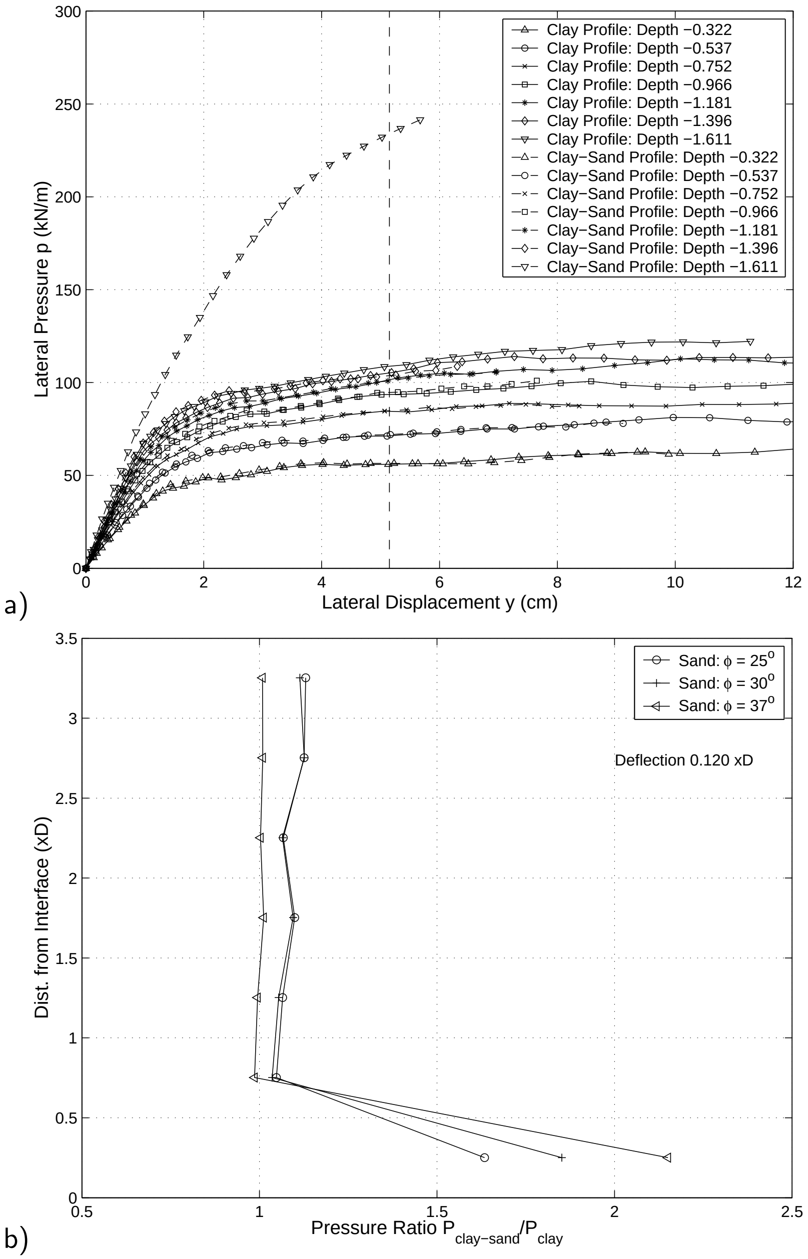

Figure 501.18: (a) Comparison of p–y curves for uniform clay versus clay with a layer of sand ($\phi' = 37^o$). (b) Pressure ratio distributions in clay layer for sands with different friction angle ($\phi' = 25^o,\ 30^o,\ 37^o$).

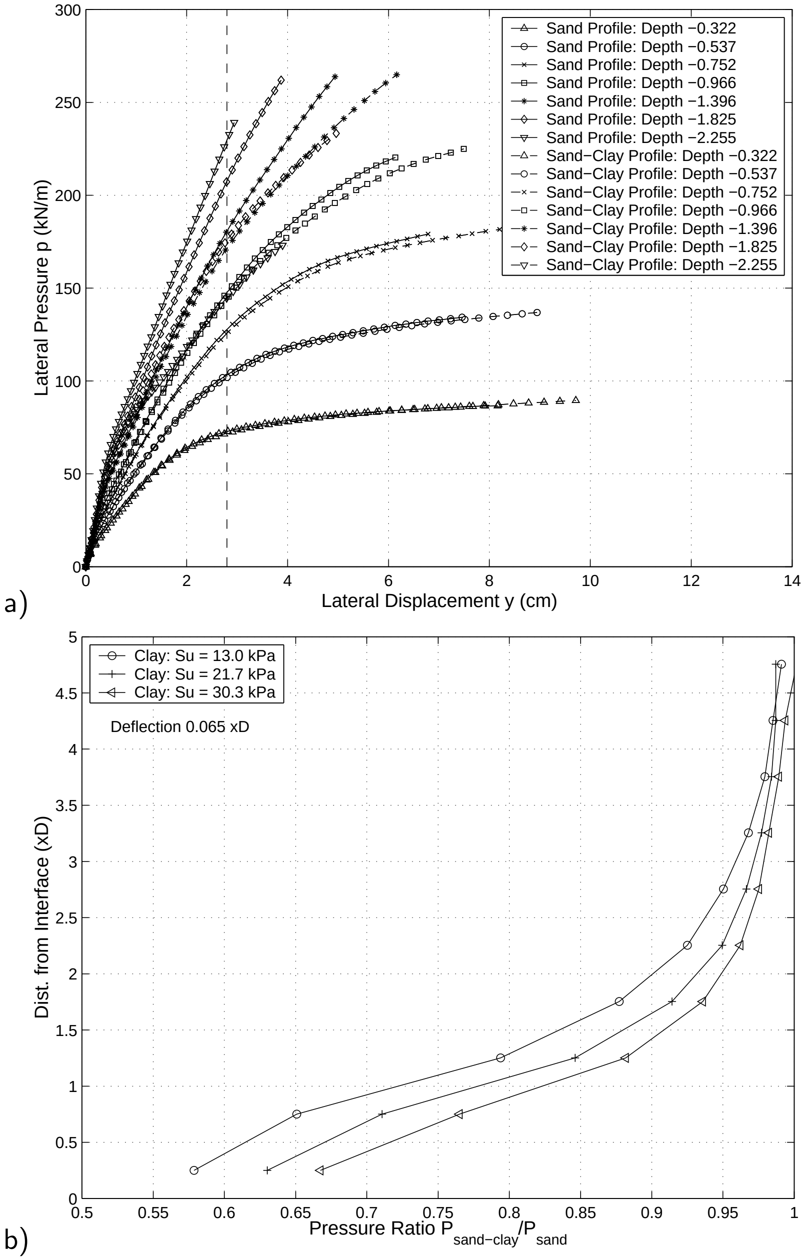

Figure 501.19: (a) Comparison of $p-y$ curves for uniform sand versus sand with a layer of soft clay ($C_u = 21.7\ kPa$). (b) Pressure ratio distributions in sand layer for clays with different undrained shear strength ($C_u = 13.0\ kPa,\ 21.7\ kPa,\ 30.3\ kPa$).

501.2.3.5 Comparison to Centrifuge Tests and LPile Results

The pile head displacements for uniform sand profile from 3D FEM, LPILE (Reese et al. Reese et al. (2000a,b)), and centrifuge test (McVay et al. McVay et al. (1998)) were plotted against pile head load in Figure 501.20. It can be seen that they agree with each other fairly well. It should be noted that the material properties for our 3D finite element simulations were not in any particular way calibrated to improve the results. They were simply used as presented in the centrifuge study by McVay et al. McVay et al. (1998) and numerical simulation by Zhang et al. Zhang et al. (1999). Whereas, the results from LPILE were back-fitted since the coefficient of subgrade reaction η_h was back-calculated as 2714 kN/m^3 (Zhang et al. Zhang et al. (1999)).

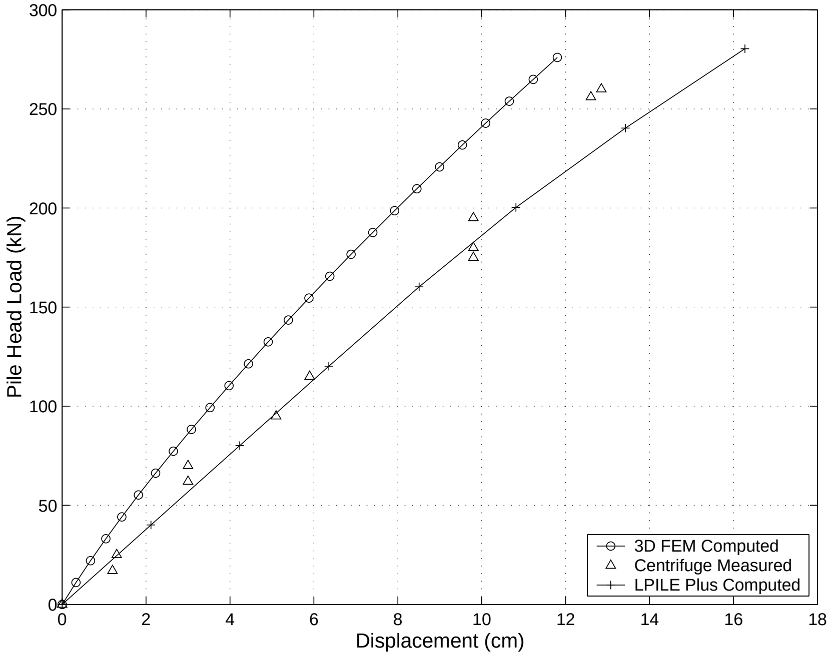

Figure 501.20: Simulated versus experimental pile head displacements.

The bending moments, shear forces and lateral pressures of uniform sand and clay profiles from 3D FEM and LPILE were plotted against pile depth at several pile head loads in Figure 501.21 and 501.22. In general, there is a good agreement between the results from FEM and LPILE in uniform sand profile. In uniform soft clay profile, it is noted that the pressures at shallow depth from LPILE are smaller than those computed by FEM, which agrees with one of the findings by the work of Steven and Audibert Stevens and Audibert (1979). For example, the pressures at lateral load of 120kN and 200kN from LPILE are only about half of those from FEM. Because the pressures at shallow depths are so small in LPILE that the pile head has to deform much more than in FEM and the passive pressure zone in LPILE extends to fairly large depth.

Since LPILE currently uses the equivalent depth method developed by Geogiadis Georgiadis (1983) for layered soil profiles, the LPILE output pressure distribution along pile depth, especially across the layer interface does not take into account of the layering effect, thus it is not that meaningful to compare pressure distributions of layered profiles from LPILE versus FEM.

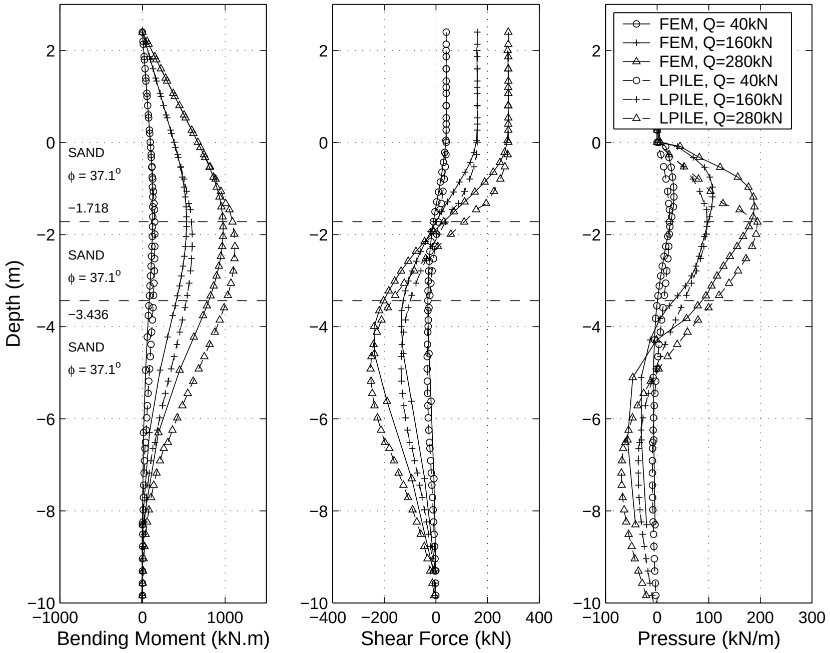

Figure 501.21: Comparison of bending moment, shear force and pressure computed by FEM and LPILE in uniform sand profile(case #3).

It is also interesting to compare the $p-y$ curves derived from FEM with those used in LPILE. Figures 501.24 and 501.23 show FEM derived and LPILE used $p-y$ curves for uniform clay and sand profiles, respectively. It should be noted that the coefficient of subgrade reaction η_h was again back-calculated as 8969 kN/m^3 in order to get a reasonable $p-y$ curves. From Figures 501.24 (a) and (b), it is clear that $p-y$ curves in sand profile from LPILE have lower resistance at depth close to ground surface. The $p-y$ curves for clay profile shown in Figures 501.24 (a) and (b) are seen to have much lower resistance at shallow depths.

501.2.4 Summary

This paper presents results from a finite element study on the behavior of a single pile in elastic–plastic soils. The analysis included single pile behavior in sand, clay and layered soils. Based on the results

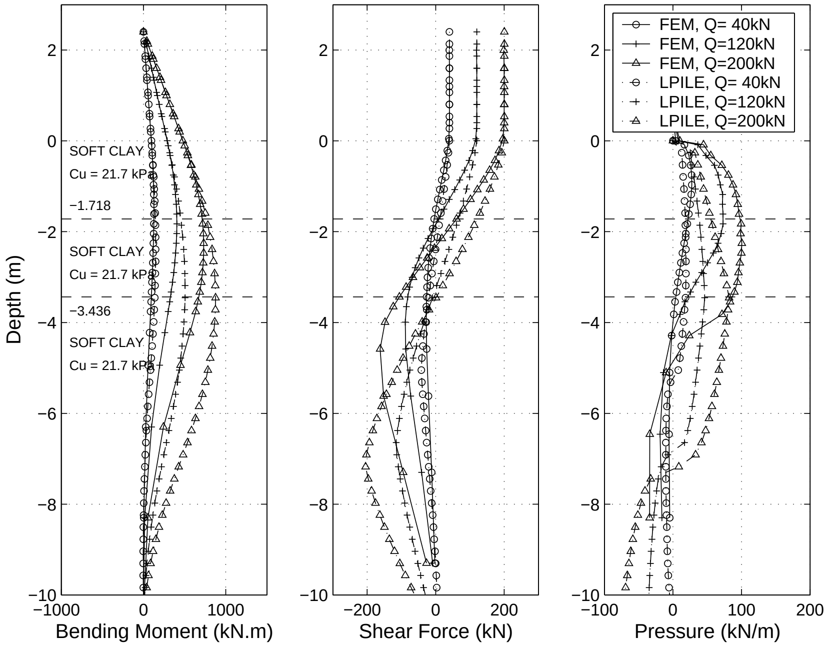

Figure 501.22: Comparison of bending moment, shear force and pressure computed by FEM and LPILE in uniform soft clay profile(case #1).

presented, it is concluded that three dimensional finite element analysis using very simple elastic-plastic soil models can predict the pile head deflection with very good accuracy.

The main findings of this numerical study can be summarized as follows:

- When a sand layer is present within a clay deposit, the increase in lateral pressure in clay near the interface is confined to a narrow zone, up to two times of pile width, therefore the layering effect in this case is not prominent.
- When a clay layer is present within a sand deposit, the reduction in pressures spread well into the sand layer (up to four times of pile width). The layering effects are of more importance in this case since the disturbance zone is large and the pressure reduction is significant. Reduction factors are given in terms of charts of pressure reduction versus the distance from the interface.

In addition, comparison with centrifuge data shows generally a good agreement between the bending moments, shear forces and lateral resistance. Moreover, a comparison with results from program LPILE, used in extensively in practice, show some discrepancies ultimate pressures in shallow soil layers.

501.3 Study of soil layering effects on lateral loading behavior of piles

Material presented here has been previously published in our paper Yang and Jeremić (2005).

501.3.1 Introduction

The theory of beams on a Winkler-type subgrade (Hartog (1952)), also known as the p–y approach, has been widely used to design piles subjected to lateral loading. Based on that theory, the method models the lateral soil–foundation interaction with empirically derived nonlinear springs (p–y curves). The advancement of computer technology has made it possible to study this problem using more rigorous elastic–plastic Finite Element Method (FEM).

Here mentioned are a few representative examples of finite element studies of pile foundations. Muqtadir and Desai (1986) studied the behavior of a pile–group using a three dimensional (3D) program with nonlinear elastic soil model. An axisymmetric model with elastic-perfectly plastic soil was used by Pressley and Poulos (1986) to study group effects. Brown and Shie (1990a), Brown and Shie (1990b), Brown and Shie (1991), and Trochanis et al. (1991) conducted a series of 3D FEM studies on the behavior of a single pile and a pile group with elastic-plastic soil model. These researchers used interface elements to account for pile–soil separation and slippage. Moreover, Brown and Shie derived p–y curves from FEM data, which provide some comparison of the FEM results with the empirical design procedures in use. Kimura et al. (1995) conducted 3D FEM analysis of the ultimate behavior of laterally loaded pile groups in layered soil profiles with the soil modeled by Drucker–Prager model and pile modeled by nonlinear beam elements. A number of model tests of free– or fixed–headed pile groups under lateral loading in homogeneous soil profiles have been simulated by Wakai et al. (1999) using 3D elasto-plastic FEM. Pan et al. (2002) studied the performance of single piles embedded in soft clay under lateral soil movements. A good correlation between the experiments and the analysis has been observed in these studies. All these results demonstrated that FEM can capture the essential aspects of the nonlinear problem.

Information about the lateral behavior of piles in layered soil profiles is very limited. Some analytical studies have been conducted by Davisson and Gill (1963) and Lee and Karunaratne (1987) to define the influence of pile length, the thickness of upper layer and the ratio of stiffness ratio of adjacent layers on the pile response based on the assumption that the soil is elastic. Reese et al. (1981) conducted small scale laboratory tests on a 25 mm diameter pile and a field test with 152 mm diameter pile in layered soils and found that there was a relatively good agreement between deflections measured in the tests and deflections computed using homogeneous p–y curves at small loads. Georgiadis (1983) proposed an approach which is currently used in the `LPILE` program (Reese et al. (2000a,b)). This method assumes the p–y curves of the first layer are the same as those for homogeneous soils. The effects of upper layers on the p–y curves of the lower layers are accounted for by the equivalent depth of the overlying layers based on strength parameters.

To the Authors' knowledge, there is no literature reporting on FEM study of layering effects on the behavior of laterally loaded piles in layered profiles. However, it is of great interest to investigate the layering effects since in practice, most of soil deposits are layered systems. In a predominantly clay site with a minor sand layer, the sand layer will still be counted on to provide most of the soil resistance. In this case, the layering effects (probably reduction of resistance in the sand layer) must be considered. Current practice is to *"make an educated guess to reduce the sand p–y curves to account for the soil layering effects"* (Lam and Law (1996)). Obviously, an educated guess might not result in optimal design. It is very important to find out how these layers in the layered system affect each other in order to carry out a more accurate analysis of pile foundation and therefore provide a more effective way for the design of pile foundations in layered soil systems.

This paper describes four 3D finite element models of a laterally loaded pile embedded in uniform and layered soil profiles, with the dimensions and soil parameters similar to those used in the centrifuge studies by McVay et al. (1998) and Zhang et al. (1999). Visualization tool Joey3D (Yang (2002)) was used to compute the bending moment, shear force and lateral resistance diagrams along the pile. Model calibration, comparison of finite-element analysis results with those from centrifuge tests and the `LPILE` program, and comparison of finite-element generated p–y curves with traditional p–y curves are summarized in a separate paper (Yang and Jeremić (2003). In this paper, p–y curves from each model were cross compared to illustrate both the effects of an intermediate soft clay (or sand) layer on the p–y curves of the sand (or soft clay) layers and the effects of sand (or soft clay) layers on the intermediate soft clay (or sand) layer. In addition, a limited parametric study was conducted to further investigate the layering effects in terms of lateral resistance ratios. The OpenSees OpenSees Development Team (Open Source Project) (2000-2006) finite element framework was employed for all the computations. Soil modeling was performed using the Template Elasto–Plastic Framework (Jeremić and Yang (2002)) and solid elements while the piles were modeled using linear elastic solid elements, all developed by the Authors.

501.3.2 Finite Element Pile Models

Single pile finite element models with the dimensions similar to the prototype model described in the above centrifuge tests were developed and a number of static pushover tests were simulated with 3D FEM using uniform soil and layered soil cases. The models for all cases were illustrated in Figure 501.25 (a). There are four main analysis models. Two of them are dealing with uniform sand and clay deposits,

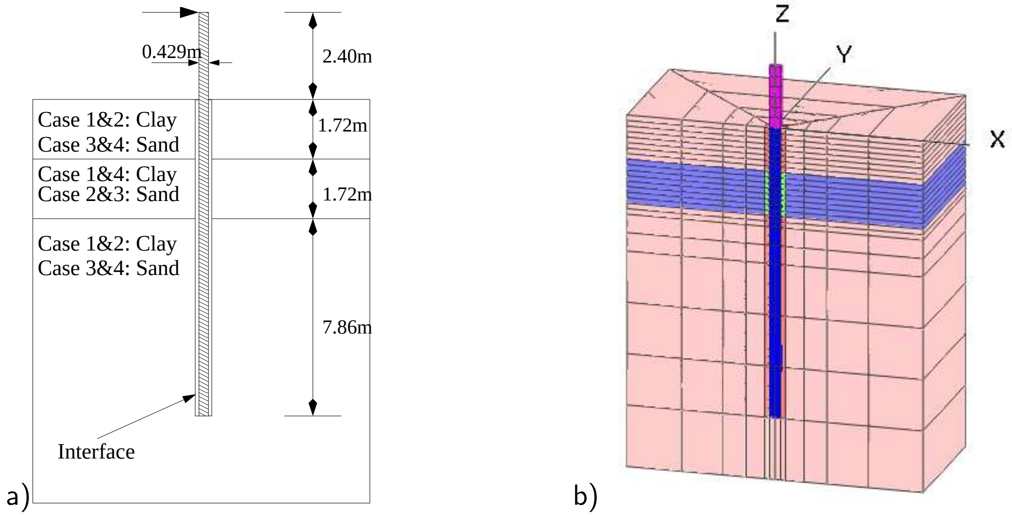

Figure 501.25: (a) Single pile models, dimensions and layers for models #1, #2, #3 and #4, including pile-soil interfaces and (b) 3D mesh of the single pile model.

while the other two are featuring layered soil deposits. In particular, model # 1 has a uniform soft clay deposit, model # 2 includes top and bottom layers of soft clay with an interlayer of medium dense sand. Model # 3 features uniform medium dense sand deposit, while model # 4 features top and bottom layers of medium dense sand with an interlayer of soft clay.

Figure 501.25 (b) shows the finite element mesh for all four models. Based on symmetry, only half of the model is meshed. Twenty–node brick elements are used to mesh the soil, pile and pile–soil interface. The square pile, with a width of 0.429 m and length of 13.7 m[1], is divided into four elastic elements (per cross subsection) with the properties of aluminum. The mesh is refined at the upper part of the model in order to provide data points for the computation of shear force and lateral resistance of sufficient reliability as well as for investigation of the layering effects. Additional finite element analysis of a cantilever beam using the same mesh as the pile was carried out and comparison of the beam displacement from FEM and beam theory solution indicated that the mesh was fine enough to capture the pile behavior. As to the boundaries, the sides and bottom of the model are fixed with the exception of the symmetric boundary, which is only supported in Y direction. Since the sides are 13 times of the pile width away from the pile center, it is believed that the fixed boundaries have very limited effects on the results. In addition to that the model size is closely following that of the physical, centrifuge model, which resided in a container of similar size. The pile–soil interface is represented by one thin layer of elements. The purpose of this layer is to mimic the installation effects on the pile (drilled or driven). It

---

[1] All dimensions are from the centrifuge study, prototype scale.

also serves a purpose of a simplified interface which allows for tension cut-off (gapping) and controlled, coupling of horizontal and vertical resistance according to Coulomb frictional laws.

501.3.3 Constitutive Models

Two simple models were used in this numerical study. Specifically, clay was modeled by von Mises material model which is completely defined with the undrained shear strength. Sand was simulated by Drucker–Prager material model with nonassociated flow rule, defined with the friction and dilation angles. The reason for using such simple models is that the experimental results used in comparison with simulations did specify only very limited number of material properties for sands. Furthermore, a small number of model parameters needed by simple models are convenient for parametric study. In both material models, the Young's moduli vary with confining pressure, as shown in Eqn. (501.2) (cf. Janbu (1963), Duncan and Chang (1970)):

$$E = E_o \left(\frac{p}{p_a}\right)^a \tag{501.2}$$

where E_o is Young's Modulus at atmospheric pressure, p is the effective mean normal stresses, p_a is the atmospheric pressure, and a is constant for a given void ratio. In this work, 0.5 was used.

The following parameters were used for medium dense sand: friction angle $\phi = 37.1^o$, Shear modulus G at a depth of 13.7 m = 8960 kPa (E_o = 17400 kPa), Poisson's ratio $\nu = 0.35$ and unit weight $\gamma = 14.50$ kN/m^3. These parameters were given by Zhang et al. (1999). A dilation angle of $\psi = 0^o$ is used in this work (Brown and Shie (1990a)). The undrained shear strength, Young's modulus, Poisson's ratio and unit weight of clay were chosen to be $C_u = 21.7$ kPa, $E_0 = 11000$ kPa, $\nu = 0.45$, $\gamma = 11.8$ kN/m^3, respectively. The interface elements were simulated by Drucker–Prager model with a friction angle $\phi = 25^o$, and a dilation angle $\psi = 0^o$. All material properties were summarized in Table 501.1.

Table 501.1: Material properties of sand, clay, pile and soil–pile interface used in FEM analysis.

Soil	E_o (kPa)	ν	γ (kN/m^3)	ϕ $(^o)$	ψ $(^o)$	C_u (kPa)
Medium dense sand	17400	0.35	14.5	37.1	0	–
Loose sand	16000	0.35	14.1	34.5	0	–
Clay	11000	0.47	11.8	–	–	21.7
Pile	69000000	0.33	26.8	–	–	–
Soil–pile interface	Variable	Variable	Variable	25	0	–

501.3.4 Comparison of p–y Behavior in Uniform and Layered Soil Deposits

This subsection presents representative results related to the behavior of piles in uniform and layered soil deposits. Specifically the p–y response curves derived for 3D FEM results for homogeneous and layered soil deposits are compared with each other to investigate the layering effects.

501.3.4.1 Uniform Clay Deposit and Clay Deposit with an Interlayer of Sand.

The p–y curves of uniform clay deposit and clay deposit with a layer of sand were compared in Figure 501.26. It is clearly seen that the p–y curve ($Z = -3.75D$) close to the interface ($Z = -4D$) is significantly different from that in uniform soil profile.

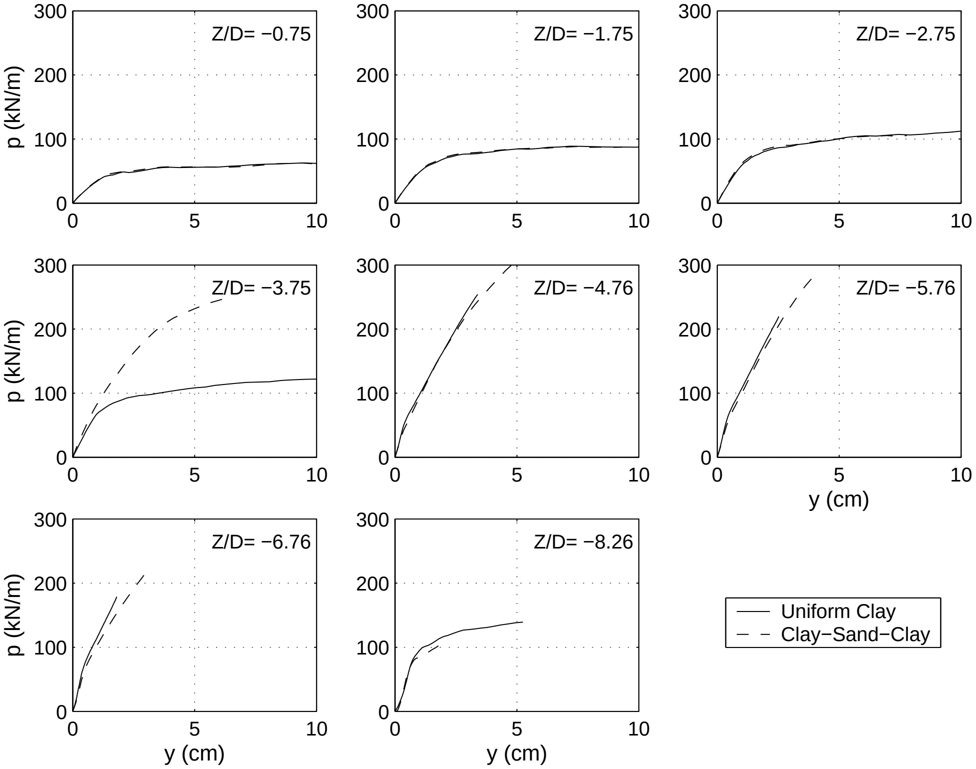

Figure 501.26: Comparison of p–y curves of uniform clay deposit versus clay deposit with an interlayer of sand (Sand: $\phi = 37^o$; Clay: $C_u = 21.7$ kPa).

In order to measure the magnitude of the effects of the intermediate sand layer on the lateral resistance of the soft clay layers and vice versa, the ratios of soil lateral resistances in the layered (p) and uniform models ($p_{homog.\ model}$) at several lateral displacements (i.e. 0.5%, 1.0%, 2.0%, 2.5%, 8.0% and 10.0% of pile width D) were computed and plotted against vertical coordinate (Z) normalized by pile width D in Figures 501.27 and 501.28[2]. In addition, the results from two more analyses of the same model with different sands (friction angle ϕ were varied from 25^o to 30^o, while originally, the friction angle was set to 37^o) were also included in these figures.

From Figure 501.27, it is observed that the lateral resistance ratios are independent of friction angle ϕ of sand at small lateral displacements ranging from 0.5% to 1.0% of pile width D. When the lateral displacement is greater than 1.0%, the variation in ϕ starts to affect the lateral resistance ratio, as shown in Figure 501.28.

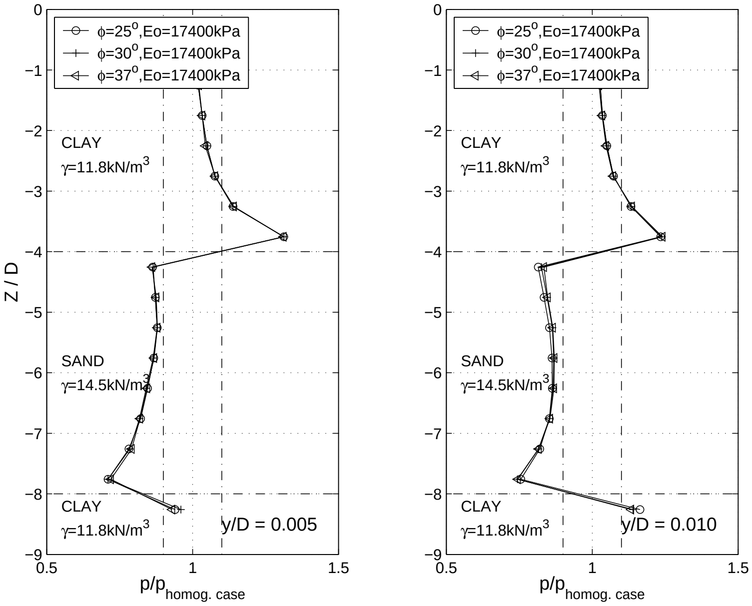

Figure 501.27: Lateral resistance ratio distributions (Clay:$C_u = 21.7\ kPa, E_o = 11000\ kPa$) for sands with various ϕ at lateral displacements of 0.5% and 1.0% pile width.

Overall, the effect of the sand layer reduces to less than 10% at about one pile width above the upper sand interface and the lateral resistance ratio at a quarter pile width above the upper sand interface is 1.3 at lateral deflection of 0.5% pile width. It may be noted that the two dashed vertical lines in the lateral resistance plots correspond to lateral resistance ratios of 0.9 and 1.1, indicating $\pm 10\%$ change in lateral resistance. The 10% change will be used to judge the extent of influence throughout the rest of the paper. The resistance ratio below the lower sand interface was not processed since the mesh is becoming coarse and the results are affected by mesh effects and numerical differentiation, and the pile displacements are very small.

Besides the effect the sand interlayer has on the clay layer, it is interesting to observe in Figure 501.27

---

[2] The lateral resistance ratio is only shown for the upper clay layer since the resistance corresponding to large y is not available at larger depth due to the fact that the pile is loaded at the pile head and the deflection decreases quickly as depth increases. Also due to the limit of space, plots for 2.0%, 2.5% pile width are not shown in this paper.

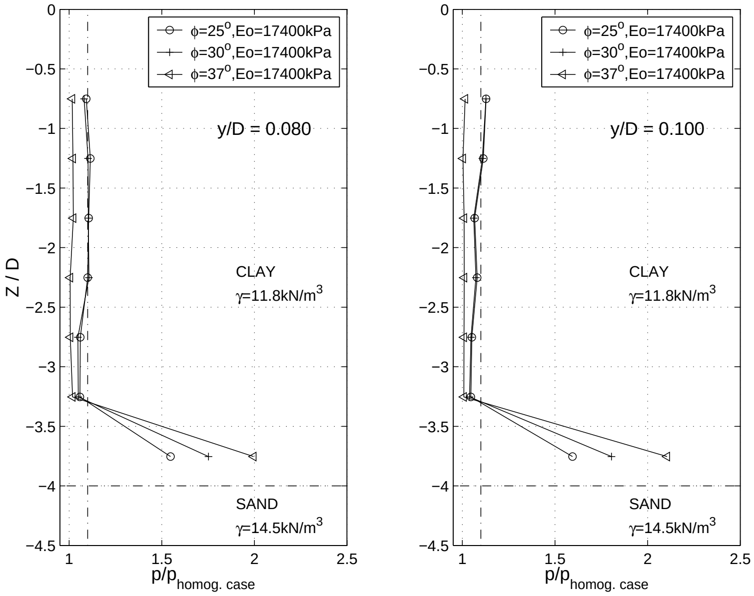

Figure 501.28: Lateral resistance ratio distributions in clay layer ($C_u = 21.7\ kPa, E_o = 11000\ kPa$) for sands with various ϕ at lateral displacements of 8% and 10% pile width.

that the soft clay layers also have significant effect on the lateral resistance of the intermediate sand layer. The lateral resistance ratios are less than 0.9 throughout the interlayer of sand. Surprisingly, the effects are not symmetric at lateral deflection of 0.5%. The resistance ratio is 0.85 at 0.25D below the upper sand interface, while that is 0.72 at 0.25D above the lower sand interface. This non–symmetry is probably due to the non–symmetric deformation[3] mode in the pile. As the pile is loaded laterally at the pile head, the right–hand–side sand close to the pile below certain depth tends to move downward to the right, which can be observed in Figure 501.32 (b). Therefore, the sand close to the upper interface moves against sand, while that close to the lower interface moves against soft clay. This type of movement results in the larger reduction in resistance at the lower sand interface than at the upper sand interface. The decrease in lateral resistance is mainly due to the lower stiffness in the adjacent soft clay layers. In addition, the smaller unit weight of the soft clay results in smaller mean effective normal stresses in the sand layer than the homogeneous model, which will reduce the stiffness of the sand and therefore also contribute to the reduction in lateral resistance at the intermediate sand layer.

---

[3] Non–symmetric with respect to the horizontal plane in between the interfaces (midway through the sand layer).

501.3.4.2 Uniform Sand Deposit and Sand Deposit with an Interlayer of Soft Clay.

By comparing the p–y curves of uniform sand deposit and sand deposit with an interlayer of soft clay, it was found that the effect of soft clay on the lateral resistance of sand propagates further away from the interface than Clay-Sand-Clay case, as described above in subsection 501.3.4.1. In addition to that, it was found that the heave in front of the pile will affect the lateral resistance of sand at shallow depth. Therefore, for sand deposit with an interlayer of soft clay, the thickness of upper sand layer was increased from 1.72 m to 2.36 m (the thickness of the soft clay layer was kept the same) to investigate the range of layering effects. Three models were analyzed by only varying the undrained shear strength C_u (i.e. 13.0, 21.7 and 30.3 kPa) of the soft clay layer.

Similar to the previous analysis, the p–y curves from the uniform deposit and the re-configured layered deposit were compared in Figure 501.29 and the lateral resistance ratios at several lateral displacements (i.e. 0.5%, 1.0%, 2.0%, 2.5%, 5.0% and 6.5% of pile width D) for all three models were computed and shown in Figures 501.30 and 501.31. It may be observed from Figure 501.29 that obvious difference may be observed in several $p--y$ curves further away from the interface.

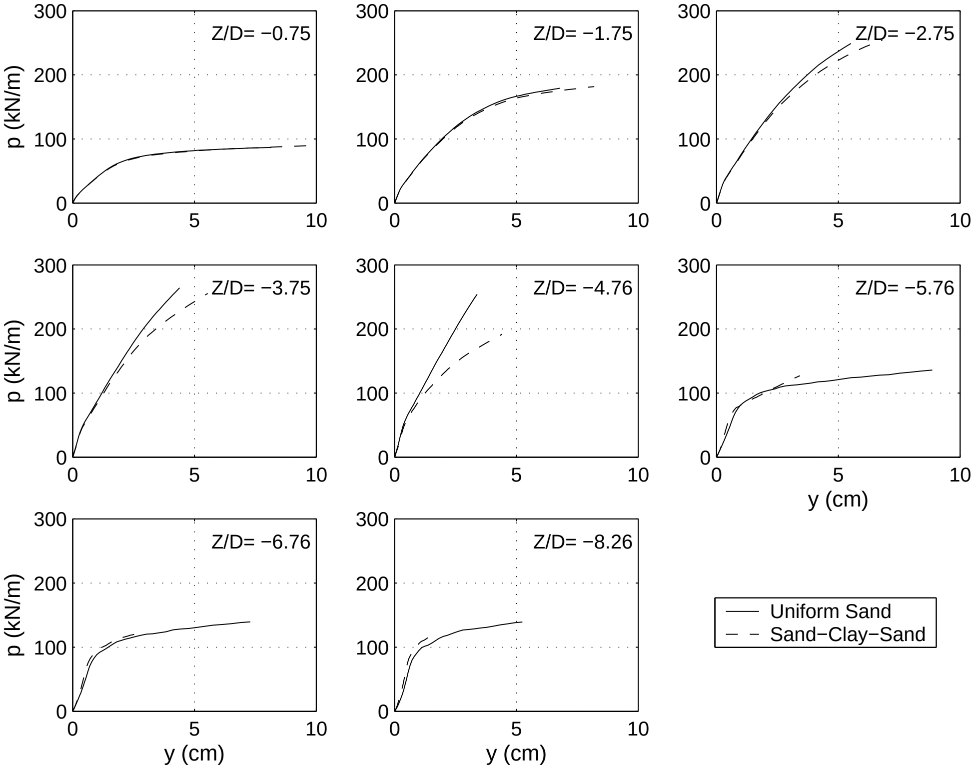

Figure 501.29: Comparison of p–y curves for uniform sand deposit versus sand deposit with an interlayer of soft clay (Sand: $\phi = 37^o$; Clay: $C_u = 21.7\ kPa$).

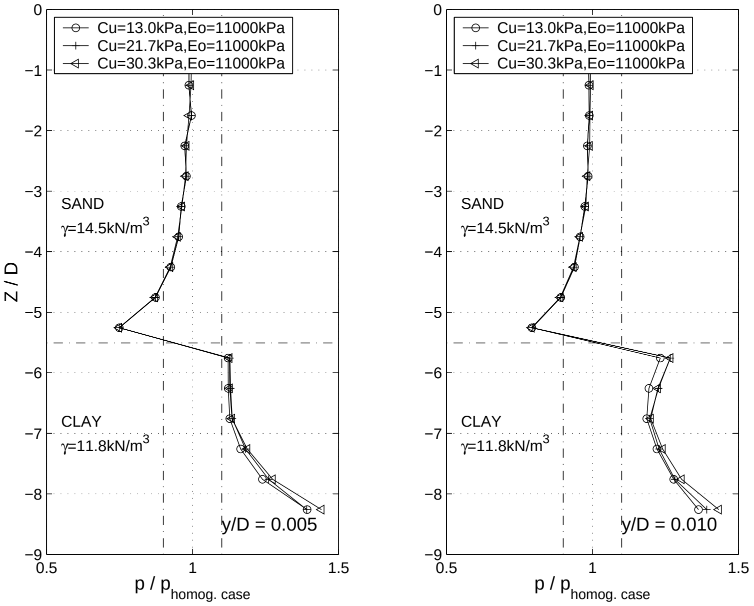

Figure 501.30: Lateral resistance ratio distributions (Sand:$\phi = 37^o, E_o = 17400\ kPa$) for clays with various C_u at lateral displacements of 0.5% and 1.0% pile width.

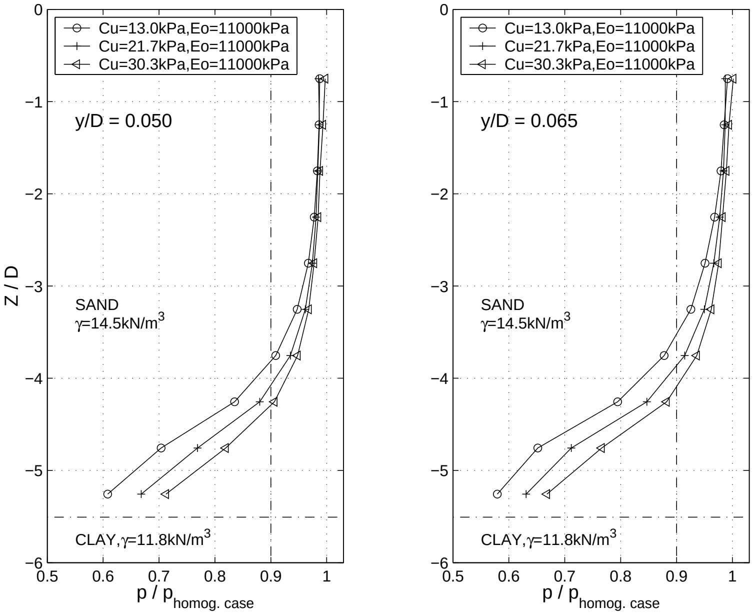

Figure 501.31: Lateral resistance ratio distributions (Sand:$\phi = 37^o, E_o = 17400\ kPa$) for clays with various C_u at lateral displacements of 5.0% and 6.5% pile width.

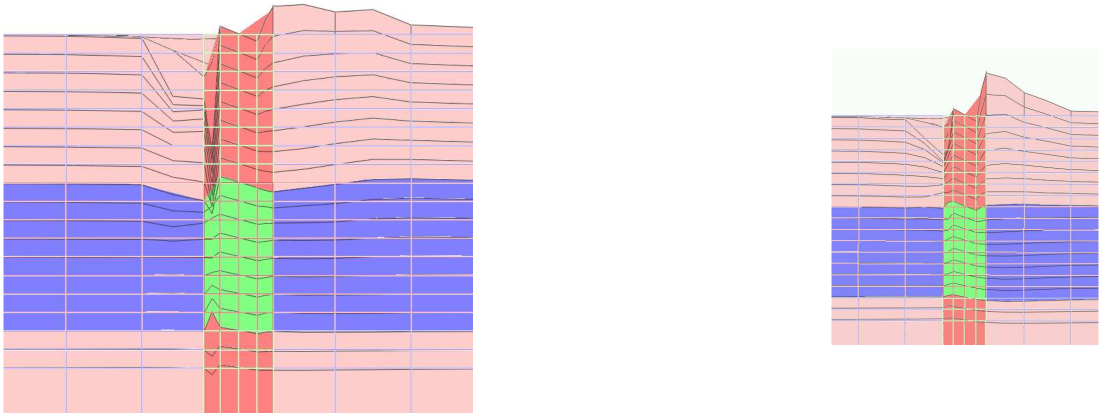
From Figure 501.30, it is noted that the effects of the intermediate soft clay layer are also independent of its undrained shear strength at small lateral displacements ranging from 0.5% D to 1.0% D. When the lateral displacement is greater than 1.0% D, the change in C_u starts to affect the lateral resistance ratio, as shown in Figure 501.31. Similar to the Clay–Sand–Clay model, the effect of the intermediate soft clay layer reduces to less than 10% at one pile width above the clay interface. The lateral resistance ratio at 0.25D above the clay interface is about 0.75. For large lateral displacements ranging from 5.0% D to 6.5% D, the 10% change in lateral resistance extends to 1.5 D - 2 D, as can be observed in Fig. 501.31. It may be noted that, at a lateral displacement of 6.5% D, the lateral resistance ratio at 0.25D above the clay interface changes from 0.58 to 0.67 when C_u increases from 13.0 kPa to 30.3 kPa.

Figures 501.32 (a) and (b) show the details of displaced models around the interfaces for the Sand-Clay-Sand and Clay-Sand-Clay profiles, respectively. The deformed model was overlapped with undeformed model for comparison. Ground heave can be easily observed in front of the pile from both figures. It is noted from Figure 501.32 (a) that the sand crosses the upper clay interface and moves into the intermediate soft clay layer. The movement slightly strengthens the soft clay soil and partially causes the slight increase of lateral resistance at the top of soft clay layer. Most importantly, the movement will soften the sand close to the upper layer interface, due to the reduction of confinement to the sand. For the Clay-Sand-Clay profile, the stronger sand layer penetrates into the softer clay layers at both interfaces. This penetration softens the sand close to both interface, due to the same reason as above.

501.3.5 Parametric Study for the Lateral Resistance Ratios in Terms of Stiffness and Strength Parameters.

To further investigate the effects of soil stiffness on the lateral resistance ratios at small displacement and/or large displacement, further analyses were carried out for the Clay–Sand–Clay and Sand–Clay–Sand models by changing both stiffness parameter (i.e. E_o) and strength parameter (C_u for clay, or ϕ for sand) using the same finite element models as above. The model configurations and intermediate layer soil parameters were summarized in Tables 501.2 and 501.3.

Lateral resistance ratios were plotted in Figures 501.33 and 501.34 for the Clay–Sand–Clay model, and in Figures 501.35 and 501.36 for the Sand–Clay–Sand model. By comparing Figures 501.28 and 501.34 for pile displacements of 8% D and 10% D, and Figures 501.31 and 501.36 for pile displacements of 5% D and 6.5% D, it is clear that the lateral resistance ratios are almost the same for the upper layer soil even if the stiffness parameter E_o of intermediate layer soil was varied by more than 30%. However, the lateral resistance ratios at small displacement (0.5% D and 1.0% D) were obviously influenced by the variation of E_o, as can be observed by comparing Figures 501.27 and 501.33 for the Clay–Sand–Clay model, and Figures 501.30 and 501.35 for the Sand–Clay–Sand model. For medium pile displacements



(a) (b)

Figure 501.32: Details of displaced model indicating ground heave and movement of soils across the layer interfaces at lateral load of 400 kN: (a) sand deposit with an interlayer of soft clay and (b) clay deposit with an interlayer of medium sand. The pile elements are removed so that the interface layer in the middle can be seen clearly.

Table 501.2: Summary of model configurations and intermediate sand layer parameters for Clay–Sand–Clay model in the parametric study.

Case	Soil Profile	Depth of Interfaces		Intermediate Sand Layer	
		Upper	Lower	E_o (kPa)	ϕ
1	Clay–Sand–Clay	-1.72 m	-3.43 m	11500	25^o
2	Clay–Sand–Clay	-1.72 m	-3.43 m	13500	30^o
3	Clay–Sand–Clay	-1.72 m	-3.43 m	17400	37^o

Table 501.3: Summary of model configurations and intermediate clay layer parameters for Sand–Clay–Sand model in the parametric study.

Case	Soil Profile	Depth of Interfaces		Intermediate Clay Layer	
		Upper	Lower	E_o (kPa)	C_u (kPa)
1	Sand–Clay–Sand	-2.36 m	-4.08 m	8000	13.0
2	Sand–Clay–Sand	-2.36 m	-4.08 m	11000	21.7
3	Sand–Clay–Sand	-2.36 m	-4.08 m	12500	30.3

(e.g. 2% D and 2.5% D), both stiffness and strength parameters have effects on the lateral resistance ratios.

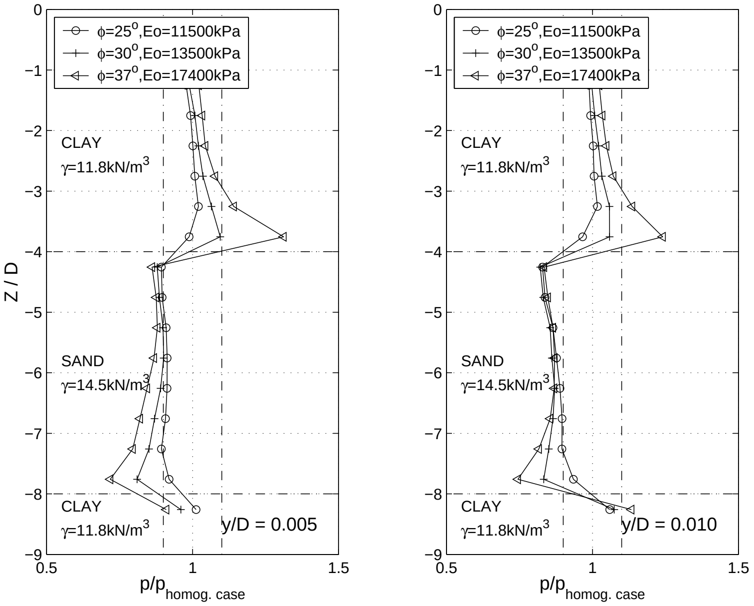


Figure 501.33: Lateral resistance ratio distributions (Clay:$C_u = 21.7\ kPa, E_o = 11000\ kPa$) for sands with various ϕ and E_o at lateral displacements of 0.5% and 1.0% pile width.

It will be useful to relate the effects of (a) the relative stiffness which controls the lateral resistance ratio at small lateral displacements and (b) the relative strength which determines the lateral resistance ratio at large lateral displacements with the lateral resistance ratio. To exclude the effects of unit weight, only the results above the upper interface in the Sand–Clay–Sand model are processed. The ratio of Young's moduli of clay and sand soils was used to define the relative stiffness $R_{stiffness}$ of the two layers.

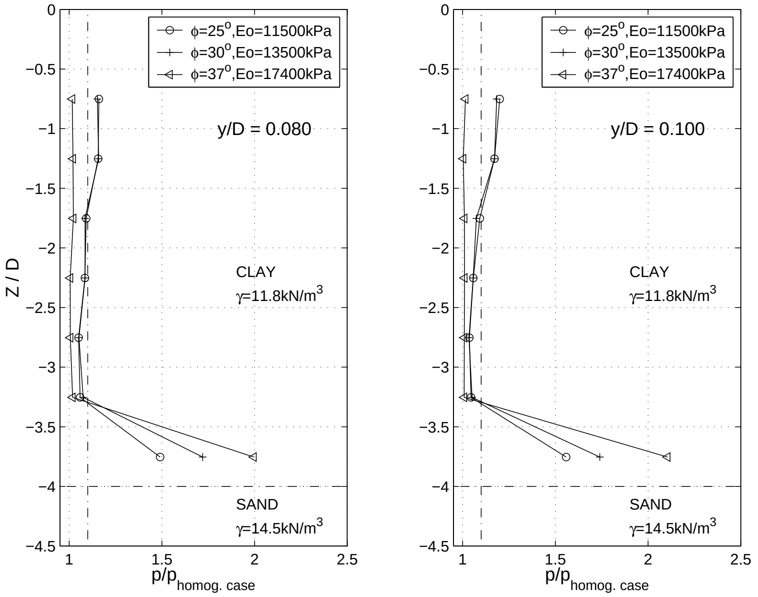

Figure 501.34: Lateral resistance ratio distributions in clay layer ($C_u = 21.7\ kPa, E_o = 11000\ kPa$) for sands with various ϕ and E_o at lateral displacements of 8% and 10% pile width.

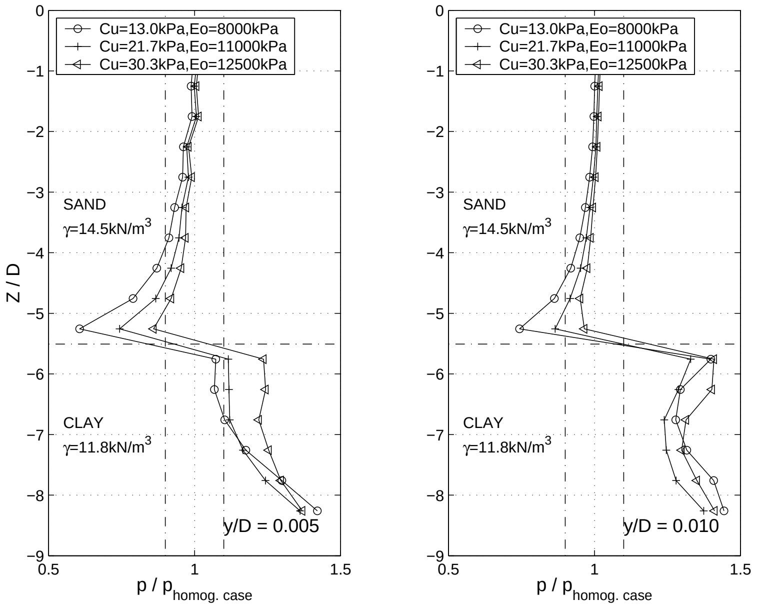

Figure 501.35: Lateral resistance ratio distributions (Sand:$\phi = 37^o, E_o = 17400\ kPa$) for intermediate layer of clays with various C_u and E_o at lateral displacements of 0.5% and 1.0% pile width.

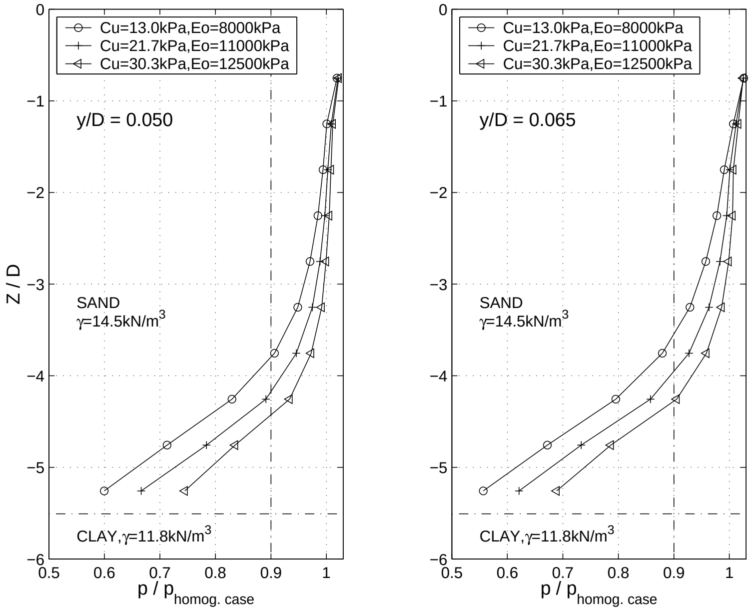

Figure 501.36: Lateral resistance ratio distributions (Sand:$\phi = 37^o, E_o = 17400\ kPa$) for clays with various C_u and E_o at lateral displacements of 5.0% and 6.5% pile width.

On the other hand, the ratio of largest lateral resistances of uniform clay and sand[4] at the upper interface (-2.36 m) was used to define the relative strength $R_{strength-FEM}$, as described in Equations (501.3) and (501.4).

$$R_{stiffness} = \frac{E_{o-clay}}{E_{o-sand}} \tag{501.3}$$

$$R_{strength-FEM} = \frac{p_{clay-FEM}}{p_{sand-FEM}} \tag{501.4}$$

The lateral resistance ratios at lateral displacement of 6.5% D were plotted against C_u in Figure 501.37. For comparison, the relative stiffness $R_{stiffness}$ and relative strength $R_{strength-FEM}$ were also included in the same plot.

As can be observed from this plot, the lateral resistance ratio decreases from 0.69 to 0.56 almost proportionally as C_u drops from 30 kPa to 13 kPa at 0.25 D above the upper interface, and the ratio is greater than the relative strength $R_{strength-FEM}$. Since the ultimate resistance of uniform sand will be larger than the computed largest value (which is still increasing , as can be observed from Figure 501.29 at Z=-3.75D) and that of uniform clay almost will almost remain the same (refer to Figure

---

[4] It would be better to use the ultimate lateral resistances for both clay and sand to define the relative strength but these values are not available from the current numerical results since pile displacement y is not large enough.

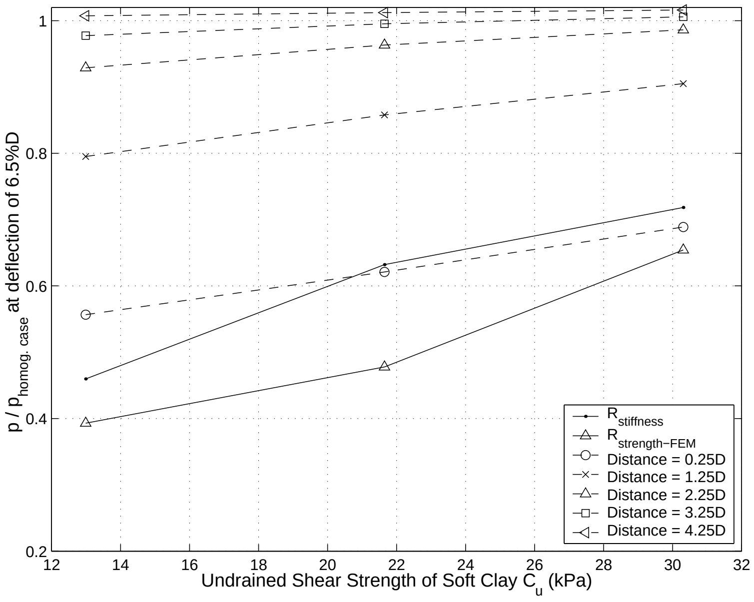

Figure 501.37: Lateral resistance ratios in the upper sand layer ($\phi = 37^o$) at various distances from the interface for pile displacement of 6.5% pile width.

501.26 at Z=-3.75D), this relative strength value will drop and the above statement still holds. There is certain correlation between the lateral resistance ratio close to the upper interface and $R_{strength-FEM}$ at 6.5%D pile displacement. As the distance to the upper interface increases, this correlation diminishes. The relative stiffness curve intercepts with the lateral resistance ratio curves at 0.25D above the upper interface. This implies that the presence of the clay, which is softer than the sand, somehow caused the layered system to be softer than either of the homogeneous models. This seems illogical, and in fact previous discussions and comparisons showed that $R_{strength-FEM}$ is more important than $R_{stiffness}$ at these large relative displacements.

It is also interesting to examine the relationship between the lateral resistance ratio and the relative variables (i.e. strength and stiffness) when lateral displacement increases, as presented in Figures 501.38 and 501.39. Figure 501.38 shows that the lateral resistance ratios at 0.25D above the interface decreases and come closer to the relative strength $R_{strength-FEM}$ curve as the lateral displacement increases from 4.0%D to 6.5%D. The relative stiffness $R_{stiffness}$ was also plotted in Figure 501.38 and it intercepts with the lateral resistance ratio curve, which has similar implications as the above discussion for Figure 501.37 and is illogical. On the other hand, as the lateral displacement decreases from 1.5%D to 0.5% D, the lateral resistance ratios keep decreasing and come closer to the relative stiffness ratio $R_{stiffness}$, as shown in Figure 501.39. There is almost a linear relationship between the lateral resistance ratio and the relative stiffness at small displacements.

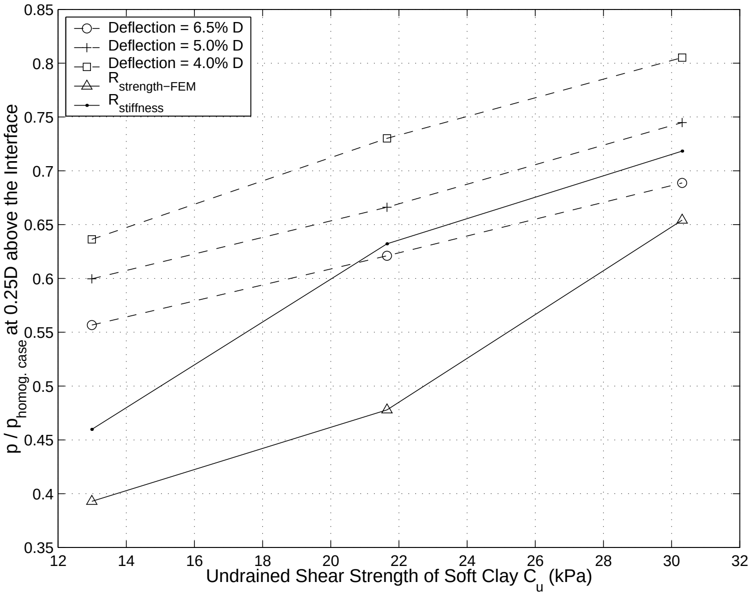

Figure 501.38: Lateral resistance ratio at a quarter pile width above the upper clay interface for various deflections.

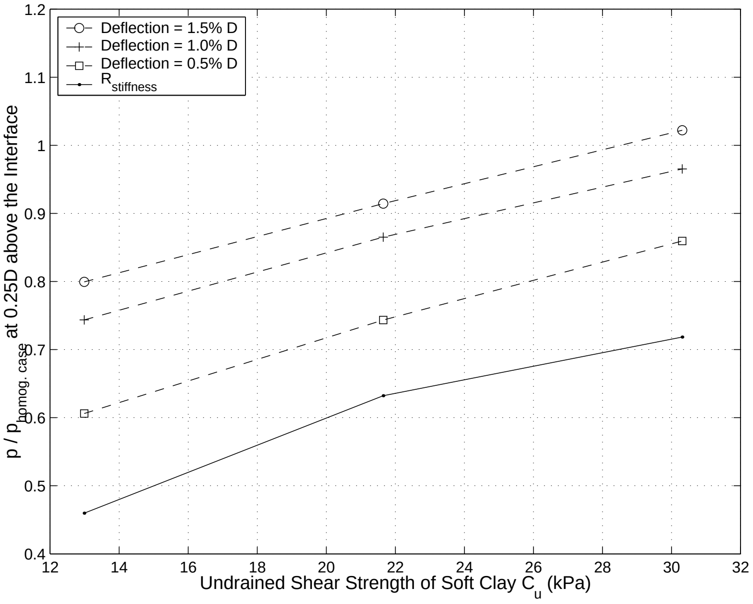

Figure 501.39: Lateral resistance ratio at one quarter pile width above the upper clay interface for clays with various C_u and E_o at small pile displacements ranging from 0.5% to 1.5% pile width.

From the above analysis, it is safe to say that the lateral resistance ratio is dominated by the relative stiffness $R_{stiffness}$ at small displacement (i.e. $\leq$ 0.5%D), while that is controlled by the relative strength $R_{strength-FEM}$ at large displacement (i.e. $\geq$ 4.0%D). For small displacement, the smaller the displacement is, the closer the lateral resistance ratio is to the relative stiffness; for large displacement, the larger the displacement, the closer the lateral resistance ratio is to the relative strength.

Figures 501.40, 501.41 and 501.42 summarize observed lateral resistance ratios in layered profiles. Figure 501.40 shows the lateral resistance ratios in the intermediate sand layer corresponding to various relative stiffness $R_{stiffness}$ at pile displacement of 0.5%D for the Clay–Sand–Clay model. Figures 501.41 and 501.42 show the lateral resistance ratios corresponding to various relative stiffness $R_{stiffness}$ and relative strength $R_{strength-FEM}$ at pile displacements of 0.5% D and 6.5% D for the Sand–Clay–Sand model. The effects of the intermediate clay layer on the upper sand layer reduce to less than 10% at a distance of 0.5 to 1.5 D above the interface at small pile displacement (e.g. 0.5% D), while that effects reduce to less than 10% at a distance of 1.25 to 2.0 D above the interface at large pile displacement (e.g. 6.5%D).

One may notice that the lateral resistance ratios corresponding to the relative stiffness $R_{stiffness} =$ 0.63 in Figures 501.40 and 501.41 are not the same. The ratios close to the lower sand interface in the Clay–Sand–Clay model is slightly larger than that in the Sand–Clay–Sand model. This difference is due to the fact that the lateral resistance ratios in the intermediate sand layer also include the effects of smaller unit weight of upper layer clay.

501.3.6 Summary

This subsection summarizes results from finite element analysis on the behavior of a single pile in elastic–plastic layered soils. Based on the results presented, the following conclusions can be drawn.

1. The layering effects are two–way. Not only the lower layers are affected by the upper layers, but the upper layers are also affected by the lower layers. Furthermore, the layering effects are not symmetric. In the case of pile laterally loaded at the pile head, the effect of an interface extends further into the layer above the interface than it does into the layer below the interface at small displacements.

2. In the Clay–Sand–Clay model, the lateral resistance of soft clay increases by as much as 30% and the effect extends to one pile width above the upper sand interface for $R_{stiffness} = 0.63$ at small pile displacement (0.5%D). Nonetheless, the increase of lateral resistance in the upper clay layer at large pile displacement (8–10%D) extends only one finite element above the upper sand interface.

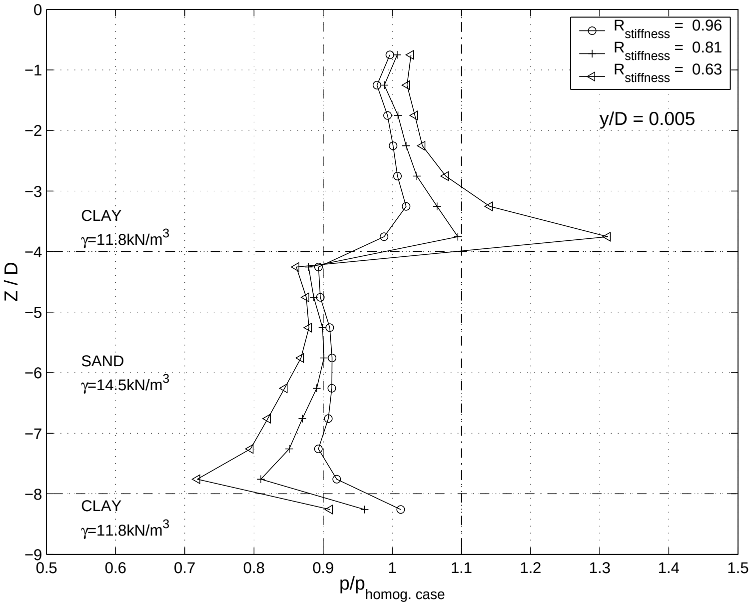

Figure 501.40: Summary of observed lateral resistance ratios from FEM analysis for the Clay–Sand–Clay profile at small deflection (y/D=0.5%).

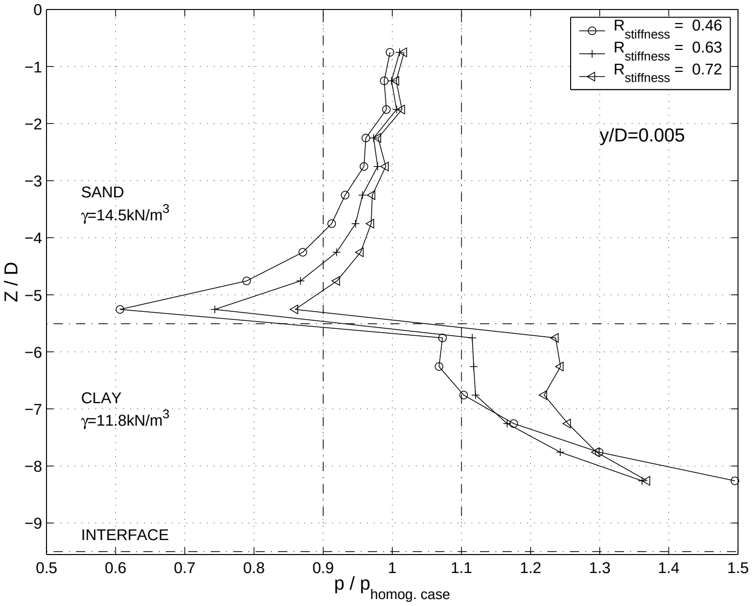

Figure 501.41: Summary of observed lateral resistance ratios from FEM analysis for the Sand–Clay–Sand profile at small deflection (y/D=0.5%).

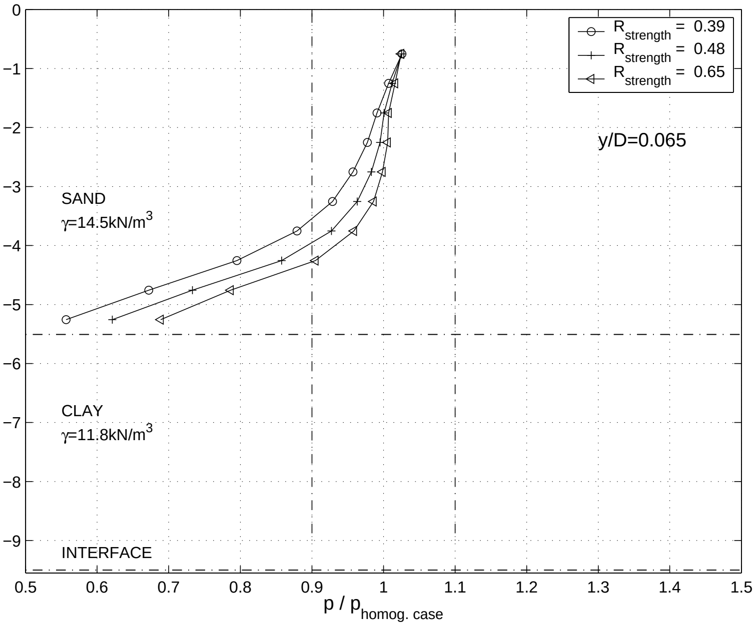

Figure 501.42: Summary of observed lateral resistance ratios from FEM analysis for the Sand–Clay–Sand profile at large deflection (y/D=6.5%).

On the other hand, the clay layers also have significant effects on the lateral resistance of sand throughout the intermediate layer.

3. In the Sand–Clay–Sand model, the intermediate clay layer has considerable effects on the lateral resistance of the upper sand layer, and the sand layers also have significant effects on the lateral resistance of the intermediate clay layer, causing 10 to 40% increase in its lateral resistance.
4. The lateral resistance ratio is dominated by the relative stiffness at small displacements (i.e. $\leq$ 1.0%D), while that is controlled by the relative strength at large displacements (i.e. $\geq$ 5.0%D).

It must be pointed out that the above observed lateral resistance ratios may only be applied to similar stratigraphies, pile deformation modes, and other conditions considered in this work. Further analyses are needed to investigate the effects of other stratigraphies, pile deformation modes, pile diameters, and other factors, in order to draw more general guidelines. Future studies with a refined mesh around the interface will provide better resolution of the resistance ratio around the interface. Future studies of the effects of the interface layer on the layering effects will also be very interesting.

501.4 Numerical Study of Group Effects for Pile Groups in Sands

Material presented here has been previously published in our paper Yang and Jeremić (2005).

501.4.1 Introduction

Single pile foundations have been successfully modeled by the $p-y$ approach, as implemented in LPILE (Reese et al. Reese et al. (2000a)). However, the behavior of a pile within a group may differ greatly from that of a single pile and vary depending on the position due to the interaction between the neighboring piles. To study this interaction effects, only a couple of field tests have been carried out because of the large costs incurred. Brown et al. Brown et al. (1988) conducted cyclic loading tests on instrumented 3×3 steel pile group. The p–multiplier concept was presented based on the measured soil resistance data and specific p–multipliers were suggested for the three rows. Ruesta and Townsend Ruesta and Townsend (1997) reported an in-situ test on piles at Roosevelt Bridge. Rollins et al. Rollins et al. (1997) tested another full–scale pile group founded in clay and suggested a set of p–multipliers for corresponding pile groups. Ng et al. Ng et al. (2001) presented results on full–scale lateral load tests of one single pile and three pile groups with large–diameter bored piles. Besides in-situ testing, many centrifuge tests were conducted to predict the behaviors of pile groups under static and dynamic loading. Recently, McVay et al. McVay et al. (1995) McVay et al. (1998) conducted a series of lateral load tests on large pile groups (3×3 to 7×3) founded in sands to study the interaction effects within a group.

Based on these field and centrifuge tests, it was found that:

1. All the test results have clearly shown that the lateral resistance of a pile within the group is strongly influenced by its row position and the p–multiplier method was suggested by Brown et al. Brown et al. (1988) to account for this behavior. Specifically, each row within the group is assigned a different p–multiplier f_m and the p–y curve for a single pile is multiplied by f_m to produce p–y curves for all the piles in the same row.

2. The p–multipliers are independent of soil density and only depend on the pile geometry. And at sufficient deformation and under static loading, they are constant for practical purposes (McVay et al. McVay et al. (1998)).

3. For 3–diameter spacing, the suggested p–multiplier f_m was 0.8, 0.4, 0.3 (front row to back row) for the 3×3 group (Brown et al. Brown et al. (1988)), 0.8, 0.4, 0.3, 0.3 for the 4×3 group, and 0.8, 0.4, 0.3, 0.2, 0.3 for the 5×3 group, and 0.8, 0.4, 0.3, 0.2, ..., 0.3 for all larger group size (McVay et al. McVay et al. (1998)).

4. For concentric loading (located at the geometrical center of the pile group), the difference between the side and middle piles within a row is small and may be neglected, while the moments in the side piles within a given row are slightly larger than that in the middle piles but may be represented by the average (McVay et al. McVay et al. (1998)).

Together with the physical modeling, a few numerical simulations have also been performed. We mention a few representative finite element studies of pile groups. Maqtadir and Desai Muqtadir and Desai (1986) studied the behavior of a pile-group using a three dimensional program with nonlinear elastic soil model. An axisymmetric model with elastic-perfectly plastic soil was used by Pressley and Poulos Pressley and Poulos (1986) to study group effects. Brown and Shie Brown and Shie (1990a) Brown and Shie (1990b) Brown and Shie (1991) and Trochanis Trochanis et al. (1991) conducted a series of 3D Finite Element Method (FEM) studies on the behavior of single pile and pile group with elastic-plastic soil model. In particular, interface element was used to account for pile-soil separation and slippage. Moreover, several model and field tests of free- or fixed-head pile groups have been analyzed by Kimura et al. Kimura et al. (1995) and Wakai et al. Wakai et al. (1999) using 3D elasto-plastic FEM.

This paper describes 3D elastic-plastic finite element modeling of two pile groups founded in sands with emphasis on the interaction effects within pile group. Specifically, bending moment and load distribution in individual piles were examined and compared with centrifuge test data. Special attention was given to out-of-loading-plane bending moment and p–y behavior of individual piles in a group. The OpenSees OpenSees Development Team (Open Source Project) (2000-2006) finite element framework was employed to complete all the computations. Soil modeling was performed using the Template Elastic–Plastic approach (Jeremić and Yang Jeremić and Yang (2002)).

This paper is organized as follows. Section 501.4.2 summarizes the centrifuge tests and describes finite element models including the soil elastic–plastic model used for 3×3 and 4×3 pile group simulations. Section 501.4.5 presents a number of results and discussion describing simulated behavior of analyzed pile groups. In particular, presented are developed plastic zones (Section 501.4.6), pile bending moments (Section 501.4.7), pile load distributions (Section 501.4.8), comparison of $p-y$ curves for individual piles (Section 501.4.9), and comparison with centrifuge tests (Section 501.4.10). Section 501.4.11 gives concluding remarks.

501.4.2 Pile Models

501.4.3 Summary of Centrifuge Tests

In the centrifuge tests reported by McVay et al. McVay et al. (1998), 3×3 to 7×3 pile groups embedded in homogeneous sands under lateral load were tested. The rectangular–shaped sample container was fabricated from aluminum alloy with an inside dimensions of 0.254 m wide, 0.457 m long, and 0.305 m high. The piles were spaced by three times the pile width and the pile caps (made of aluminum) were rigidly connected with the piles. The model square piles and pile cap were fabricated from solid square aluminum (alloy 6061) bars. Each individual pile is 9.5 mm wide and 304.8 mm long. To simulate the installing effects of field driven piles, the piles were driven in flight into sands by hydraulic equipment and tested at 45 g.

The sands (artificially mixed by a number of different gradations) studied were at two different relative densities: a loose sand with relative density Dr=36%, unit weight γ = 14.05 kN/m^3 and a medium dense sand with Dr = 55%, γ = 14.50 kN/m^3. The shear modulus G, Poisson's ratio ν and friction angle ϕ are 8230 kN/m^2, 0.35, 34.5^o for the loose sand and 8960 kN/m^2, 0.35, 37.1^o for the medium dense sand. It is noted that the friction angles were determined from drained triaxial compression tests, and the shear moduli were back–computed from instrumented vertical load tests (Zhang et al. Zhang et al. (1998)) and were valued at a depth of 13.7 m.

501.4.4 Finite Element Pile Models

Among these tested pile groups, 3×3 and 4×3 groups were chosen to be modeled in prototype scale using 3D elasto–plastic finite element method to investigate pile group interaction effects. The typical layout of 4×3 pile group is shown in Fig. 501.43. The whole centrifuge model in prototype scale is 22.8 m wide, 20.6 m long and 13.2 m deep. Only half of each centrifuge model is meshed considering the symmetry . Figure 501.44 shows the finite element mesh for the 4×3 pile group. Additional finite element analysis of a cantilever beam using the same mesh as an individual pile in the group was carried out and comparison of the displacement at the top of the beam from FEM and beam theory solution indicated that the mesh was fine enough to capture the pile behavior. Soil, pile and soil–pile interface are all modeled with twenty node brick elements. Each pile consists of four elements (per cross section) made of elastic material with properties corresponding to aluminum. There are 1268 and 1414 brick elements in the two models respectively. The sides and bottom of each model are fixed in all three coordinate directions with the exception of the symmetric boundary, which is only supported in the direction perpendicular to the symmetry plane. This type of boundary conditions are fairly close to the actual friction boundary conditions in the centrifuge tests.

All the parameters except the Young's moduli for sands were the same as from the centrifuge studies. The Young's modulus is assumed to depend on the mean effective normal stress p' (Manzari and Dafalias Manzari and Dafalias (1997)) as:

$$E = E_o \left(\frac{p'}{p_a} \right)^n \tag{501.5}$$

where E_o is Young's modulus at the atmospheric pressure, $p'=\sigma_{ii}/3$ is the mean effective normal stress, p_a is the atmospheric pressure, and n is constant for a given void ratio. Usually 0.5 is used for n. For the medium dense sand, the Young's modulus at the atmospheric pressure computed by Eqn. (501.5) (Lateral pressure coefficient $K_o = 0.55$ was used) from the back–computed shear modulus was 200000 kPa and then adjusted to be 17400 kPa for the medium dense sand, so as to well simulate the load–displacement curve obtained from centrifuge tests. For the loose sand, the computed Young's modulus at the atmospheric pressure from the back–computed shear modulus was 18700 kPa and similarly adjusted to be 16000 kPa.

Sand was simulated by Drucker–Prager material model with nonassociated flow rules. Since the centrifuge studies we used to compare our simulations against did specify only the friction angle of test sands which were obtained from drained triaxial compression tests, the yield surface was chosen to agree with Mohr–Coulomb hexagon at triaxial compression. Future study using Mohr–Coulomb material model will be useful to determine the effects of varying friction angle in Drucker–Prager model on the results. Since there is no test data on the dilation angle ψ of the tested sands, a dilation angle of 0^o was used in this work, as similar dilation angle was also used in Brown and Shie Brown and Shie (1990a). The soil–pile interface was represented by one thin layer of elements. The material of the interface element was also simulated by Drucker–Prager model with a friction angle of 25^o, a dilation angle of 0^o, and the same Young's modulus and Poisson's ratio as corresponding sands. In the future, a realistic dilation angle needs to be used for sand to further investigate the effects of dilation angle on the pile group interaction behavior, especially the out–of–loading–plane bending moment.

501.4.5 Simulation Results

In this section we present results related to the behavior of 3×3 and 4×4 pile groups in loose and medium dense sands. A number of static pushover tests were simulated using FEM. Specifically, modified Newton–Raphson method were used to solve the system of equations in the finite element level and implicit algorithm (Jeremić and Yang Jeremić and Yang (2002)) was used in constitutive level integration. Results are also compared with those from the centrifuge studies by McVay et al. McVay et al. (1998) and Zhang et al. Zhang et al. (1999).

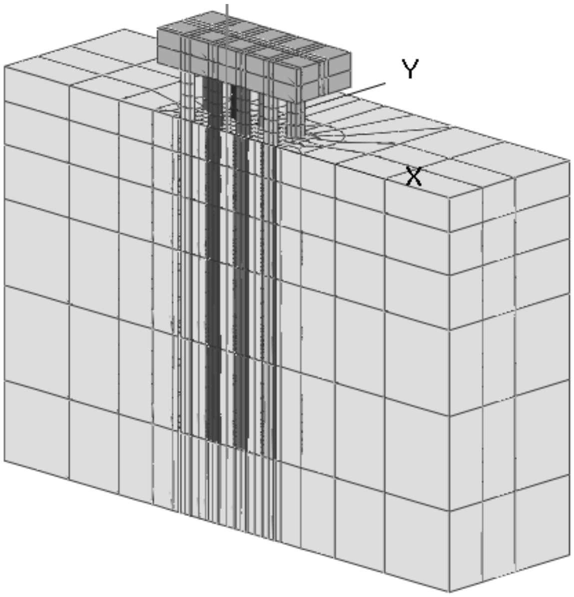

Figure 501.44: Finite element mesh for half of 4 × 3 pile group.

501.4.6 Plastic Zone

The static pushover tests were conducted using load control at the pile head with the loading applied in the X direction. The final plastic zones (represented by plastified Gauss points) for two pile groups are depicted in Figures 501.45 and 501.46. In particular, Figure 501.45 shows different views of the 3D plastic zone developed in the 3 × 3 pile group at the lateral load of 2,200 kN. Figure 501.46 shows the different views of the 3D plastic zone developed in the 4 × 3 pile group at the lateral load of 2,970 kN. Both figures clearly show a wedge shaped plastic zone at the shallow depth. Also apparent is the propagation of the plastic zone (shear yielding) along the pile–soil interface, resulting from the rocking behavior of the group.

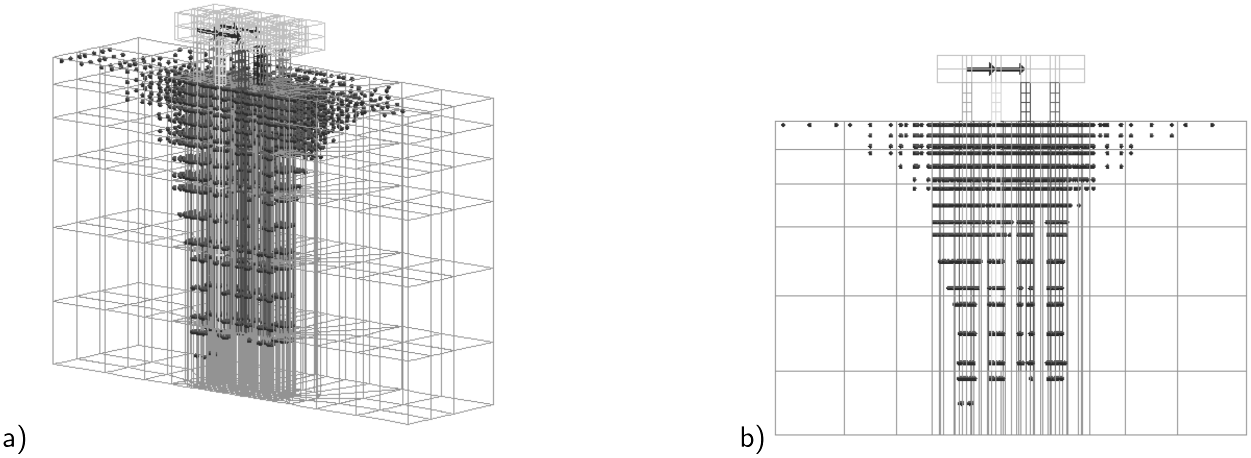

Figure 501.46: Plastic Gauss–Points for the 4×3 pile group: (a) 3D view and (b) side view.

501.4.7 Bending Moment

The maximum bending moment in the piles often controls the design of pile groups and therefore has to be analyzed accurately. In order to generate the bending moments from the stress field in piles vertical stresses at Gauss points from each pile element are integrated numerically. The moments with reference to the Y-axis (M_y) of each individual pile in the 3×3 and 4×3 pile groups are plotted in Figure 501.47 and 501.48, respectively. Figure 501.47 shows the moment diagrams of the 3×3 group at a lateral load of 2200 kN. The calculated maximum moment for each pile occurs at the pile cap, which is consistent with the fixed pile cap condition. The lead row piles, for both side and middle piles, in both 3×3 and 4×3 pile groups, carry the maximum bending moment. It is also interesting to note that in the 4×3 group, the moment diagrams for the piles in the third and fourth rows appear to be almost identical, which implies that they behave almost the same within the group.

The variations of maximum bending moments in each pile of 3×3 and 4×3 groups are illustrated in Figures 501.49 and 501.50, respectively. The maximum moments develop in the lead–row side piles, while the smallest maximum moments occur in the trail–row middle piles in both groups. It is obvious that the maximum moments developed in the middle and side piles within the lead row are quite different for both pile groups, implying the load shared by each pile in the same row is different. For example, in the 3×3 group, the maximum moment in the middle pile at the end load is 600 kN.m, while that of the side pile is 670 kN.m, the difference is about 11%. For the 4×3 pile group, the maximum moment on the lead–row side pile was about 10% greater than that for the lead–row middle pile.

It is interesting to look at the moments with reference to the X-axis (out-of-loading-plane moment, M_x). Figure 501.51 (a, b) shows M_x diagram for each pile as well as deformed piles for the 3×3 pile group. Similar plots for the 4×3 pile group are shown in Figure 501.53 (a, b). The maximum value of M_x in the 3×3 pile group reaches 50 kN.m, which is about 8% of the maximum value of M_y. For the 4×3 pile group, the maximum value of M_x is about the same amount, which is about 6% of the maximum value of M_y.

It is noted that the signs of the M_x moments in the lead and trail rows are different, indicating the bending directions are opposite to each other. This is further verified by looking at the deformed shape of the pile group shown in Figure 501.51(b) with only the displacement in Y direction shown. This kind of bending is caused by the the complex displacement field of the soil surrounding the pile group, as illustrated by the horizontal displacement vector and contour plots of displacement in X direction in Figures 501.52 and 501.54 for the 3×3 and 4×3 pile groups, respectively. The soil in front of the lead row tends to "squeeze into" the group, while the soil outside of the trail row tends to "come back" toward the pile group when the pile group is moving forward, which consequently results in the fact that

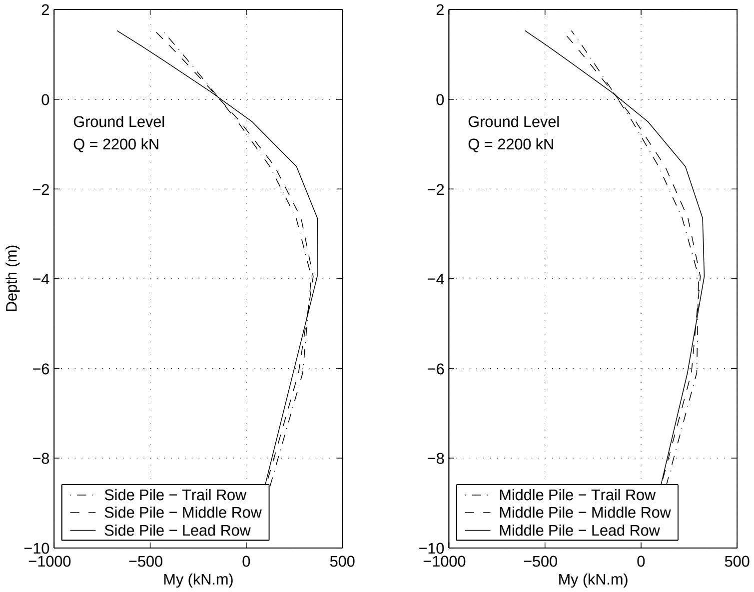

Figure 501.47: Comparison of bending moment diagram at lateral load of 2200 kN for piles in 3×3 group.

501.4.8 Load Distribution

In order to compute the load taken by each pile, the values of bending moment at element centers along with the boundary condition at the bottom of pile (zero moment) were fitted with a 5th order polynomial by least square technique. According to the theory of beam on a Winkler-type subgrade (Hartog Hartog (1952)), the moment curve was differentiated once to compute the shear force. Then, the shear forces at three sampling points between the ground surface and the pile cap were averaged to compute the load carried by each individual pile. The accuracy of the load measuring scheme has been verified by comparing the total load actually applied on the pile cap and the sum of all loads carried by each individual pile.

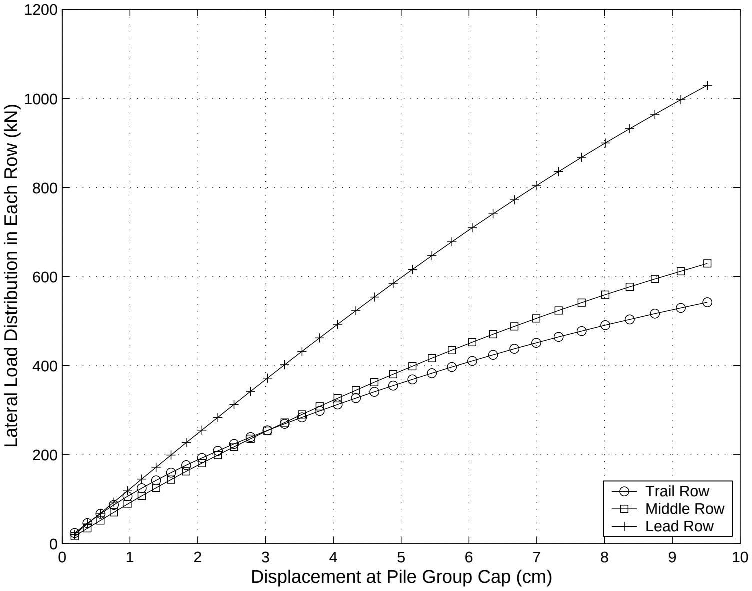

Figure 501.55: Variations of load taken by each row in the 3×3 group.

Figures 501.55 and 501.56 show the load and percentage of total load carried by each row of the 3×3 group. It is easily seen that not only the load but the percentage of total load taken by each row, especially the lead and trail rows, change steadily during loading process. It is observed in Figure 501.55 that the lead row and trail row share almost the same amount of load at small lateral displacement. However, as deflection increases, the lead row picks up the load much faster that the trail row, although the load taken by the three rows all increase.

More interestingly, the variation in the percentage of load carried by each row exhibits completely different trends. In the initial loading stage, the percentage shared by the lead row increases and that by the trail row drops quickly, while the percentage shared by the middle row almost remains constant.

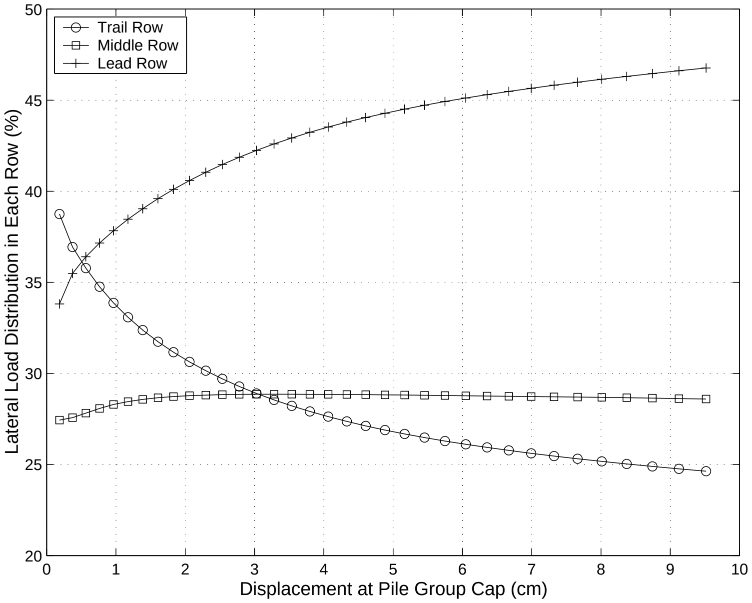

Figure 501.56: Variations of percentage of total load taken by each row in the 3×3 group.

In the final loading stage, however, the percentages carried by the lead and trail rows tend to stabilize. The lead row takes the most load, more than 46%, while the trail row takes the least, only around 25%. In addition, Figure 501.56 shows that the trail row takes a greater percentage of load than the lead row at small lateral deformation, which were attributed to some load measuring error and the fact that the denominator is relatively small.

Similar plots for the 4×3 group are shown in Figures 501.57 and 501.58. While the lead row still carries much more load that the trail row, the third row and the trail row share almost the same amount of load at large lateral displacement, which is in agreement with the fact that the same p–multiplier was recommended for the third and fourth row by McVay et al. McVay et al. (1998). It should also be observed from Figures 501.57 and 501.58 that the lead row carries more than twice the load of the trail row.

It is worthwhile noting that the distribution of load in the same row can be quite different. Figures 501.59 and 501.60 show the variations of load and the percentage of total load taken by each pile of the 3×3 group, respectively. Similar plots for the 4×3 group are shown in Figures 501.61 and 501.62. It is obvious that the piles at the sides take more load than the piles in the middle at the same row. For the 3×3 group, the side pile in lead row takes 350 kN or 16% of total load while the middle pile takes 325kN or 14.6% of total load at the end of loading.

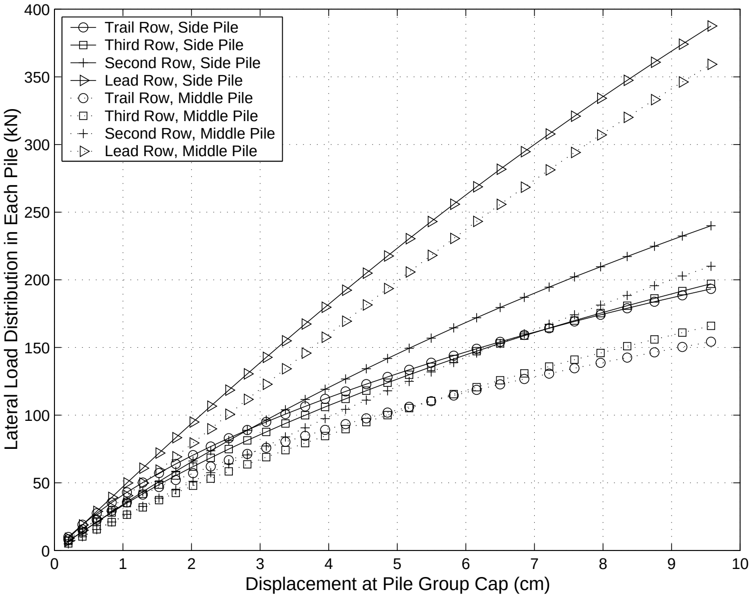

Figure 501.61: Variations of load taken by each pile in the 4 × 3 group.

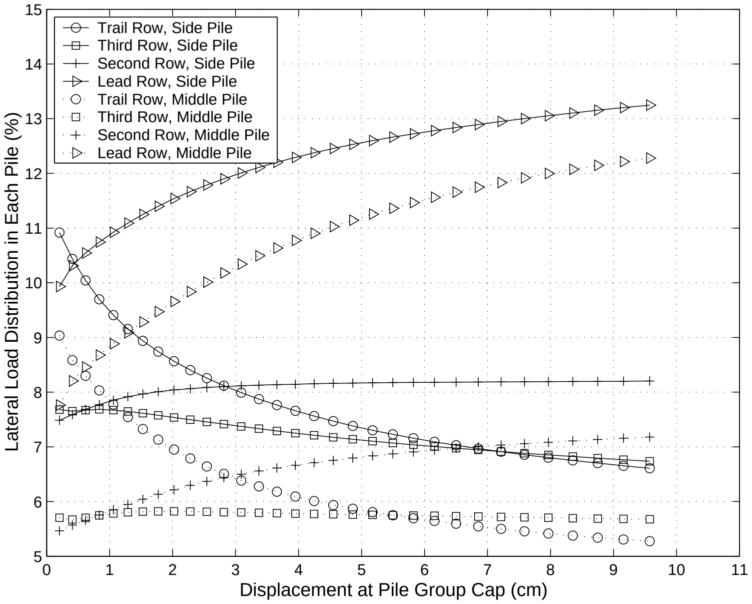

Figure 501.62: Variations of percentage of total load taken by each pile in the 4 × 3 group.

501.4.9 $p-y$ Curve

To further investigate the behavior of each pile, it is worthwhile to examine the p–y behavior of each pile in the group. The fitted moment curve and the resulting displacement from FEM were used to derive the $p-y$ curves according to beam theory. Figures 501.63, 501.64, 501.65 and 501.66 show the derived $p-y$ curves at given depths for all individual piles in the two groups. As is evident from $p-y$ plots for the two groups, the piles in the lead row exhibit much larger resistances than the piles in the middle and trail rows at large lateral displacement, due to the well–known "shadowing effect". Comparison of the $p-y$ curves at different depths in the same pile shows that the lateral resistance p increases as depth increases. For example, at deflection of 4 cm in the 3D (3 pile diameters) spaced 3×3 group, the lateral resistance on the lead-row side pile is 120 kN/m at a depth of -1.54 m, while it is only 90 kN/m at a depth of -0.58 m. This is caused by the increases in vertical stress and Young's modulus as depth increases.

More interestingly, it is seen that the p–y curves of the lead–row and trail–row piles at the depth of -1.54 m are identical at small lateral displacement ($y <$ 0.5 cm). Then the p–y curves of the piles within the trail row soften drastically as lateral displacement increases in the 3×3 group. Similarly for the 4×3 group, both the p–y curves of the lead–row and trail–row piles, and the p–y curves of the third–row and second–row piles at the depth of -2.04 m are almost identical at small lateral displacement ($y <$ 0.7 cm). As deflection increases, the p–y curves of the trail–row and third–row piles soften quickly.

Obviously, each pile in the group exhibits quite different behavior than each other. It is believed that the different behavior of each pile is directly related to the yielding of soil in front of these piles. This observation can be verified by the fact that the softening behavior of the trail-row piles starts at larger lateral displacement as the depth increases, since the plastic zone first develops at the ground surface and then extends downward as deflection increases. These observations also imply that the p–multiplier approach might not be appropriate, especially at small deflection, since it obtains the $p-y$ curves for piles within the group by simply scaling the single–pile $p-y$ curve. In addition, as a comparison with 3D (3 pile diameters) spaced pile group, also plotted in Figures 501.63 and 501.64 is the p–y curve of a lead–row side pile from a 6D spaced pile group. It is apparent that the lateral resistance increases with the increase of spacing.

501.4.10 Comparison with the Centrifuge Tests

The pile head displacements for the two pile groups from 3D FEM and centrifuge tests (McVay et al. McVay et al. (1998)) were plotted against pile head load in Figures 501.67 and 501.68. It can be seen that they agree with each other fairly well at the small lateral displacement and the FEM model is

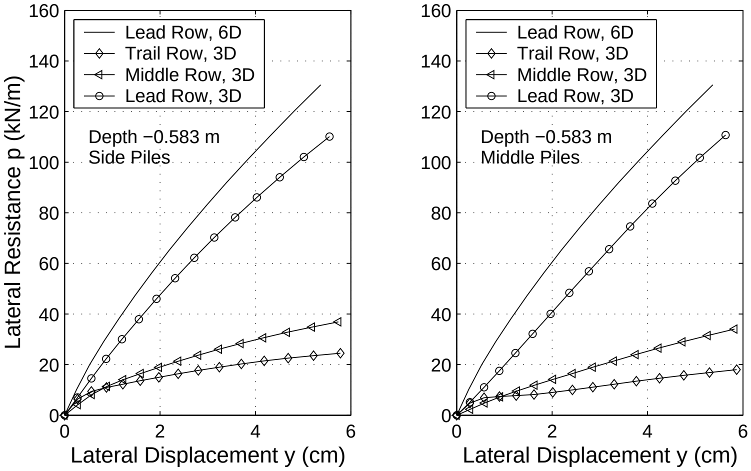

Figure 501.63: p-y curves for each individual pile in the 3×3 group at the depth -0.58m.

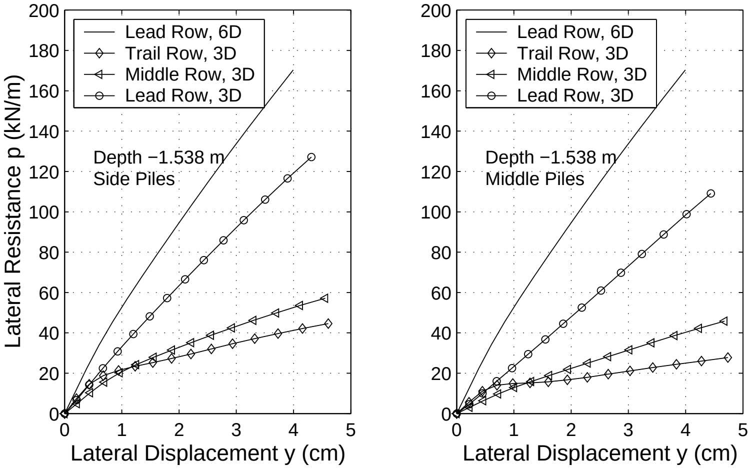

Figure 501.64: p-y curves for individual piles in the 3×3 group at the depth of -1.54m.

relatively stiffer at large lateral displacement.

The accuracy of finite element modeling can also be examined in terms of maximum bending moments. The maximum moment developed in 4×3 group was compared with that from the centrifuge study (Zhang et al. Zhang et al. (1999)) in Figure 501.69. The results from the centrifuge study are slightly larger than that from FEM, which is partially due to the relatively simple elastic-plastic soil model used. Moreover, all the above results can be further improved if the mesh is refined, since the refined pile group mesh will exhibit softer load–displacement response, and therefore develop larger bending moment in individual piles.

The percentage of total lateral load taken by each row from 3D FEM and centrifuge tests (McVay

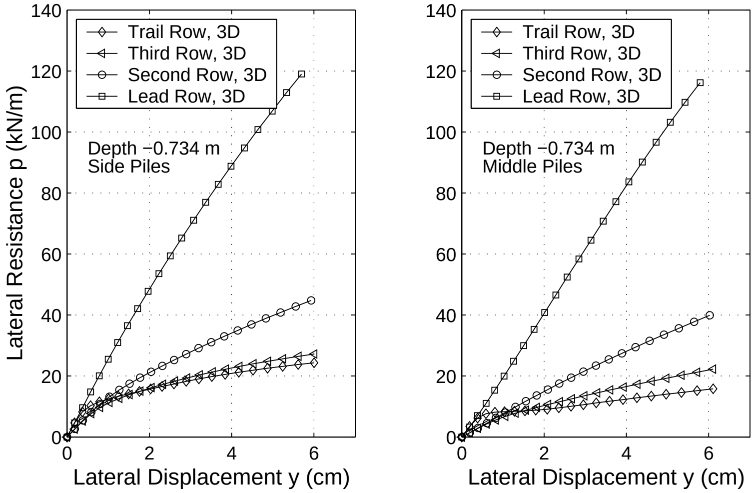

Figure 501.65: p-y curves for individual piles in the 4 × 3 group.

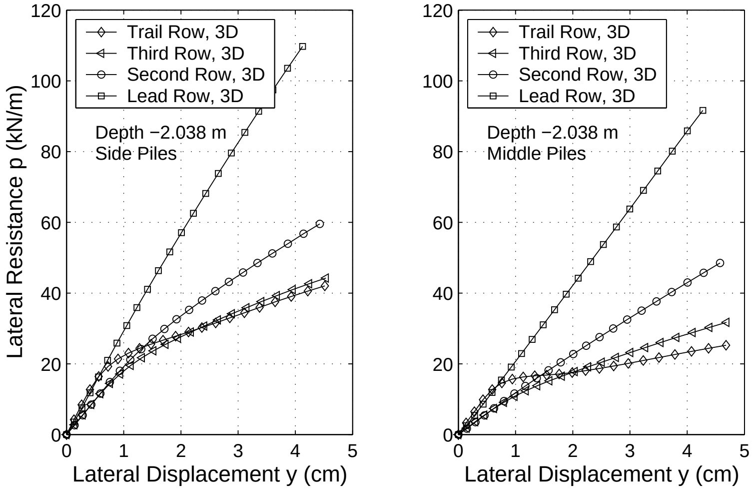

Figure 501.66: p-y curves for individual piles in the 4 × 3 group.

et al. McVay et al. (1998)) at a lateral load of 1650 kN and 2300 kN for the 3 × 3 and 4 × 3 pile groups, respectively, were compared in Figures 501.70 and 501.71. Results for both loose and medium dense sand cases are included. Figures 501.70 and 501.71 show that the density of sand does not have much effects on the load distribution. It is evident that the load distributions to all rows as obtained from FEM and centrifuge tests in all the cases for both pile groups agree very well (the differences are within 3%).

Finally, the variation of distribution of total load to each row as obtained from 3D FEM and centrifuge tests for the 4 × 3 pile group was compared in Figure 501.72. At small lateral displacement, the FEM

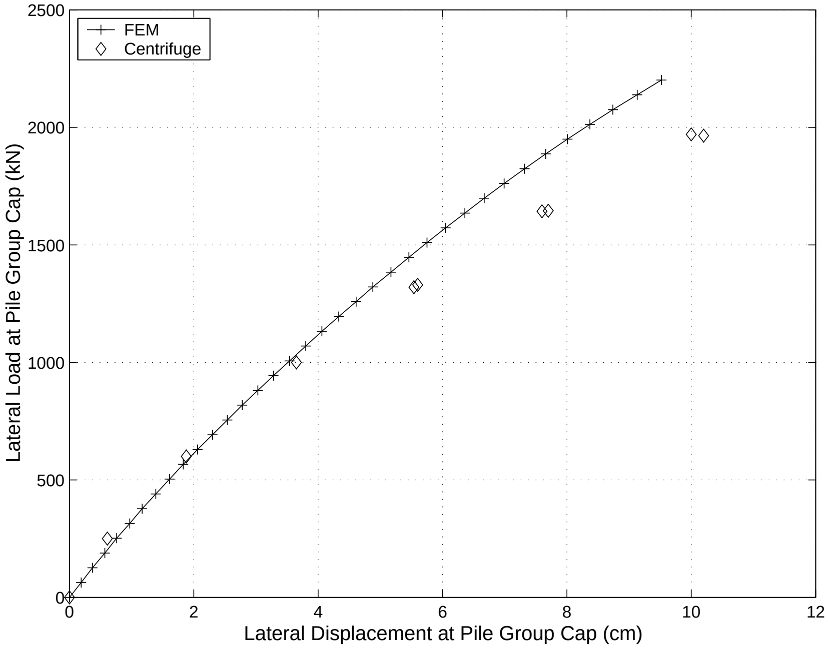

Figure 501.67: Comparison of load displacement response for the 3×3 pile group.

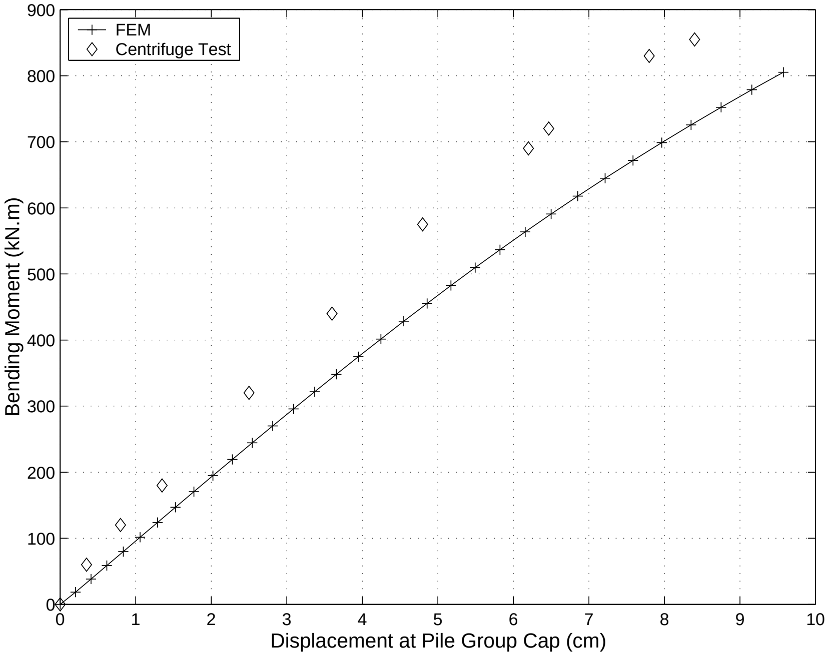

Figure 501.69: Comparison of maximum bending moment response for the 4 × 3 group.

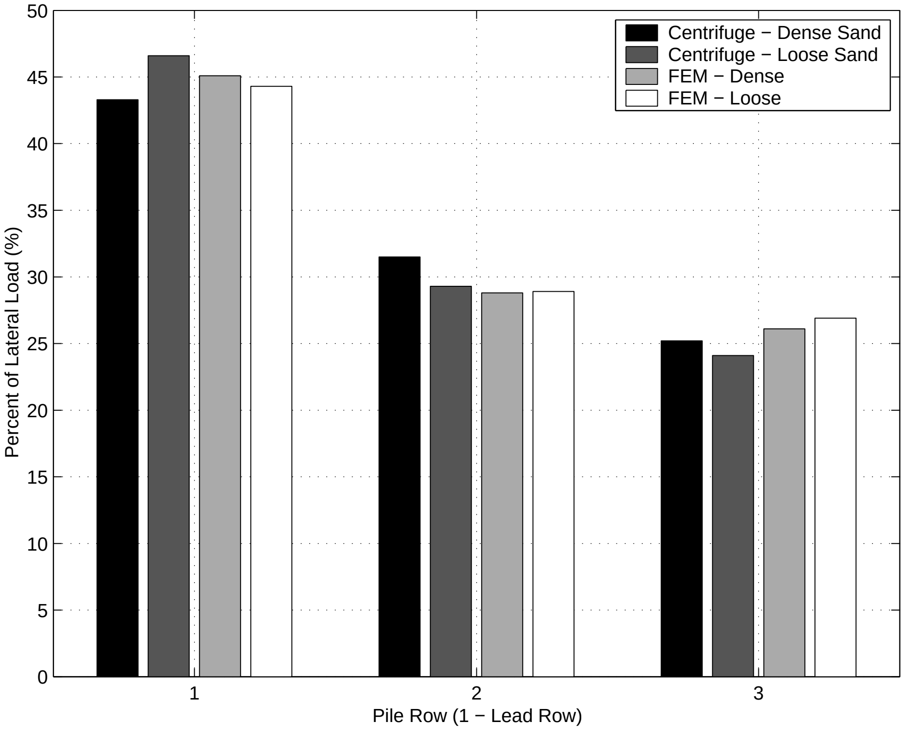

Figure 501.70: Comparison of percentage of total lateral load taken by each row in the 3 × 3 group

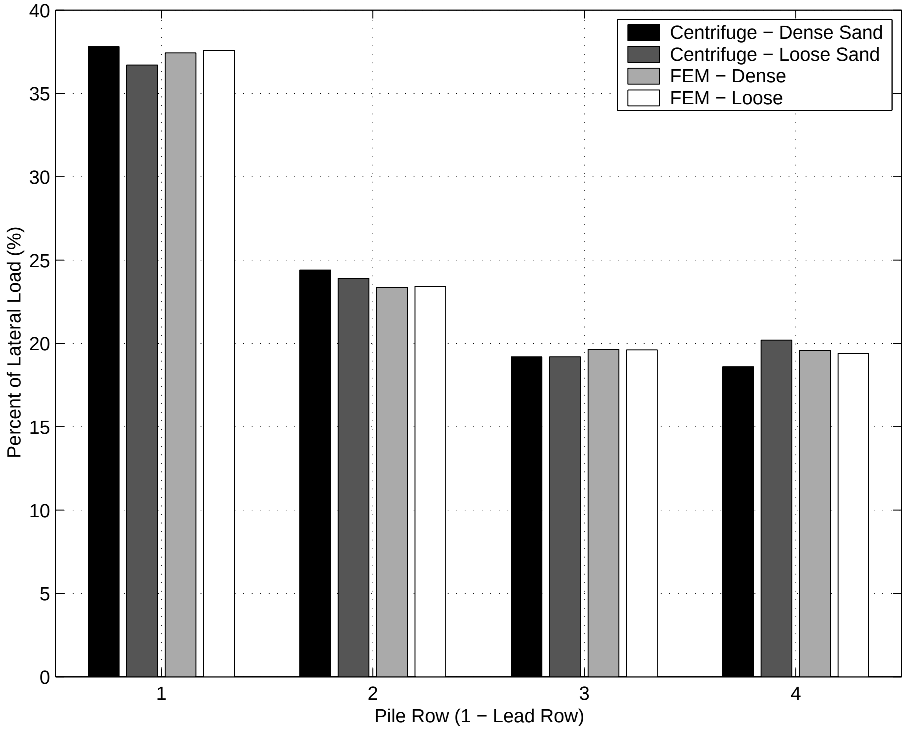

Figure 501.71: Comparison of percentage of total lateral load taken by each row in the 4×3 group

computed percentage of total load acting on the lead row was smaller than measured in the centrifuge tests and the load acting on the trail row was larger than measured in the centrifuge tests. When lateral displacement is beyond 3–4 cm, however, the FEM computed load distribution tends to stabilize and agrees well with that from centrifuge tests.

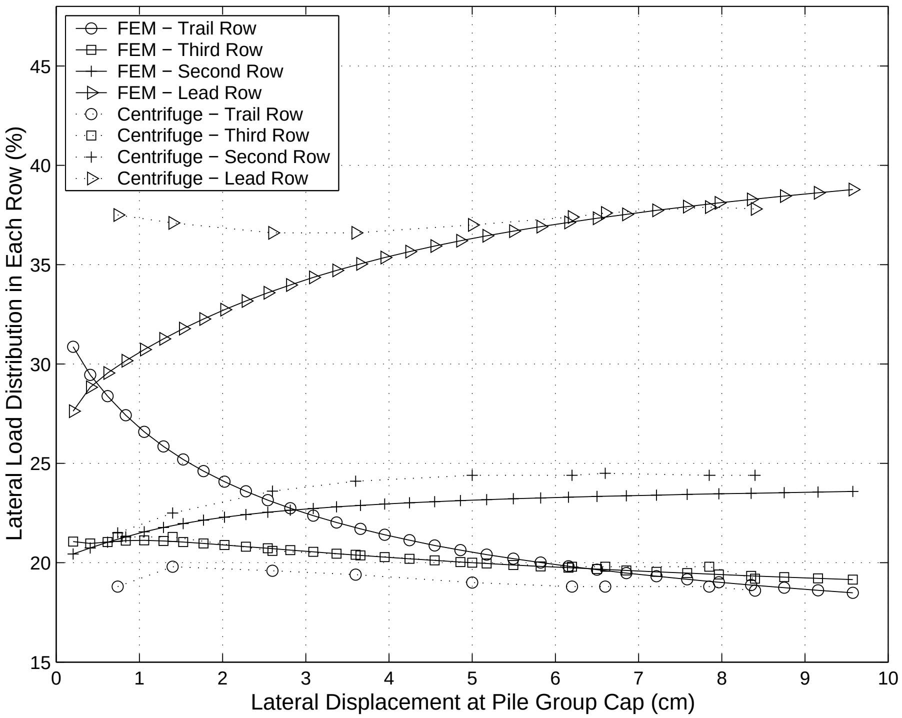

Figure 501.72: Variation of percentage of total load taken by each row in the 4 × 3 pile group.

501.4.11 Conclusions

This paper presents results from the finite element study on the interaction effects of pile groups founded in sands. Specifically the 3×3 and 4×3 pile groups were analyzed in terms of plastic zone, bending moment and load distribution among individual piles. Comparison of results from FEM and centrifuge study shows that elasto–plastic finite element analysis can predict the behavior of pile group with very good accuracy. Particularly, load distribution results from finite element analyses agree very well with that from centrifuge study.

It was shown that not only the load taken by each row in the group is different, but the load shared by individual piles and maximum bending moment developed in individual piles within the same row vary quite a bit, as observed in the centrifuge tests. Although the difference between the loads taken by lead–row middle and side piles is less than 2% of the total load, the difference between the maximum bending moments developed in the lead–row middle and side piles reaches 10–11% in the two pile groups. Interestingly, it was found that bending moment also occurs in the plane perpendicular to the loading direction.

The numerically generated p–y curves were used to study the behavior of each pile in a group. It was found that individual piles in the group exhibit quite different p–y behavior at small deflection, which means that the interaction in elastic range is different than that for loading in plastic range. Therefore, different interaction factors would be more appropriate depending on the loading range.

Since FEM can capture the critical aspects of group effects, it could now be used to systematically study various pile group configurations at much smaller cost than actual load tests, and derive interaction factors for elastic and plastic loading levels that could be used in standard design practice.

502.1 Chapter Summary and Highlights

502.2 Free Field Ground Motions

Seismic waves propagate from the source (rupturing fault) through the bedrock, surface rock and soil layers to the site of interest where a Nuclear Power Plant is located (or planned). Seismic (compressional and shear) waves do travel through various rock and soil domains, which can be represented by layers, which are sometimes horizontal, but mostly inclined. In addition to that, layers usually have variable thicknesses, creating a complex underground picture of soil/rock domains of different stiffness, mass, energy dissipating characteristics (damping). Most commonly, the stiffness of layers (horizontal and/or inclined) increases with depth. This change in stiffness results in seismic wave refraction, as shown in Figure 502.1.

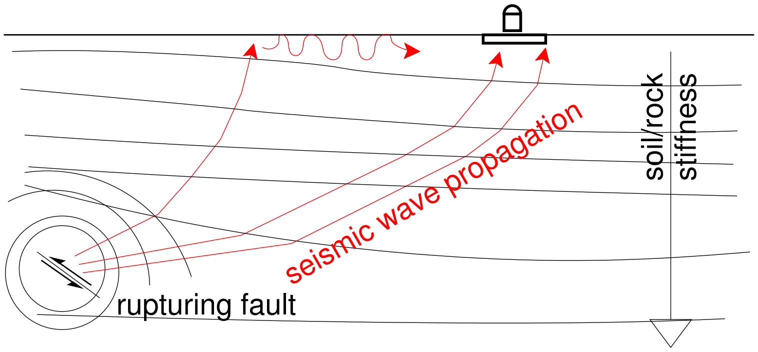

Figure 502.1: Propagation of seismic waves in nearly horizontal local geology, with stiffness of soil/rock layers increasing with depth, and refraction of waves toward the vertical direction.

When soil/rock layers are mostly horizontal, inter-layer refraction causes seismic waves (both P and S) to tend toward vertical propagation. This case is shown in Figure 502.1. However, (near) horizontal layering of geologic layers is not very frequent, unless young deposits of soil in river valleys are of concern. More often the soil/rock layers are inclined, thus creating conditions for variable directivity of seismic motions due to refraction. Figure 502.2 shows one such case where inclined soil/rock layers contribute to mainly horizontal propagation of seismic motions close to the surface, in the vicinity of an NPP.

A general conclusion can be made that seismic waves arriving at the particular site (surface) will be fully three dimensional (3C), uncorrelated, and incoming at an oblique angle. As noted by Zerva (2009), seismic motions will feature lack of correlations of motions between two monitored points at the surface. Lack of correlation is mainly due to (see more details in section 109.2.8):

- Attenuation effects,

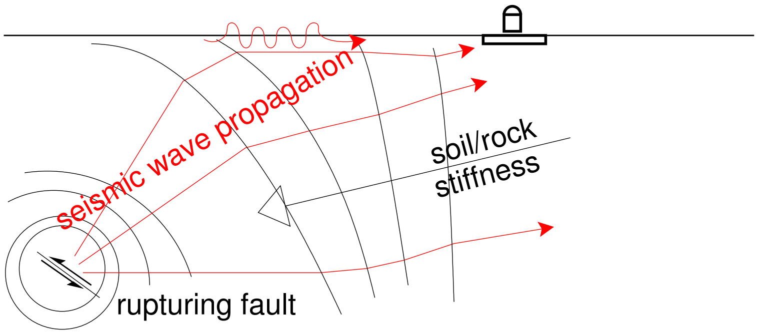

Figure 502.2: Propagation of seismic waves in inclined (close to vertical) local geology, with stiffness of soil/rock layers increasing through geologic layers, and refraction of waves away from the vertical direction.

- Wave passage effects,
- Scattering effects,
- Extended source effects

Due to all the above mentioned 3C effects, realistic modeling of seismic wave propagation can only properly be done by fully and realistically incorporating:

- Body waves (P and S),
- Surface waves (Love and Rayleigh),
- seismic waves coming at an oblique angle (which will actually be done when the above two types of waves are properly modeled),
- Full three dimensional (3C) wave field,
- Lack of correlation (incoherence) effects,
- Energy dissipation effects (damping).

502.2.1 Seismic Motions: Available Data

There exist a large number of recorded earthquake motions. Most records feature data in three perpendicular directions, East-West (E-W), North-South (N-S) and Up-Down (U-D). Number of recorded strong motions, is (much) smaller. A number of strong motion databases (publicly available) exist, mainly in the east and south of Asia, west cost of north and south America, and Europe. There are regions of world that are not well covered with recording stations. These same regions are also seismically fairly inactive. However, in some of those regions, return periods of (large) earthquakes are long, and recording of even small events would greatly help gain knowledge about tectonic activity and geology.

Ergodic Assumption. Development of models for predicting seismic motions based on empirical evidence (recorded motions) rely on Ergodic assumption. Ergodic assumption allows statistical data (earthquake recordings) obtained at one (or few) worldwide location(s), over a long period of time, to be used at other specific locations at certain times. This assumption allows for exchange of average of process parameters over statistical ensemble (many realizations, as in many recordings of earthquakes) is the same as an average of process parameters over time.

While ergodic assumptions is frequently used, there are issues that need to be addressed when it is applied to earthquake motion records. For example, earthquake records from different geological settings are used to develop GMP equations for specific geologic settings (again, different from those where recordings were made) at the location of interest.

3C (6C) versus 1C Records/Motions. Recordings of earthquakes around the world show that earthquakes are almost always featuring all three components (E-W, N-S, U-D). There are very few known recorded events where one of the components was not present or is present in much smaller magnitude. Presence of two horizontal components (E-W, N-S) of similar amplitude and appearing at about the same time is quite expectable. The four cardinal directions (North, East, South and West) which humans use to orient recorded motions have little to do with the earthquakes mechanics. The third direction, Up-Down is different. Presence of the vertical motions before main horizontal motions appear signify arrival of Primary (P) waves (hence the name). In addition, presence of vertical motions at about the same time when horizontal motions appear, signifies Rayleigh surface waves. On the other hand, lack (or very reduced amplitude) of vertical motions at about the same time when horizontal motions are present signifies that Rayleigh surface waves are not present. This is a very rare event, that the combination of source, path and local site conditions produce a plane shear (S) waves that surfaces (almost) vertically. One such example (again, very rare) is a recording LSST07 from Lotung recording array in Taiwan (Tseng et al., 1991). Figure 502.3 shows three directional recording of earthquake LSST07 that occurred on

May 20th, 1986, at the SMART-1 Array at Lotung, Taiwan.

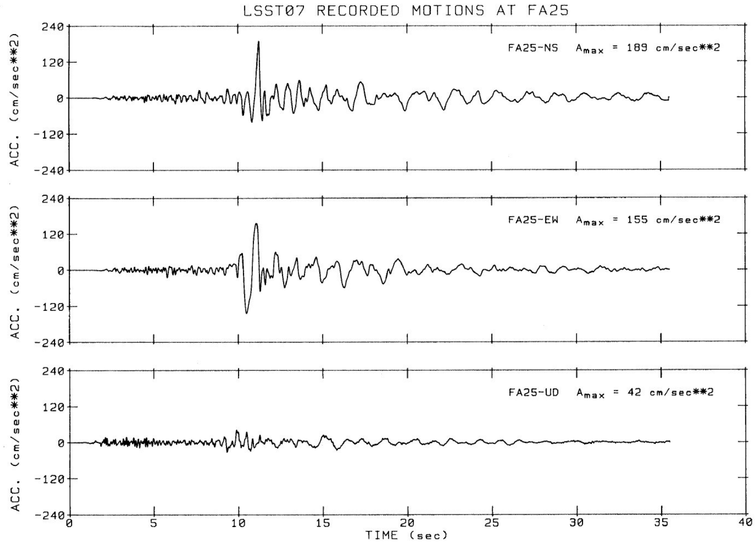

Figure 502.3: Acceleration time history LSST07 recorded at SMART-1 Array at Lotung, Taiwan, on May 20th, 1986. This recording was at location FA25. Note the (almost complete) absence of vertical motions. signifying absence of Rayleigh waves. Figure from Tseng et al. (1991).

Note almost complete lack of vertical motions at around the time of occurrence of two components of horizontal motions, signifies absence of Rayleigh surface waves. In other words, a plane shear wave front was propagating vertically and surfaced as a plane shear wave front. Other recordings, at locations FA15 and FA35 for event LSST07 reveal almost identical earthquake shear wave front surfacing at the same time (Tseng et al., 1991).

On the other hand, recording at the very same location, for a different earthquake (different source, different path) (LSST12, occurring on July 30th 1986) revels quit different wave field at the surface, as shown in Figure 502.4.

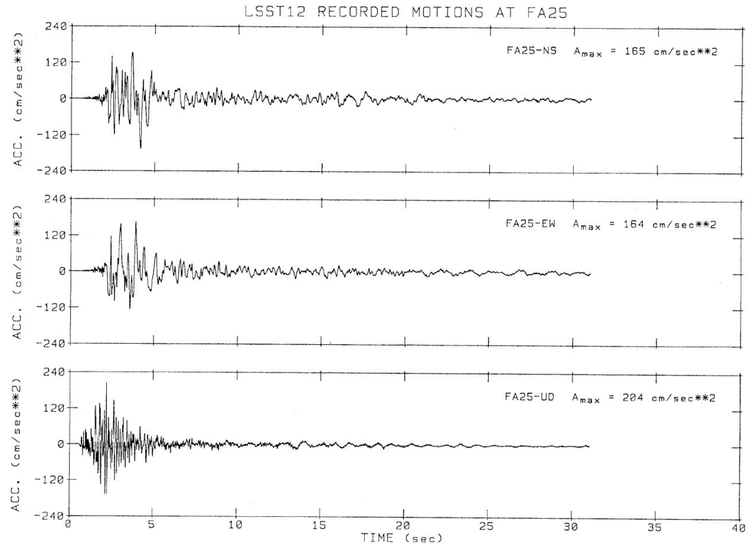

Figure 502.4: Acceleration time history LSST12 recorded at SMART-1 Array at Lotung, Taiwan, on July 30th, 1986. This recording was at location FA25. Figure from Tseng et al. (1991).

502.2.2 Multi-Directional and Seismic Input Coming in at Inclined Angle

Both multi-directional and seismic input coming at an inclined angle is possible by using (and in fact it is inherent to) the DRM, described in previous section. It is important to note that both seismic body waves (P and S) and seismic surface waves (Rayleigh and Love) are present in all situations, and do contribute to multi-directional and inclined seismic input.

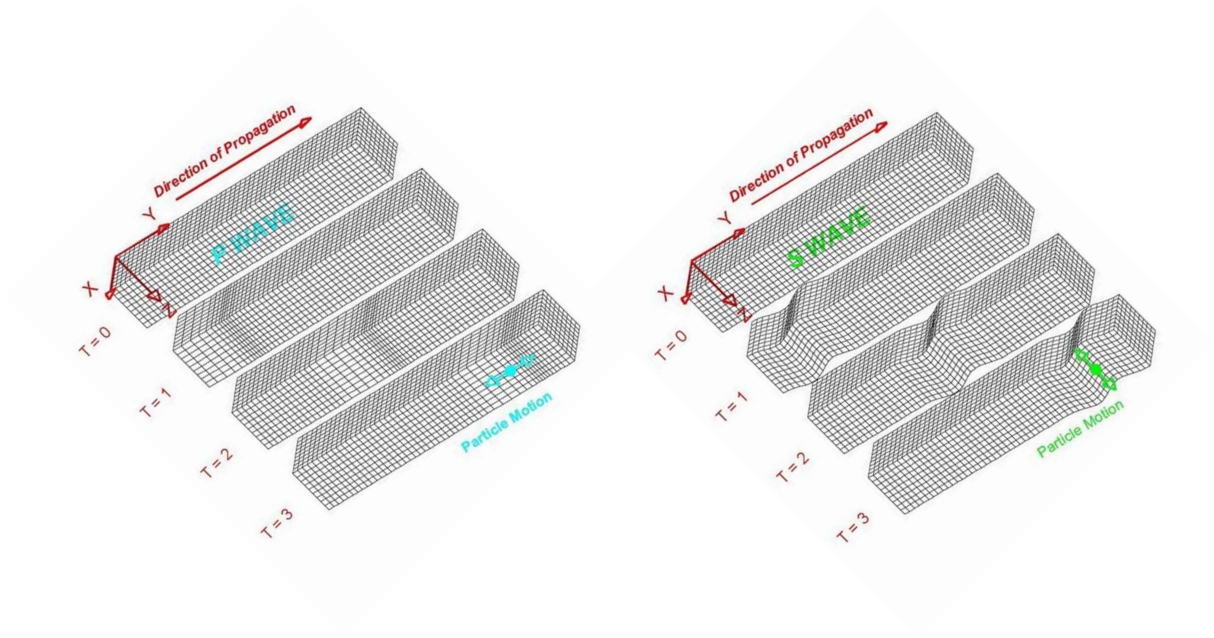

Figure 502.5: Illustration of seismic body waves, namely the P (primary) and S (secondary) waves (illustration from MTU web site).

Importance of surface waves. It has long been recognized that surface waves are responsible for majority of destruction and the seismic energy at some distance from the epicenter during earthquakes (Kramer (1996a), Semblat and Pecker (2009)). In a perfectly linear elastic half-space, Rayleigh waves become significant source of seismic motions at distance $R = h/(\sqrt{(v_p/v_R)^2 - 1})$ where h is hypocenter depth (for uniform half-space) and v_p is the compressional (primary) wave velocity, while v_R is the Rayleigh wave velocity (Kramer (1996a)). For example, if $v_R \approx 0.93 v_S = 0.93 \times 0.6 v_p = 0.56 v_p$ it follows that $R \approx 1.5h$ where v_S is the shear wave velocity (Semblat and Pecker (2009)). Of course for a case with realistic geology, the pattern of occurrence of Rayleigh waves is much more complex. However, since Rayleigh waves represent the result of interaction of body waves (P and S) with the free surface, it is safe to conclude that they are always present.

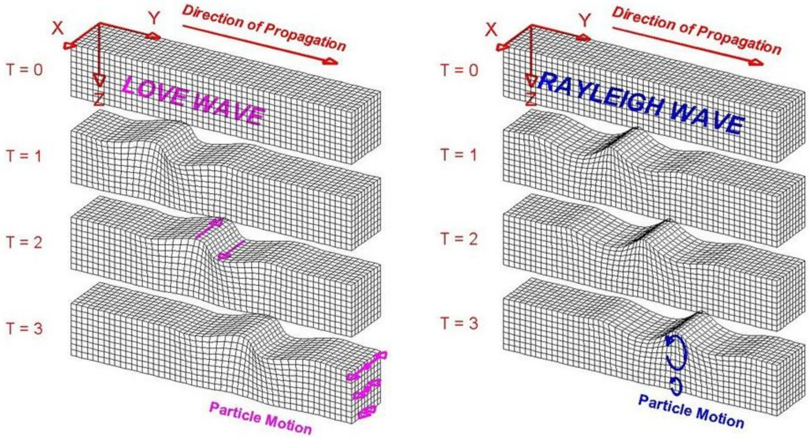

Figure 502.6: Illustration of seismic surface waves, namely the Rayleigh and Love waves (illustration from MTU web site).

502.2.3 Free Field Motion Development

For verification of and for full analysis of ESSI using the DRM, we develop seismic motions using a number of approaches

- Closed form solution,
  - One Component (1C) of three times one components (3 × 1C) using deconvolution (recommended) or convolution (not recommended, due to possible and negative interference of seismic waves at depth, see examples with the SMR)
  - Three Components (3C), plane waves, body and surface (Thomson, 1950; Haskell, 1953)
- Integration equation, Green's functions (frequency – wavenumber method, fk)
- FEM (fault slip model using Real-ESSI)
- Finite Difference models, SW4

502.2.3.1 Details of Free Field Motion Development

Closed Form Solution Analytic solutions used can impose simplified motions (not all components):

- Monochromatic harmonic wave

  - Body wave: P, SV, SH
  - Surface wave: Rayleigh, Love
  - Incident, reflected, transmitted wave components

- Ormsby wavelet
  - Body wave: P, SV, SH
  - Surface wave: Rayleigh, Love
  - Incident, reflected, transmitted wave components

- Ricker wavelet
  - Body wave: P, SV, SH
  - Surface wave: Rayleigh, Love
  - Incident, reflected, transmitted wave components

Definitions for Ormsby and Ricker wavelet are given in chapter 311.2 on page 1786.

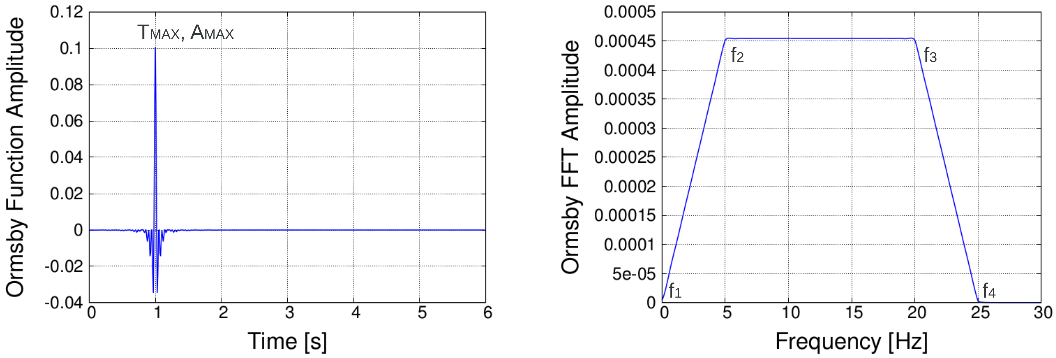

Figure 502.7: Ormsby wavelet.

Closed Form Solution – Ormsby Wavelet?

- Ormsby wavelet is a broad band signal
- Idea: "Shake" the model (or components) with a broad frequency signal to evaluate effects of different frequencies
- Verifying models, propagation of waves of different frequencies

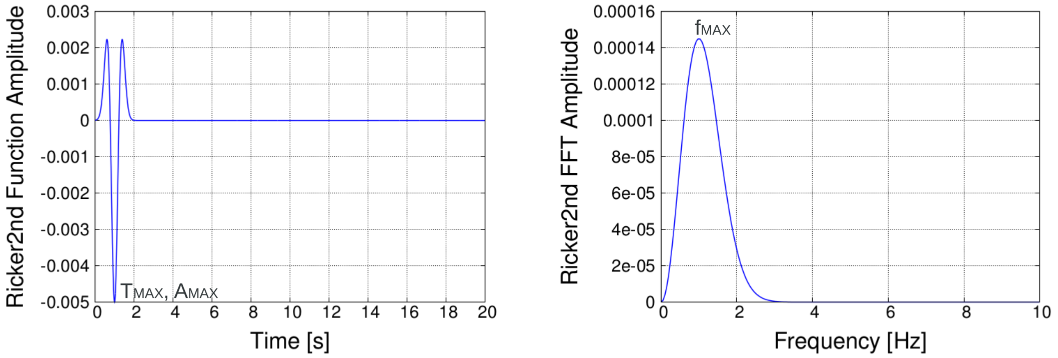

Figure 502.8: Ricker wavelet.

Closed Form Solution – Ricker Wavelet?

- Ricker wavelet is a narrow band signal
- Idea: "Shake" the model (or components) with a narrow frequency signal to evaluate its effects
- Verifying models, propagation of waves of this particular frequency

Frequency-Wavenumber Method (fk method)

- fk method developed originally by Haskell (1964), Wang and Herrmann (1980)
- Based on Green's functions
- Current fk program developed by Zhu and Rivera (2002)
- available at `http://www.eas.slu.edu/People/LZhu`
- fk program is widely used in seismology and geophysics

Fault Slip Model (FEM)

- Develop large FEM model (5km × 10km
- One element (or more) used to initiate the fault rupture
- Fault rupture can be a realistic stress drop, or Ormsby or Ricker wavelets
- Use initial set of motions before the reflections of boundaries interfere (but can use those too!)

FE Model

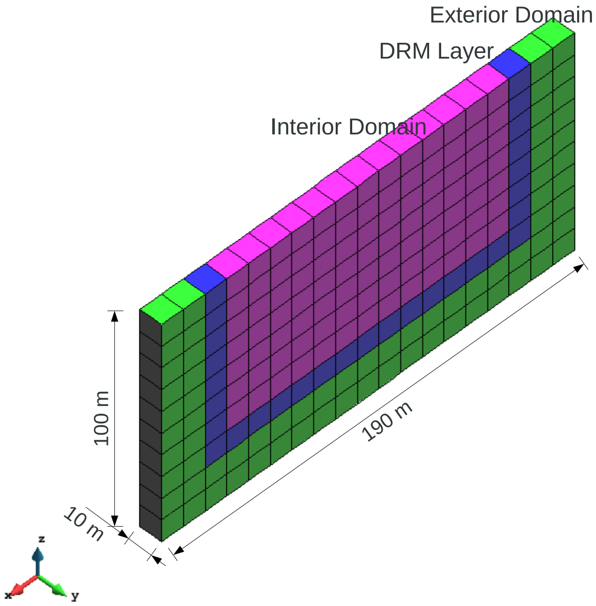

Figure 502.9: 2D model.

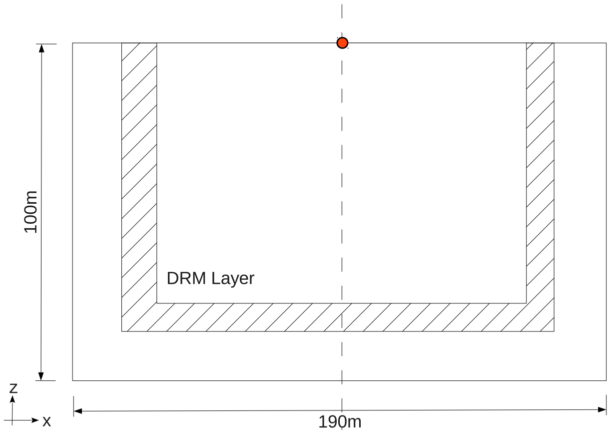

Figure 502.10: 2D model, with observation point location.

FE Model

Properties

- Model Properties
    - 190 m × 100 m × 10 m dimension
    - Vs = 100 m/s

  - Poisson's ratio = 0.3
  - Density = 2000 kg/m^3
- Input Wave Properties
  - Ricker Wavelet (dominant frequency 1 Hz)
  - Body (SH, SV), Surface (Rayleigh)
  - 0°, 30° inclination from the vertical
  - Evaluated closed-form solution (incident, reflected waves)

502.2.4 Free Field Ground Motions Development: Closed Form Solution

502.2.4.1 Three Component, 3C Motion Development

Thomson (1950), Haskell (1953)

502.2.4.2 One Component, 1C Motion Development

Note on Viscous Damping for 1C Deconvolution and Convolution. Viscous damping used in 1C analytic solution needs to be properly calibrated. For deconvolution, using analytic/closed form solution, propagation of surface record back in time to the depth the viscous damping model used is Voigt damping. Voigt viscous damping features constant damping ratio over all frequencies. For propagation of that same wave back to the surface using FEM solution, Rayleigh viscous damping is used. Rayleigh viscous damping is not constant over frequencies. Rayleigh damping parameters α and β ($C = \alpha * M + beta * K$) have to be calibrated. Calibration of Rayleigh viscous damping parameters α and β has to be done in such a way so that Rayleigh viscous damping can approximate behavior of Voigt viscous damping over main frequency range of seismic motion,

It is suggested that for deconvolution and convolution, propagation of motions upward, damping parameters first be set as zero (0.0) for both de-convolution and FEM propagation. This is done to verify the model and make sure that everything else is correct and that surface free field response can be recovered. This is important in order to make sure that surface motions can be successfully recovered from prescribed motions, through deconvolution and convolution process, that rely on different methods, and without influence of damping.

Only after model is verified with no viscous damping, one should proceed to calibrate viscous damping parameters. The common values that work well for a number of examples, using Real-ESSI, are:

```
a_0 = 10/s; // calibrated parameters
a_1 = 0.06*s; //calibrated parameters

soil_damping = 0.02; // change this value accordingly
add damping # 1 type Rayleigh with a0 = a_0*soil_damping a1 = a_1*soil_damping ↩
    stiffness_to_use = Initial_Stiffness;
```

502.2.6.1 Input Motion

The point fault (element) is located at X=3000m and Z=3000m as shown in Fig. 502.113 (that is 2000m under and 2000m to the left of surface location of interest). The source is at the angle of 45^{deg}, from the site at the middle top of the model. Pure shear is applied on the fault element in order to generate both S wave and P wave as a double couple source. In the actual analysis, equivalent nodal forces are used, and were obtained from constant surface tractions. Equivalent nodal forces for 27 nodes brick are shown in Fig. 502.38.

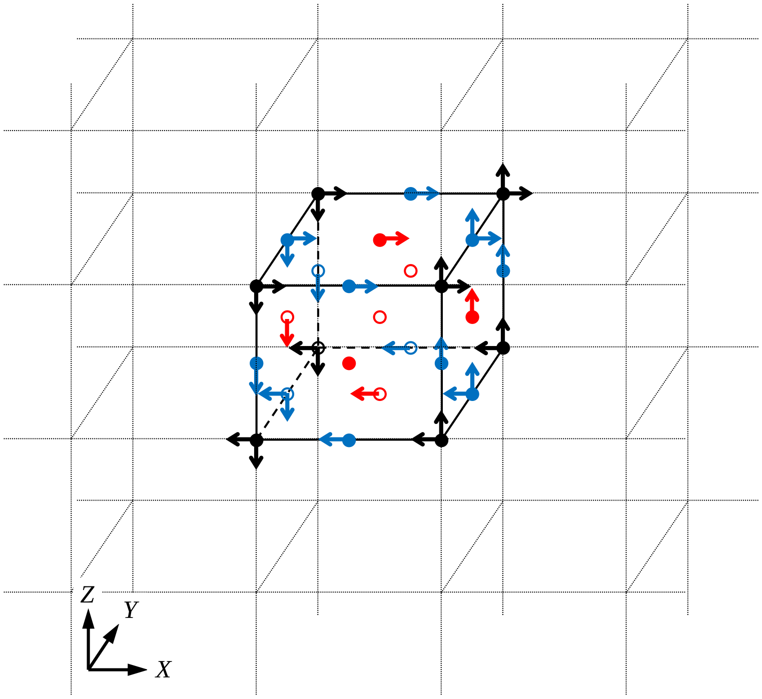

Figure 502.38: Equivalent nodal forces to apply pure shear on 27 node brick element (Loading factors: 1/36 for black, 4/36 for blue, 16/36 for red)

Ormsby wavelet is used as the time history of the shear force amplitude. The time history and its Fourier amplitude are shown in Figs. 502.39 and 502.40.

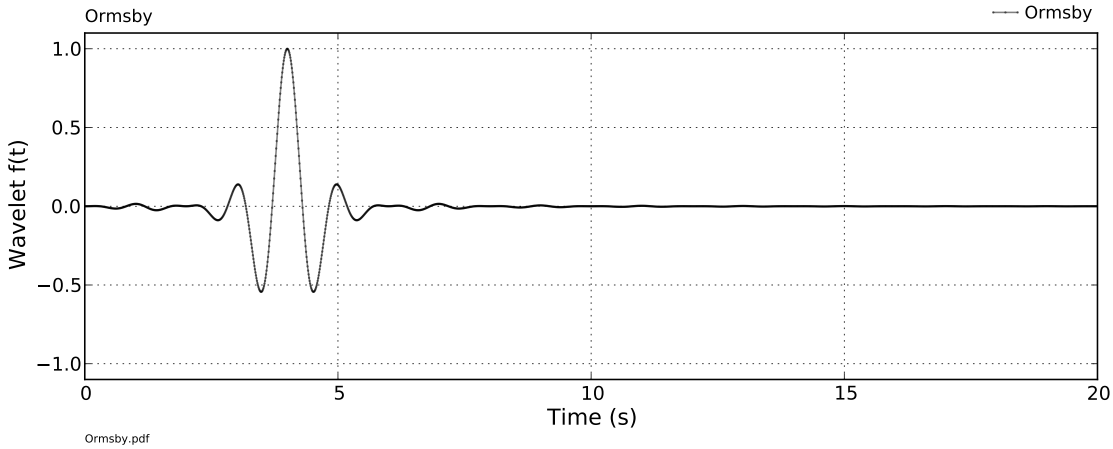

Figure 502.39: Time history of the Ormsby wavelet ($f_1 = 0$ [Hz], $f_2 = 1$ [Hz], $f_3 = 1$ [Hz], $f_4 = 1.5$ [Hz])

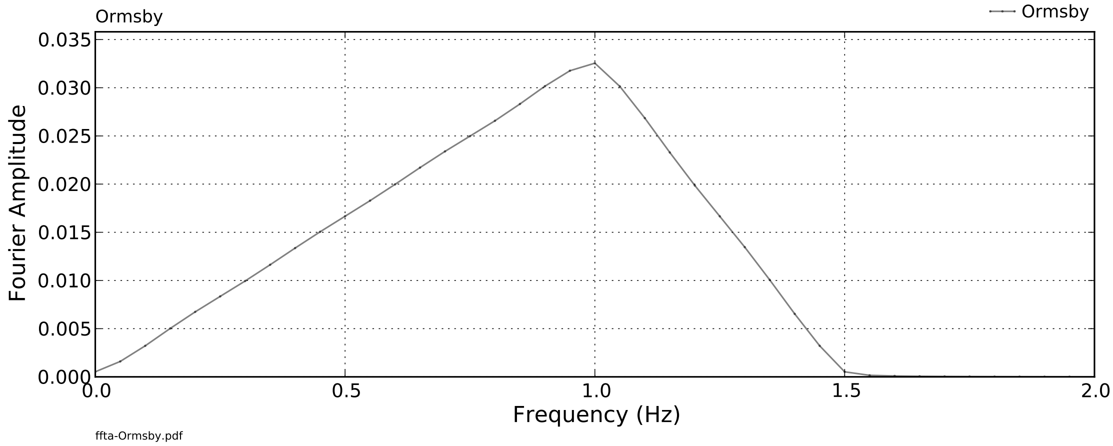

Figure 502.40: Fourier amplitude of the Ormsby wavelet ($f_1 = 0$ [Hz], $f_2 = 1$ [Hz], $f_3 = 1$ [Hz], $f_4 = 1.5$ [Hz])

502.2.6.2 Select Seismic Motions, Displacement Array Traces

The horizontal and vertical displacements, and particle motions in XZ plane at the site are observed in Fig. 502.41. Particle motions of every 1.2 sec are shown in the figure as well. Various color schemes were used for time section, to aid visualization of particle motions.

The point seismic source, as used in this case, a single finite element with cycles of pure shear, creates both primary (P, compressional) and secondary (S, shear). Initially only the P wave reaches the point of interest at the surface in the middle of the model, because of the radiation pattern and the site location (directly, at 45^{deg} away from the point source). On the other hand S wave propagates in the horizontal and vertical directions most strongly while there are traces of this wave away from these main propagation directions. With the P wave velocity $V_p = 4899 \text{m/s}$ (assumed of isotropic material) the first arrival time is 0.58 sec. Once the body waves hit the surface, surface (Rayleigh) wave is generated and propagates horizontally. Therefore, the obvious P wave particle motion can be seen only for the first 1.2 sec, while the ellipse orbit, which is the typical Rayleigh characteristic, is observed after 1.2 sec.

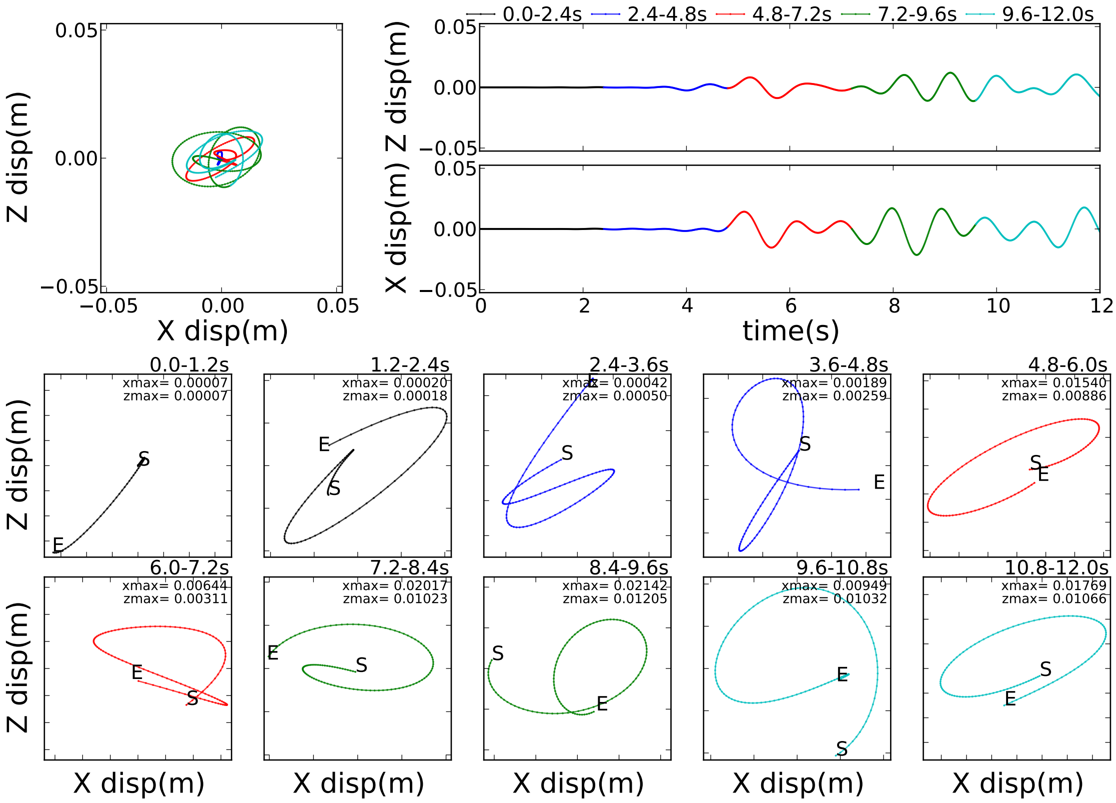

Figure 502.41: Displacement and particle motions at the site. (right top) Displacement time history, (let top) particle motion of the whole analysis, (bottom) particle motions of every 1.2 sec, S: Start, E: End

To understand wave propagation better, displacement time history and particle motions are plotted on five observatory arrays.

- Array1: diagonal array from the fault to the site (Fig. 502.42)
- Array2: horizontal array from the source (Fig. 502.65)
- Array3: vertical array upon the fault (Fig. 502.77)
- Array4: horizontal array on the surface (Fig. 502.89)
- Array5: vertical array below the site (Fig. 502.101)

Array1: Displacement time history and particle motion on Array1 are shown in Fig. 502.43 to Fig. 502.53. Fig. 502.43 and Fig. 502.53. show the resultant motions at the site and the fault respectively. It is expected that the direct wave propagating along this array is only P wave, not S wave, because of the radiation pattern and the homogeneous medium. Nodes moves in both horizontal and vertical direction together with the direct P wave. Dominant P wave can be seen at the beginning of the motion at every single nodes on this array. It is also observed that direct wave amplitude decreases when the observation point is far from the fault, a so called geometrical damping effect. Since direct S wave does not exist in this array, all non-diagonal displacements are caused by reflection wave and Rayleigh wave. Particle motion of Rayleigh wave is observed as ellipse in XZ plane. It is obviously confirmed that the effect of the Rayleigh wave is more significant as the observation point is near the surface. In order to make it easy to distinguish P and S wave propagation along the diagonal array, these resultant waves are converted into radial/transverse coordinate from vertical/horizontal coordinate (RT conversion). Converted waves of Array1 are shown in Fig. 502.54 to Fig. 502.64. It is now easy to observe P wave motion in radial direction and no S wave in Transverse direction.

Array2 and Array3: Results of Array2 are shown in Fig. 502.66 to Fig. 502.76 and results of Array3 are shown in Fig. 502.78 to Fig. 502.88. Since S wave is dominant in vertical and horizontal direction from the source while P wave is dominant in diagonal direction, only horizontal motion and vertical motion are observed well for the first several seconds until reflected wave and surface wave reach on these two arrays. Geometry damping effect is observed as well as P wave propagation in Array1. Rayleigh wave effects are propagating in depth. We can still see Rayleigh wave motion on these arrays, even though the effect of surface wave is less significant than Array1.

Array 4: Results of Array4 are shown in Fig. 502.90 to Fig. 502.100. Array4 is located on the surface and affected by surface wave effects the most.

Array 5: Results of Array5 are shown in Fig. 502.102 to Fig. 502.112. It is sometimes assumed (by others) that wave propagate in vertical direction near the surface in case of horizontally layered ground model. In this case, the incident angle is 45 degree and the vertical wave propagation assumption is obviously not valid.

502.2.6.3 Animations of Fault Slip Motions

All the motions are developed from a point source at a depth of –2km while the distance from the center of the model (where the observation point, or object of interest is) is 1km ($27^{\rm deg}$ off vertical), 2km ($45^{\rm deg}$ off vertical) and 3km ($56^{\rm deg}$ off vertical). There are three surface soil cases, homogeneous, single layer of soft soil and two layers of soft soil. Stress drop (input, pure shear at the one element) is defined by an Ormsby wavelet.

- Homogeneous soil/rock, $56^{\rm deg}$ off vertical) (link to a movie, 39MB)
- Homogeneous soil/rock, $45^{\rm deg}$ off vertical) (link to a movie, 32MB)
- Homogeneous soil/rock, $27^{\rm deg}$ off vertical) (link to a movie, 37MB)
- Single layer soft soil with homogeneous soil/rock, $56^{\rm deg}$ off vertical) (link to a movie, 30MB)
- Single layer soft soil with homogeneous soil/rock, $45^{\rm deg}$ off vertical) (link to a movie, 34MB)
- Single layer soft soil with homogeneous soil/rock, $27^{\rm deg}$ off vertical) (link to a movie, 32MB)
- Two layers of soft soil with homogeneous soil/rock, $56^{\rm deg}$ off vertical) (link to a movie, 30MB)
- Two layers of soft soil with homogeneous soil/rock, $45^{\rm deg}$ off vertical) (link to a movie, 31MB)
- Two layers of soft soil homogeneous soil/rock, $27^{\rm deg}$ off vertical) (link to a movie, 32MB)

Details motions at the top of the model:

- Homogeneous soil/rock, $45^{\rm deg}$ off vertical) motions at the top 2km × 2km (link to a movie, 30MB)
- Homogeneous soil/rock, $45^{\rm deg}$ off vertical) motions at the very top, location of observation point and/or structure (link to a movie, 134MB)

502.2.6.4 Point Fault Slip Motions, Arrays and Particle Motions

The FEM model used is shown in Fig. 502.113. The brief description of FEM model is as follows:

- Model size: $10000\text{m} \times 20\text{m} \times 5000\text{m}$
- Mesh size: 10m
- Element size: 20m (27 node brick element is used)
- Elastic parameters:
  - Poisson ratio $\nu = 0.4$
  - Shear wave velocity $V_s = 2000\text{m/s}$
- Fixed boundary at $X = 0\text{m}$, $X = 10000\text{m}$, and $Z = 0\text{m}$
- Free boundary at $Z = 5000\text{m}$
- Plane strain condition in y-direction (all nodes on $y = 0\text{m}$, $y = 20\text{m}$ are fully fixed).

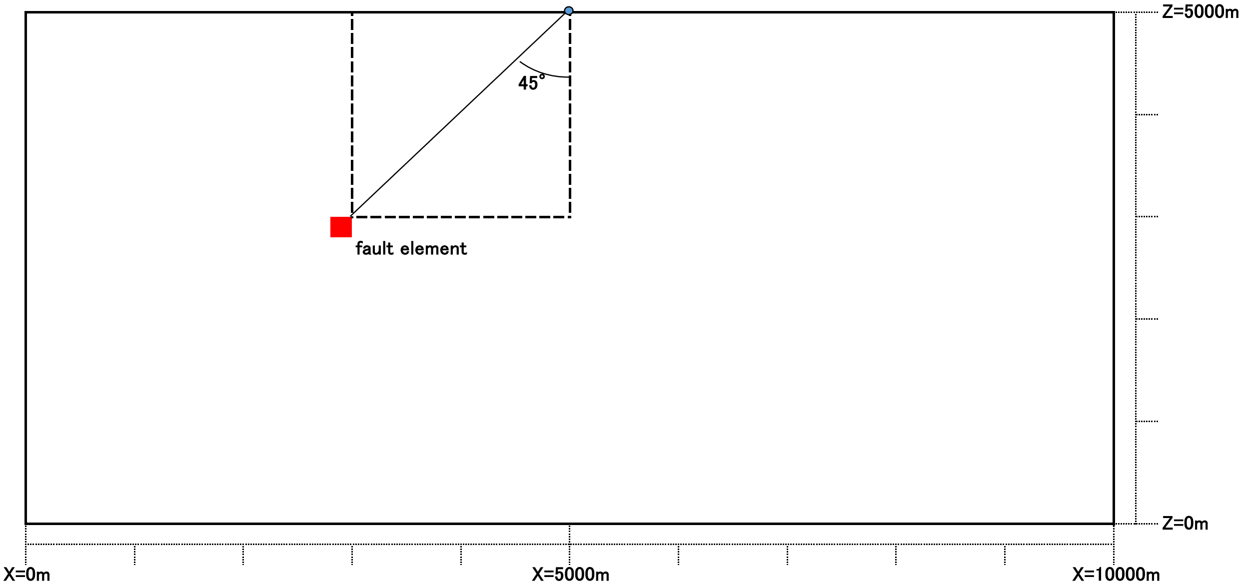

Figure 502.113: FEM model (red square:fault element, blue circle: observation site)

502.3.2 Using External Finite-Diference Seismic Code for DRM Motions

Introduction This section explores the numerical conditions under which a high-performance fourth-order finite difference code for seismic modeling, henceforth the 'seismic' code, can be coupled successfully with a general purpose parallel non-linear finite element simulator, the FEM simulator, through the use of the domain reduction method (DRM). The approach taken consists in modeling a simple homogeneous half-space subjected to a single double-couple point-source to generate motions. DRM will be used to input these motions into the FEM simulator for an equivalent model of the domain, and the response compared at a control point on the surface. The seismic code used is SW4 (Sjögreen and Petersson, 2011) developed at Lawrence Livermore National labs, while the FEM simulator will be the Real-ESSI Simulator developed at the University of California Davis. Both are high-performance parallel programs highly regarded in their respective domains of application.

As originally proposed by Bielak et al. (2003a), the DRM input motions can be generated using a different method to compute the seismic wave field than the FEM code used to model site and structure. The rationale being that both methods will be approximating the same equations of elastodynamics and should both converge to the same solution as grid spacing tends to get smaller. What was implicit in that seminal work, but not explored or tested, is the effect of using different methods with possibly different orders of convergence, and how this affects convergence of the overall method.

The advantage of using different codes is that it is possible to choose a 'seismic modeling' code which is better suited and optimized for simulating earthquakes and then use the DRM to input the resulting motions into a code which is more suitable for modeling of non-linear soil and structural behavior in the chosen site. For example, SW4 has very convenient features for the input of double couple sources and also for extended sources, a task which would be much harder to achieve in a civil-engineering oriented code such as Real-ESSI Simulator. It is important to use the proper tools for modeling task, both for efficiency and credibility of the results used for design.

When solving the elastodynamic equations, it is expected that different solution schemes will yield different solutions for the same problem. Even if the seismic code's finite difference grid points coincide spatially with the FE nodes, the different mathematical transformations involved in advancing the solution and the different orders of approximation will no-doubt lead to some degree of disagreement on the nodal values. When using the seismic code as DRM input into the FEM code it is expected that this disagreement will manifest itself in two ways: first, that the solution at a common control point within the DRM domain and on the seismic domain will differ and, second, consequently there will be a portion of the wave-field that will not be absorbed at the DRM boundary leading to outgoing motions which need to be damped out. Again, it is expected that both the difference in motions and the outgoing

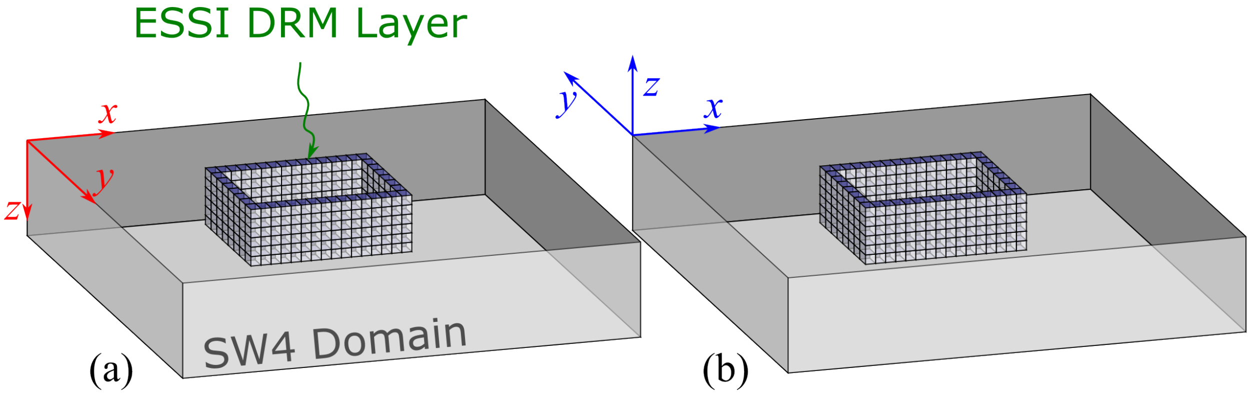

Figure 502.114: Model layout and coordinate system origin and orientation for (a) SW4 (b) Real-ESSI Simulator

wave-field will diminish with decreasing spatial and temporal discretization.

Format for Node Coordinates, for Direct Extraction of Motions from SW4 This is based on Rodgers (2017).

A list of DRM nodes need to be supplied to SW4 modeler.

This list should be a simple 4-column asci file with node-name (6-10 characters), x, y, z location relative to origin (top, center) of ESSI domain.

Example Figure 502.115 illustrates the general layout of the DRM boundary elements with respect to the SW4 model for the domain used in this study. The seismic model consists on a single material elastic box of size $8\,\mathrm{km} \times 4\,\mathrm{km} \times 4\,\mathrm{km}$, various values of the grid size are chosen ($h = 10\,\mathrm{m}$ or $20\,\mathrm{m}$), a point double-couple source is placed at $(2\,\mathrm{km},\ 2\,\mathrm{km}, 2\,\mathrm{km})$ such that it represents a reverse fault with a 45° dip. The center of both models coincide. SW4 uses a right-handed coordinate system with z-axis positive downwards, while the FE meshes developed[1] for Real-ESSI simulator use a right-handed system with z-axis upwards. Both models x-axis' and origins are made to coincide. Thus, the transformation from SW4 coordinates to Real-ESSI Simulator coordinates is:

$$x_{\mathrm{SW4}} = x_{\mathrm{ESSI}} \qquad y_{\mathrm{SW4}} = -y_{\mathrm{ESSI}} \qquad z_{\mathrm{SW4}} = -z_{\mathrm{ESSI}} \tag{502.1}$$

Figure 502.115 shows the construction of the DRM model used in this study. It consists of an internal domain (within the DRM boundary) of dimensions $200\,\mathrm{m} \times 200\,\mathrm{m} \times 40\,\mathrm{m}$ with discretization $\mathrm{d}x = \mathrm{d}y = \mathrm{d}z = h = 5\,\mathrm{m},\ 10\,\mathrm{m}$ or $20\,\mathrm{m}$. The elastic properties throughout both SW4 and Real-ESSI

---

[1] This is for convenience when using the meshing program gmsh to develop the mesh.

Table 502.1: Mesh information for DRM models used with Real-ESSI simulator.

h, m	Number of Nodes	Number of elements
20.0	28,577	3,200
10.0	78,141	9,000
5.0	295,829	35,000

Simulator domains are such that the speed of P-waves is $V_p = 2000\,\mathrm{m/s}$, the speed of S-waves is $V_s = 1000\,\mathrm{m/s}$ and the density is $\rho = 2000\,\mathrm{kg/m^3}$.

For the absorbent layer 4, 8 and 16 elements are used with Rayleigh damping ratios of $\xi = 0, 0.05, 0.1$. The Real-ESSI meshes are made up of second-order 27-node bricks with 27 Gauss-integration points. Table 502.1 summarizes the number of elements and nodes for the Real-ESSI Simulator meshes used.

The Real-ESSI meshes are generated using gmsh (Geuzaine and Remacle, 2009) and results are visualized using the custom visualizer plugin for ParaView (`https://www.paraview.org/`) (Ayachit, 2015).

Figure 502.116 shows the visualization of the displaced Real-ESSI mesh for $h = 20\,\mathrm{m}$ (left) and $h = 10\,\mathrm{m}$ (right) at time point $t = 3.40\,\mathrm{s}$. No damping was used at the absorbing boundary at this point. This instant in time corresponds to the end of the arrival of the P-wave and, it can be observed, that DRM is working to eliminate the outgoing motions as the absorbing boundary has little or no displacement. Furthermore, the $h = 10\,\mathrm{m}$ mesh seems to be doing a better job at absorbing the out-going motions. Figure 502.117 shows the same situation for time point $t = 3.93\,\mathrm{s}$. At this time the S-wave is coming into the domain. It can be seen that the $h = 20\,\mathrm{m}$ domain is producing large out-going motions while the finer domain is still handling the out-going motions.

Figures 502.116 shows the trace plots for the control point at the center of the domain for both SW4 results as well as the results with DRM when using a DRM domain with discretization $h = 20\,\mathrm{m}$ and $h = 10\,\mathrm{m}$ respectively.

P-waves are faster than S-waves, in this case, by a factor of 2. Since wave resolvability for a given time-step size is proportional to wave speed, P-waves will be better resolved than S-waves. This manifests itself in the fact that initially, for P-wave arrivals, DRM works at capturing out-going motions and later, for S-waves, some out-going motions escape the boundary. These out-going motions are not absorbed by damping since damping is not applied at this point, therefore, reflecting off the model boundaries back into the domain. This why there is oscillatory motion, corresponding to energy trapped in the system, observed after $t = 4\,\mathrm{s}$. Note that the oscillatory motion is mainly seen in the x-component and not the others.

To mitigate these trapped waves, the absorbent boundary is assigned Rayleigh damping of varying intensities. Rayleigh damping can be applied in many ways. From (Tafazzoli, 2012) several lessons can be drawn regarding how to design the absorbent boundary for maximum efficiency. The following is a summary of these lessons:

- Increasing in-absorbent-boundary damping has the general effect of reducing the amplitude of waves reflected at the domain boundary back into the internal domain.
- Sharp damping contrasts produce additional reflected waves at the DRM/absorbing boundary interface.
- Gradually increasing the damping ratio with increasing distance to the DRM boundary alleviates the reflection issue while retaining a similar damping efficiency.
- Increasing the thickness in elements of the absorbent boundary also increases the damping efficiency.
- When selecting two frequencies to provide for specification of Rayleigh damping, the best frequency is not related to the 'natural' frequency of the soil stratum as is commonly assumed in practice and some research. The best frequency is related, instead, to the frequency of the out-going waves.

In this study a uniform value for the damping ratio assigned to the Rayleigh damping coefficients is used. Figure 502.119 shows the effect that this additional damping has on DRM models with different sizes. The beneficial effect of this damping in capturing the energy leaking out from the DRM boundary is apparent.

Perfect matching of the motions obtained with SW4 and Real-ESSI simulation with DRM modeling was not achieved. A key reason for this is that the SW4 simulations were done at $h = 20\,\mathrm{m}$ while varying the mesh size for the Real-ESSI simulations. This means that SW4 motions had to be interpolated between grid spaces when the grids did not match. SW4 provides only 'nearest' neighbor interpolation for requested output stations, so an improvement on this is needed if better matching is expected. Alternatively, it is possible to achieve better agreement by decreasing the discretization on both domains.

From these experiments it is possible to extract the following design considerations when seeking to couple DRM-based finite element simulations with other forms of seismic modeling:

- Size of the DRM domain is irrelevant for the 'free-field' problem.
- Relative order of accuracy of the Finite-element mesh and the code that produces seismic input is important when designing mesh sizes for both the finite-element and the seismic simulation.

- Matching motions perfectly might result in expensive computations, beyond what is needed due to physical and numerical constraints for the propagation problem alone.
- Out-going motions due to mismatch need to be absorbed outside the DRM domain by some method.

Ultimately, the purpose of using the DRM is as the enabling technology allowing the rational modeling of perturbations of the free-field model in order to reduce the cost of jointly modeling complex site and structure response along with the seismic wave propagation problems. In such a case, out-going motions will be unavoidable and have to be dealt with efficiently. In any such study it will be very important to demonstrate that the DRM motions and forces developed agree with the free-field model as a basic way of showing the adequacy of the numerical implementations involved in the modeling effort.

Practical considerations Using SW4 to generate motions for DRM in Real-ESSI requires the following steps:

1. Generate a large-scale geologic model in SW4.
2. Generate a FEM mesh for Real-ESSI, generate the following lists:
    - Coordinates and numbers of nodes in DRM layer.
    - A flag indicating whether a particular node is internal or external.
    - List of elements in DRM layer.
3. Within the SW4 input file write recorder lines (USGS format) for all DRM nodes. Example:

```
 rec x=4037.5 y=2050.0 z=40.0 file=node000734b sacformat=0 usgsformat=1
```

4. Run SW4.
5. Collect the results for each recorded node in one DRM HDF5 input file.

Some notes to complement the above steps.

- Nodes in SW4 input file must have coordinates in SW4 coordinates. Remember that, in SW4, down is positive. The best is to develop FEM model centered around origin of a coordinate system, so that determining the position in SW4 coordinates is a simple translation and flipping of the signs for both Z and Y coordinates.

- Use the SW4 output file name in a meaninful way to determine which node number it belongs to. In the example `nodeXXXY` where `XXX` has the node number and `Y` is either `e` or `b` depending if it is an internal (boundary) node or external.
- Remember to reverse the sign of Y and Z results when writing the DRM HDF5 input file from the SW4 results.
- It is recommended to use chunking and compression in HDF5 dataset to speed up loading times and optimize storage usage.

Template code for generating HDF5 input suitable for DRM analysis in Real-ESSI.

502.3.3 Seismic Wave Propagation Modeling and Simulation: Numerical Accuracy and Stability

The accuracy of a numerical simulation of dynamic SFSI is controlled by two main parameters: a) the spacing of the nodes of the finite element model (Δh) and b) the length of the time step Δt. Assuming that the numerical method converges toward the exact solution as Δt and Δh go toward zero the desired accuracy of the solution can be obtained as long as sufficient computational resources are available.

502.3.3.1 Grid Spacing Δh

In order to represent a traveling wave of a given frequency accurately about 10 nodes per wavelength λ are required for finite element with linear displacement interpolations between nodes[2] (Bathe and Wilson, 1976; Hughes, 1987; Argyris and Mlejnek, 1991). Fewer than 10 nodes can lead to numerical damping as the discretization misses certain peaks of the wave. In order to determine the appropriate maximum grid spacing the highest relevant frequency f_{max} that is present in the model needs to be found by performing a Fourier analysis of the input motion. Typically, for seismic analysis f_{max} is about 10 Hz. By choosing the wavelength $\lambda_{min} = v/f_{max}$, where v is the wave velocity, to be represented by 10 nodes the smallest wavelength that can still be captured partially is $\lambda = 2\Delta h$, corresponding to a frequency of $5f_{max}$. This is true for finite elements with linear interpolation of displacements.

In general, for finite elements with different interpolation of displacements the following conclusion can be made about the number of elements used for proper wave propagation:

- Linear interpolation finite elements (1D 2-node truss, 2D 4-node quad, 3D 8-node brick): $h^{LE} \leq v/(10 f_{max})$
- Quadratic interpolation finite elements (1D 3-node truss, 2D 9-node quad, 3D 27-node brick): $h^{QE} \leq v/(2 f_{max})$
- Structural elements (beams, shells) have at least quadratic interpolation functions (Euler-Bernoulli beam uses cubic Hermite polynomials) and since material is very stiff, and wave propagation speed is very high, these elements usually satisfy wave propagation criteria a priori.

For example, element size for propagating $f_{max} = 20$ Hz, for for linear interpolation element $\Delta h^{LE} \leq v/200$ Hz while for quadratic interpolation element $\Delta h^{QE} \leq v/40$ Hz. When material plastifies, element size needs reduction, depending on the reduction in (shear) wave velocity.

---

[2] If quadratic finite elements are use, for example a 27 node brick than only two elements are needed per wave length as they can properly represent the single wave (as they have quadratic interpolation for displacements, and feature 5 along the wave).

Nonlinear, Inelastic, Elastic-Plastic Material: It is very important to note that recommended grid spacing changes if material stiffness changes. In other words, for softer material grid spacing is to be be reduced. This means that for elastic-plastic material, when material plastifies the element size should be reduced. Detailed analysis if grid spacing, finite element size for elastic-plastic material is provided by Watanabe et al. (2017).

502.3.3.2 Time Step Length Δt

The time step Δt used for numerically solving nonlinear vibration or wave propagation problems has to be limited for two reasons. The stability requirement depends on the numerical procedure in use and is usually formulated in the form $\Delta t / T_n <$ value. T_n denotes the smallest fundamental period of the system. Similar to the spatial discretization T_n needs to be represented by about 10 time steps. While the accuracy requirement provides a measure on which higher modes of vibration are represented with sufficient accuracy, the stability criterion needs to be satisfied for *all* modes. If the stability criterion is not satisfied for all modes of vibration, then the solution may diverge. In many cases it is necessary to provide an upper bound to the frequencies that are present in a system by including frequency dependent damping to the model.

The second stability criterion results from the nature of the finite element method. As a wave front progresses in space it reaches one point after the other. If the time step in the finite element analysis is too large the wave front can reach two consecutive elements at the same moment. This would violate a fundamental property of wave propagation and can lead to instability. The time step therefore needs to be limited to

$$\Delta t \; < \; \frac{\Delta h}{v} \tag{502.2}$$

where v is the highest wave velocity.

502.3.3.3 Nonlinear Material Models

If nonlinear material models are used the considerations for stability and accuracy as stated above don't necessarily remain valid. Especially modal considerations need to be examined further for these cases. It is however save to assume that the natural frequencies decrease as plastic deformations occur. The minimum time step required to represent the natural frequencies of the dynamic system can therefore taken to be the same as in an elastic analysis.

A high frequency component is introduced due to plastic slip and counter balancing of the resulting displacement. This is especially true if a linear algorithm with no iterations within one time step is used. Figure 502.120 shows a part of an acceleration time history from an analysis involving elastic-plastic

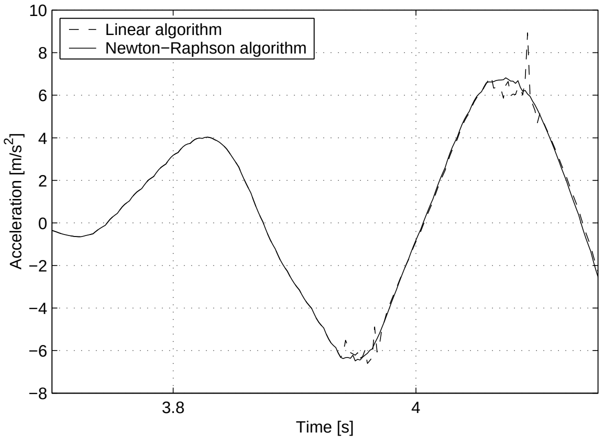

Figure 502.120: Resulting acceleration using Linear and Newton-Raphson algorithms

material. It can be seen that the out-of-balance forces at the end of a time step can be quite large if a linear algorithm is used. While the Newton-Raphson algorithm minimizes out-of-balance forces within one time step the linear algorithm requires several time steps to return to a stable equilibrium path.

The frequencies corresponding to these peaks are typically of the order of $1/(\text{a few}\,\Delta t)$. Normally the time step is small enough so that these frequencies don't interfere with the input motion. They can be prevented from propagating through the model by an appropriate choice of algorithmic or material damping.

For stability the time step used in a nonlinear analysis needs to be smaller than in a linear elastic analysis. By how much it has to be reduced is difficult to predict as this depends on many factors such as the material model, the applied loading or the numerical method itself. Argyris and Mlejnek (1991) suggest the time step to be reduced by 60% or more compared to the time step used in an elastic analysis. The best way to determine whether the time step is appropriate for a given analysis consists in running a second analysis with a reduced time step.

502.3.4 Seismic Wave Propagation Modeling and Simulation: Domain Boundaries

One of the biggest problems in dynamic SFSI in infinite media is related to the modeling of domain boundaries. Because of limited computational resources the computational domain needs to be kept small enough so that it can be analyzed in a reasonable amount of time. By limiting the domain however an artificial boundary is introduced. As an accurate representation of the soil-structure system this boundary has to absorb all outgoing waves and reflect no waves back into the computational domain. The most commonly used types of domain boundaries are presented in the following:

- Fixed or free

  By fixing all degrees of freedom on the domain boundaries any radiation of energy away from the structure is made impossible. Waves are fully reflected and resonance frequencies can appear that don't exist in reality. The same happens if the degrees of freedom on a boundary are left 'free', as at the surface of the soil.

  A combination of free and fully fixed boundaries should be chosen only if the entire model is large enough and if material damping of the soil prevents reflected waves to propagate back to the structure.

- Absorbing Lysmer Boundaries

  A way to eliminate waves propagating outward from the structure is to use Lysmer boundaries. This method is relatively easy to implement in a finite element code as it consists of simply connecting dash pots to all degrees of freedom of the boundary nodes and fixing them on the other end (Figure 502.121).

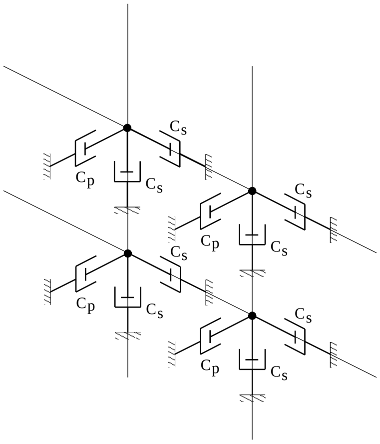

Figure 502.121: Absorbing boundary consisting of dash pots connected to each degree of freedom of a boundary node

Lysmer boundaries are derived for an elastic wave propagation problem in a one-dimensional semi-infinite bar. It can be shown that in this case a dash pot specified appropriately has the same dynamic properties as the bar extending to infinity (Wolf, 1988). The damping coefficient C of the dash pot equals

$$C = A \rho c \tag{502.3}$$

where A is the section of the bar, ρ is the mass density and c the wave velocity that has to be selected according to the type of wave that has to be absorbed (shear wave velocity c_s or compressional wave velocity c_p).

In a 3d or 2d model the angle of incidence of a wave reaching a boundary can vary from almost 0° up to nearly 180°. The Lysmer boundary is able to absorb completely only those under an angle of incidence of 90°. Even with this type of absorbing boundary a large number of reflected waves are still present in the domain. By increasing the size of the computational domain the angles of incidence on the boundary can be brought closer to 90° and the amount of energy reflected can be reduced.

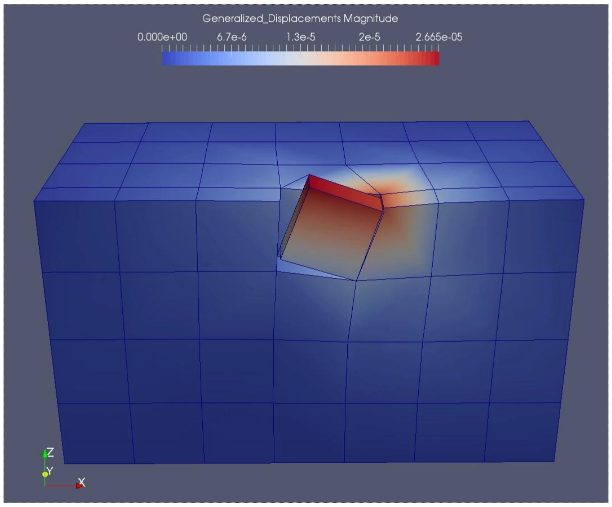
- Infinite elements
- More sophisticated boundaries modeling wave propagation toward infinity (boundary elements)

For a spherical cavity involving only waves propagating in radial direction a closed form solution for radiation toward infinity, analogous to the Lysmer boundary for wave propagation in a prismatic rod, exists (Sections 3.1.2 and 3.1.3 in Wolf (1988)). Since this solution, in contrast to the Lysmer boundary, includes radiation damping it can be thought of as an efficient way of eliminating reflections on a semi-spherical boundary surrounding the computational domain.

More generality in terms of absorption properties and geometry of the boundary are provided by the various boundary element methods (BEM) available in the literature.

502.3.5 Soil/Rock Modeling and Simulation

502.3.6 Soil/Rock – Foundation Contact (Slipping and Gaping) Modeling and Simulation



502.3.7 Buoyancy Modeling and Simulation

For self weight and other static loads, and if we assume infinitely stiff structures, buoyant force B can be calculated and applied as a single resultant force directed upward. Calculation of static buoyant force is based on the Archimedes principle: "Any object immersed in water is buoyed up by a force equal to the weight of water displaced by the object", and therefor such a buoyancy force is given as:

$$B = \rho_w g V \tag{502.4}$$

where $\rho_w = 999.972\ \mathrm{kg/m^3}$ is the mass density of water (at temperature of $+4^o$C with small changes of less than 1% up to $+40^o$C), $g = 9.81\ \mathrm{m/s^2}$ is the gravitational acceleration, and V is the volume of displaced fluid.

For seismic and other dynamic loading, and for structures which have finite stiffness (real stiffness), effects of buoyant (pressure) force will have to be modeled and simulated using methods that are more sophisticated than the simple static approach noted above.

Two main approaches to buoyancy modeling are described below:

- Sharp contrast in permeability (naturally occurring), between soil/rock and foundation concrete can be used to model buoyant pressures (and consequentially buoyant forces). This approach has been used before (Cheng and Jeremić, 2009b) and it works quite satisfactory if gap is not expected to form between soil/rock and concrete. Using sharp contrast approach, the buoyant forces are created by providing physical permeabilities for soil/rock (permeable rock, which can have high permeability) and for concrete which is quite impermeable (but not absolutely impermeable, permeability of concrete is couple of orders of magnitude lower than that of soil/rock). When the water tries to move (natural process due to pore water pressure gradient), it is restricted by the low permeability of the concrete, and thus forms a region of pressure (hydrostatic for static loading, or a different, dynamic pressure that results from dynamic behavior of soil/rock). This pressure is actually acting as a buoyant force on the concrete foundation. However, this approach only works well when there is no gap opening. In addition to that, there are modeling problems, with high pressure gradient close to the boundary between soil/rock and concrete, modeler needs to carefully mesh that region, to overcome too large pressure gradients in single layer of finite elements. A better approach, with or without gap opening is to use special coupled contact/interface finite element described below.

- Special coupled contact/interface finite element explicitly models water displacements and pressures and allows for explicit gap opening, filling of gap with water, slipping (frictional) when the gap is closed, and pumping of water as gap opens and closes. This contact/interface element incorporates the pore water pressure information, as well as the information about the displacement (movement) of pore water within a gap. It is based on a previous version of the contact/interface element with two important features in addition to features available to the dry contact element:

- Pore water pressure values (physical values obtained from simulation) from one side of the special coupled contact/interface element (side in contact/interface with saturated soil/rock) will be communicated (directly transferred) to the other side of this element. With this water pressure information available, the applied water pressure will be acting on the foundation finite elements. Foundation finite element will integrate pressure field on a given face (or faces) of the element and will create a buoyant force. Integration of pressure on an element face into buoyant forces is done using standard finite element procedure for calculating nodal forces (these are the buoyant forces in our case) from face pressures (Jeremić et al., 1989-2025):

  $$F_{Ia}^{buoyant} = \int_{S^m} f_a^{buoyant} \; H_I \; dS^m \tag{502.5}$$

  where $F_{Ia}^{buoyant}$ is the buoyant force at each node of the foundation finite element, $f_a^{buoyant}$ is the distribution of buoyant pressures on a face the foundation finite element, and H_I is a standard shape function of the foundation finite element (in our case, linear for 8 node brick, or quadratic for a 27 node brick). The integration is performed over a surface area S^m of each finite element face where buoyant pressures are present. With buoyant forces acting at the bottom (or sides) of a foundation, a proper reduction (change) of contact/interface pressures (forces) will be calculated. This means that the slipping (frictional) criteria of the contact/interface element will have all the necessary information about the normal forces (now reduced because of buoyant forces) and will determine is the contact/interface will slip and remain attached (at the location of that contact/interface element).

- Gap opening (physical values obtained from simulations) will be used to create suction and compression pore/gap water field. This will be achieved by connecting the displacements of the pore fluid from soil/rock finite elements (we will be using u-p-U finite elements for soil/rock modeling (Jeremić et al., 2008)), to the contact/interface element node on the opposite side of the special coupled contact element. This way, if the gap opens, and the contact/interface element now features an opening, the water displacements from the soil/rock side of the contact/interface element will be "pulled" to follow the uplifting foundation. This water movement will create pressure gradients in the soil/rock elements beneath, which will be accurately modeled using fully coupled u-p-U finite elements for soil/rock (Jeremić et al., 2008; Jeremić and Cheng, 2009).

Using above described approach to modeling will provide for high fidelity modeling and simulation of the buoyant pressures/forces, which will resolve all the difficulties related to this modeling.

502.4 Step by Step, Hierarchical Inelastic ESSI Analysis

502.4.1 ESSI Model Verification

ESSI Model Verification consists of gradual, hierarchical development of the large, detailed ESSI model, with verification of model response as sophistication level increases.

Recommended nonlinear/inelastic modeling and simulation phases for an SSI system are shown in Figure 502.122.

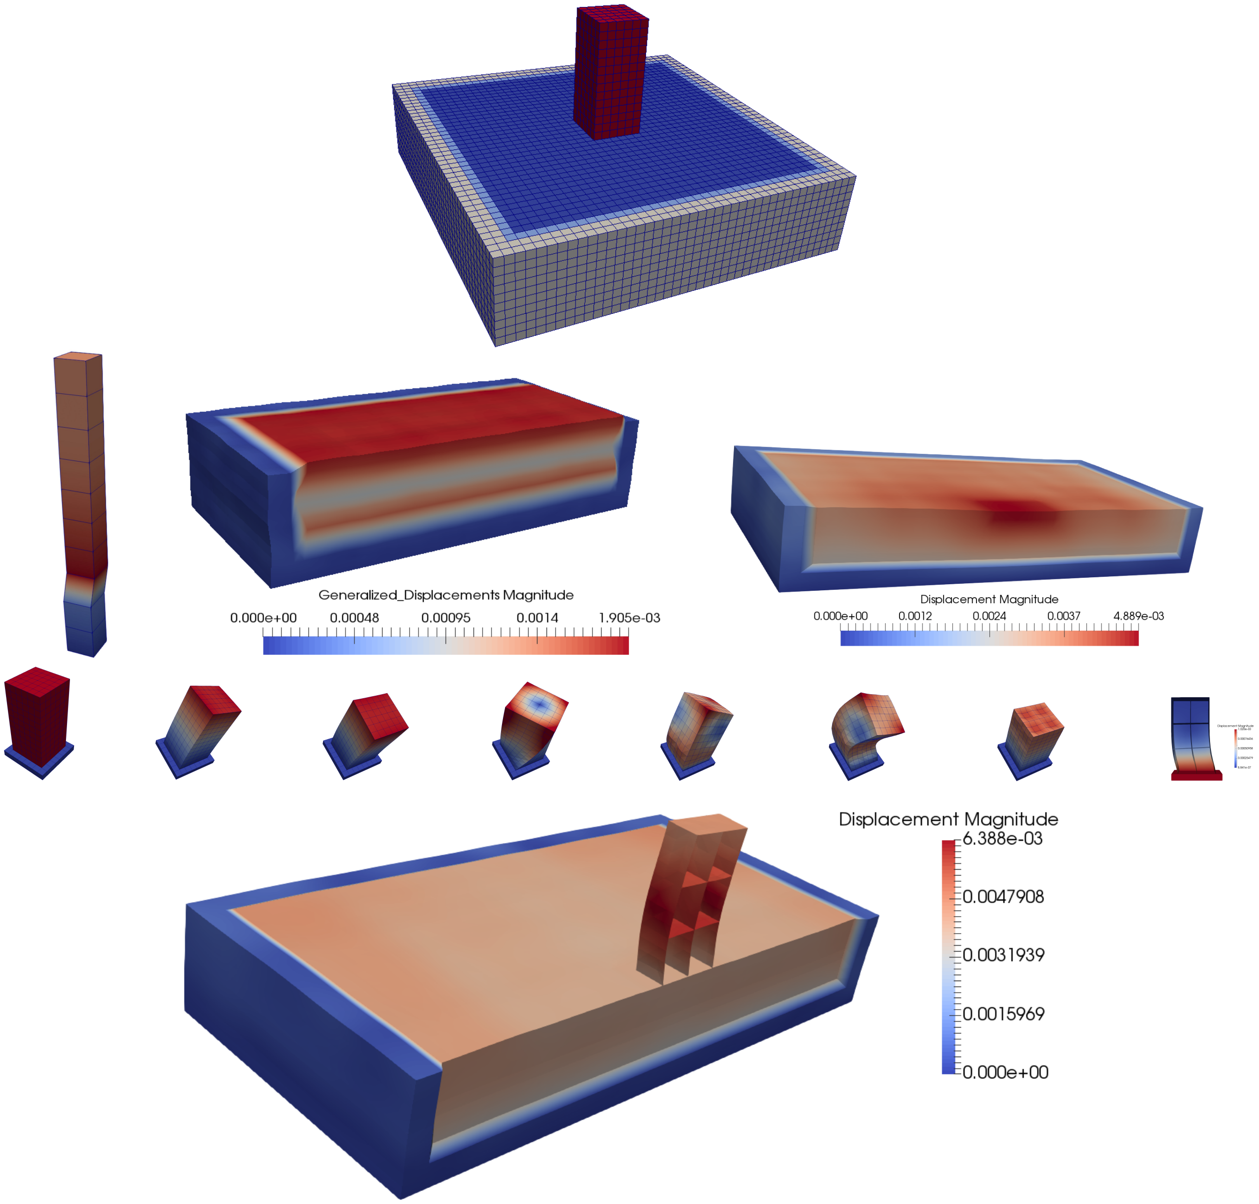

Figure 502.122: Step by step, hierarchical inelastic ESSI modeling and simulations.

It is highly recommended to proceed in phases, from simpler to more sophisticated, while employing sound engineering judgement at the end of each phase in order to understand static and dynamic response of the system and its components. For example, for an SSI system shown in Figure 502.122, advice is to follow these steps:

- start with a 1D model for one component (1C) shear wave, SV free field wave propagation, linear elastic soil, simple wavelet motions (Ricker, Ormsby)
- For a 1D-1C free field wave propagation, linear elastic soil, use more realistic motions, using

deconvolution of surface motions and convolution of rock motions from depth

- For a 1D model, apply 1 component (1C) vertical motions, a free field P wave
- For a 1D model, apply 2 component (2C), shear wave, SV, motions, for a free field wave propagation,
- For a 1D model, apply 3 component (3×1C) motions, for a free field wave
- For a 1D-1C, 1D-2C and 1D-3×1C free field wave propagation, update soil model to mild nonlinear/inelastic and perform wavelet and seismic motions, as noted above
- For a 1D-1C, 1D-2C and 3×1C models, update soil model to more realistic nonlinear/inelastic model and perform wavelet and seismic motions, as noted above
- Develop a 3D model of a free field and follow above steps, 3D-1C, 3D-2C, 3D-3×1C, elastic, inelastic, wavelet, realistic seismic input
- For a 3D model develop full 3C motions, inclined waves, and test your system, using phased modeling of material (elastic-inelastic), and motions, wavelets, then realistic seismic motions
- For a 3D-1C, 3D-2C and 3D-3×1C, models, add foundation slab, follow steps from above, elastic, inelastic soil, wavelets, realistic motions.
- Develop model of a structure, fully fixed DoFs at the bottom and perform eigen-analysis.
- For a fixed base structural model, apply motions from above,
- Progression in modeling sophistication from simpler material models, linear elastic, to more sophisticated, inelastic material models, should be followed for each component of the model, soils, structures, special elements, &c.
- Finally you might be able to develop a full 3D model, first linear then slowly nonlinear/inelastic, first simple motions, wavelets, then more realistic 1C, 2C, 3×1C and 3C motions

Progression in modeling sophistication from simpler material models, linear elastic, to more sophisticated, inelastic material models, as suggested above, should be followed by progression of simulation sophistication, as noted below:

- Start with linear elastic material models for all components, including bonded contact/interface/joints.

- Proceed with explicit, non convergence check simulation at both constitutive and global levels:
  - On constitutive level, use Forward Euler algorithm. Theory for the Forward Euler, explicit constitutive algorithm is described in Section 104.3, on page 206, in Jeremić et al. (1989-2025). Commands for constitutive level Forward Euler algorithm are given in Section 205.3.5.15, on page 1117, in Jeremić et al. (1989-2025).
  - With Forward Euler, explicit computations on the constitutive level, it is only appropriate to use global, finite element algorithm with no convergence check, that is also known as the explicit global algorithm. This algorithm is described in some detail in Section 107.3, on page 523, in Jeremić et al. (1989-2025). Commands for constitutive level Forward Euler algorithm are given in Section 205.3.5.14, on page 1116, in Jeremić et al. (1989-2025).
- For fully implicit algorithm, with enforcement of equilibrium on constitutive and global, finite element levels, proceed with Backward Euler (or one of the variants) on constitutive level and Newton algorithm (or one of variants) on global level:
  - On constitutive level, use Backward Euler algorithm. Theory for the Backward Euler, implicit constitutive algorithm is described in Section 104.4, on page 207, in Jeremić et al. (1989-2025). Commands for constitutive level Forward Euler algorithm are given in Section 205.3.5.15, on page 1117, in Jeremić et al. (1989-2025).
  - With Backward Euler, implicit computations on the constitutive level, it is appropriate to use global, finite element algorithm with or without convergence check, that is, one can use either explicit or implicit global algorithm. Thesealgorithm is described in some detail in Section 107.3, on page 523, in Jeremić et al. (1989-2025). Commands for constitutive level Backward Euler algorithm are given in Section 205.3.5.14, on page 1116, in Jeremić et al. (1989-2025).

A section from IAEA TECODC chapter will be used for this section ...

Pecker et al. (2022)

Input files for all the examples are available online at this LINK. All the examples can run directly at the Amazon Web Services, through Real-ESSI image.

502.4.2 ESSI Model Validation

Quality assurance and confidence in aalysis results is developed through full program verification, all the available model validation, as described in in chapters in part 300 on page 1436. For a particular model that is analyzed, step by step analysis procedures are decribed in section 502.4 on page 2354.

It is higtly advisable to perform ESSI model validation as well. ESSI model validation increases confidence in validity of modeling results. ESSI model validation consists of developing models for all the components of the large detailed model, and performing analysis of each of these components using material parameters that are used in large detailed model. While this activity does not strictly represent validation, as results do not have to be directly compared to available tests results, ESSI model validation provides engineers with a way to crudely, approximately assess simple mechanical behavior model components.

For example, a number of elastic and inelastice models might be used to model behavior of soil and rock beneath the structure. Single finite element models are to be developed, models that replicate simple behavior, for example simple shear, pure shear, triaxial conditions, etc. Similarly, structural model components, fibers, beams, shells, are developed and tested using simple loads, 1D uniaxial loads, pure bending, etc. Interface, contact joint models shouls also be developed.

These simple models are to be numerically analyzed, tested, using sets of material parameters/properties that are used in a large, detailed model. Engineering analyst is to inspect simple mechanial responses, and, using her/his experience and engineering judgement, assess approximately if material parameters used for modeling provide reasonable mechanical response for model components.

Chapter 503

Earthquake-Soil-Structure Interaction, Bridge Structures

(2003-2007-2011-)

(In collaboration with Dr. Guanzhou Jie)

503.1 Chapter Summary and Highlights

503.2 Case History: Earthquake-Soil-Structure Interaction for a Bridge System

503.2.1 Prototype Bridge Model Simulation

The final objective this work is to improve current modeling techniques through the comparative study between numerical and experimental components. In this work, a whole prototype bridge model has been built using finite element techniques demonstrated in previous sections. Domain Reduction Method (Bielak et al., 2003b; Yoshimura et al., 2003b) (DRM) has been used to reduce the model size while still preserves the accuracy of the ground motion analysis.

503.2.1.1 Soil Model

Capitol Aggregates, a local quarry located in the south of Austin, has been selected to be the test site for this project. Site characterization has been preformed to collect information on the soil (Kurtulus et al., 2005). Based on the only triaxial test data available, a nonlinear soil constitutive model is developed in this work for prototype finite element analysis.

Undrained triaxial compression test has been carried out on one, $1.5in$ diameter triaxial test specimen trimmed from an undisturbed soil sample obtained from borehole at an approximate depth of $10.6ft$. The initial size and index properties of the soil specimen are given in Table 503.1 (Kurtulus et al., 2005).

Table 503.1: Index Properties of the Undisturbed Triaxial Test Specimen

Soil Index Property	Inital	After Consolidation	Failure
Diameter D $(inch)$	1.50	1.48	1.56
Height H $(inch)$	3.00	2.87	2.56
Total Unit Weight γ_t (pcf)	107.3	111.1	112.8
Water Content w (%)	18	18	18
Dry Unit Weight γ_d (pcf)	90.9	94.3	95.7
Void Ratio e[1]	0.84	0.77	0.75
Degree of Saturation S_r[1](%)	57	62	64

[1] Specific Gravity G_s is assumed to be 2.68.

In the triaxial cell, the specimen was allowed to come into equilibrium (compress/consolidate with drainage lines open) under an isotropic pressure equal to the assumed in-situ mean total stress, which is about $5.6psi$. Upon equilibrating, the specimen was sheared under undrained conditions with a strain rate of $\%1$ per hour. No pore pressure readings were taken since the specimen was unsaturated. The resulting stress-strain curve is presented in Figure 503.1. An estimate of the undrained shear strength in terms of total stresses was measured as $13.41psi$ $(1931psf)$ at about 9% strain. The specimen failed in a bulging mode. The index properties of the specimen at failure are presented in Table 503.1.

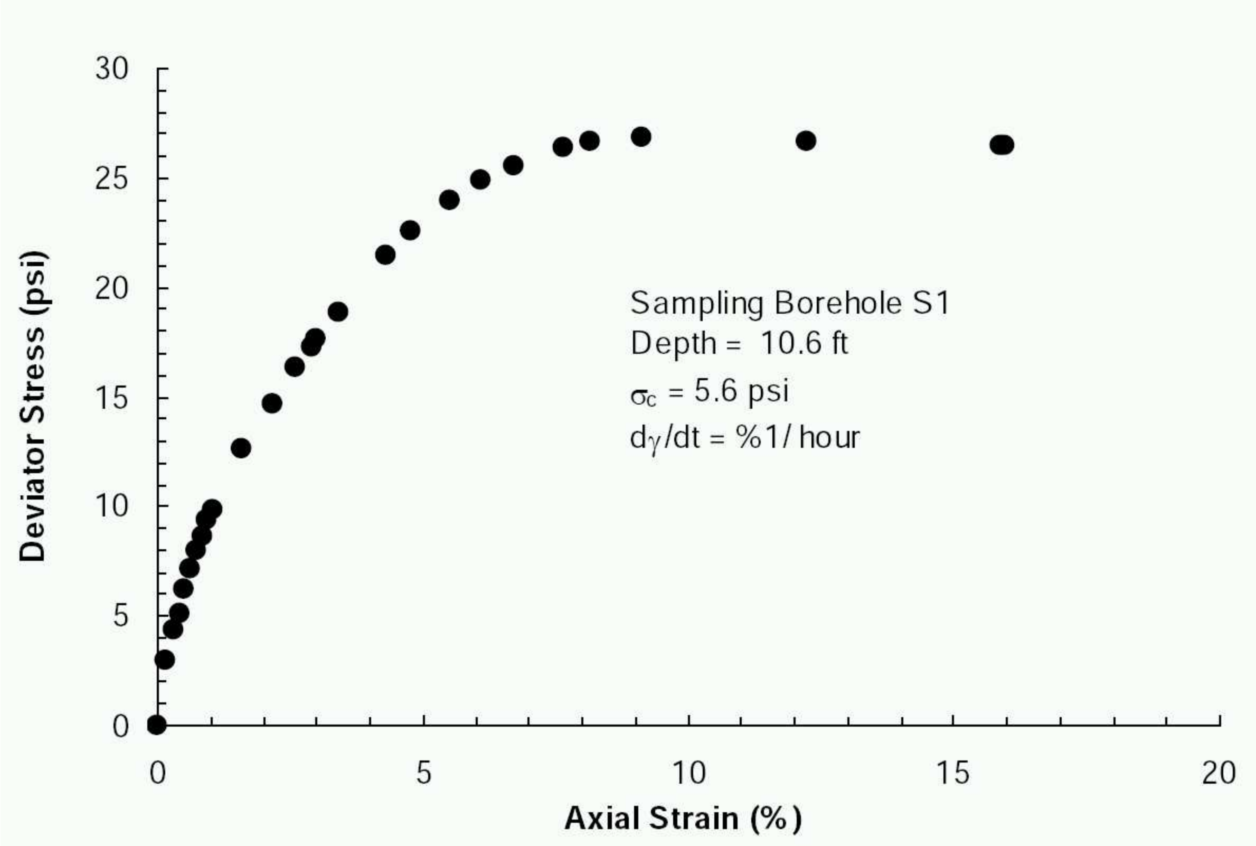

Figure 503.1: Total Stress Strain Curve Determined from Undrained Triaxial Compression Test (Undisturbed Sample from Depth $10.6ft$)

Based on the laboratory triaxial test data, a nonlinear elastic-plastic soil model has been developed to calibrate the finite element simulation. Associative Drucker-Prager plasticity model, combined with nonlinear Armstrong-Frederick kinematic hardening rule, yields good match between laboratory data and numerical results, as shown in Figure 503.2. The same model has been exposed to various confinements to test robustness of the model for soils at different depths.

503.2.1.2 Element Size Determination

The accuracy of a numerical simulation of dynamic SFSI (Soil-Structure-Foundation-Interaction) problems is controlled by two main parameters (Preisig, 2005):

1. The spacing of the nodes of the finite element model Δh

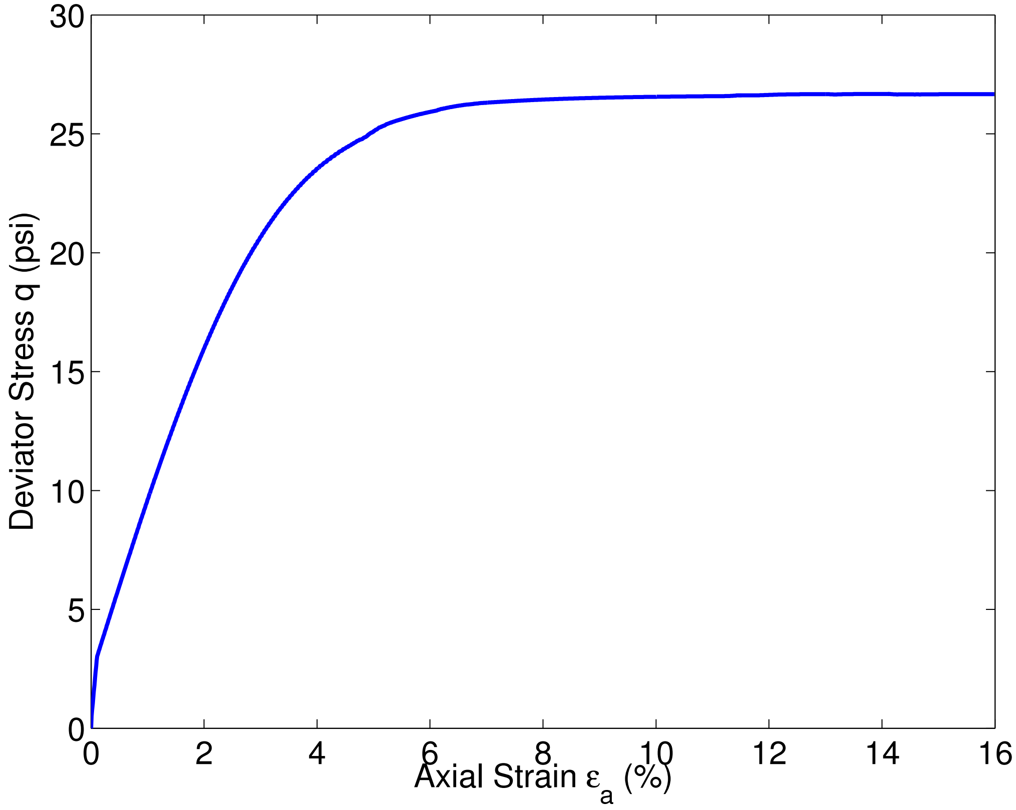

Figure 503.2: Total stress strain curve obtained using simulation of triaxial test (from depth $10.6 ft$)

2. The length of the time step Δt.

Assuming that the numerical method converges toward the exact solution as Δt and Δh go toward zero the desired accuracy of the solution can be obtained as long as sufficient computational resources are available.

As presented in Preisig (2005), in order to represent a traveling wave of a given frequency accurately about 10 nodes per wavelength are required. Fewer than 10 nodes can lead to numerical damping as the discretization misses certain peaks of the wave. In order to determine the appropriate maximum grid spacing the highest relevant frequency f_{max} that is present in the model needs to be found by performing a Fourier analysis of the input motion. Typically, for seismic analyses f_{max} is about $10 Hz$. By choosing the wavelength $\lambda_{min} = v/f_{max}$, where v is the wave velocity, to be represented by 10 nodes the smallest wavelength that can still be captured partially is $\lambda = 2\Delta h$, corresponding to a frequency of $5 f_{max}$.

The maximum grid spacing should not exceed

$$\Delta h \leq \frac{\lambda_{min}}{10} = \frac{v}{10 f_{max}} \tag{503.1}$$

where v is the smallest wave velocity that is of interest in the simulation.

Table 503.2: Maximum Element Size Determination ($f_{max} = 10HZ$)

Depth (ft)	Thickness (ft)	v_{shear} (fps)	Δh_{max} (ft)	h_{max} (m)
0	1	320	3.2	0.98
1	1.5	420	4.2	1.28
2.5	4.5	540	5.4	1.65
7	7	660	6.6	2.01
14	7.5	700	7.0	2.13
21.5	17	750	7.5	2.29
38.5	half-space	2200	22.0	6.7

In this work, the prototype site chosen is Capitol Aggregates, a local quarry located in the south of Austin. According to the site characterization report Kurtulus et al. (2005), we obtain Table 503.2 for element size determination.

Mechanical properties of soil changes with cyclic loadings. In order to predict more accurately the dynamic behaviors of soil subject to earthquake loadings, various laboratory and in situ tests have been performed to examine the degradation of dynamic soil properties. Equivalent linear model has been used extensively in practice (Kramer, 1996b). Moduli reduction curve (G/G_{max}) and damping ratio relationship have been obtained for prototype soil at the site of Capitol Aggregates as shown in Figure 503.3.

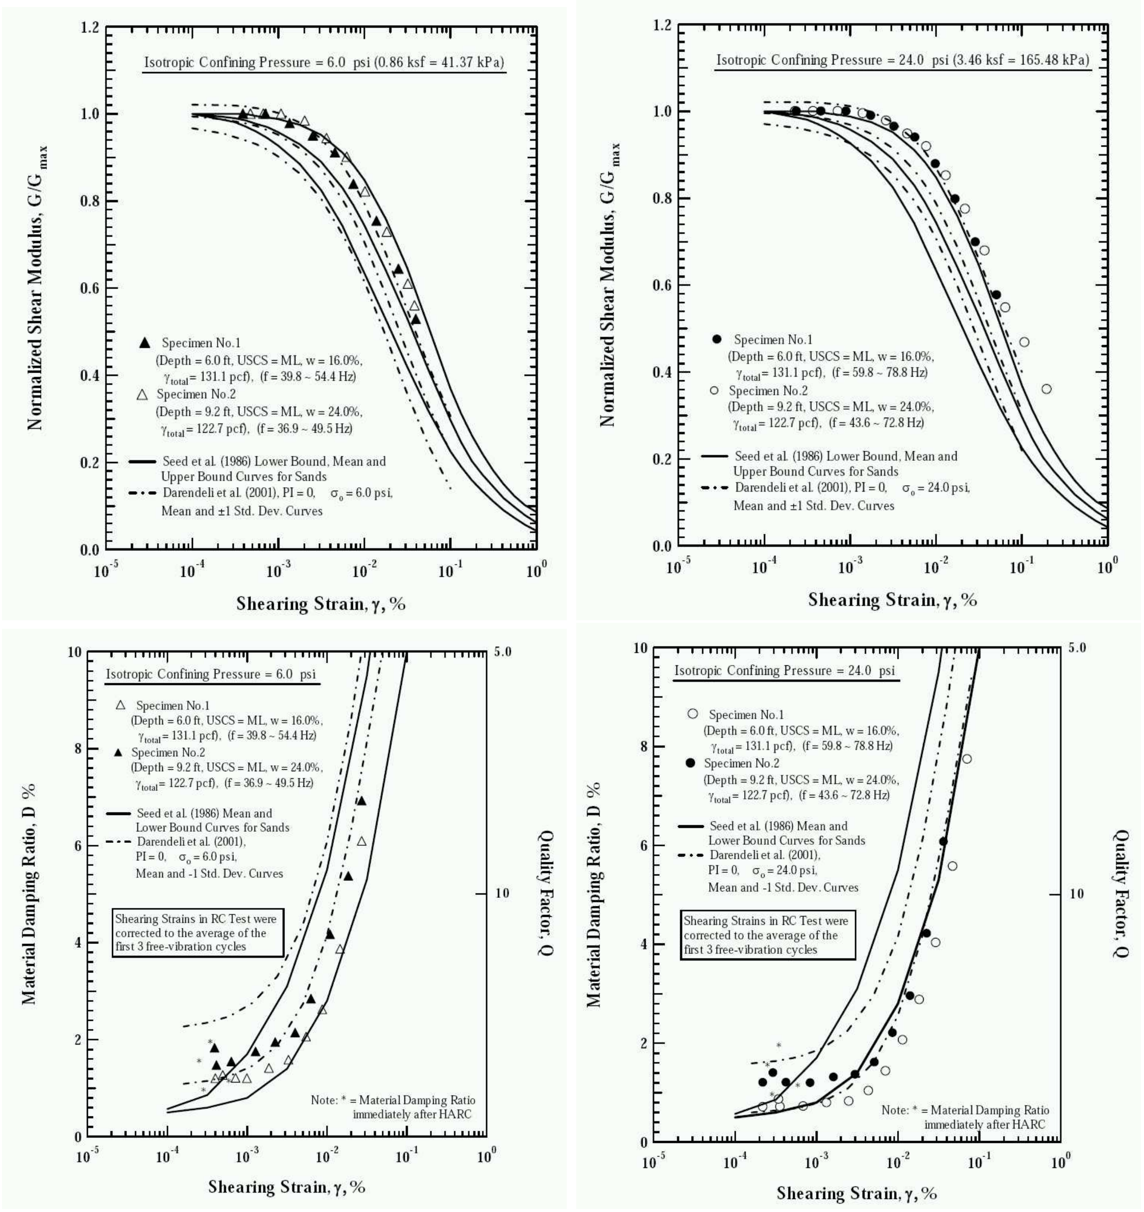

Figure 503.3: Comparison of the Variation in Normalized Shear Modulus and Damping Ratio with Shearing Strain from the Resonant Column Tests with Modulus Reduction Curves proposed by Seed et al. (1986) and Darendeli (2001) (Kurtulus et al., 2005)

Table 503.3: Element Size Determination after Degradation of $G(v_s)$ ($f_{max} = 10HZ$)

Depth (ft)	Thickness (ft)	v_s (fps)	Min G/G_{max}[2]	Min v_s	Δh_{max} (ft)	h_{max} (m)
0	1	320	0.36	192	1.92	0.59
1	1.5	420	0.36	252	2.52	0.77
2.5	4.5	540	0.36	324	3.24	0.99
7	7	660	0.36	396	3.96	1.21
14	7.5	700	0.36	420	4.20	1.28
21.5	17	750	0.36	450	4.50	1.37
38.5	half-space	2200	0.36	1320	13.20	4.02

[2] The value is obtained from the lab test data, which corresponds to 0.2% strain level.

The degradation of dynamic soil properties as observed in experiments has to be considered in finite element analysis in order to capture more accurate behaviors. As the shear wave velocity correlates with shear modulus by Equation 503.2,

$$v_{shear} = \sqrt{\frac{G}{\rho}} \tag{503.2}$$

we can readily obtain the dynamic degradation of wave velocities. This leads to smaller element size required for detailed simulation of wave propagation. The newly calculated element sizes are listed in Table 503.3. A three bent prototype finite element model has been developed with element size $\Delta h = 0.6$m as shown in Figure 503.4

503.2.1.3 Time Step Length Requirement

As stated in Preisig (2005), the time step Δt used for numerically solving nonlinear vibration or wave propagation problems has to be limited for two reasons. The stability requirement depends on the numerical procedure in use and is usually formulated in the form $\Delta t = T_n <$ value. T_n denotes the smallest fundamental period of the system. Similar to the spatial discretization T_n needs to be represented by about 10 time steps. While the accuracy requirement provides a measure on which higher modes of vibration are represented with sufficient accuracy, the stability criterion needs to be satisfied for all modes. If the stability criterion is not satisfied for all modes of vibration, then the solution may diverge. In many cases it is necessary to provide an upper bound to the frequencies that are present in a system by including frequency dependent damping to the model.

The second stability criterion results from the nature of the finite element method. As a wave front progresses in space it reaches one point after the other. If the time step in the finite element analysis is

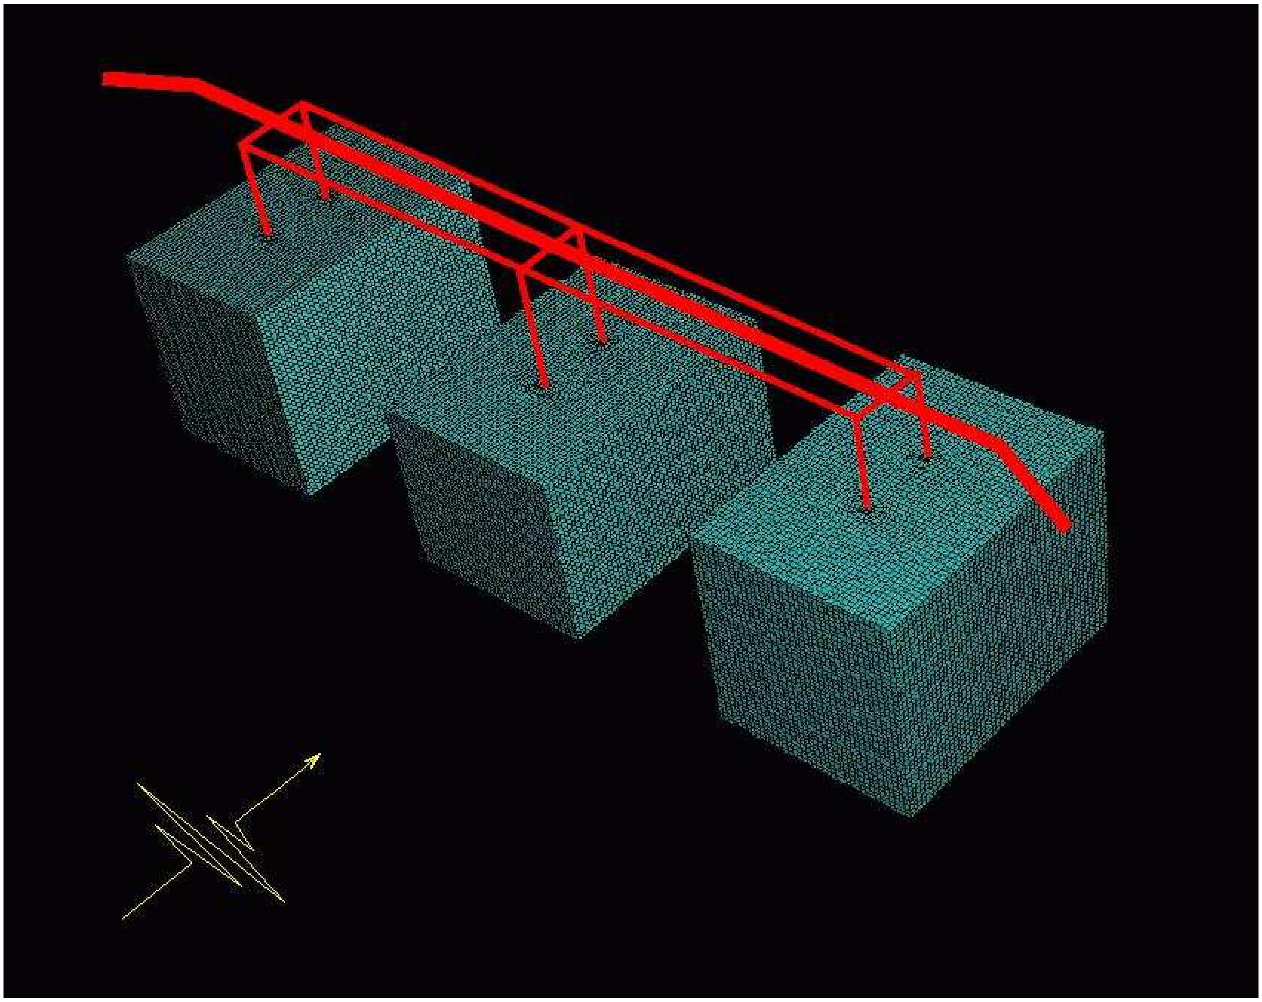

Figure 503.4: Detailed Three Bent Prototype SFSI Finite Element Model - 3 Bent SFSI, 484,104 DOFs, 151,264 Elements, Frequency Cutoff 10Hz, Element Size 0.3m, Minimum G/G_{max} 0.08, Maximum Shear Strain γ 1%

too large the wave front can reach two consecutive elements at the same moment. This would violate a fundamental property of wave propagation and can lead to instability. The time step therefore needs to be limited to

$$\Delta t < \frac{\Delta h}{v} \tag{503.3}$$

where v is the highest wave velocity.

According to Table 503.3, the time step requirement can be obtained as

$$\Delta t < \frac{\Delta h}{v} = 0.00256 \tag{503.4}$$

in seconds.

503.2.1.4 Domain Reduction Method

Domain reduction method was originally proposed in Bielak et al. (2003b); Yoshimura et al. (2003b) The theory aims at reducing the size of simulation domain by means of variable interchange. This method features a two-stage strategy for complicated three dimensional earthquake engineering simulations. The first is an auxiliary problem that simulates the earthquake source and propagation path effects with a model that encompasses the source and a background structure from which the localized feature has been removed. The second problem models local site effects. Its input is a set of equivalent localized forces derived from the first step. These forces act only within a single layer of elements adjacent to the interface between the exterior region and the geological feature of interest. The beauty of this theory comes from the fact that we can use established numerical and/or experimental approaches to solve the first-stage wave propagation problem. With the outcome of the first phase solution, we greatly reduce the size of the problem and then efforts can be focused on the second phase to deliver more accurate simulation on local responses. This approach can be successfully used in soil-foundation-structure-interaction finite element modeling without the need to incorporate unnecessary far-field motion simulations.

503.2.1.5 Structural Model

The nonlinear structure model developed in this work is a joint effort of UCB and UCD. Experimental data has been collected from UNR shaking table tests to calibrate the structural models. The effort in this work has been focused on how to integrate advanced structure model with geotechnical model to enable full-scale prototype simulations. The assumption that the plastic hinge forms either on the top of column or at the fixed bottom does not hold for SFSI problems. This restriction has been removed as the geotechnical and structural models are connected together.

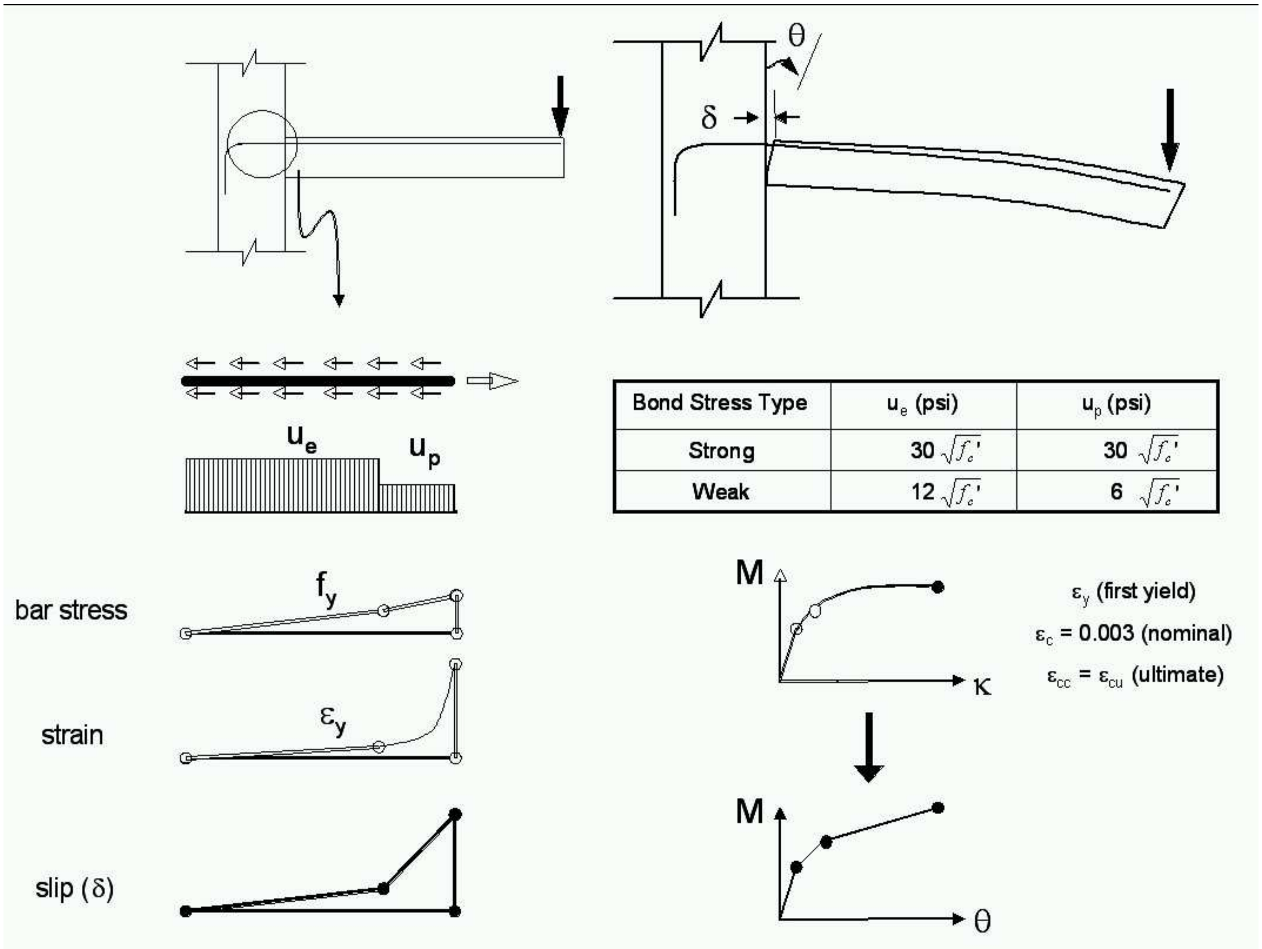

Figure 503.5: Simplified Hinge Model Developed for SFSI Prototype Simulations (Dryden, 2005)

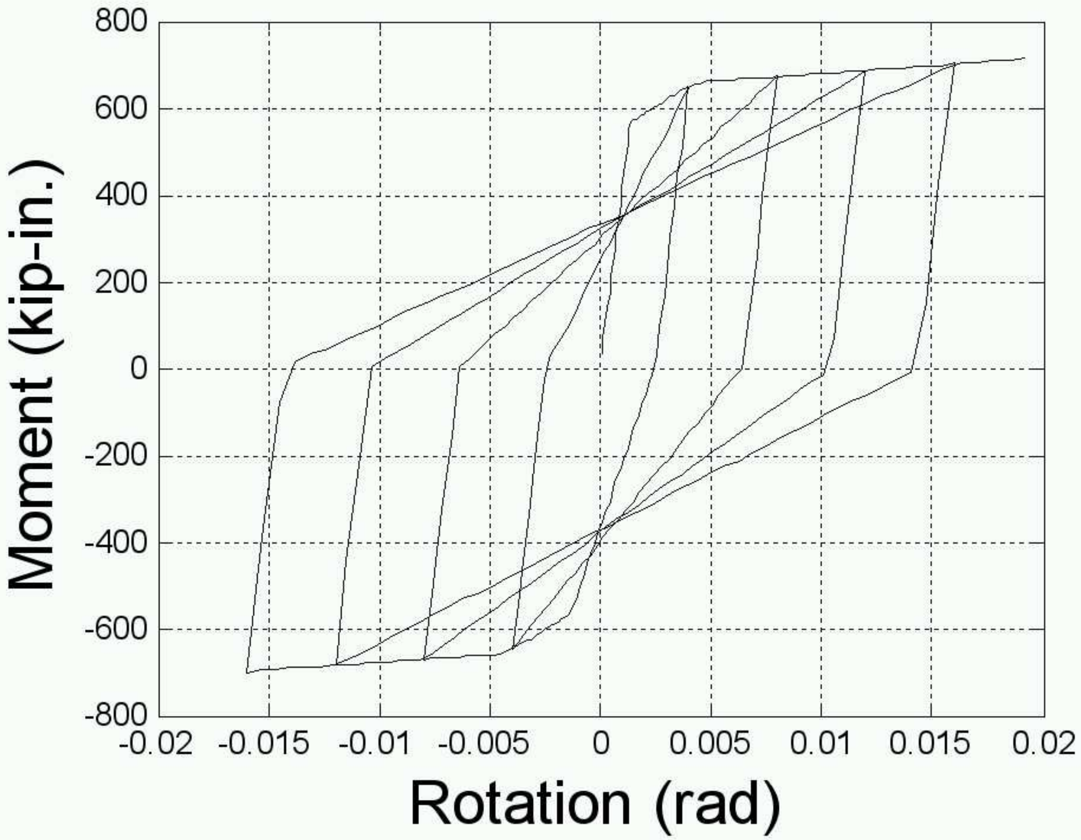

Figure 503.6: Moment-Rotation Relationship of Structural Hinge Model (Dryden, 2005)

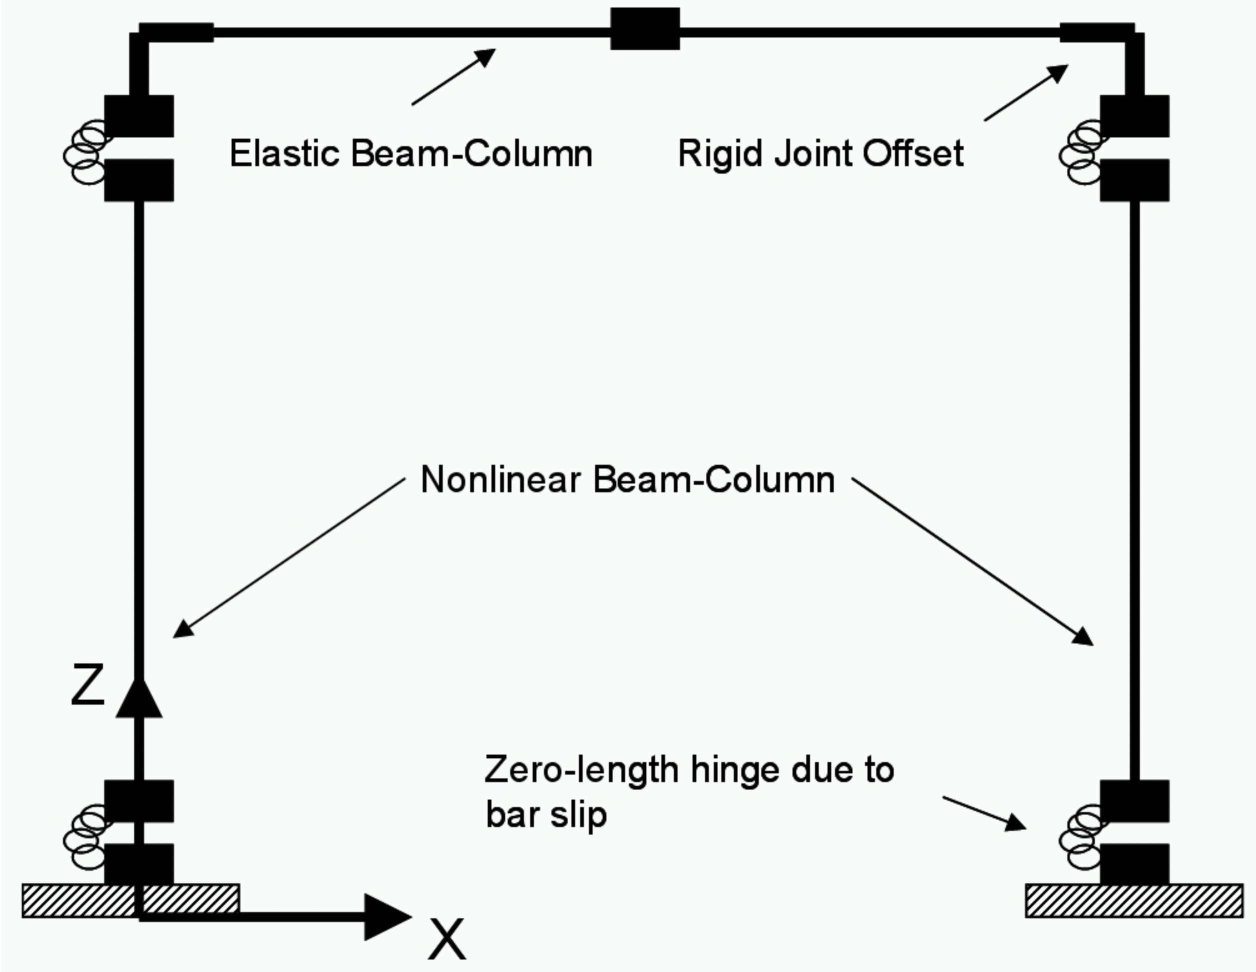

Figure 503.7: Developed structural model (Dryden, 2005).

503.2.1.6 Simulation Scenarios

In order to fully investigate how the relative strength of soil to the structure can affect the system behaviors, a thorough parametric study has been performed. The prototype model used in this work is a 4-span bridge structure with 3 bents. The supporting soil foundation can be varied according to different site conditions. The mesh of the prototype finite element model is shown in the Figure 503.8. The underlying soil of the bridge can be soft bay mud or stiff sand. In order to fully investigate the SFSI response, various scenarios are simulated as shown in Table 503.4 and results are analyzed.

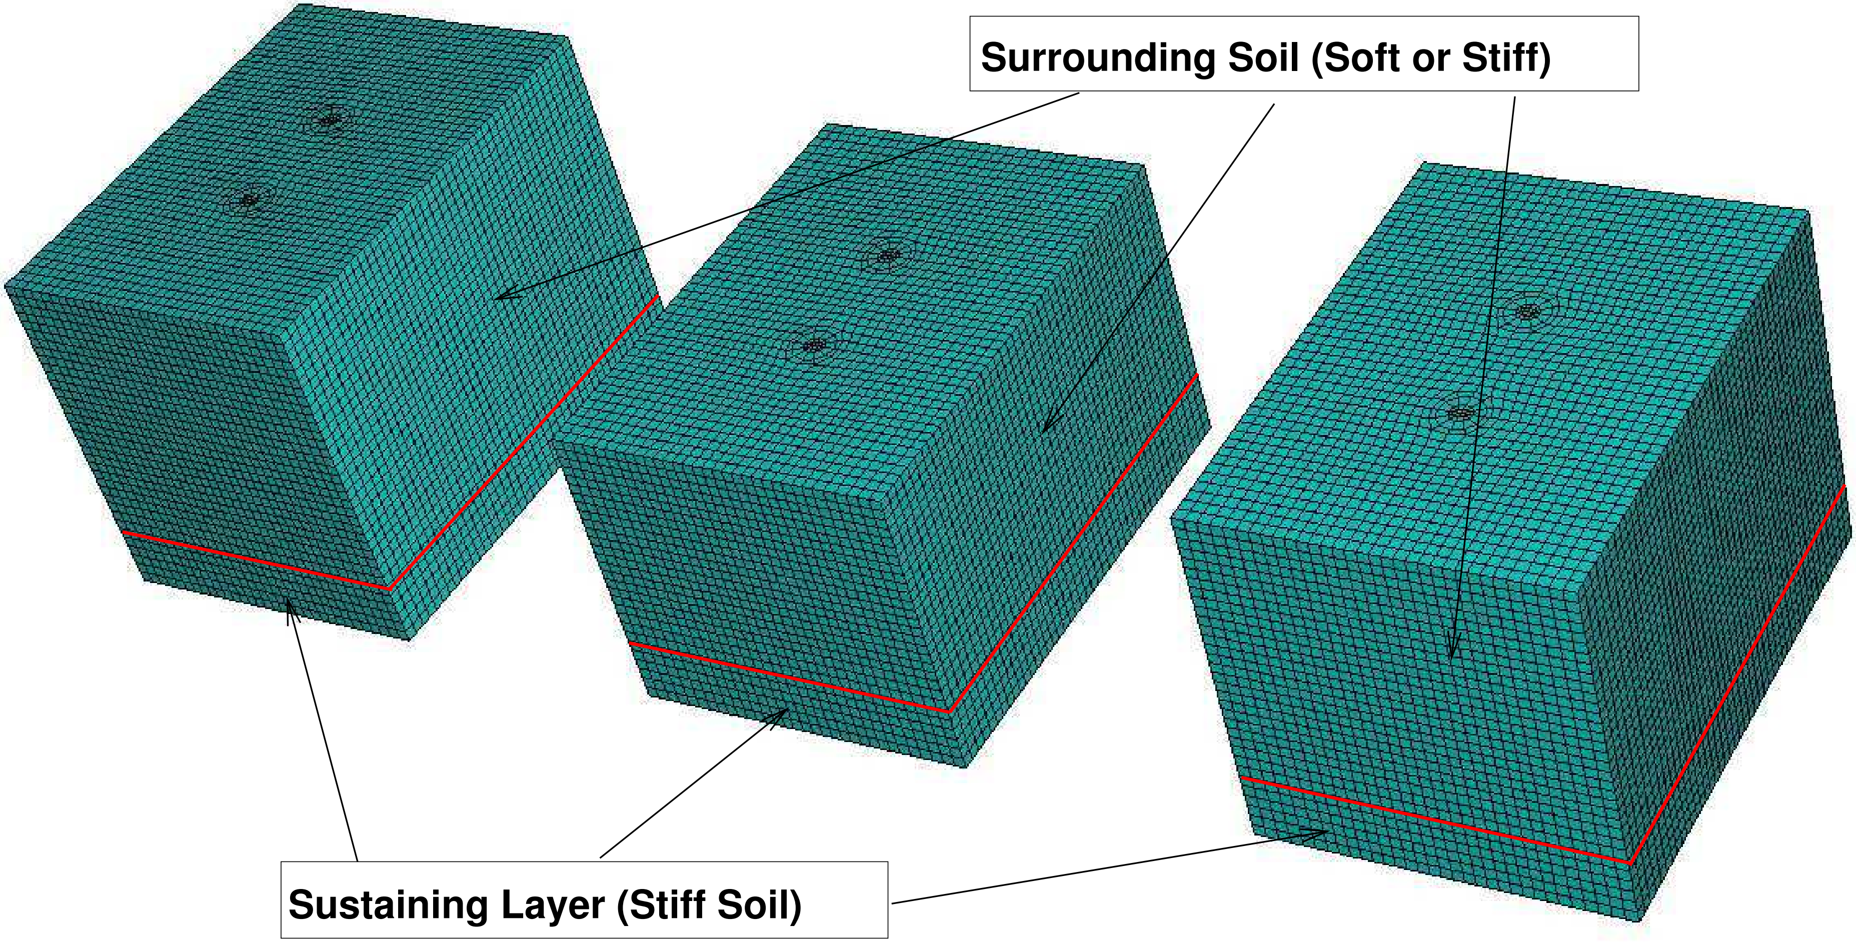

Figure 503.8: Finite Element Model for 3 Bent Prototype Bridge System

Table 503.4: Simulation Scenarios for Prototype SFSI Studies

Simulation Cases	Soil Block 1	Soil Block 2	Soil Block 3
Case 1	Stiff Sand	Stiff Sand	Stiff Sand
Case 2	Stiff Sand	Stiff Sand	Soft Clay
Case 3	Stiff Sand	Soft Clay	Stiff Sand
Case 4	Stiff Sand	Soft Clay	Soft Clay
Case 5	Soft Clay	Stiff Sand	Stiff Sand
Case 6	Soft Clay	Stiff Sand	Soft Clay
Case 7	Soft Clay	Soft Clay	Stiff Sand
Case 8	Soft Clay	Soft Clay	Soft Clay

Constitutive Modeling of Stiff Sand For the stiff sand, the constitutive model developed in previous sections, as shown in Table 503.1 will be used.

Constitutive Modeling of Soft Clay This soil model aims at simulating in-situ undrained behavior of soft bay mud. Undrained shear strength can be easily determined and a simple von Mises model is used in this research.

503.2.2 Earthquake Simulations - 1994 Northridge

Starting from this section, detailed numerical simulation results will be presented to show how the finite element simulation techniques can be used in prototype earthquake simulations. The results are presented here, and discussions will follow. Figure 503.9 shows the input motion recorded from 1994 Northridge which contains lots of high frequency contents. There are totally two motions are selected for this work, one with primary short period (high frequency) contents, and the other with primary long period (low frequency) contents. The purpose is to study every single component of the SFSI system trying to expose how each affects the SFSI system response.

503.2.2.1 Input Motion

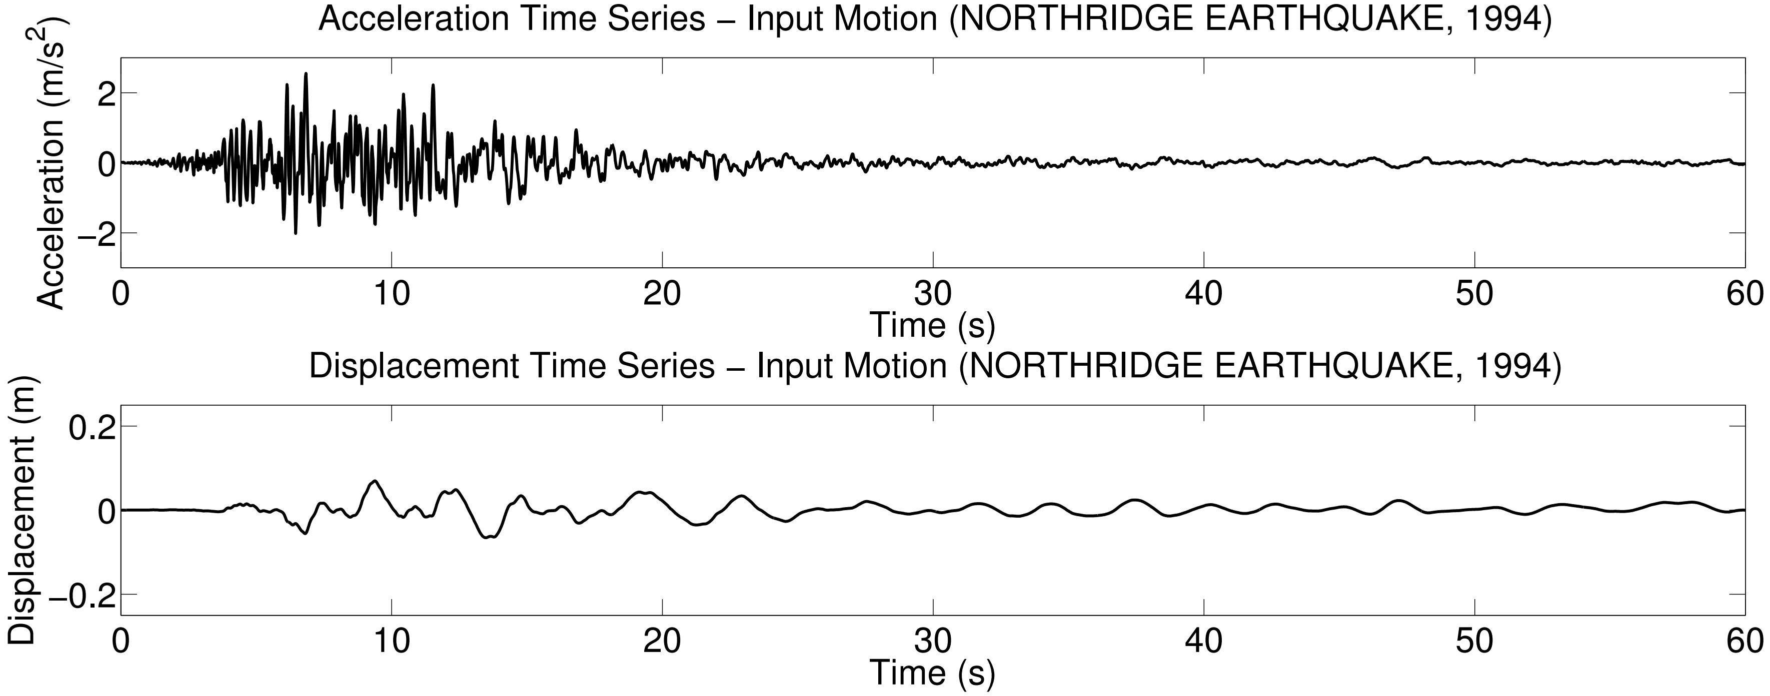

Figure 503.9: Input Motion - Century City, Northridge Earthquake 1994

503.2.2.2 Displacement Response

This section presents the displacement results from numerical simulations.

There are a couple of interesting things that deserve attention. Firstly, in the 1994 Northridge earthquake which contains much high frequency content, the structural response from softer soil actually is smaller than those on top of stiff soil. This is interesting because it basically controdicts the common notion that stiffer the soil, stabler the structure. That is the case for static design. But for earthquake design, we are presenting different stories. Secondly, we see the soil displacement near structure is largely affected by the SFSI. So the question if it is valid to apply outcrop motion directly to fixity point to excite the structure, just as people commonly do, might need a revisit.

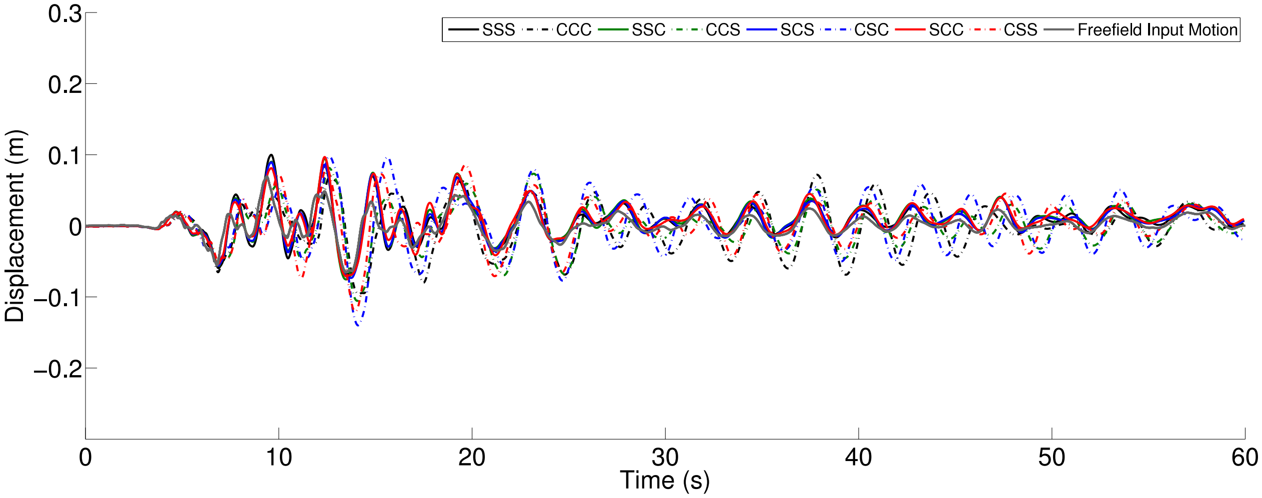

Figure 503.10: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 1)

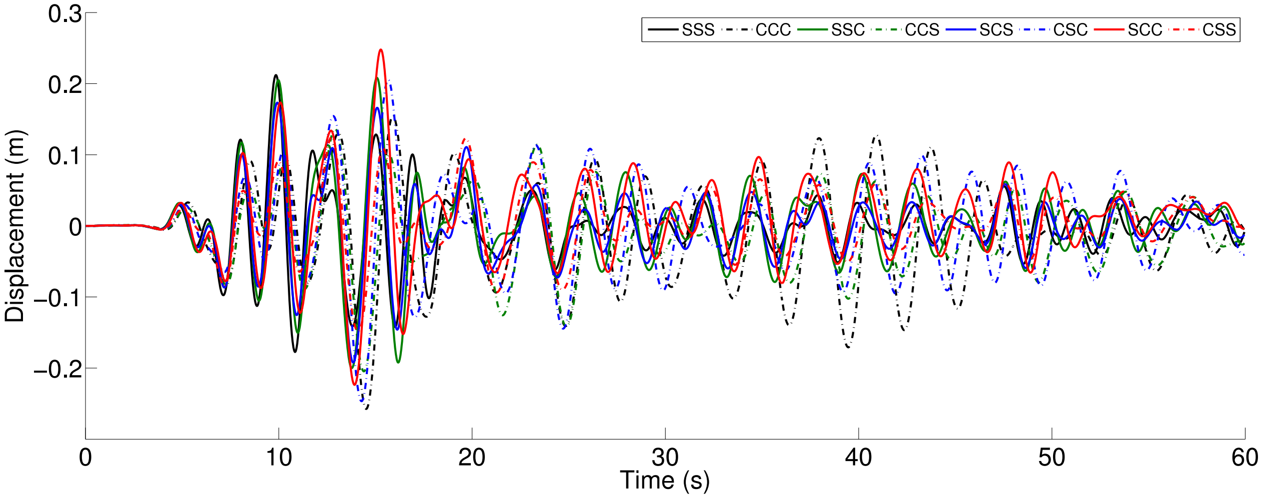

Figure 503.11: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 1)

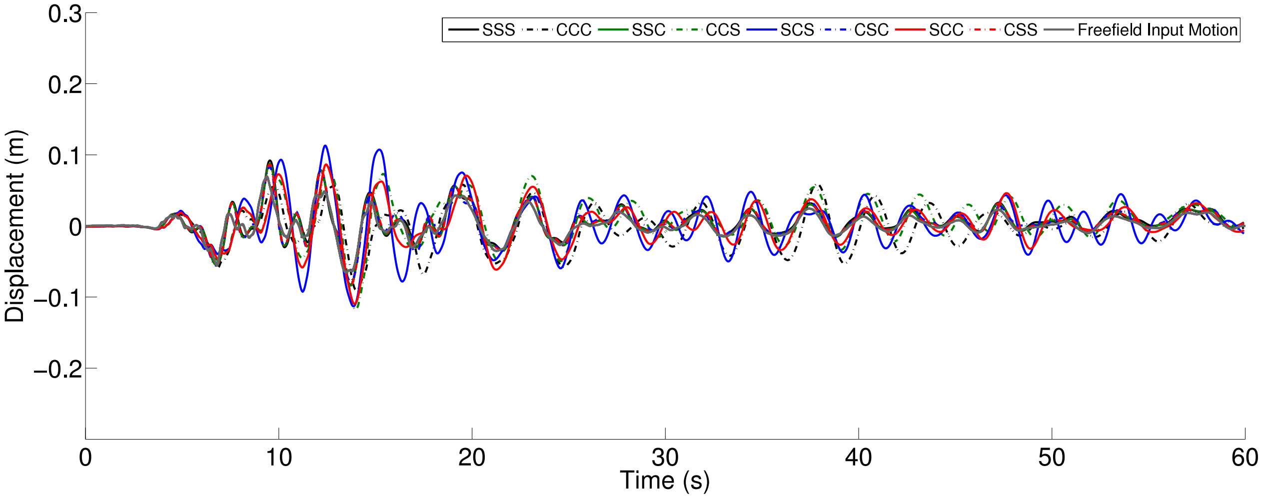

Figure 503.12: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 2)

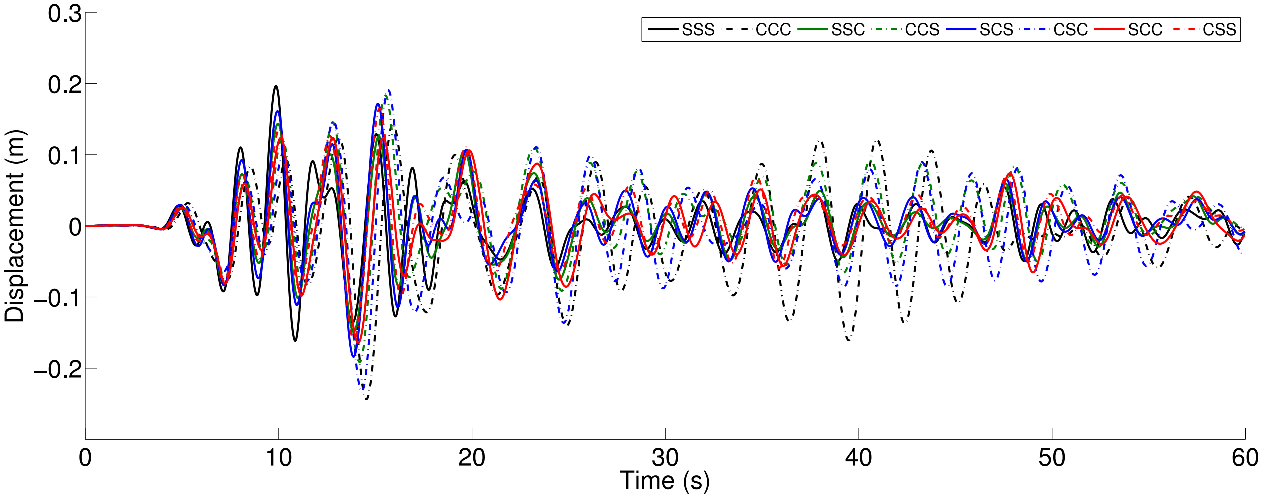

Figure 503.13: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 2)

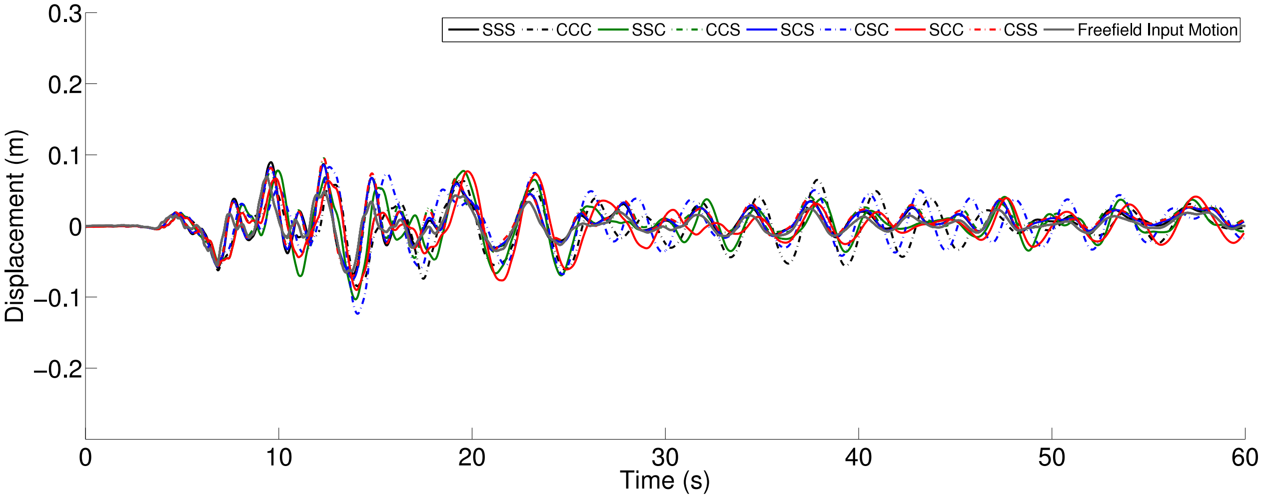

Figure 503.14: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 3)

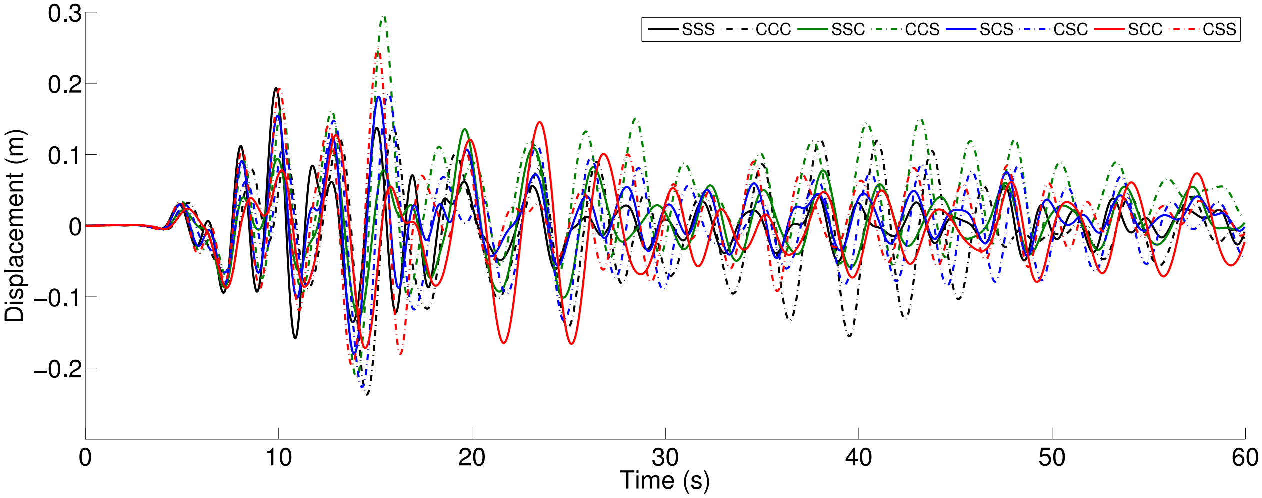

Figure 503.15: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 3)

503.2.2.3 Acceleration Response

The acceleration results are shown in this section, which also supports the observation that stiffer soil might not necessarily enhance the stability of the structure. Acceleration time series consistently show that the stiff soil will excite larger amplification for structures.

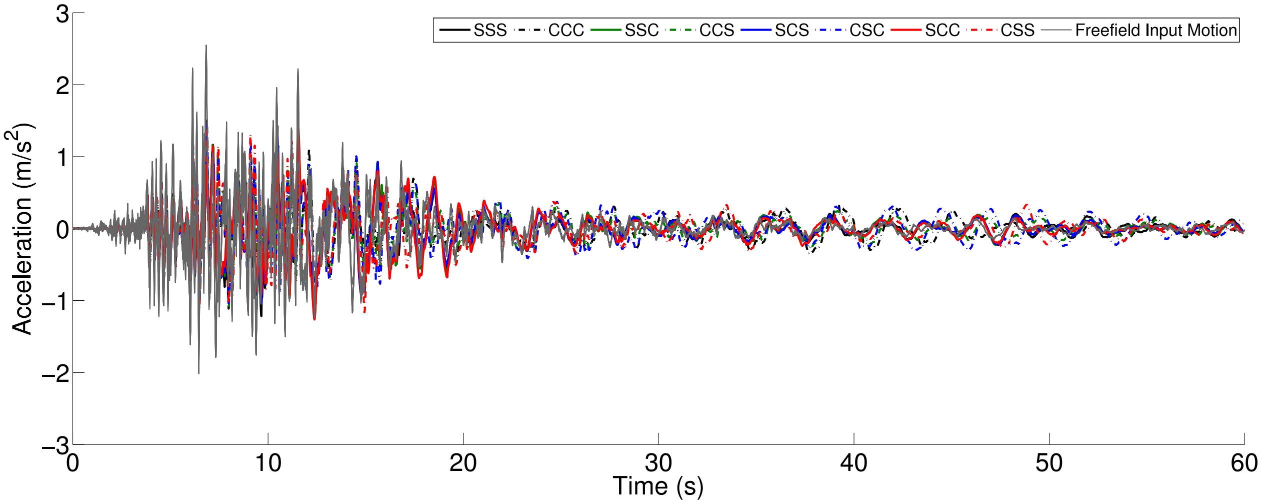

Figure 503.16: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 1)

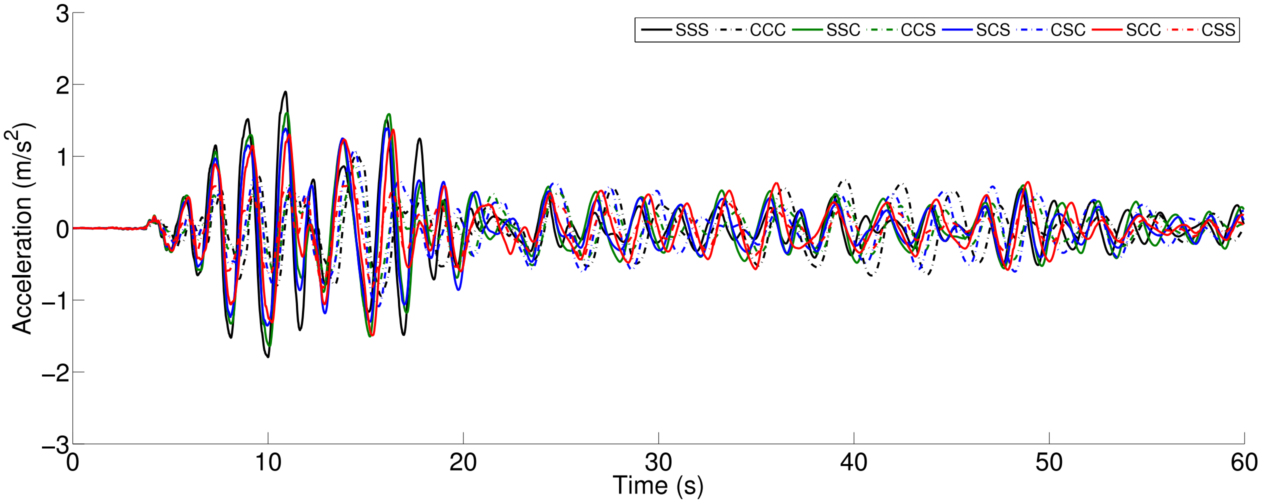

Figure 503.17: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 1)

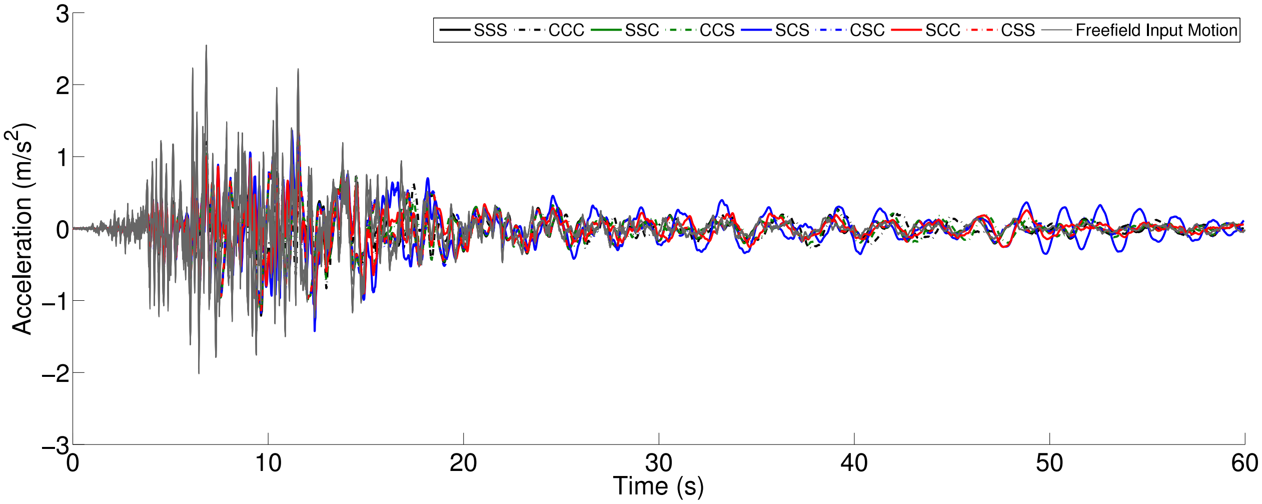

Figure 503.18: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 2)

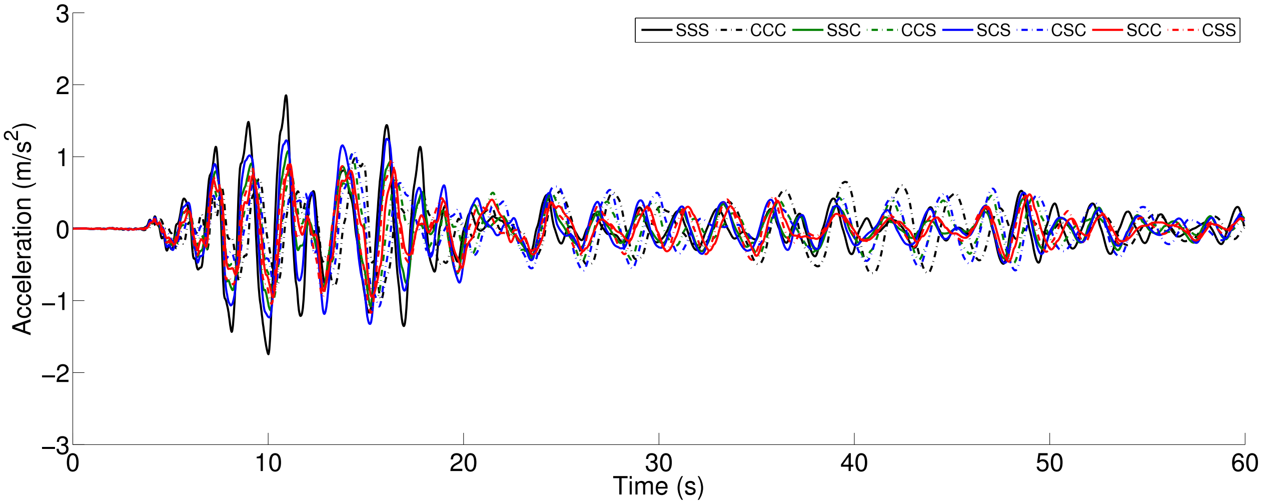

Figure 503.19: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 2)

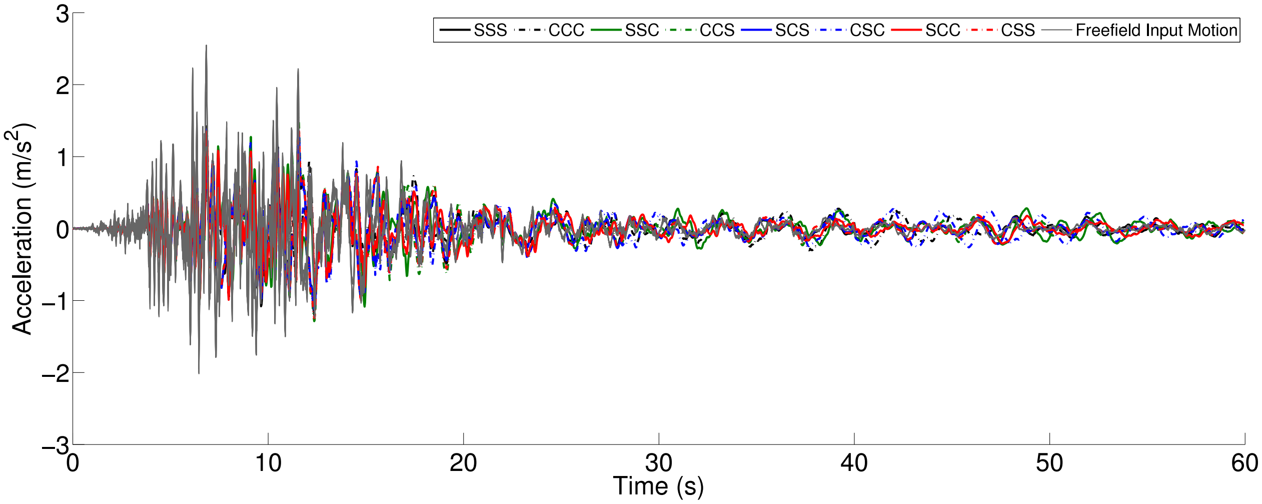

Figure 503.20: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 3)

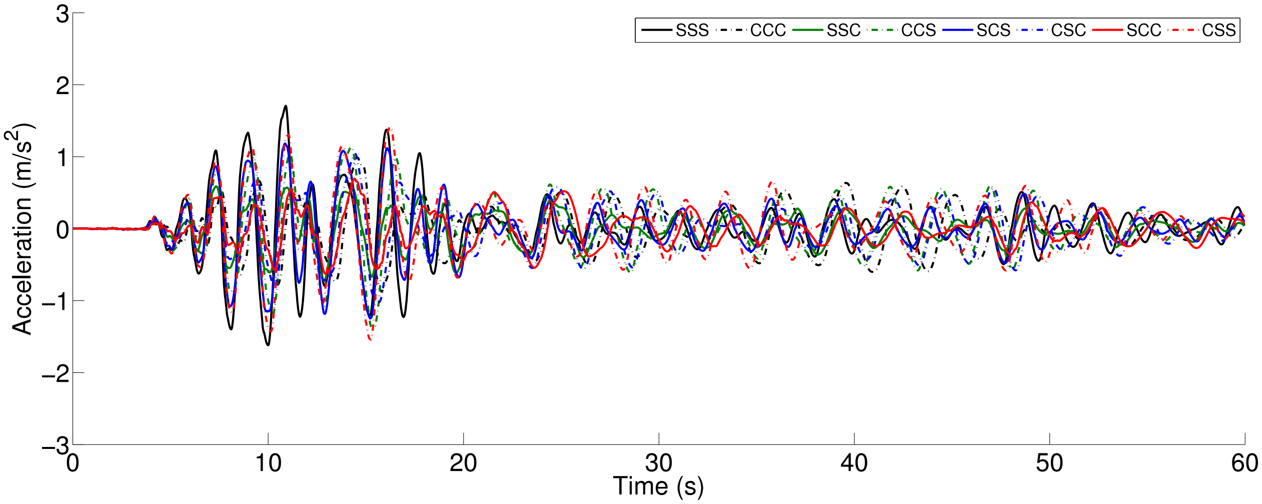

Figure 503.21: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 3)

503.2.2.4 Displacement Response Spectra

It will be very interesting to look into the frequency domain what is going on. The structure is always stiffer than underlying soils. So if the underlying soil is stronger, it implies the natural frequency of the stiff soil will be closer to the structure on top of it.

If, the input motion contains much high frequency content, it will directly excite the stiffer soil so the structure on top will receive very large amplification. This conclusion is supported by following plots.

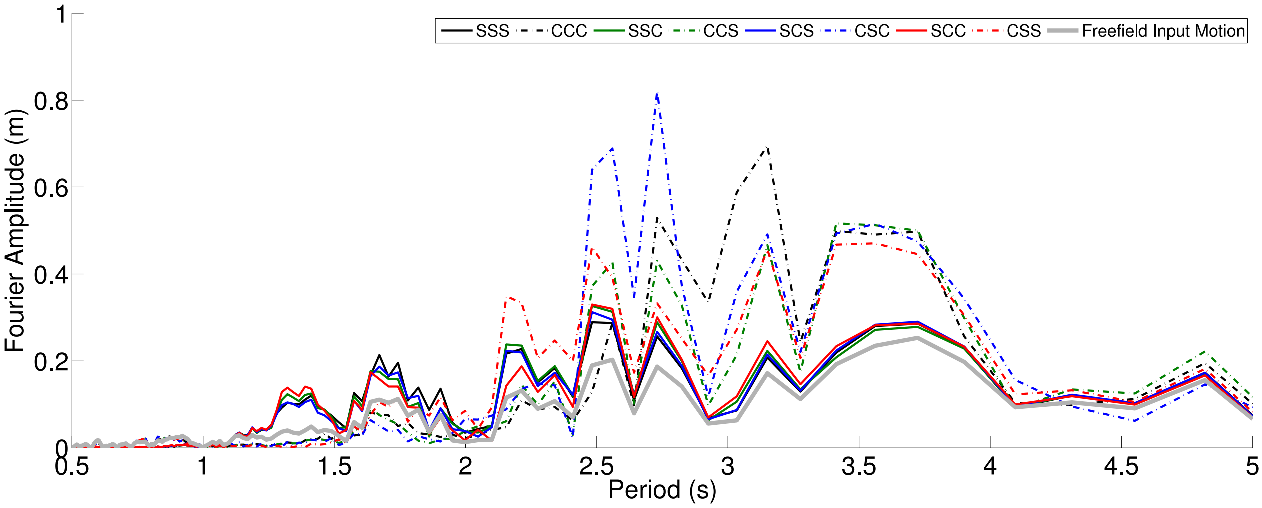

Figure 503.22: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 1)

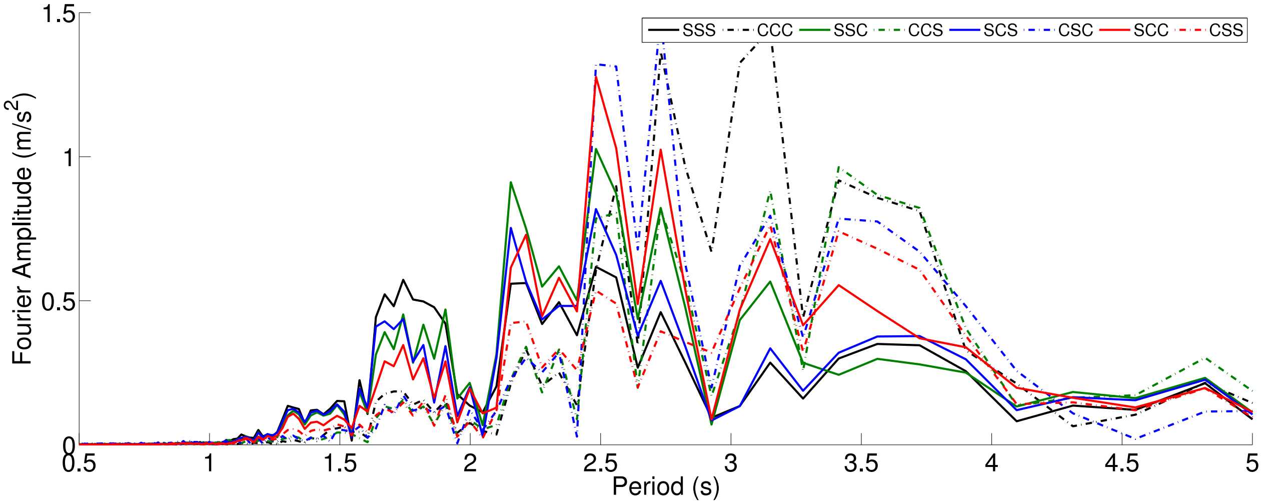

Figure 503.23: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 1)

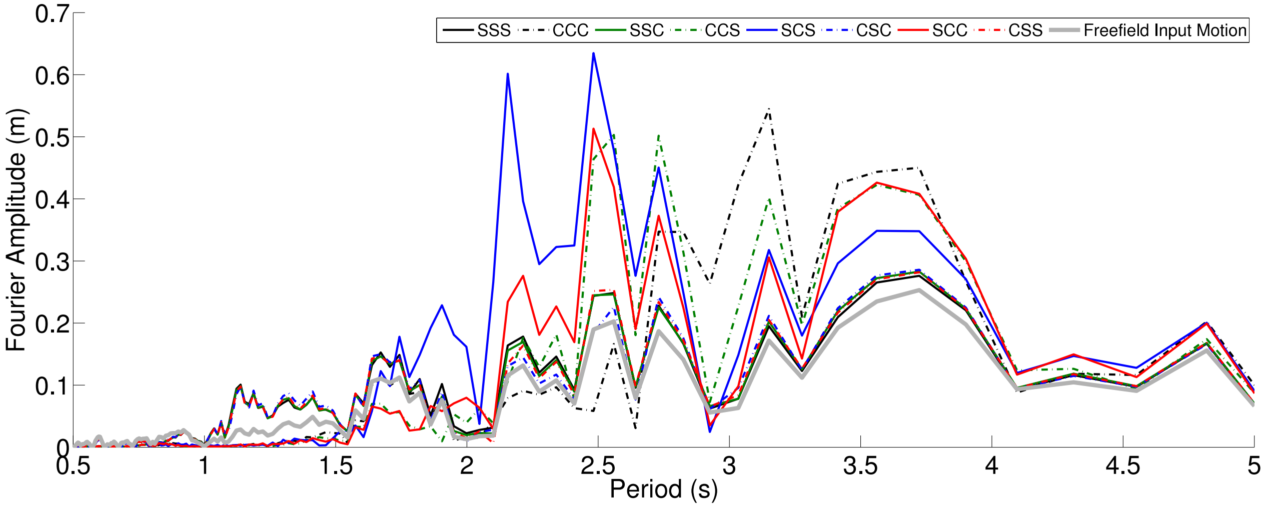

Figure 503.24: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 2)

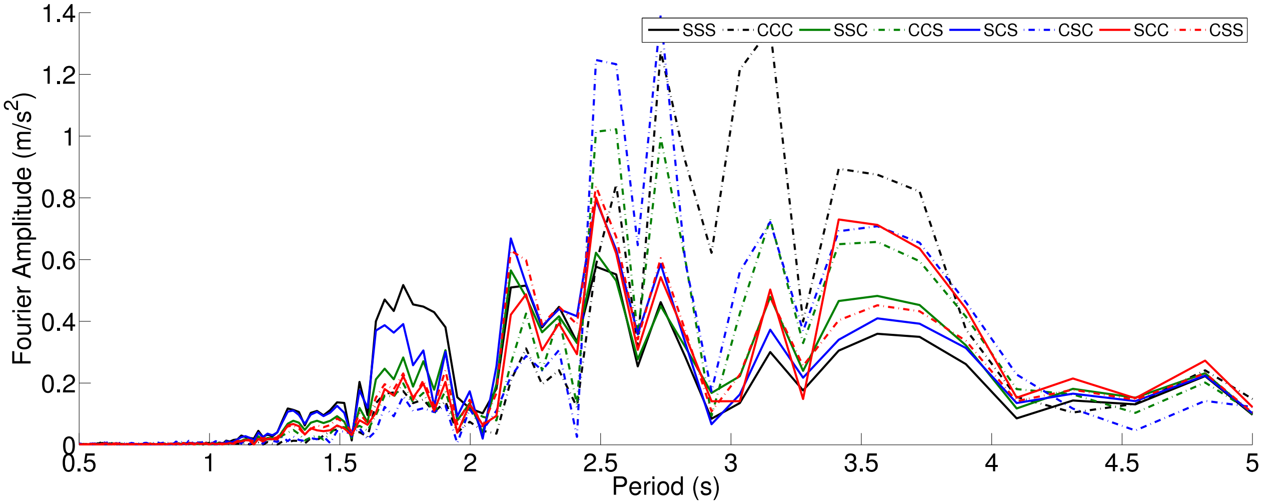

Figure 503.25: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 2)

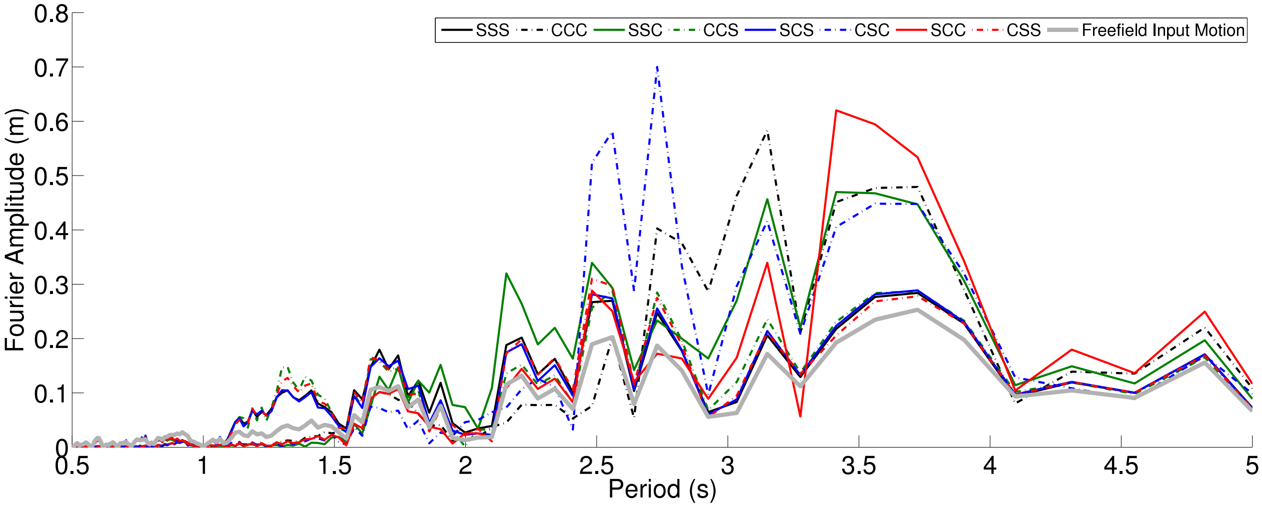

Figure 503.26: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 3)

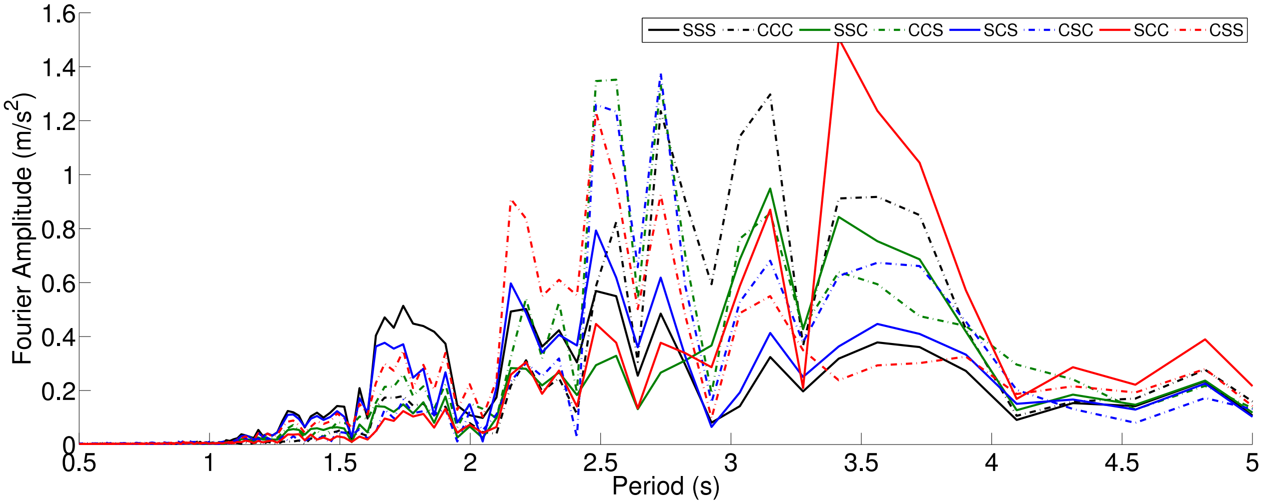

Figure 503.27: Simulated Displacement Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 3)

503.2.2.5 Acceleration Response Spectra

The acceleration spectra have also been plotted to support the observation we made before. The consistent discovery is that stiffer soil will have amplification concentrated to the lower period side. If the input motion also have lower period contents, those will amplify the response the structure can see.

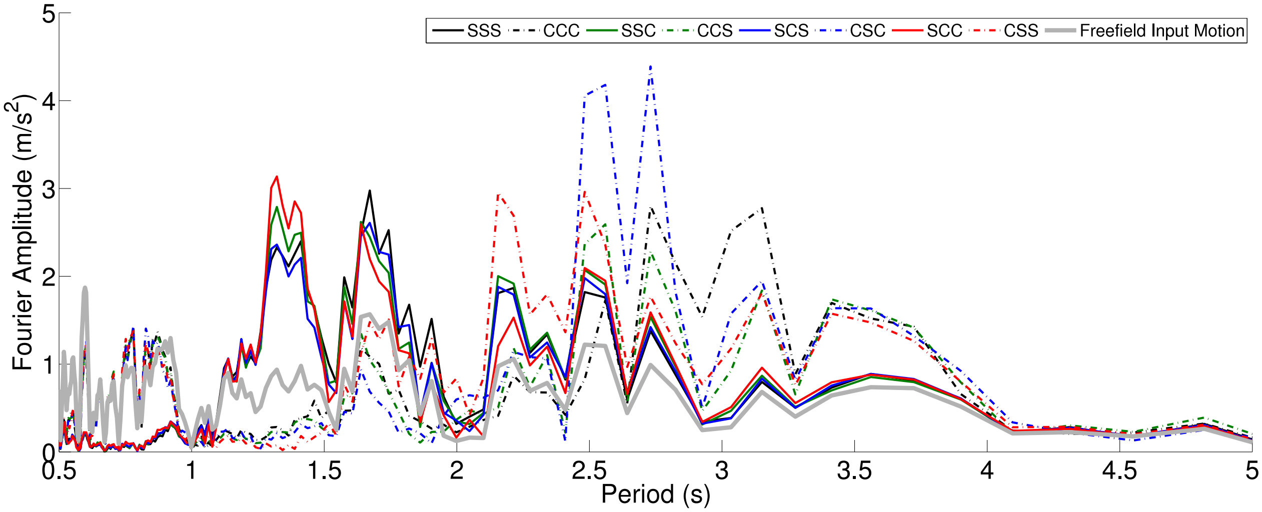

Figure 503.28: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 1)

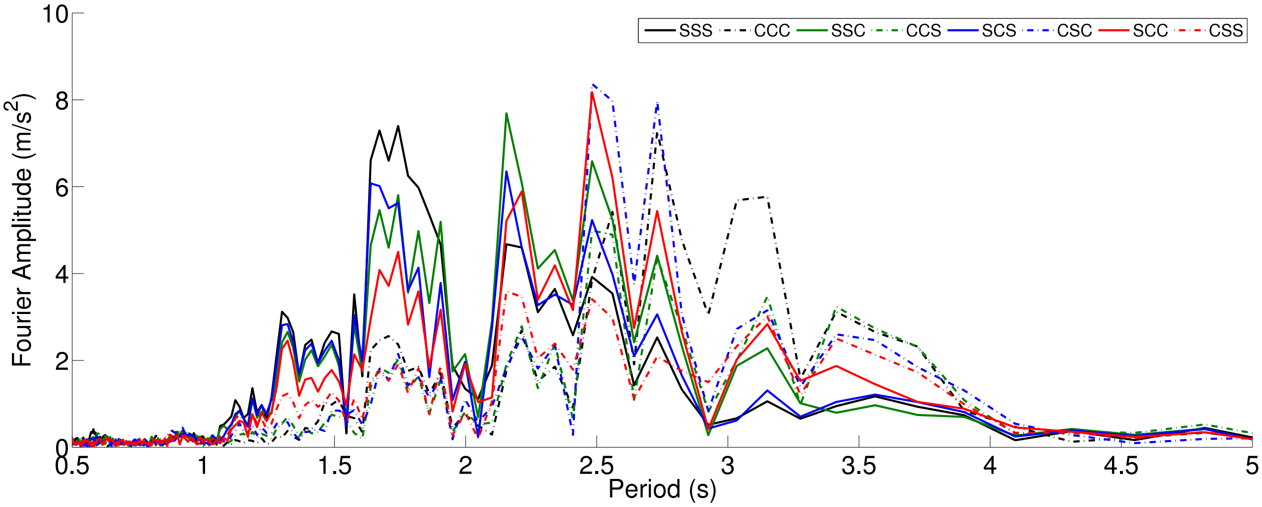

Figure 503.29: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 1)

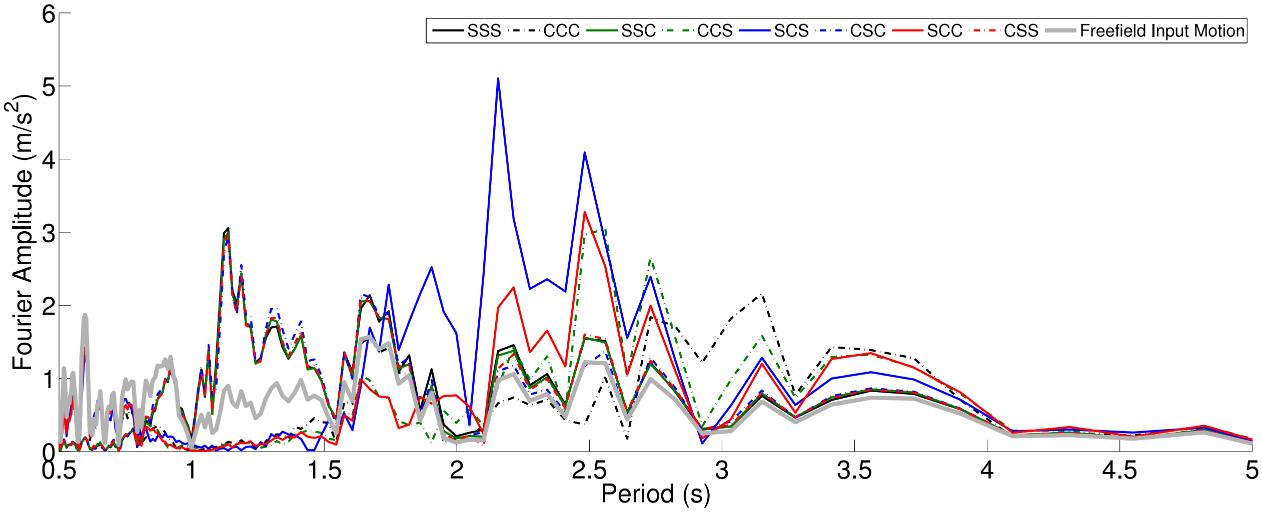

Figure 503.30: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 2)

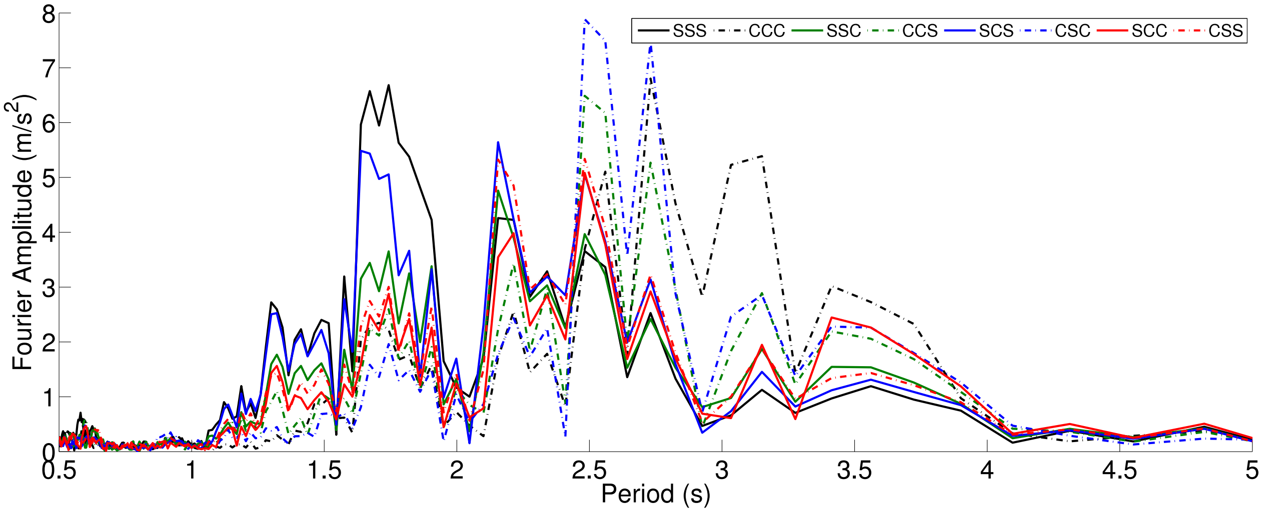

Figure 503.31: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 2)

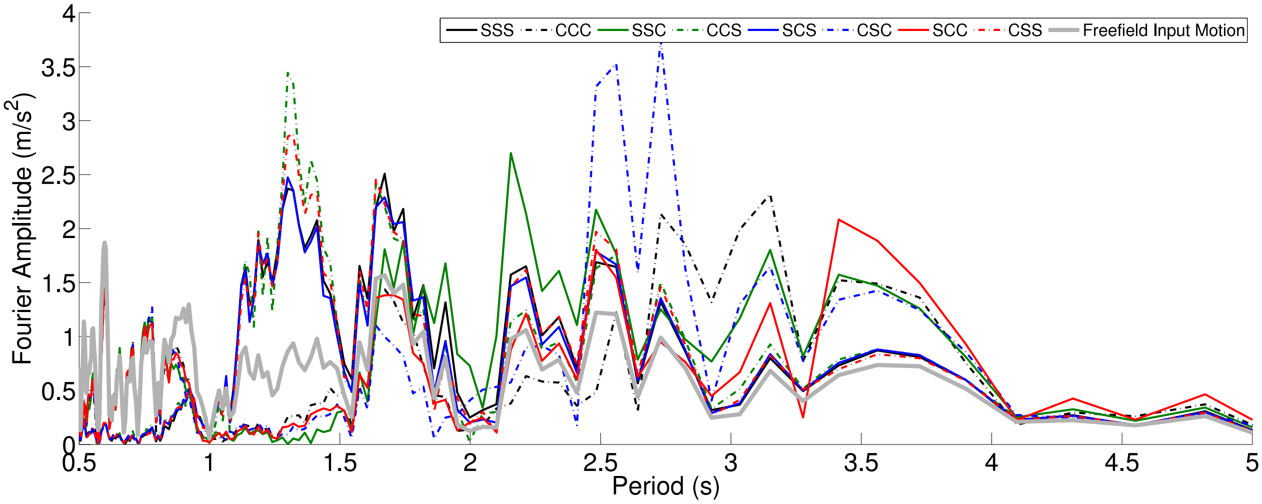

Figure 503.32: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases with Free Field Motions (Soil Block 3)

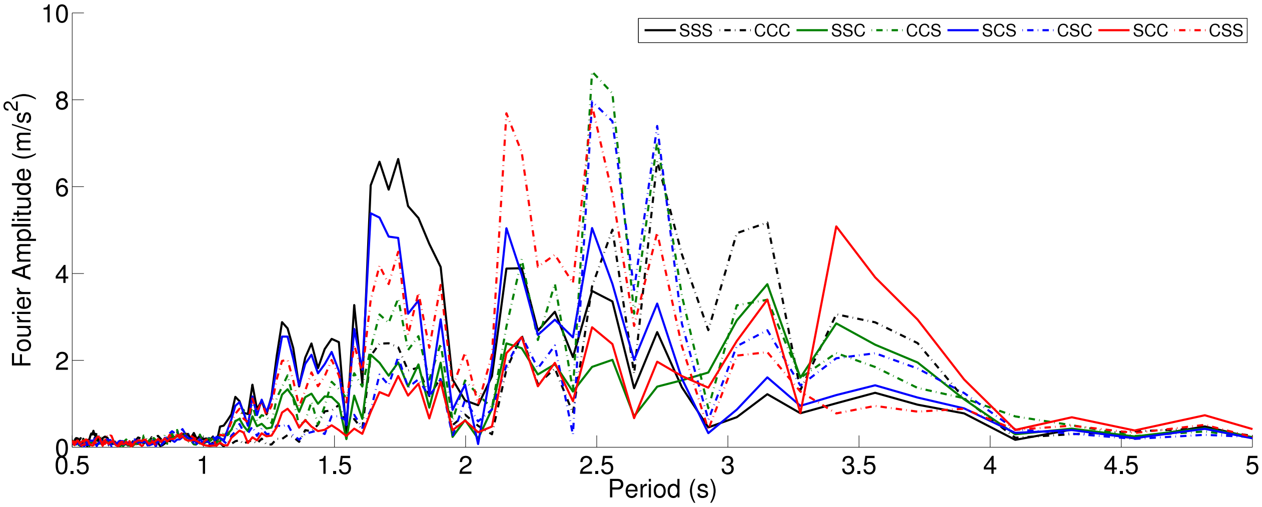

Figure 503.33: Simulated Acceleration Response Spectra, Northridge 1994, Century City, Comparison of Eight Cases (Structure Bent 3)

503.2.2.6 Structural Response

Finally we come to the point that we can see exactly how the structure responds to excitation mechanically. The moment time series shown here tells some important stories during dynamic shaking. Firstly, the structure on top of stiffer soil will yield much faster than those in soft soils. This makes perfect sense after the observations we made in previous sections. The input motion contains very similar frequency content as the stiff soil so stiff soil and the structure on top of it are excited much more than the soft-soil-structure system. Secondly, The structure on top of soft soil will see larger residual response than the stiffer soil. This exactly tells the story that the soft soil will respond much largely to the long period content of input motions which is much closer to the natural period of the soft soil.

503.2.3 Earthquake Simulations - 1999 Turkey Kocaeli

It has been well observed that the characteristics of input ground motion also affects the SFSI system response. From the perspective of soil dynamics, stiffer soil will have shorted natural period and thus higher natural frequency. One can argue that the conclusion that has been established in Section 503.2.4.1 might exactly reflect the case that for earthquake input motions containing much high frequency content, the stiff soil will always receive much stronger shaking. The 1994 Northridge earthquake has been known to contain very high frequency component as shown in Figure 503.40.

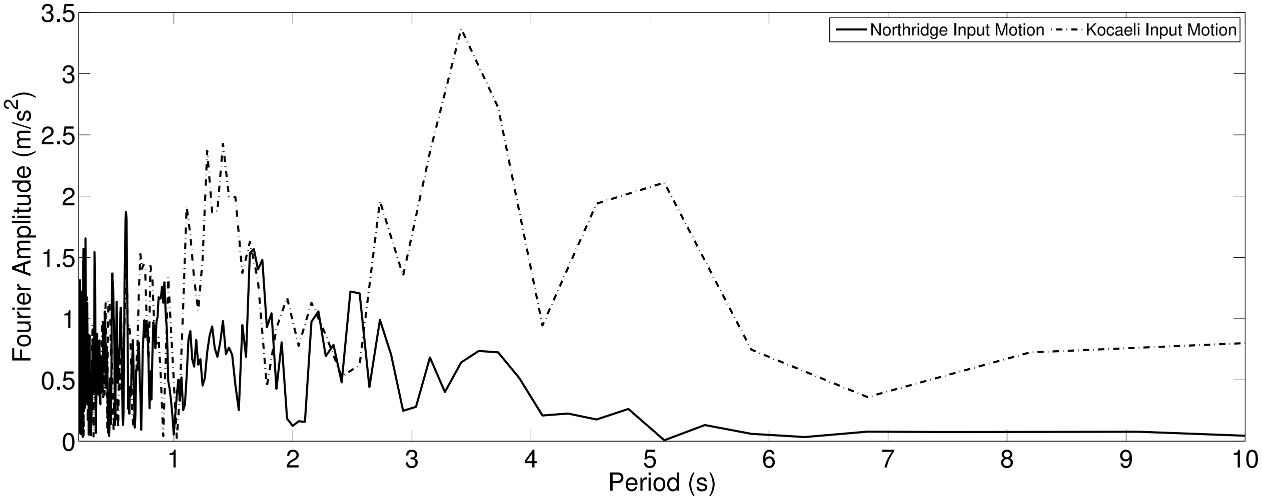

Figure 503.40: Frequency Contents of Ground Motions - Acceleration Time Series

So it will be also legitimate to question that if the ground motion has much long frequency (long period) content, the structure supported by soft soil might be the one to be exposed.

In this work, the question has been studied using the exact finite element models that we created in the previous sections.

The 1999 Turkey Kocaeli earthquake motion recorded at station Yarimca (YPT330) has been used as the target long period motion to study the SFSI behavior with different soil profiles.

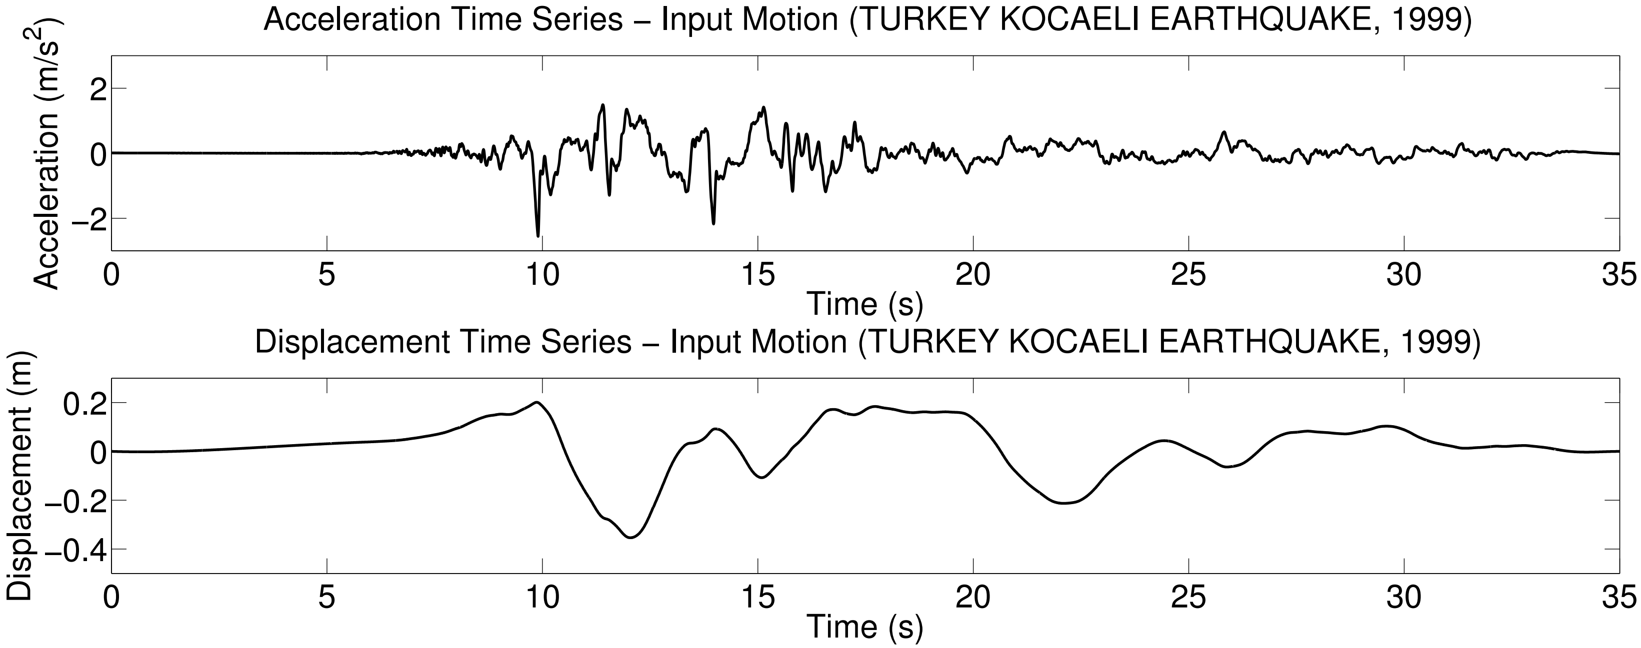

Figure 503.41: Input Motion - Turkey Kocaeli Earthquake 1999

It has been shown in this work that long period (low frequency) motion will excites stronger response from softer clay soil layers which has a lower natural frequency as opposed to the conclusion we draw before in Section 503.2.4.1.

503.2.3.1 Displacement Response

This section is designed specifically to expose the effect of input motion on SFSI system responses. From the pictures shown below, you can see that now the structure on top of soft soil will show much larger response from the shaking. The story behind is obvious to explain. Now the input motion from Turkey Kocaeli earthquake contains primary long period content, which is similar to the natural frequency content of the soft soil. During shaking, this underlying resonance excites the response of the whole SFSI to a larger degree. While on the other hand, the stiff soil now is further away from the primary frequency of the input motion. The consequence is that now the stiff soil will not see much excitation, neither will the structure on top of it.

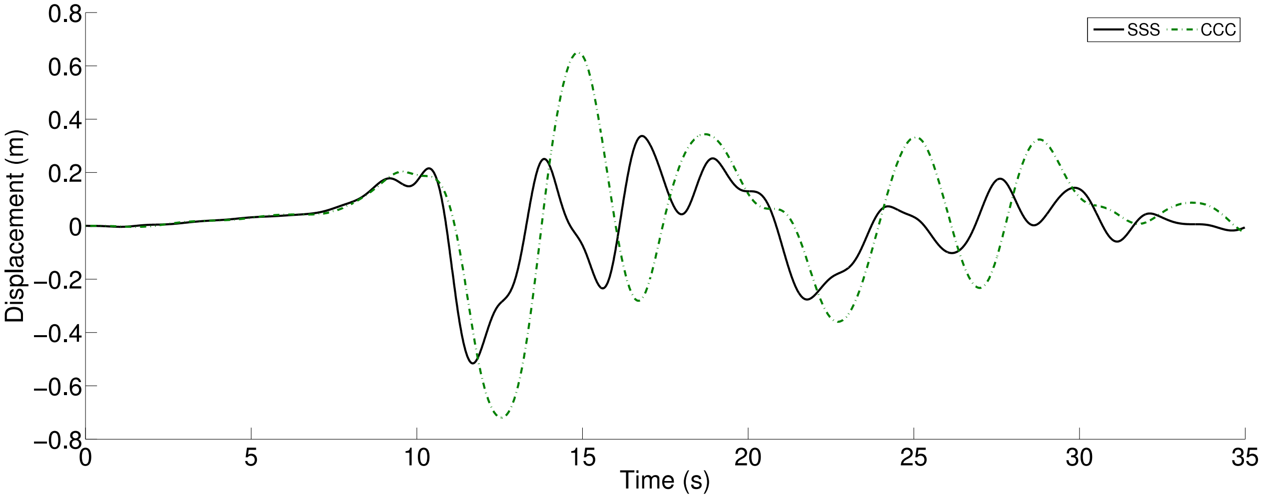

Figure 503.43: Simulated Displacement Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 1)

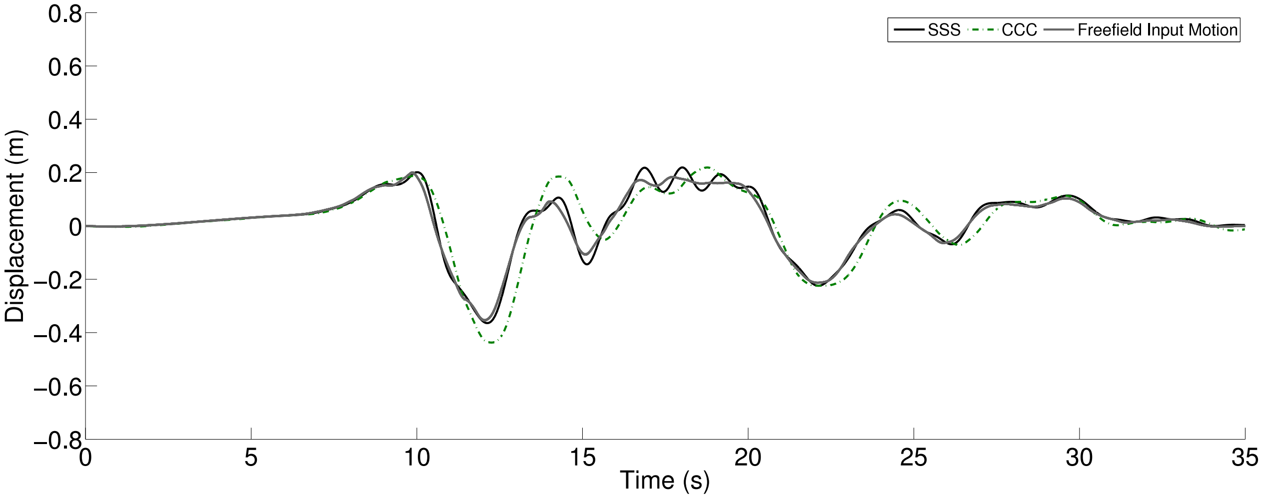

Figure 503.44: Simulated Displacement Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 2)

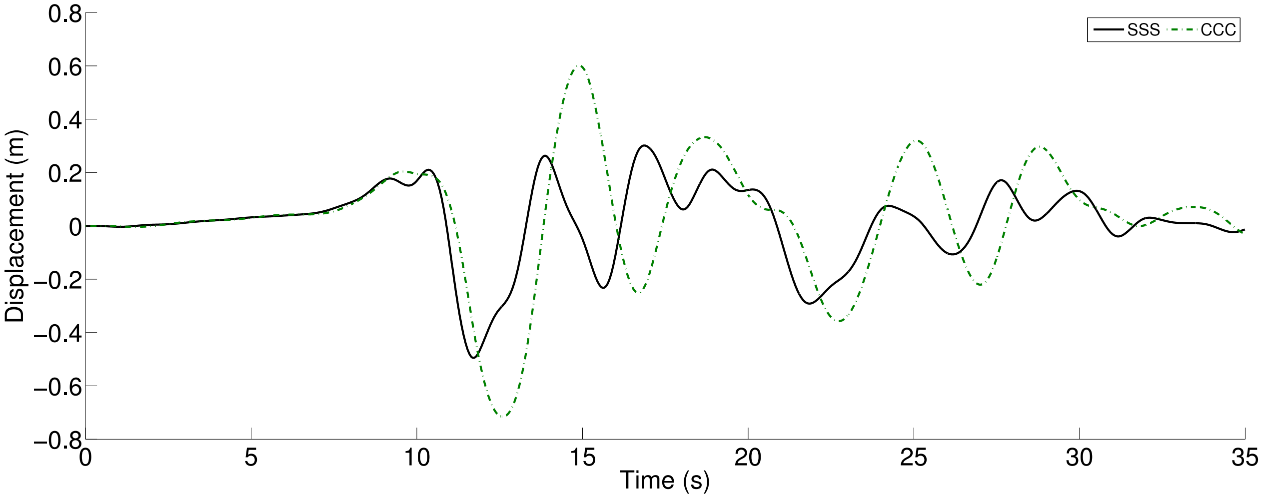

Figure 503.45: Simulated Displacement Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 2)

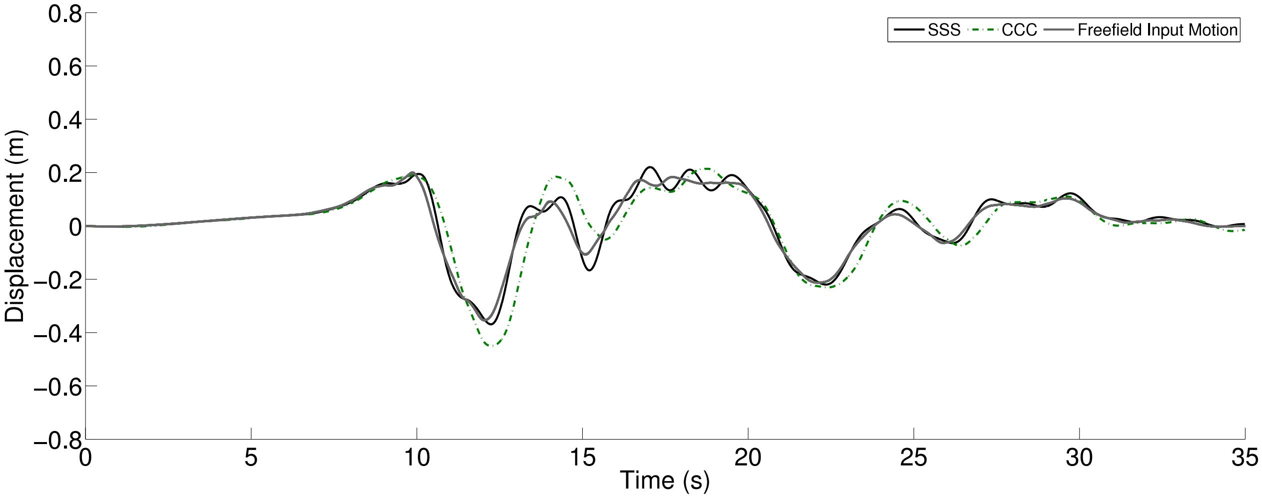

Figure 503.46: Simulated Displacement Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 3)

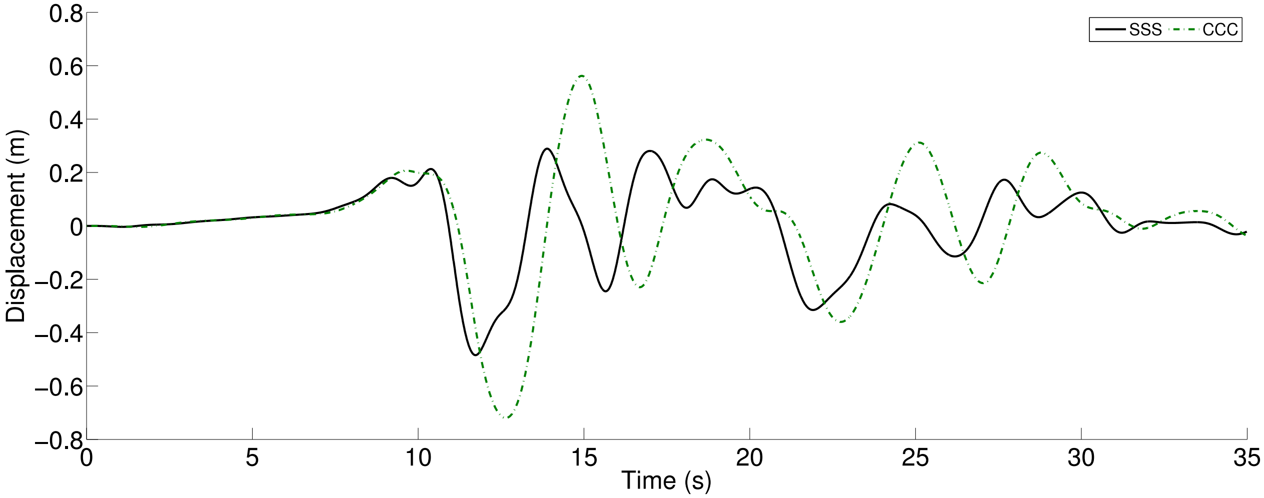

Figure 503.47: Simulated Displacement Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 3)

503.2.3.2 Acceleration Response

Acceleration plots might not show as clearly as those in displacement plots due to the reason that acceleration is derivative of displacement, so acceleration is more responsive to higher frequency contents than lower frequency contents. This effect actually can be observed from any recorded displacement and acceleration spectra records. The acceleration spectra will shift to the low period or high frequency side. This observation will be further explained in later sections when we discuss the moment time series.

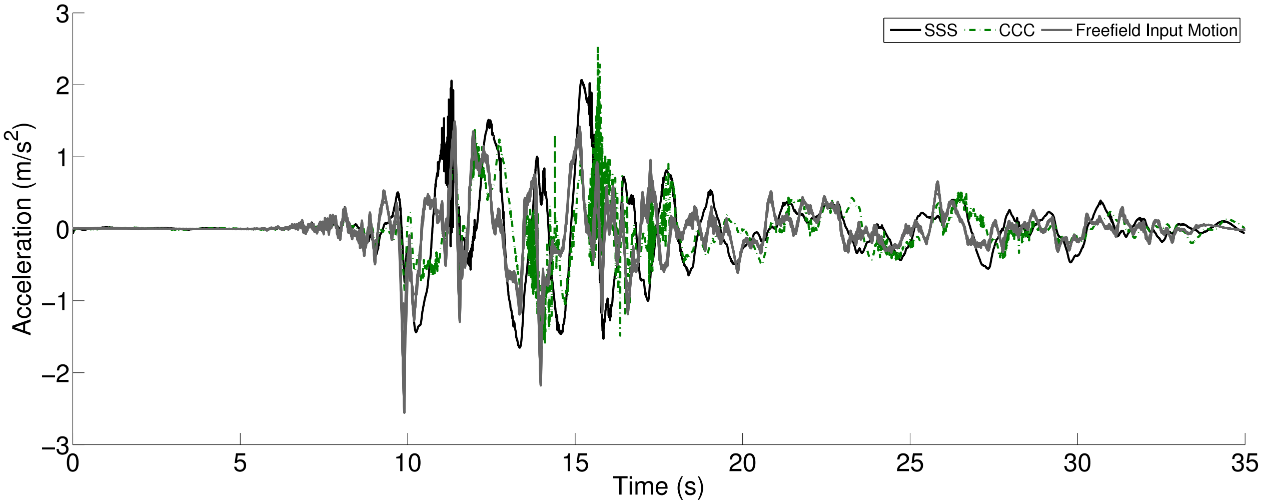

Figure 503.48: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 1)

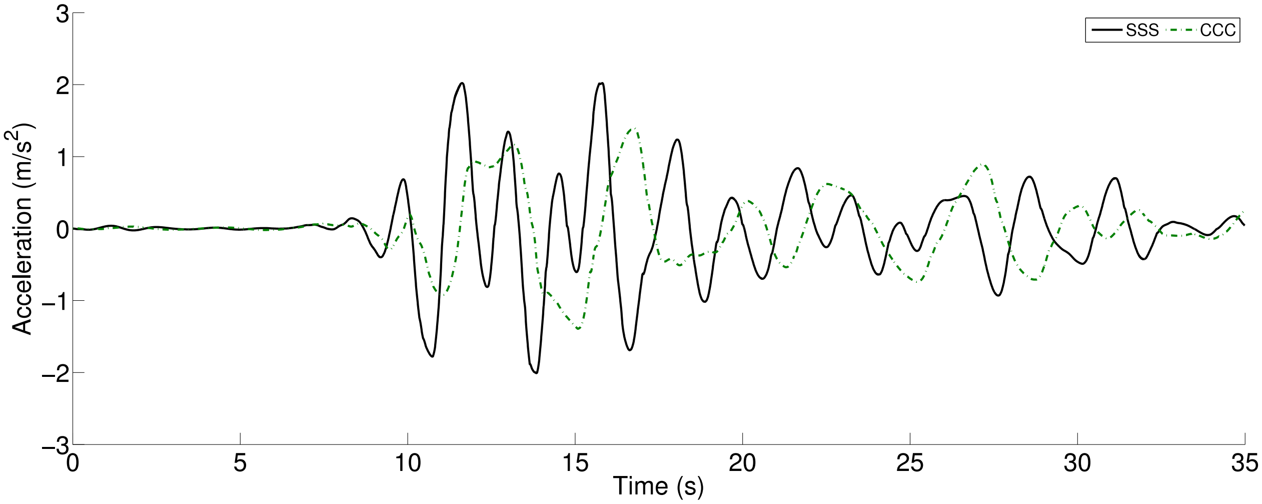

Figure 503.49: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 1)

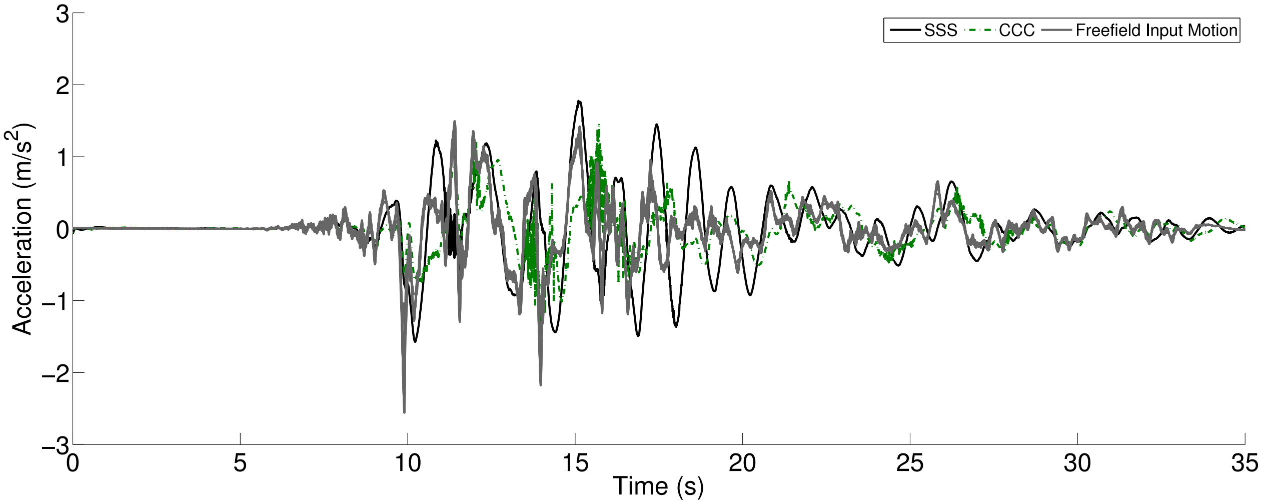

Figure 503.50: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 2)

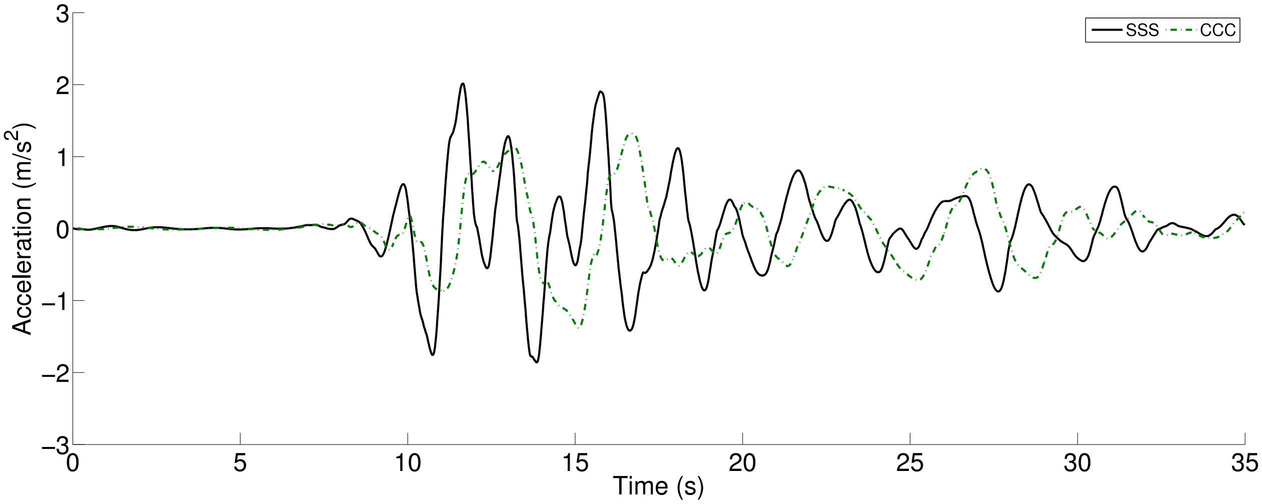

Figure 503.51: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 2)

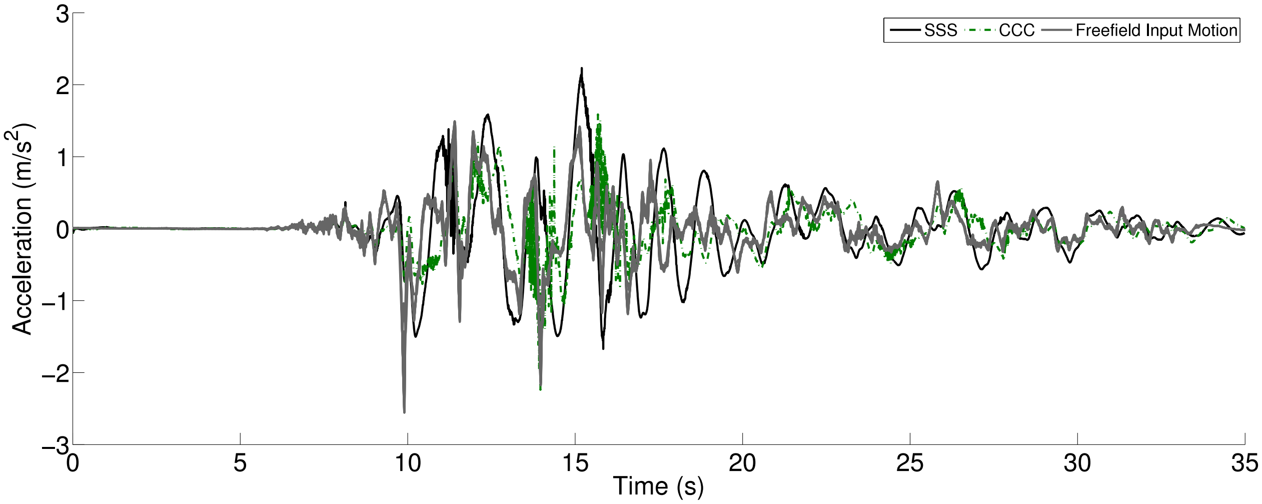

Figure 503.52: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 3)

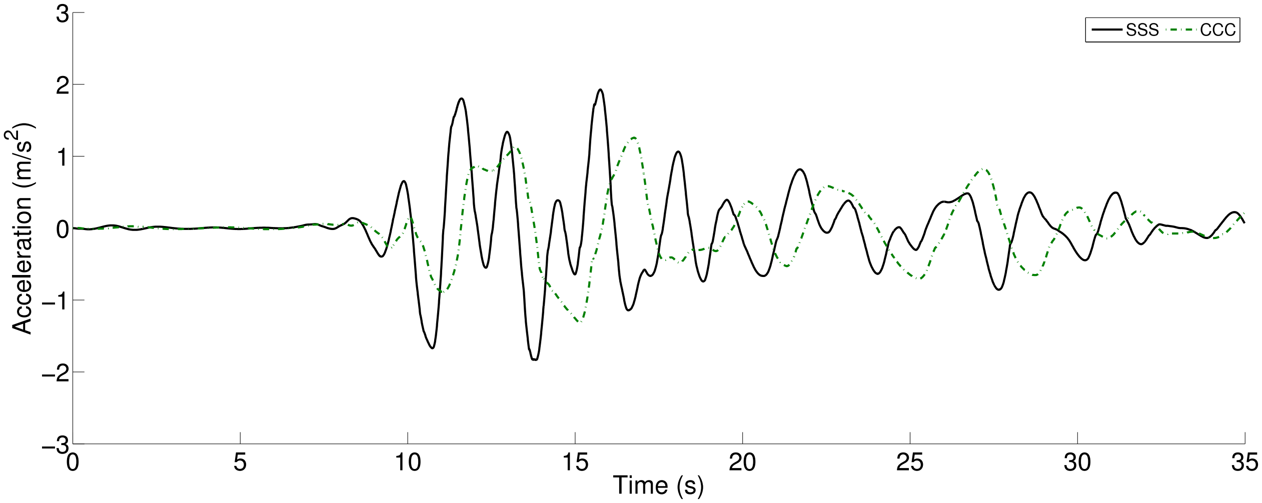

Figure 503.53: Simulated Acceleration Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 3)

503.2.3.3 Displacement Response Spectra

The response spectra are useful tools to look deep into the frequency domain. As we explained before, the Turkey Kocaeli shaking was picked for this study because it contains much longer period contents that were not present in the 1999 Northridge earthquake. In this section, we can clearly see how the soil foundation can affect the structures on top of it. Firstly, structures supported by stiff soil will only see amplification from those low period, high frequency components. Correspondingly, structures supported by soft soil tend to respond much more to long period, low frequency components of the shaking motion. Secondly, this plots exactly show how important the SFSI analysis is. It will not make much sense if one wants to analyze the structure without acknowledging the characteristics of the underlying soil foudation and the input motion. How the structure behaves is the combination of answers to many questions such as the stiffness of soil and the frequency contents of the motions.

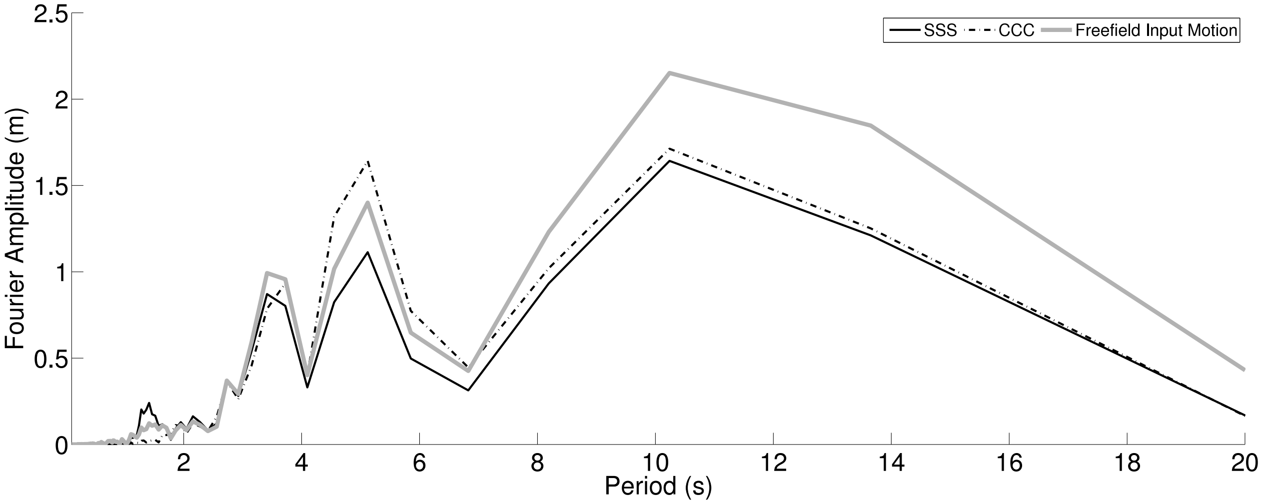

Figure 503.54: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 1)

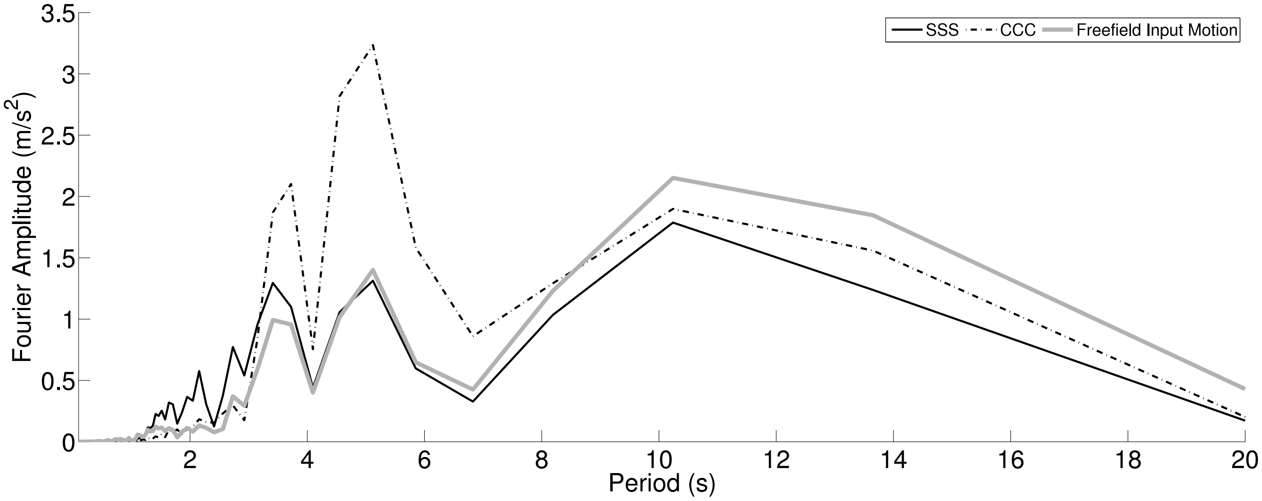

Figure 503.55: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 1)

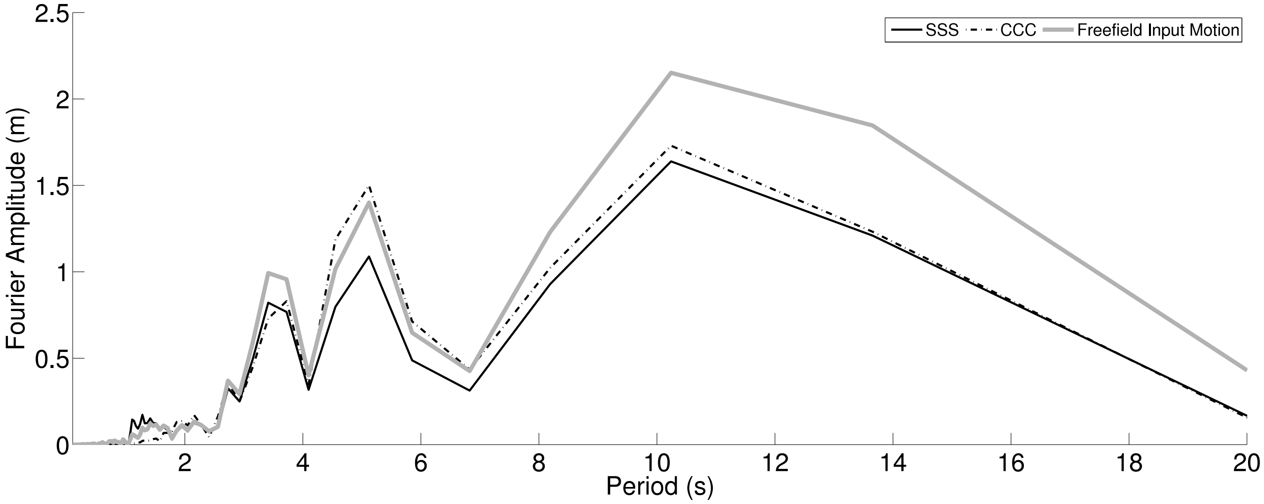

Figure 503.56: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 2)

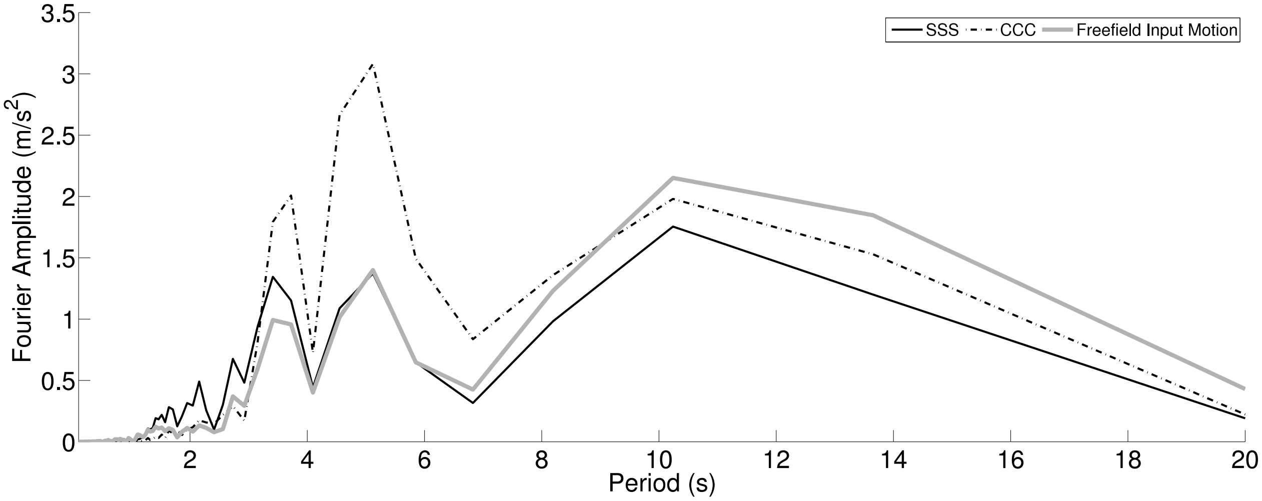

Figure 503.57: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 2)

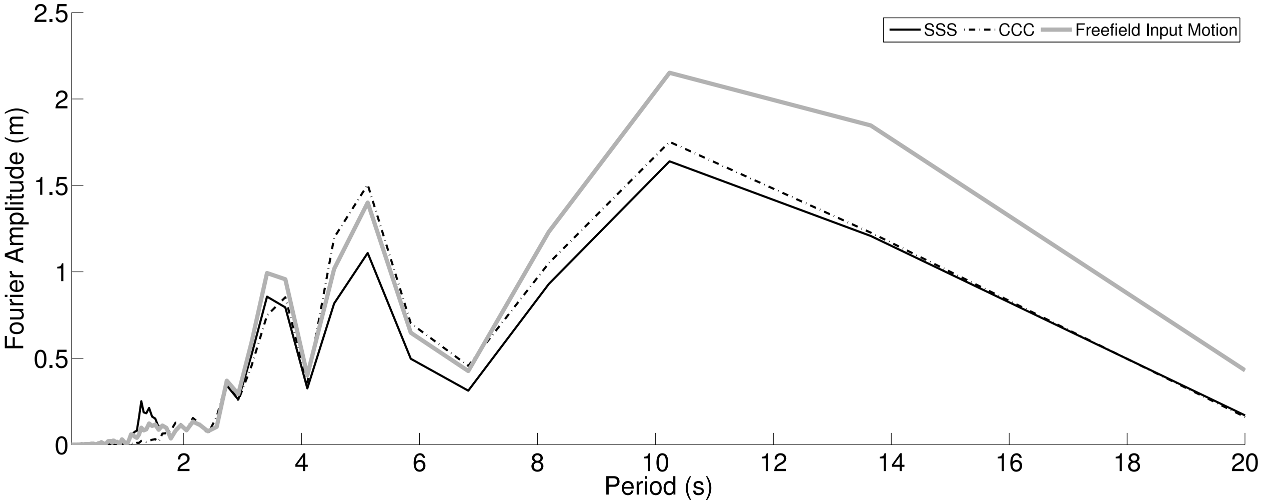

Figure 503.58: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 3)

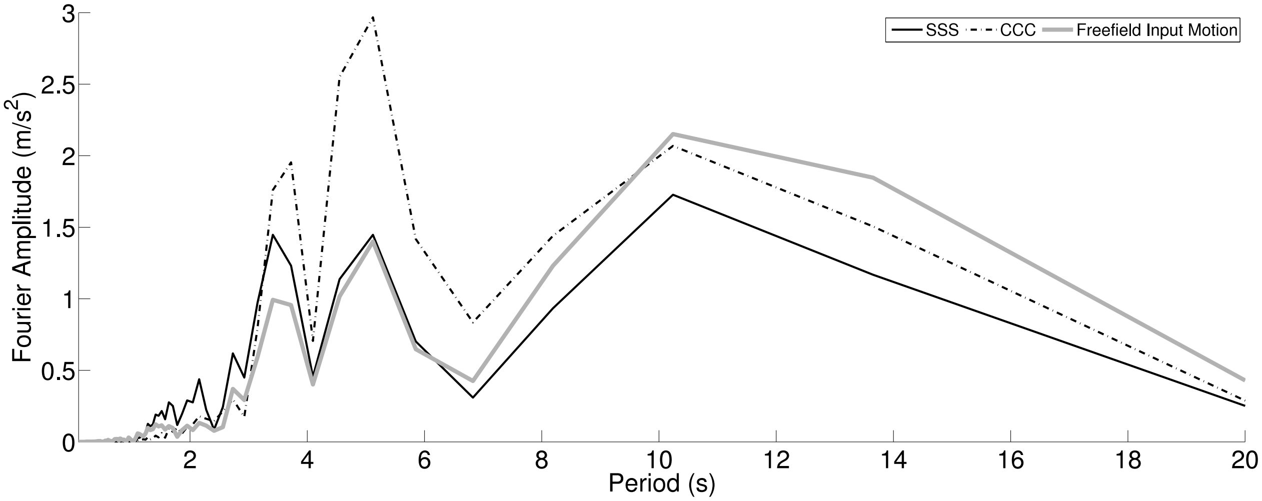

Figure 503.59: Simulated Displacement Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 3)

503.2.3.4 Acceleration Response Spectra

As we discussed before, the acceleration response shows much focused content to the high frequency (low period) side as acceleration is the derivative of displacement. But it is still clearly shows the difference between the structures supported by stiff soil and those supported by soft soil. SFSI is crucial in the sense that the structure response must be determined by both short period and long period components. The overall response is determined by the primary periods of both underlying soil and the input motion.

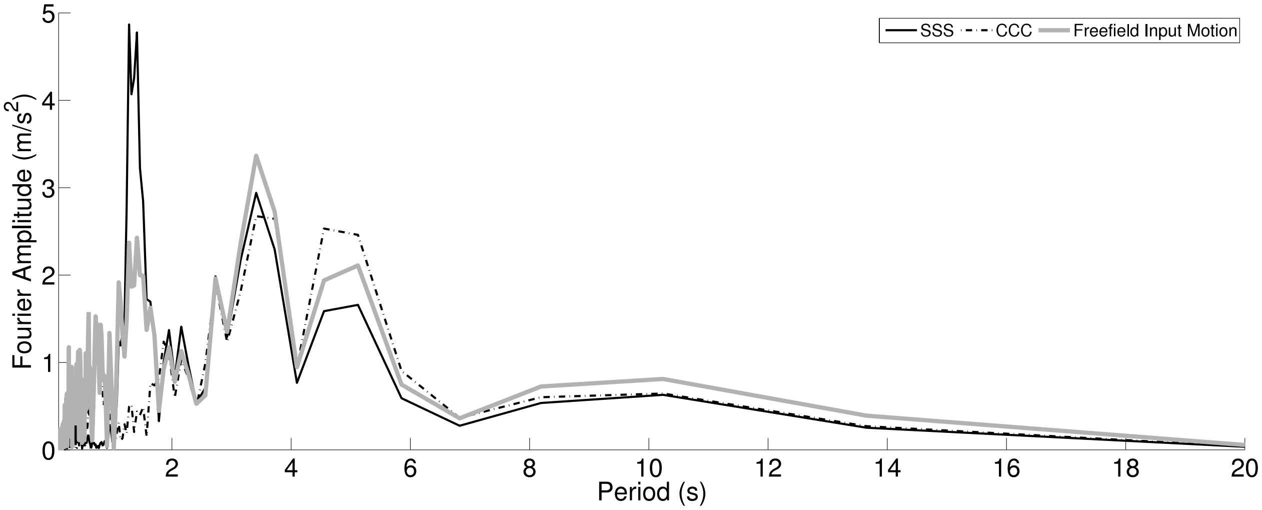

Figure 503.60: Simulated Acceleration Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases with Free Field Motions (Soil Block 1)

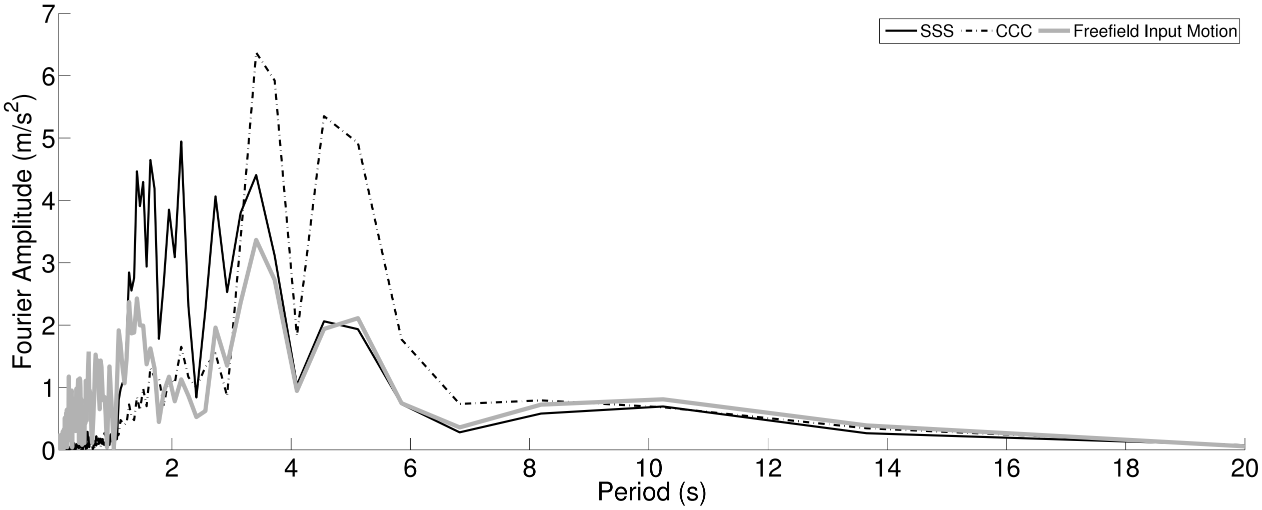

Figure 503.61: Simulated Acceleration Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 1)

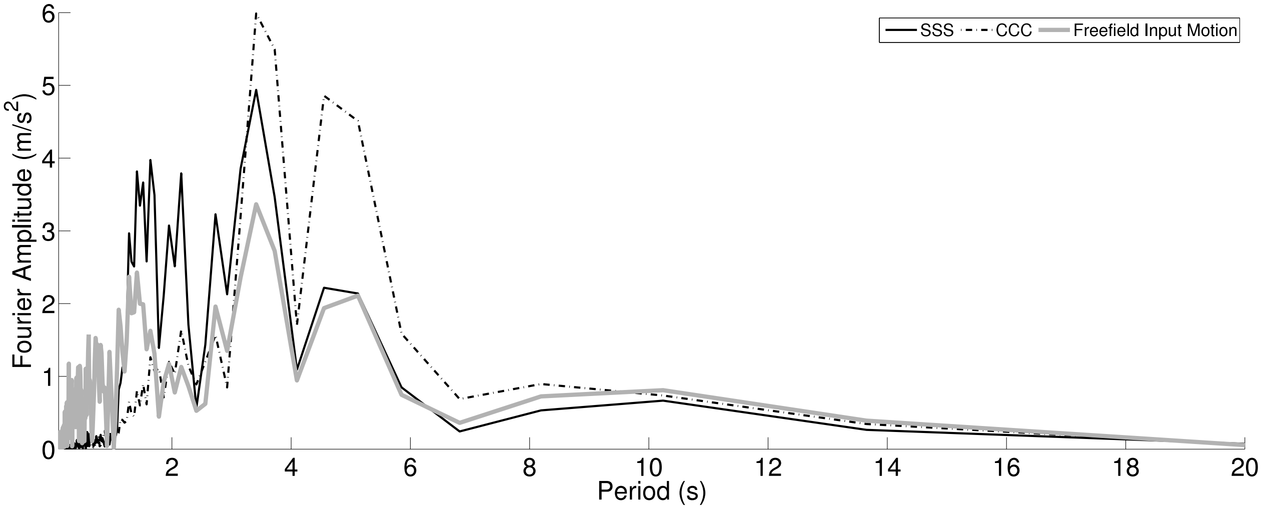

Figure 503.65: Simulated Acceleration Response Spectra, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 3)

503.2.3.5 Structural Response

The structure response now directly shows how differently the structure can react to the same input motion, given different soil conditions. We can again see the structure on top of soft soil exhibits much response to long period content especially for the fact that the structure on top of the soft soil reaches maximum moment for about 3 seconds, which is not present in the stiff soil case. This is also consistent with the observation that the displacement of the structure supported by soft soil is much larger due to the much longer time for plastic slip when the plastic moment is reached.

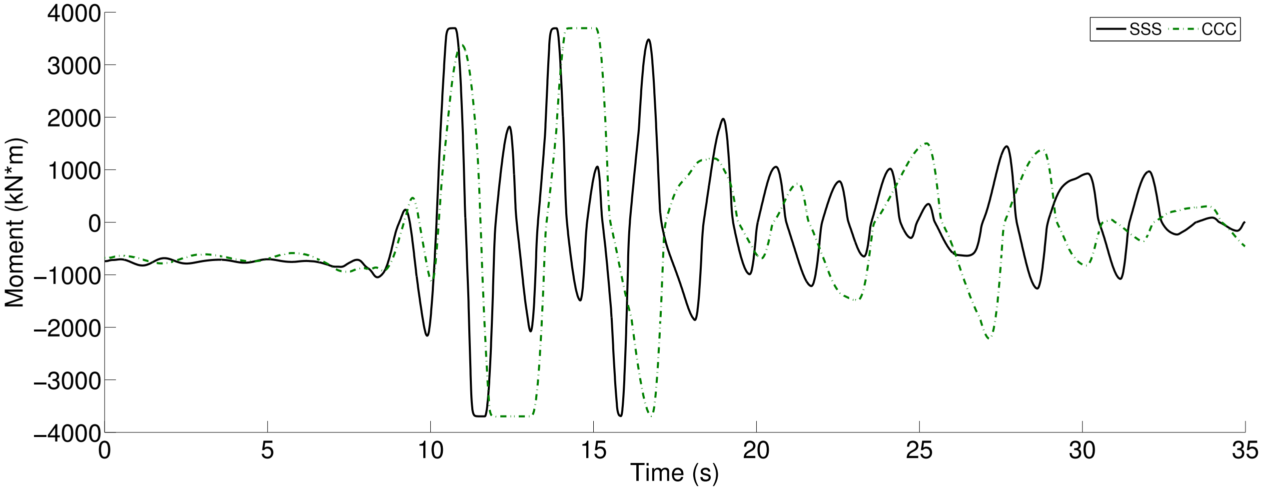

Figure 503.66: Simulated Maximum Moment Time Series, Turkey Kocaeli 1999, Yarimca, Comparison of Two Cases (Structure Bent 1 Pile 1)

503.2.4 Earthquake Soil Structure Interaction Effects

In the following sections we analyze various Earthquake Soil Structure Interaction (ESSI) effects.

503.2.4.1 How Strength of Soil Foundations Affects ESSI

It has been well known that stiffer soil layer will provide higher bearing capacity of structures so site improvements will always be preferred in engineering practice when one talks about foundation design.

While for dynamic cases, this widely-held impression will not be valid anymore. In order to see how stiffness of soil can affect the response of the whole ESSI system during earthquake shaking, two distinct scenarios listed in Table 503.5, Case 1 with all stiff soil foundations, and Case 8 with all soft soil foundations have been extracted to show the dynamic system response.

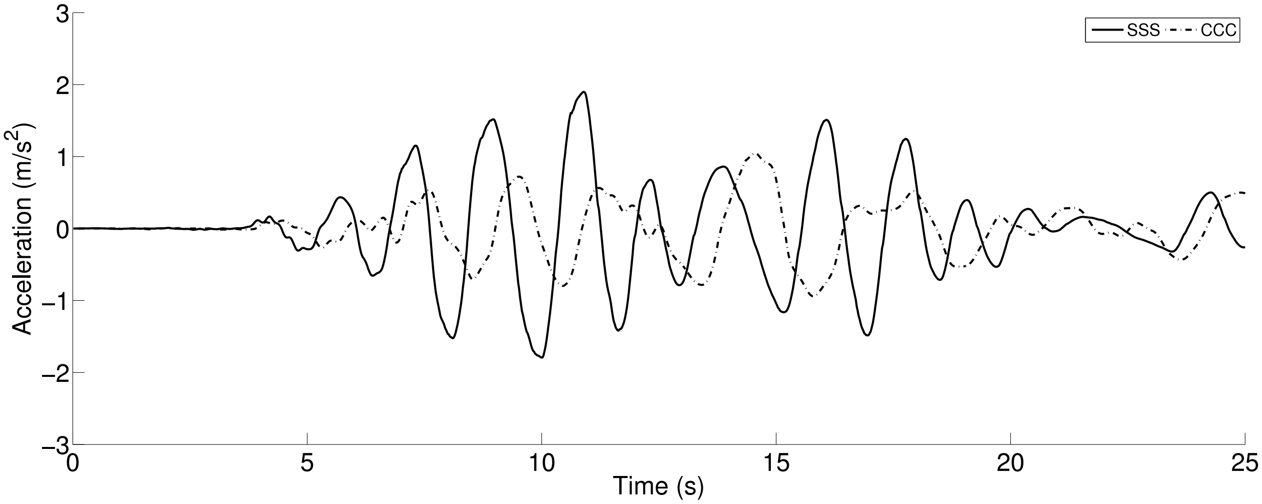

Figure 503.72: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 1)

Case 1 and Case 8

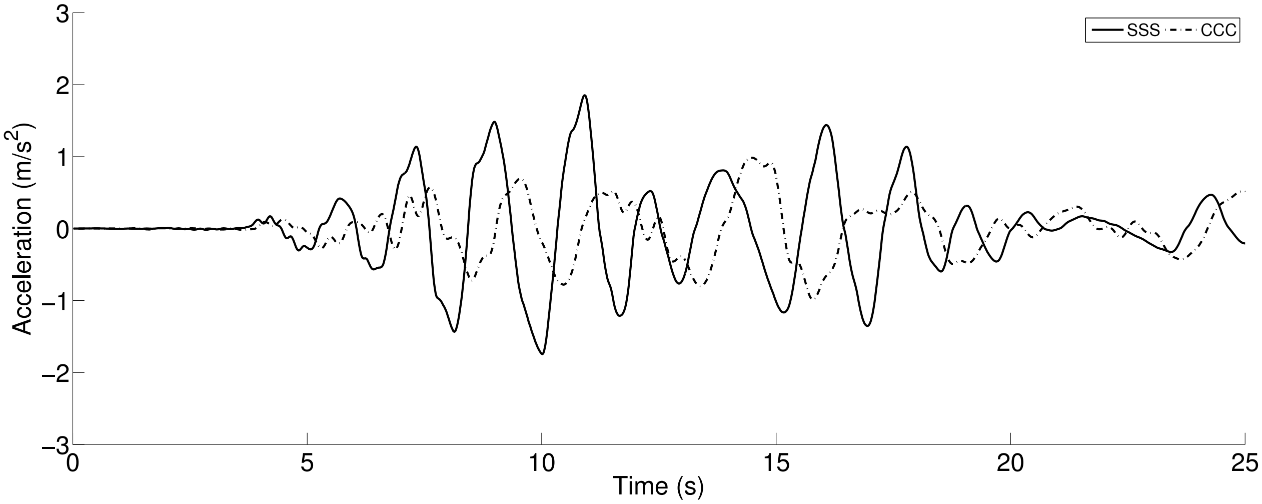

Figure 503.73: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 2)

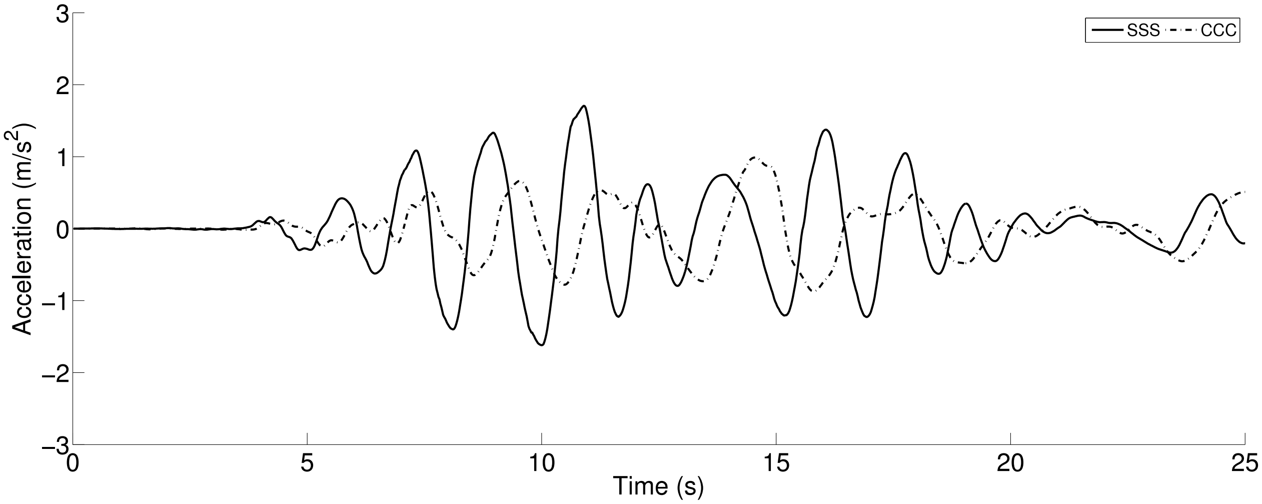

Figure 503.74: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 3)

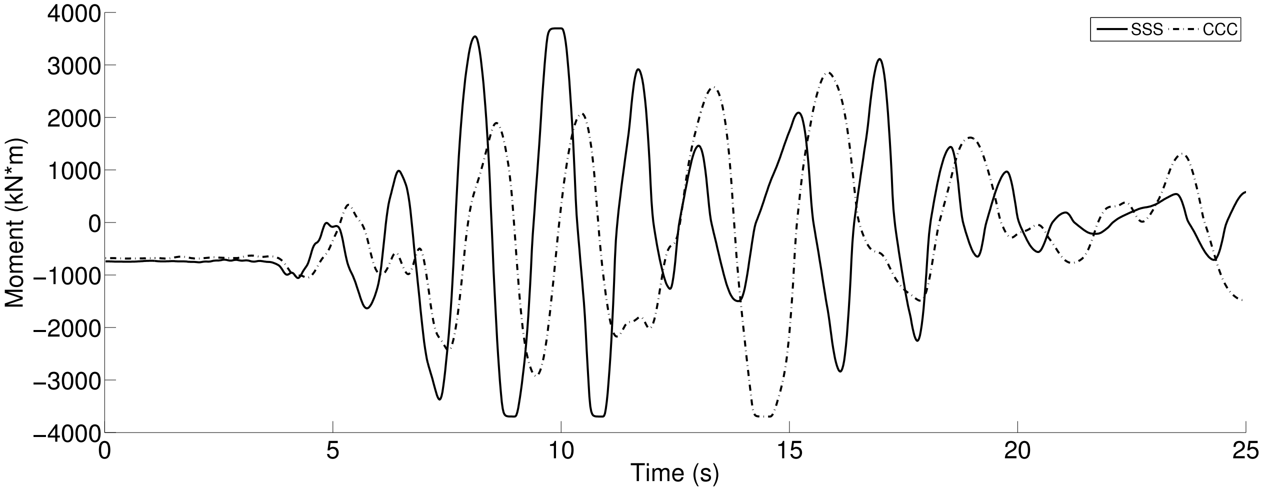

Figure 503.75: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 1)

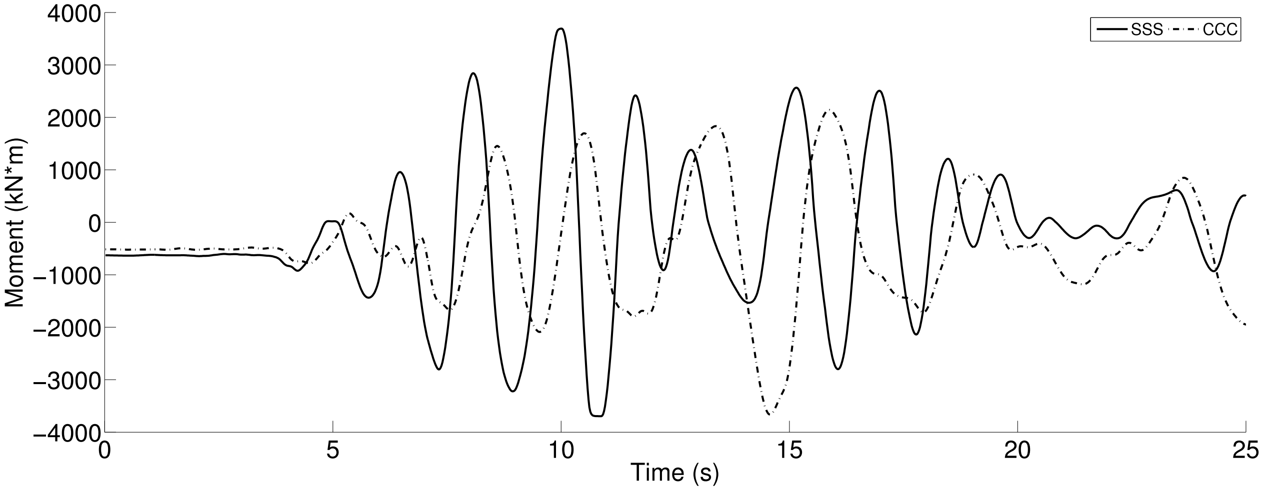

Figure 503.76: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 2)

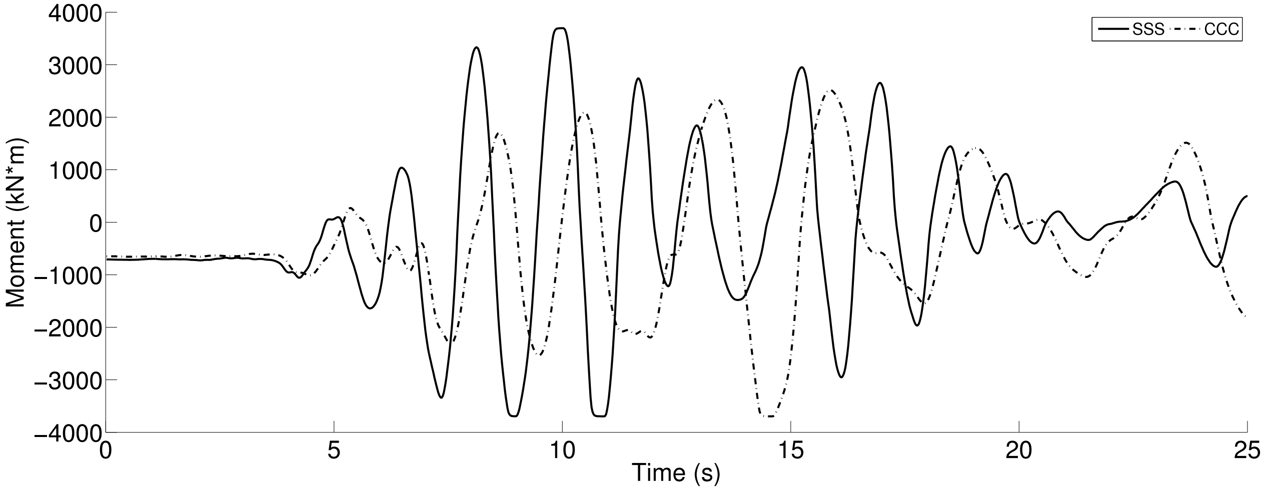

Figure 503.77: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Structure Bent 3)

It has been shown in this research that if the soil layer is stiffer, structures will see much more amplification from earthquake shaking. Figures 503.72 to 503.74 show the acceleration response from ESSI systems with stiff sand and soft clay, which clearly shows that stiff sand delivers much stronger energy input to superstructures. The superstructures on top of stiffer soil also yield sooner than softer soil layers as shown in maximum moment time series Figures 503.75 to 503.77. This observation proves one interesting point that in order to improve structural stability, site improvement is not necessarily improving the dynamic resistance of the ESSI system. In later section of this work, further observation will be made to correlate this conclusion with the characteristics of the input motion.

As for the soil side, near-structure soil motion will be also affected by ESSI. So the traditional way of assuming that recorded ground motion can be used as input motion to ESSI analysis should be revisited. According to Figures 503.78 503.79 503.80, we can see that stiff soil also shows stronger surface motion records during earthquake shaking.

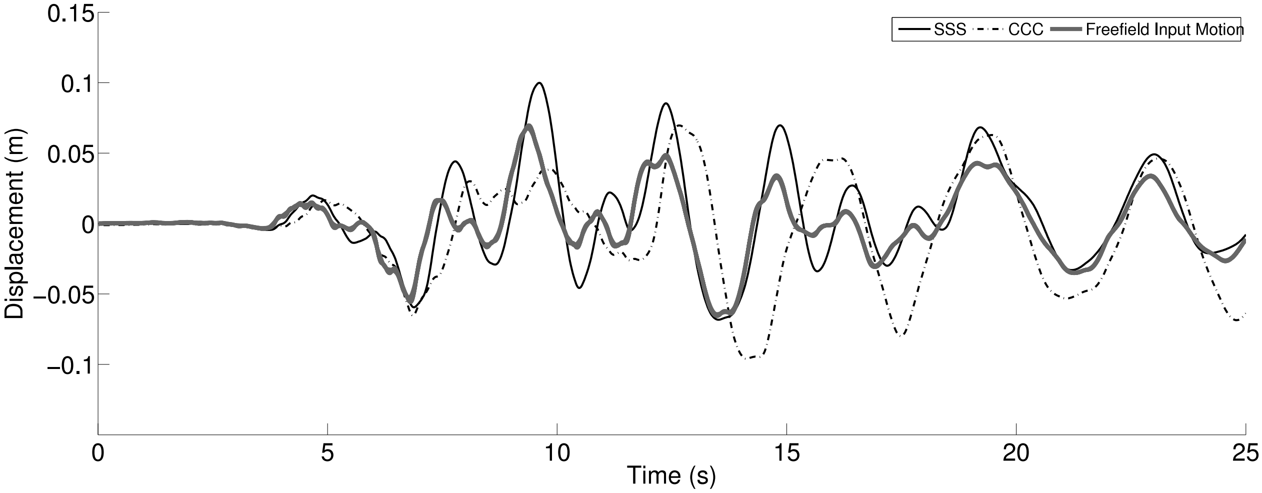

Figure 503.78: Simulated Displacement Time Series, Northridge 1994, Century City, Comparison of Two Cases - First 25s (Soil Block 1)

Simulation Cases	Soil Block 1	Soil Block 2	Soil Block 3
Case 3	Stiff Sand	Soft Clay	Stiff Sand

503.2.4.2 How Site Non-Uniformity Affects ESSI

Bridge is always constructed over gulfs or bays. It is a common case that for multi-span bridge, different bents will inevitably sit on soil foundations with totally different strength. This site nonuniformity complicates design because individual structure response might be largely varied.

In order to study the effects of site non-uniformity on the dynamic response of ESSI system, Case 3 listed in Table 503.6 has been selected as the test bed of our simulation. This scenario corresponds to the case that a 4-span bridge sits on solid abutments but with much softer bay-mud type foundation in the middle of a bay.

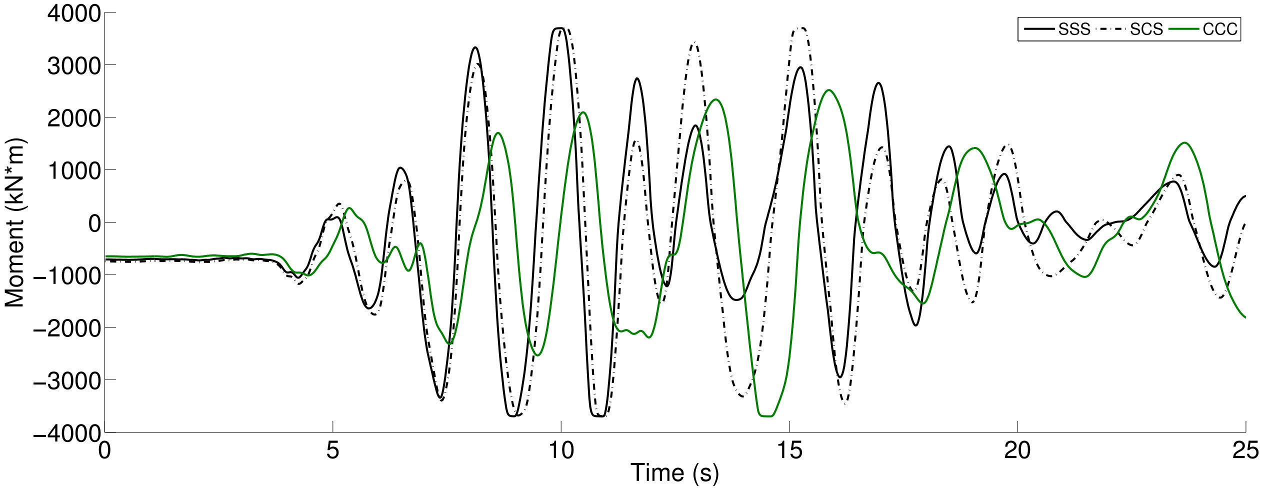

Figure 503.86: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

Table 503.7: Simulation Scenarios for Prototype ESSI Studies

Simulation Cases	Soil Block 1	Soil Block 2	Soil Block 3
Case 2	Stiff Sand	Stiff Sand	Soft Clay
Case 5	Soft Clay	Stiff Sand	Stiff Sand

From acceleration Figures 503.81, 503.82, 503.83, and moment Figures 503.84, 503.85 and 503.86, we can clearly see that due to the presence of a soft soil block, all structures show smaller magnitude in response. This is especially true for the superstructure that directly sits on top of the softer soil foundation. For Case 3 listed in Table 503.6, the superstructure (bent 2) gets much smaller response because it is right on top of clay (bay mud) foundation. As a matter of fact, the middle bent (bent 2) does not yield at all.

We want to extend this observation to other cases as listed in Table 503.7. Case 2 shows the scenario that the soil foundation supporting bent 3 is soft bay mud, while Case 5 shows it for bent 1.

The same reasoning can be applied to these similar cases. Figures 503.87 to 503.92 show the results of Case 2 and Figures 503.93 to 503.98 for Case 5.

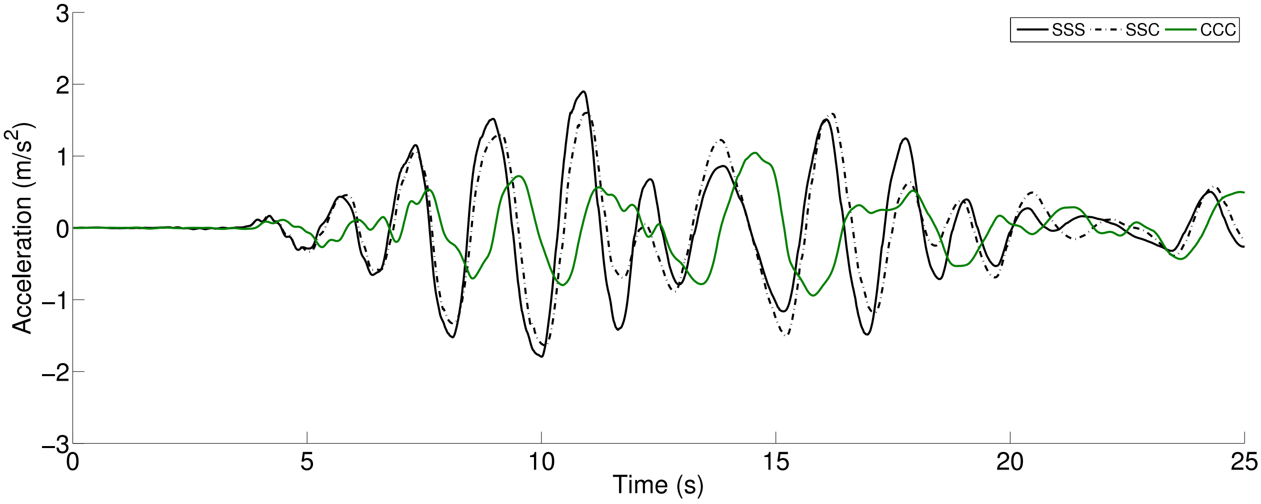

Figure 503.87: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 1)

Case 2

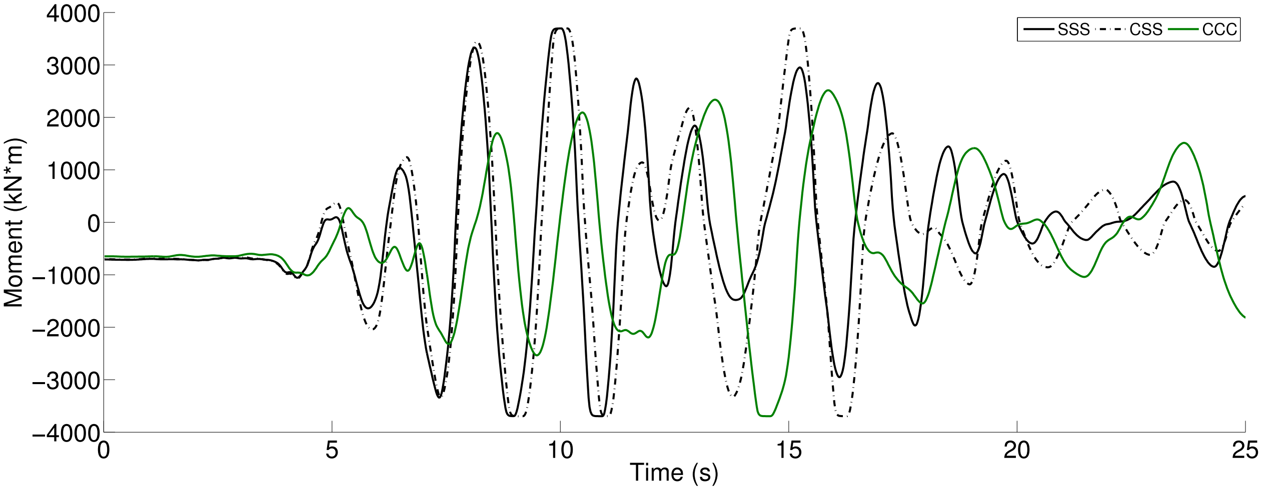

Figure 503.98: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

Table 503.8: Simulation Scenarios for Prototype ESSI Studies

Simulation Cases	Soil Block 1	Soil Block 2	Soil Block 3
Case 4	Stiff Sand	Soft Clay	Soft Clay
Case 6	Soft Clay	Stiff Sand	Soft Clay
Case 7	Soft Clay	Soft Clay	Stiff Sand

As a final conclusion, if there exists one substantially weaker soil layer for the ESSI system, the dynamic response for the whole ESSI system will be attenuated. The structure that directly sits on top of the soft soil block will receive significantly smaller excitation during earthquake shakings.

The other side of story can be also formulated using results obtained in this work. What if there is a substantially stronger soil foundation in the ESSI system? It would be worthwhile exploring the other side of reasoning. In this work, three other cases have been used to observe how the ESSI system will behave for the cases that one soil block is much stronger that the other blocks as listed in Table 503.8.

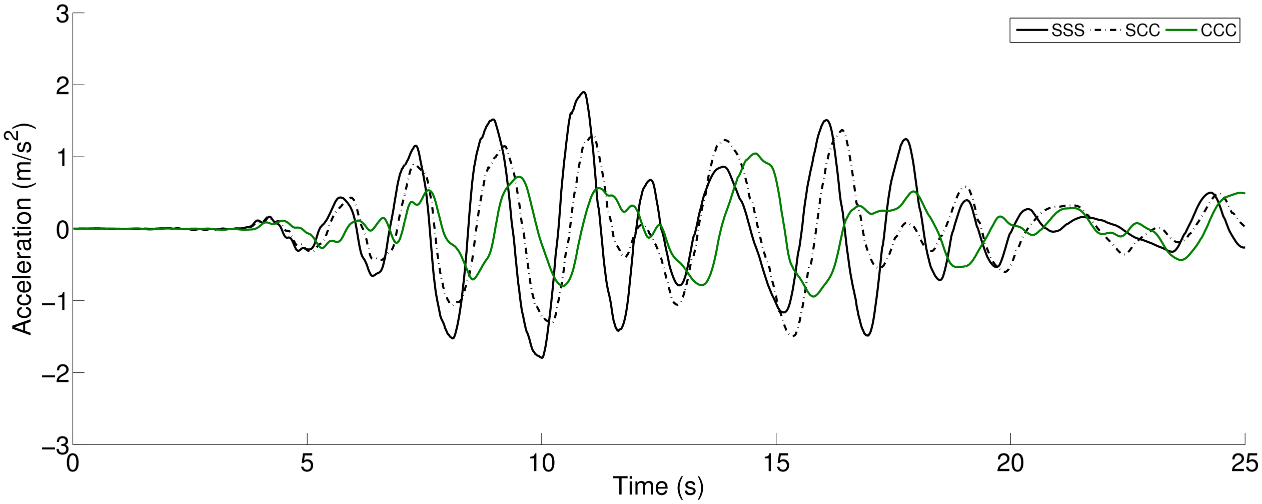

Figure 503.99: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 1)

Case 4

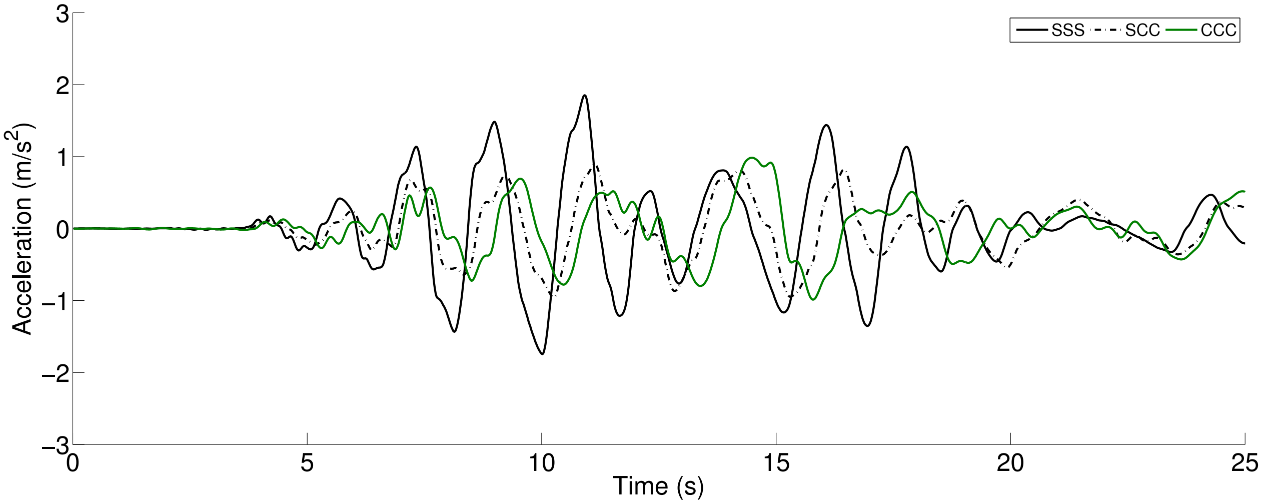

Figure 503.100: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 2)

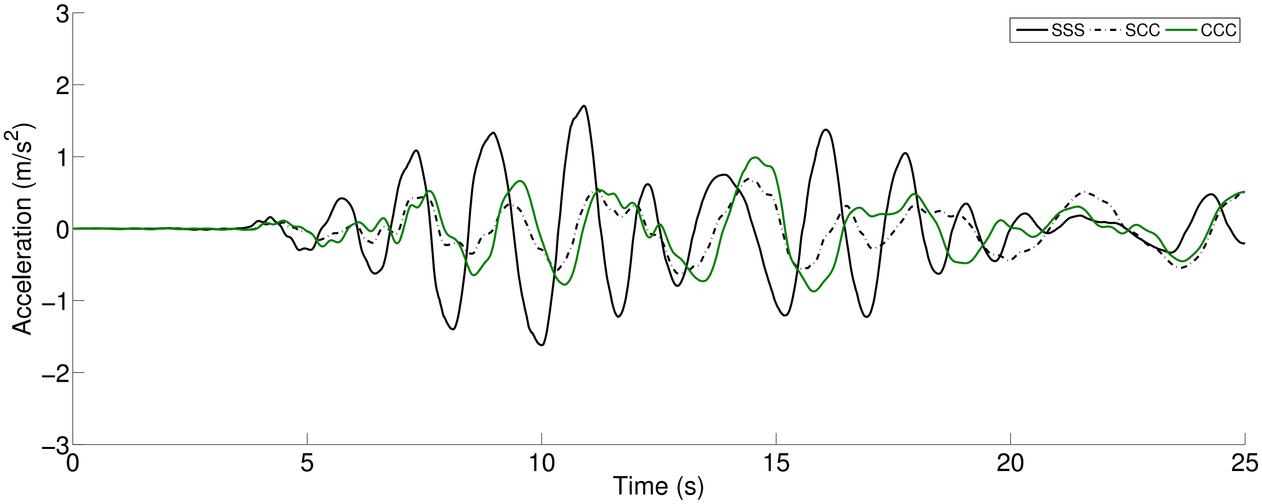

Figure 503.101: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

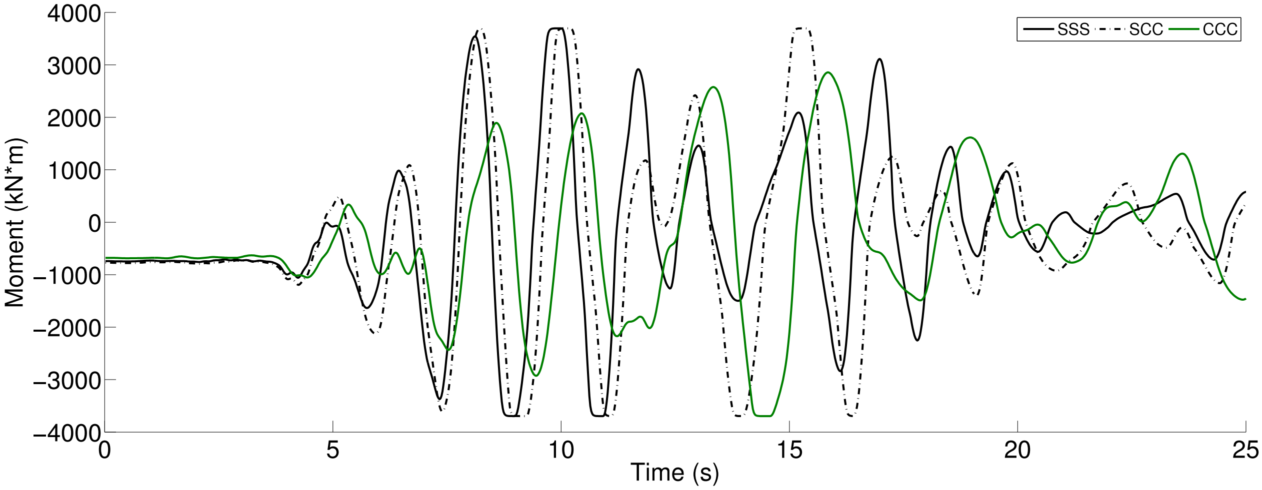

Figure 503.102: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 1)

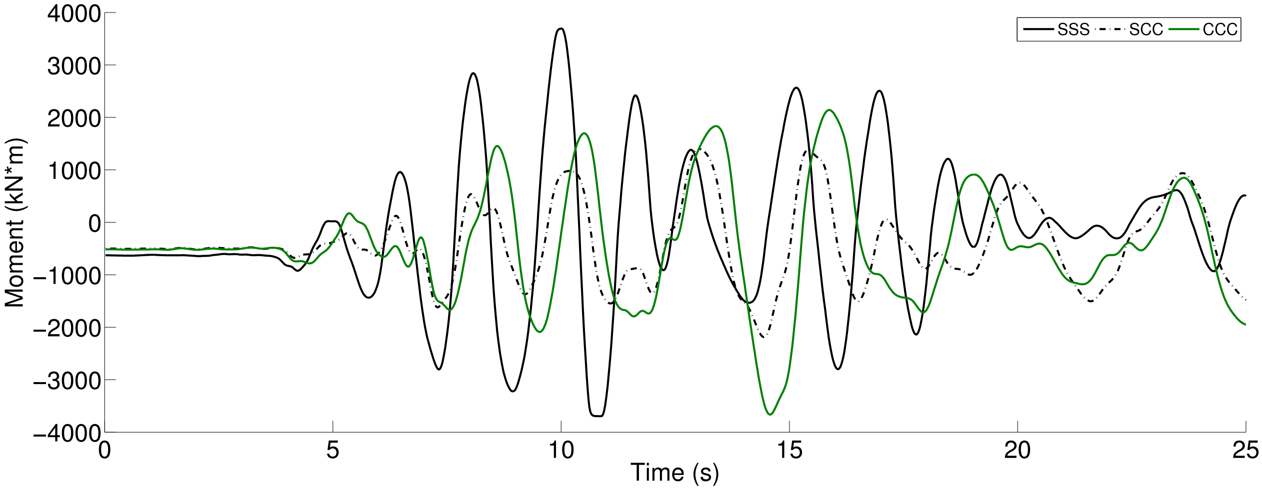

Figure 503.103: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 2)

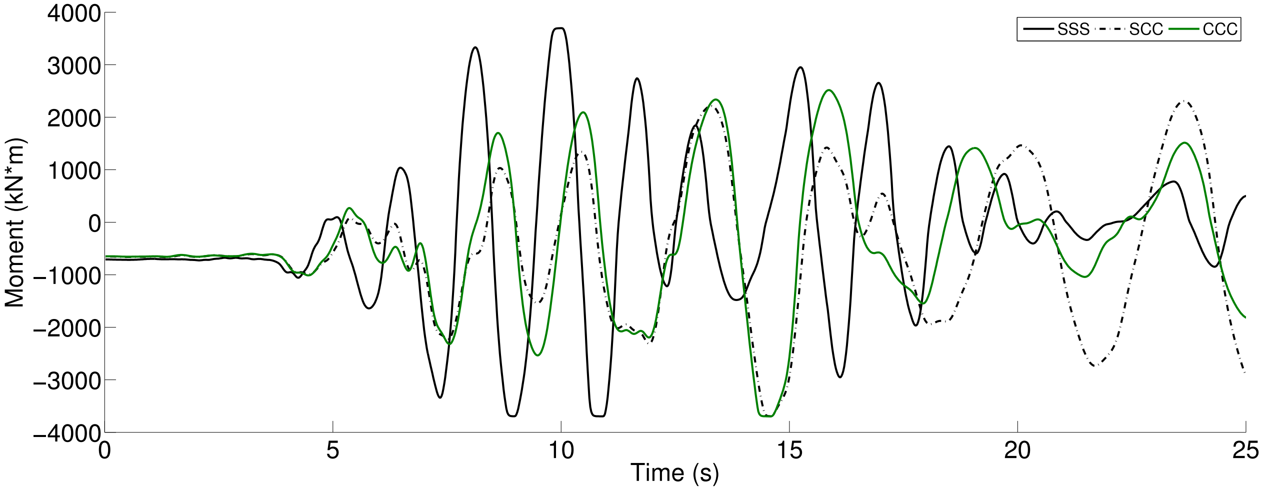

Figure 503.104: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

It can easily be seen from Figures 503.99 to 503.104 that the structure on top of the strong soil block will exhibit much bigger response and while the other structures sitting on weaker soil blocks will not get much shaking at all.

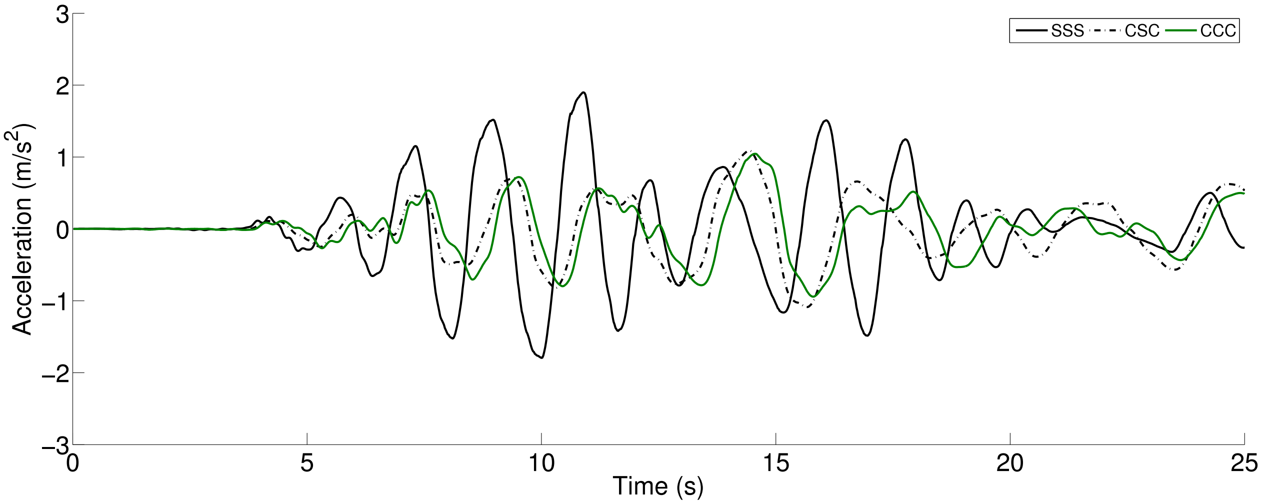

Figure 503.105: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 1)

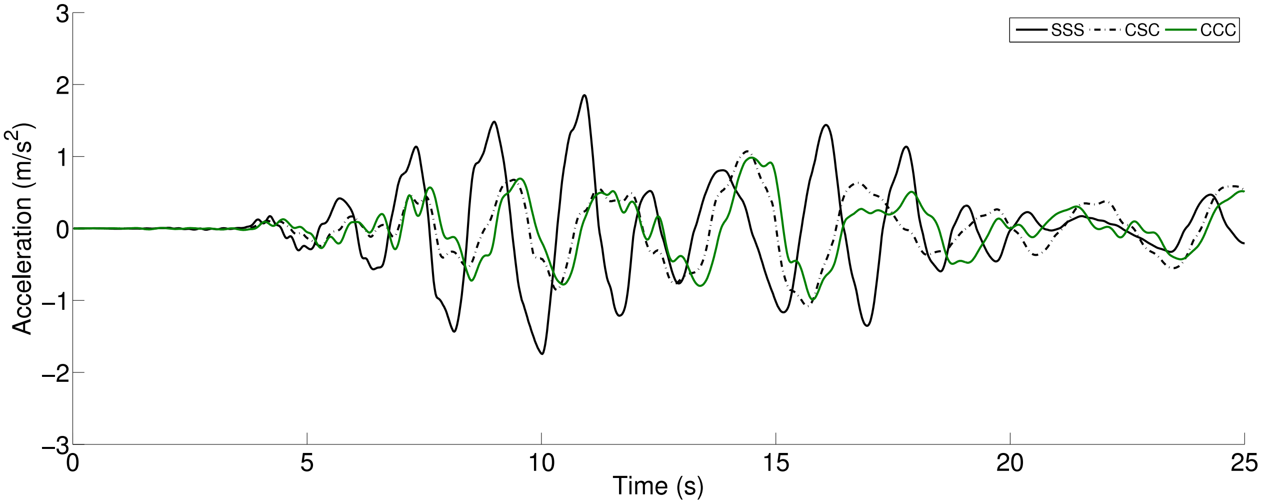

Figure 503.106: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 2)

Case 6

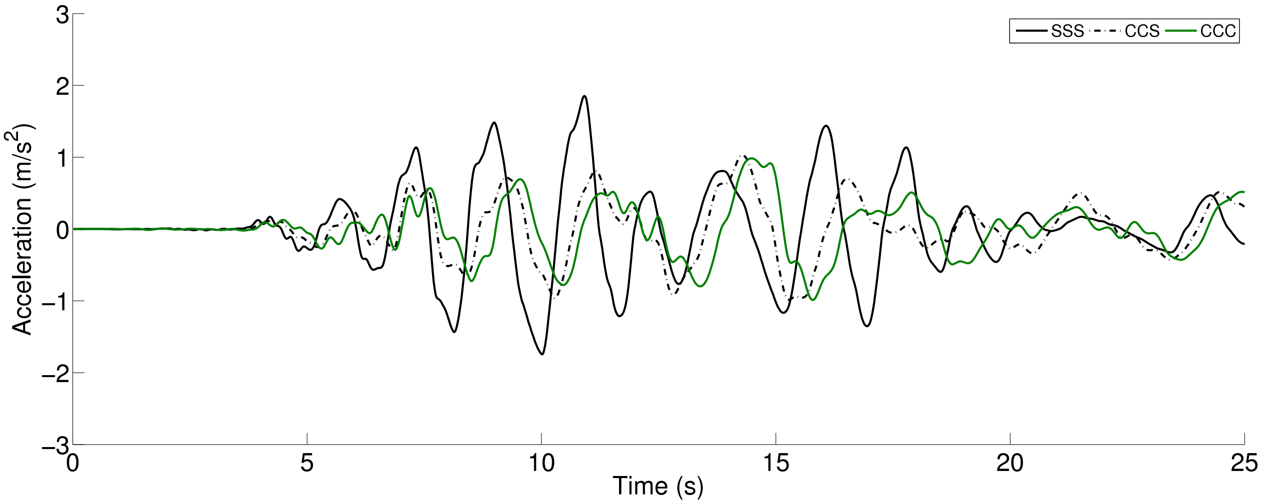

Figure 503.112: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 2)

Case 7

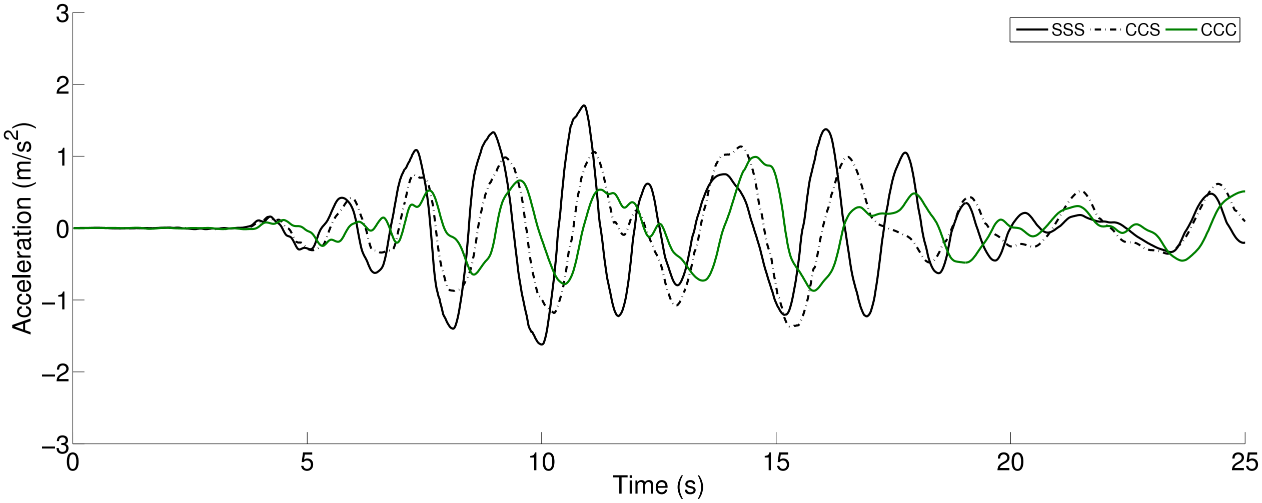

Figure 503.113: Simulated Acceleration Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

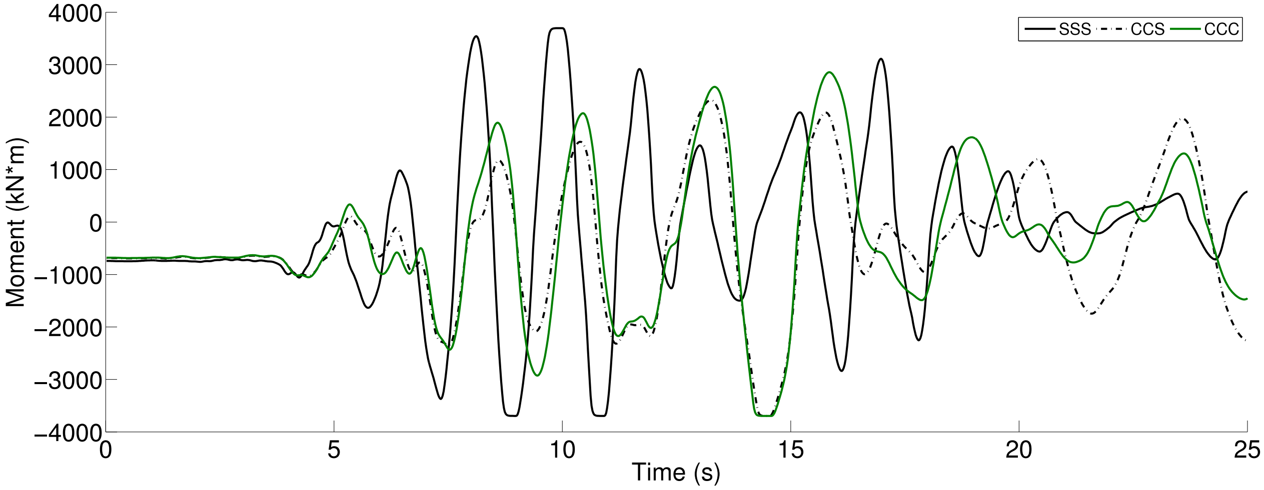

Figure 503.114: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 1)

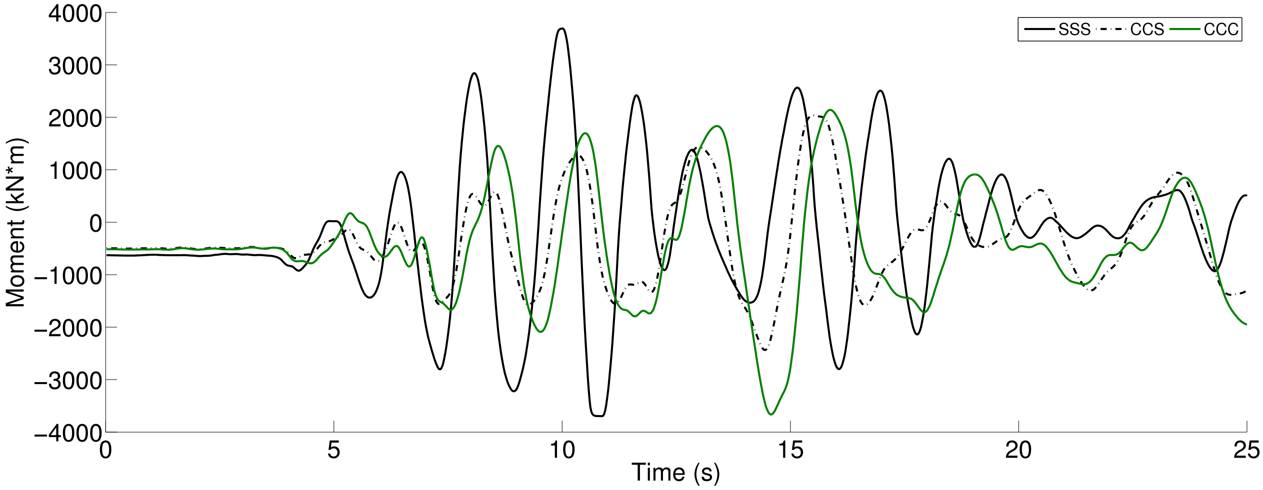

Figure 503.115: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 2)

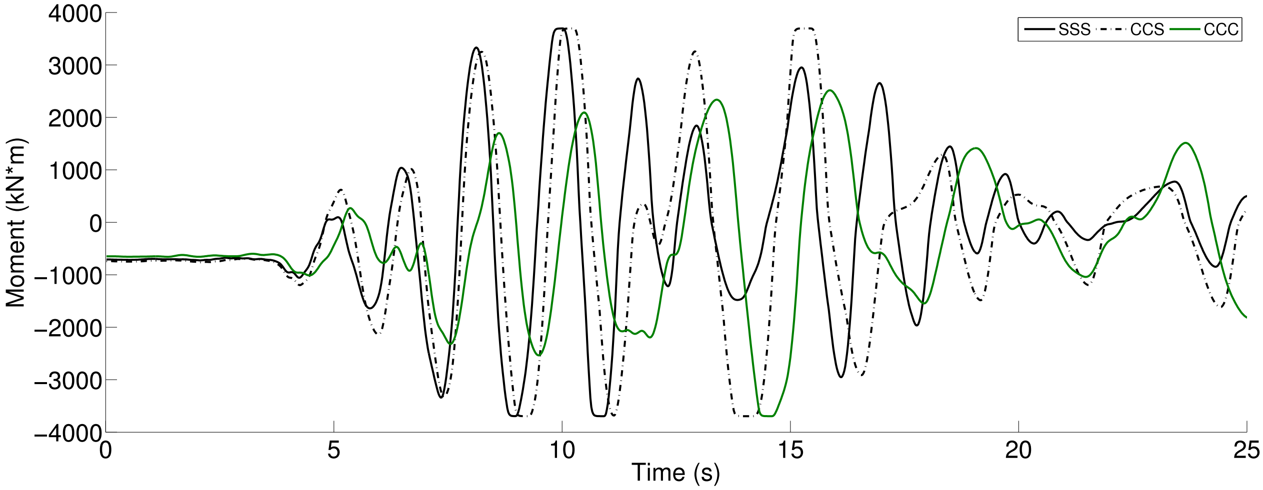

Figure 503.116: Simulated Maximum Moment Time Series, Northridge 1994, Century City, Comparison of Three Cases - First 25s (Structure Bent 3)

As a conclusion, dynamic behaviors of the ESSI system on non-uniform sites can be much more complicated than the uniform case. Generally speaking, the existence of soft soil foundation will attenuate the dynamic response of the whole ESSI system. The structure supported by soft soil block will see far less shakings than the ones supported by stiff soil. From the design perspective, the structure on top of strong soil foundations should be designed to higher safety with larger margin.

503.2.4.3 How Input Motion Affects ESSI

All the results have been shown in previous section, the purpose is to investigate how the whole ESSI system will respond to excitations with different predominant frequency.

From Figure 503.117 and 503.118, we can clearly see the difference in frequency contents of the two ground motions studied. THe 1999 Turkey Kocaeli earthquake contains more long period components that are not present at the 1994 Northridge site.

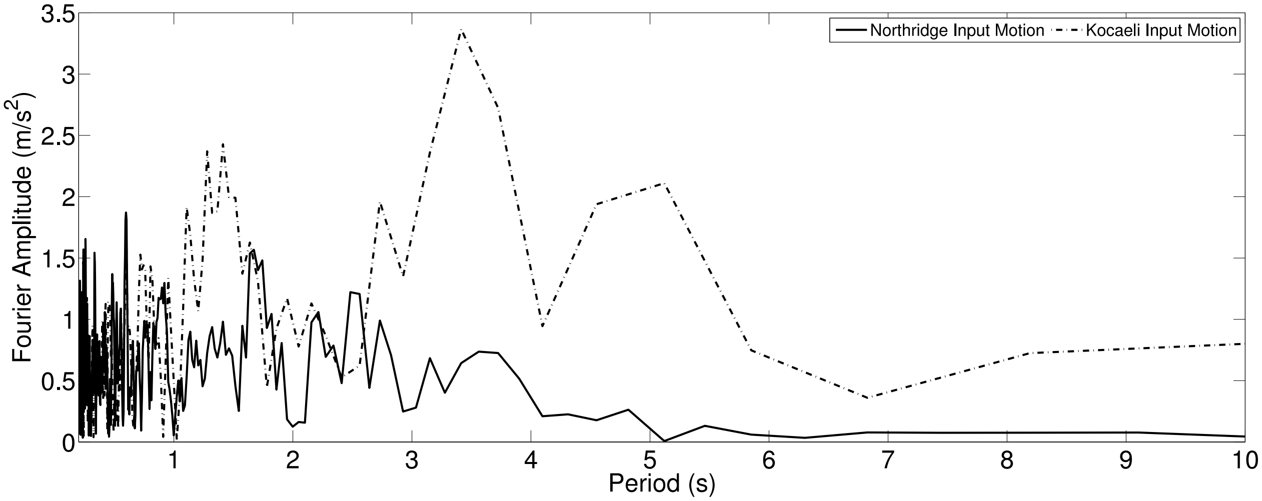

Figure 503.117: Frequency Contents of Ground Motions - Acceleration Time Series

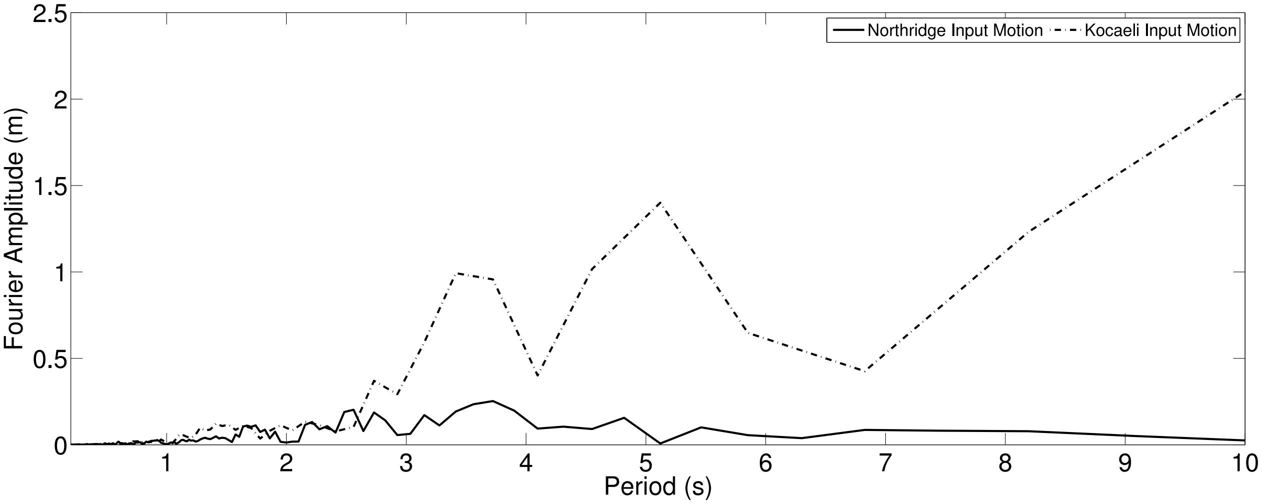

Figure 503.118: Frequency Contents of Ground Motions - Displacement Time Series

Depending on different site conditions, ESSI system will exhibit varied response to excitations with different predomiant frequencies. As we can see from Figure 503.42 to Figure 503.47, the structure sitting on softer soil foundations now exhibits much larger structural response when it is subject to long period excitations. This conclusion has been supported by every single plot that records the response spetra of structures such as Figure 503.61, Figure 503.63 and Figure 503.65. For the long perdominant periods present in the Kocaeli earthquake, the structures supported by soft clays exhibit much larger amplification than those supported by stiff soils.

It is also worthwhile to look deeper into the transfer function that tells some other aspects of the simulation scenarios. We can see from Figure 503.119 to Figure 503.130 that in terms of transfer function, which defines the amplification from soil surface to top of the structure, the structure is able to pick up much high frequency content that is not present within the soil layers. The visual representation of this is that the transfer function has much larger value at the high frequency end (low period end). This can be explained that typically people construct pile foundation inside the stiff soil (or bedrock). In our simulation, we also have a very stiff sustaining layer to provide pile tip resistance. The results shown in transfer functions make sense and also verifies our numerical model. Acceleration results are also shown as following.

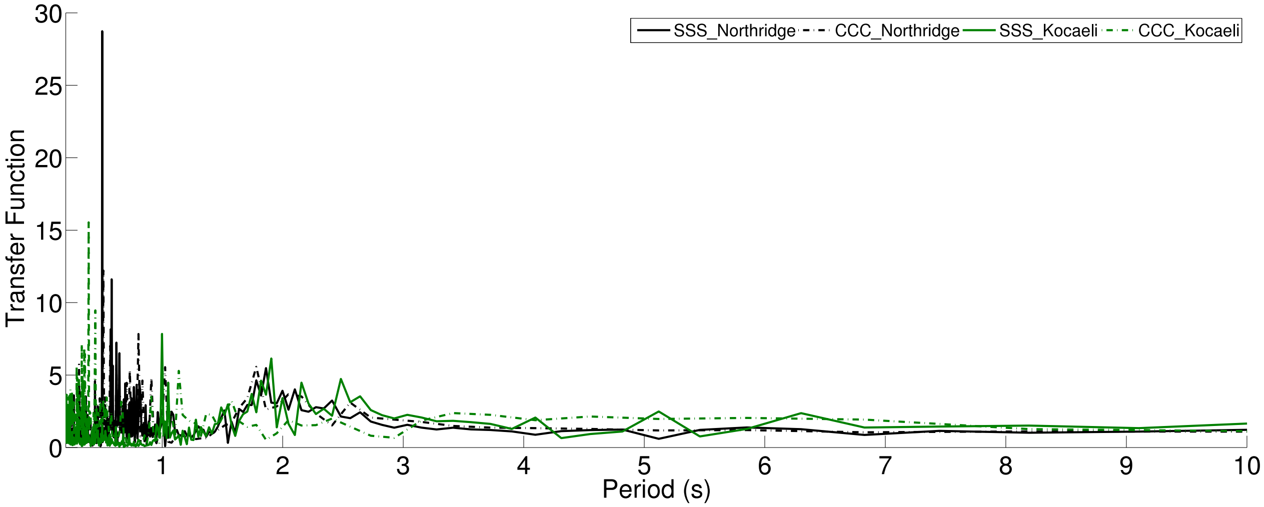

Figure 503.119: Transfer Function of Simulated Displacement Time Series for Both Long Period and Short Period Motions (Structure Bent 1, from Soil Surface to Top of Bent)

Chapter 504

Earthquake-Soil-Structure Interaction, Nuclear Power Plants

(2010-2011-2012-2017-2018-2019-2020-2021-2023-)

(In collaboration with Dr. Nima Tafazzoli, Prof. José Abell, Dr. Yuan Feng, Prof. Sumeet Kumar Sinha, Prof. Han Yang and Dr. Hexiang Wang, Dr. Katarzyna Staszewska)

504.1 Stick/Solid Finite Element Model

The 3D finite element model is shown in Figure (504.1). The finite element model is created using both 8 node brick elements for modeling the soil part and 27 node brick elements for modeling the foundation part, and displacement beam element for structural components.

The size of the model is $140m$ along the X and Y directions, and $50m$ along the Z direction (the height of the soil layer). Shear wave velocity of the soil is considered to be $700m/s$ with density of $2200kg/m^3$. Foundation has the height of $5m$ embedded in the soil layer, with size of $90m$ in each horizontal direction. Concrete is chosen to have shear wave velocity of $2000m/s$ with density of $2400kg/m^3$. The size of the elements are $5m$ in each direction for both foundation and soil elements. Structural beam is composed of 12 displacement beam elements attached to each other with different stiffness and mass properties. Domain Reduction Method is used to apply the input effective forces. Both 1C and 3C wave propagation cases are using the same finite element model for second stage of DRM analysis.

Frictional contact/interface elements are placed at the interface of foundation and soil layer. The contact/interface element used here has the same normal and tangential stiffness with magnitude of $10^8 N/m$. Friction ratio and cohesion of the contact/interface element are $\mu = 0.4$ and $c = 0.0$ respectively. Contact elements are oriented along the Z axis of global model.

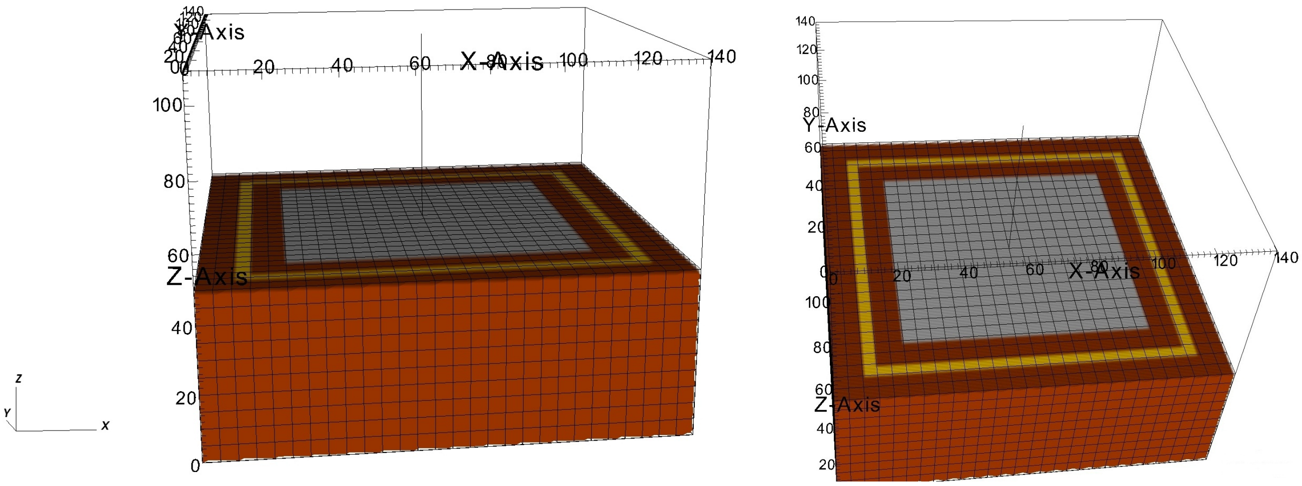

Figure 504.1: 3D finite element SFSI model considering slipping behavior at the interface of foundation and soil layer

In general it is accepted that in order to represent a traveling wave of a given frequency, the size of the finite elements have to have about 10 nodes per wavelength λ (Hughes (1987); Argyris and Mlejnek

(1991)). Using fewer than 10 nodes per wave length λ specially for linear elements leads to numerical damping of higher frequencies as such element discretization misses certain frequencies of the wave. In order to satisfy this requirement, the size of the mesh should satisfy Equation (504.1) which is a function of the maximum frequency (f_{max}) of the input motion and also the shear wave velocity of the media $V_s = \sqrt{G/\rho}$ where G is the shear modulus and ρ is density of the soil.

$$\Delta h \leq \lambda/10 = V_s/(10 f_{max}) \qquad (504.1)$$

In this model, the size of the elements are chosen to be $5m$ in each direction. Considering that the shear wave velocity of the soil is $700m/s$, the maximum frequency able to be propagated through this model is $14Hz$.

504.1.1 Slipping behavior of SFSI models by considering 1C wave propagation

In this section, slipping behavior of SFSI systems is studied under 1C seismic wave propagation assumption to come up with the input motion to be used for the model prepared for second stage of DRM. Morgan Hill earthquake and Ricker wavelets are used as the source of motion.

Domain Reduction Method is used to apply the input effective forces. In order to obtain the displacement and acceleration time histories used for calculating the DRM layer effective forces, a finite element soil column with shear behavior is considered representing the 1C wave propagation. The motions are applied at the base of the 1C finite element model and propagated through the soil column using multiple support excitation pattern.

504.1.1.1 Morgan Hill earthquake

Figures (504.2) to (504.3) show the acceleration and displacement time histories and FFT of the Morgan Hill earthquake at the base of the 1D model. Figure (504.4) shows the acceleration time histories recorded at the bottom and top of the structure in X and Z directions.

As it is observed, the acceleration time history of slipping and no-slipping model has differences in amplitude and the phase in X direction of the model. However, the differences in phases of the recorded motions seems to be more along the Z direction. It shows that considering the slipping behavior has caused a lag in phase of the response. Comparison of displacement time histories of the same models is shown in Figure (504.5) along X and Z directions. As it is shown, displacement time histories along X direction are quite similar in this case while along Z direction they have different amplitudes due to initial settlement and different phases. FFT of the accelerations do not have much of a difference in terms of frequency content (shown in Figure (504.6) but they are different in amplitude which has been observed in acceleration time histories as well. In general it is observed that in this earthquake the the magnitude of accelerations and displacements are less at top of the structure comparing to the ones recorded at the bottom of the structure for both slipping and no-slipping behavior cases.

Figure (504.7) shows the distribution of sliding at the interface of foundation and the soil layer at 9 different time steps of analysis from 0.5 to 1.3 seconds. As it is observed, location of maximum sliding is changed along the foundation in time while magnitude and direction of the applied motion changes. Slipping happens at the specific steps and parts of the interface zone in which the applied force is more than the resistant one.

504.1.1.2 Ricker wave

In order to investigate more, the Ricker wave with dominant frequency of $1Hz$ is used for analysis of the same model. The maximum of this function happens at 1 second. Figures (504.8) and (504.9) show the acceleration and displacement time histories as well as the FFT of the Ricker wave respectively.

As shown in Figure (504.10), displacement time history of top of the structure along X direction is higher when slipping behavior is not considered, while along Z direction it is higher considering the slipping behavior. Since structural components have rotational degrees of freedom, the slipping behavior and gaps in the model will lead to have more rotational movement and rocking of the foundation. There is also a phase lag in response of the structure in slipping behavior model. The displacement time histories at the bottom of the structure are slightly different in X direction. It can also be observed that along Z direction, the response of the structure in slipping model is higher comparing to the no-slipping one.

In this analysis slipping behavior make the movement to be less along the X direction. This might be due to the fact that while the foundation and structure are moving, there are gaps created at some parts of the interface which will affect the rocking movement of the foundation.

Figure (504.11) shows the FFT of the acceleration at the bottom and top of the structure. As it is observed, there is a slight shift in predominant frequency of the response between the slipping and no-slipping behavior. By considering the slipping behavior, the dominant frequency of the motion is decreased along the X direction while is increased along the Z direction. This means that the system gets softer along X direction and stiffer along Z direction. This is due to the gap openings and slidings at the foundation and soil layer interface. Since sliding happens along the X direction, and also considering the gap openings occur along the Z direction which can lead to the rocking of the foundation, it makes the system softer along the X direction. In general this shows the fact that the natural frequency of the system can be changed due to the slipping behavior.

Figures (504.12) and (504.13) show the distribution of gap openings and slidings at the interface of foundation and the soil layer at 9 different time steps of analysis from 0.5 to 1.3 seconds. It can be observed from Figure (504.12) how the location of gap openings are changed on different parts of the contact/interface as the dynamic motion is applied. The location of gap openings are changed from one side to the other while the magnitude and direction of the applied motion changes. The maximum of the gap openings at these time steps happen at 1.3 second with maximum amount of $0.1m$ on the right side of the interface. Maximum sliding at the shown range of time steps happens at 1.0 second with maximum value of $0.07m$ on the left side of the interface.

504.1.2 Slipping behavior of SFSI models by considering 3C wave propagation

In this section, the same finite element SFSI model as previous section is used with 3C wave propagated motions as input motions for simulations. The input motion used here is Ricker wave (as shown in Figure (504.8)).

In order to study the slipping behavior of SFSI considering 3C wave propagation for first stage of DRM simulation, a finite element model with dimensions of $10000m \times 50m \times 5000m$ is considered. Two cases are studied here with the source of motion (fault) to be located at $(x = 3000m, y = 0, z = 3000m)$ and $(x = 3000m, y = 0, z = 3000m)$. Figures (504.14) and (504.15) show these two cases respectively.

The size of the elements is chosen to be $50m$ in all directions for both cases in order to reduce the computational time. The soil parameters are: shear wave velocity of $700m/s$ and density of $2200kg/m^3$. Analyses for the fault slip model are done by applying the motion at the nodes of one element. This is done in order to represent the the wave propagation starting from the fault using multiple support excitation pattern. This is representing the first stage of analysis of DRM in which a big model including the fault is considered for free field case in order to obtain the required motions for DRM layer.

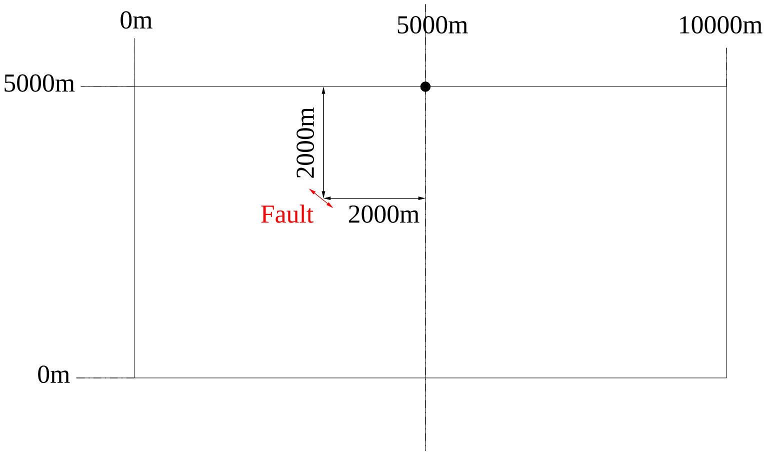

Figure 504.14: Domain to be analyzed for the 1^{st} stage of DRM with fault located at an angle of 45° with respect to the top middle point of the model

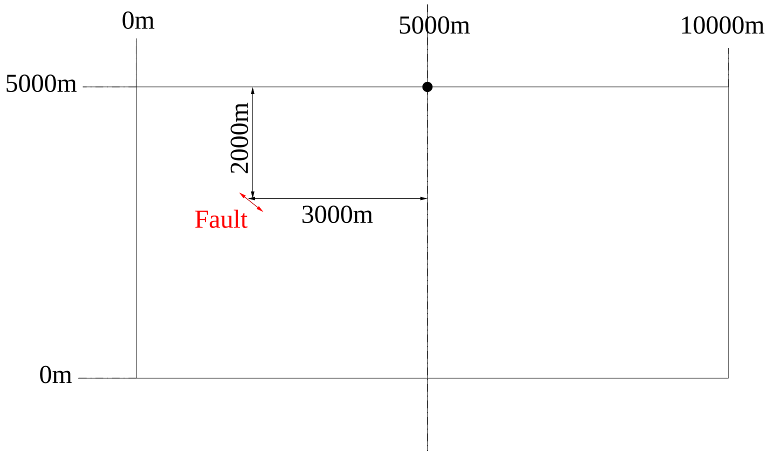

Figure 504.15: Domain to be analyzed for the 1^{st} stage of DRM with fault located at an angle of 34° with respect to the top middle point of the model

504.1.2.1 Ricker wave, with fault located at 45° towards the top middle point of the model

For the first case to be studied here, Ricker wavelet is considered as an input motion with dominant frequency of $1Hz$. The fault is located with angle of 45° toward the top middle point of the model (Figure (504.14)).

Displacement time histories of the structure along X and Z directions are shown in Figure (504.16). It is observed that along the X direction, the amplitude of displacement is little less at the beginning of the shaking of the slipping behavior model and a slight phase lag can be observed as well. However, when the actual pick of the motion is gone, it is shown that the motion for no-slipping model will damp out sooner. So the magnitude of displacements are higher at this time range for slipping model which could be because of the gap/sliding at the interface zone. The displacement time histories do not have a significant difference at the bottom of the structure. Displacement time histories observed along the Z direction shows the fact that magnitude of displacements for slipping model is higher and will damp out later comparing to the no-slipping model.

Acceleration time histories along X and Z directions at the bottom and top of the structure are shown in Figure (504.17). It is observed that along the X direction the amplitude of acceleration is less considering the slipping behavior and also there is a phase lag in the observed motion. However, the amplitude of the acceleration along Z direction is much higher in case of considering the slipping case. This is the same behavior observed in 1C wave propagation as well but with higher difference in time histories amplitudes.

As shown in Figure (504.18), the dominant frequency of the response in case of slipping is less than the one observed in no-slipping case along X direction while it is higher along Z direction.

Figures (504.19) and (504.20) show the distribution of sliding at the interface of foundation and the soil layer at 9 different time steps of analysis from 4.5 to 5.3 seconds. It can be observed from Figure (504.19) that maximum gap opening of $0.12m$ is occured at 4.7 seconds while the location of the openings are changed during the analysis. In addition, maximum sliding at the interface zone in this case happens at 4.8 seconds with magnitude of $0.03m$. In both gap and slide distribution plots, it can be observed that the place of maximum is close to the middle of the foundation which is where the structure is located.

Distribution of cumulative dissipated energy due to sliding of the foundation and soil layer contact/interface zone is shown in Figure (504.21). By modeling the slipping behavior at the interface zone, part of the seismic energy is dissipated through the sliding and rocking of the foundation and therefore, less amount will be transferred to the structural components. Figure (504.22) shows how energy can be dissipated during the analysis for the point at the middle of the interface zone (location of the structure).

When sliding happens, some part of the energy is dissipated as shown while there will be no change in dissipated energy if the foundation and soil are sticking to each other.

504.1.2.2 Ricker wave, with fault located at 34° towards the top middle point of the model

The last simulation to be studied here is the case which the location of the fault has an angle of 34° with respect to the top middle point of the model (Figure (504.15)). Same Ricker wave is used as an input motion to be propagated through the model built for first stage of DRM analysis. In this case, since the source of the motion is farther from the interested domain (comparing to previous case with the angle of 45°), motions will arrive later at the interface zone, and structure start shaking later.

Displacement time histories at the bottom and top of the structure are recorded and shown in Figure (504.23) along X and Z directions. Comparing to the previous case along X direction, at the beginning of the shaking the magnitude of the displacement for slipping behavior model is a bit smaller while it damps out sooner as well. Along the X direction, the trend of the displacement time histories are pretty much the same with a slight difference in magnitudes in time.

Acceleration time histories of the structure are shown in Figure (504.24) along X and Z directions. The same behavior is observed here as previous case such that the amplitude of the acceleration is significantly higher for case of no-slipping along the X direction while it is less along the Z direction. The seismic wave damps out sooner along X direction in case of considering the slipping behavior.

The frequency content change is shown in Figure (504.25) by comparing the FFT of the accelerations obtained from the model considering the slipping behavior and the one with no-slipping behavior. It can be observed that there is a slight change in frequency content and predominant frequencies along both X and Z directions.

Figure (504.26) shows the distribution of gap openings along the soil-foundation contact/interface zone for 9 time steps from 4.5 to 5.3 seconds. The maximum gap opening happens at 4.5 seconds with magnitude of $0.12m$. On the other hand, the sliding at the contact/interface zone is shown in Figure (504.27) with maximum magnitude of $0.0035m$ happening at 4.5 seconds. In this case, the maximum sliding happens around the location of the structure.

Figures (504.28) and (504.29) show the distribution of the dissipated seismic energy at the interface zone and dissipated energy time history at the middle of the contact/interface zone respectively.

Soil-Structure-Soil-Structure Interaction. Soil-Structure-Soil-Structure Interaction (SSSSI) need to be taken into account sometimes, as it might contribute to higher levels of seismic shaking for NPPs. It seems that in the case of making an assumption of elastic soil and rock beneath the NPP foundation, the SSSSI will have a larger effect most of the time, while with the inclusion of elastic-plastic models for soil and rock under the NPP foundation, those SSSSI influences will be reduced most of the time. This is illustrated in one of the models that was developed for analyzing SSSSI. While SSSSI for two NPPs (of similar stiffness and mass) conforms to the above observations, it is noted that SSSSI influences of smaller structures on larger (NPPs) can be mostly neglected, the SSSSI influence of larger structures (NPPs) on smaller structures Probably cannot be neglected.

There are a number of ways to model SSSSI.

- Direct Models. The simplest and most accurate is to develop a direct model of both (two or more) structures on subsurface soil and rock, to develop input seismic motions and analyze results. While this approach is the most involved, it is also the most accurate, as it allows for proper modeling of all the structure, foundation and soil/rock geometries and material without making any unnecessary simplifying assumptions.

- Symmetry and Anti-Symmetry Models. These models are sometimes used in order to reduce complexity and sophistication of the direct model (see recent paper by Roy et al. (2013) for example). However, there are a number of concerns regarding simplifying assumptions that need to be made in order for these models to work. These models have to make an assumption of a vertically propagating shear waves and as such do not take into account surface waves (Rayleigh, Love, etc) that carry significant amount of seismic energy. These surface waves will additionally excite NPP for rocking and twisting motions, which will then be transferred to adjacent NPP by means of additional surface waves. If only vertically propagating waves are used for input (as is the case for symmetry and anti-symmetry models) energy of input surface waves is neglected. It is noted that depending on the surface wave length and the distance between adjacent structures, a simple analysis can be performed to determine if particular surface waves, emitted/radiated from one structure toward the other one (and in the opposite direction) can influence adjacent structures. It is noted that the wave length can be determined using a classical equation $\lambda = v/f$ where λ is the length of the (surface) wave, v is the wave speed[1] and f is the wave frequency of interest. Table504.4 below gives Rayleigh wave lengths for four different wave frequencies $(1, 5, 10, 20$ Hz and for three different Rayleigh (very close to shear) wave velocities $(300, 1000, 2500$ m/s):

---

[1] For Rayleigh surface waves, their speed is just slightly below the shear wave speed (within 10%, depending on elastic properties of material), so a shear wave speed can be used for making these Rayleigh wave length estimates.

Table 504.4: Rayleigh wave length as a function of wave speed [m/s] and wave frequency [Hz].

	1.0Hz	5.0Hz	10.0Hz	20Hz
300m/s	300m	60m	30m	15m
1000m/s	1000m	200m	100m	50m
2500m/s	2500m	500m	250m	125m

It is apparent that for given separation between NPP buildings, different surface wave (frequencies) will be differently transmitted with different effects. For example, for an NPP building that has a basic linear dimension (length along the main rocking direction) of 100m, the surface wave the low frequency waves (1Hz) in soft soil ($v_s \approx 300$m/s) will be able to encompass a complete building within a single wave length, while for the same soil stiffness, the high frequency (20Hz) will produce waves that are too short to efficiently propagate through such NPP structure. On the other hand, for higher rock stiffness ($v_s \approx 2500$m/s), waves with frequencies all the way up to approximately 5Hz and maybe even 10Hz, have an extent that can easily be affecting a building with a 100m dimension.

Further comments on symmetric and antisymmetric models:

- Symmetry: motions of two NPPs are out phase and this represents an unrealistic case, unless the wave length of surface wave created by one NPP (toward the other NPP) is so large that half wave length will encompass both NPPs. This type of motions (symmetry) is illustrated in figure 504.3.3 below

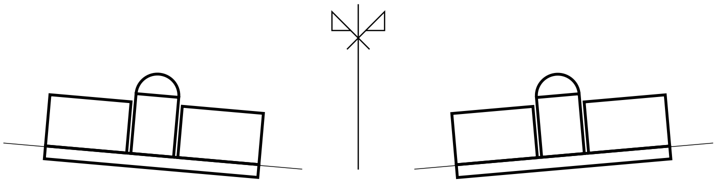

Figure 504.54: Symmetric mode of deformation for two NPPs near each other.

- Antisymmetry: motions of two NPPs are in phase and while that is more realistic than the symmetry case, still requires perfect matching of 1C input motions and the soil/rock conditions beneath, and as such is not realistic. This type of SSSSI is illustrated in figure 504.3.3 below

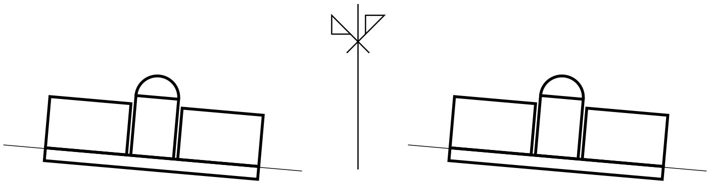

Figure 504.55: Anti-symmetric mode of deformation for two NPPs near each other.

504.3.4 Model #04, Small Modular Reactor (SMR)

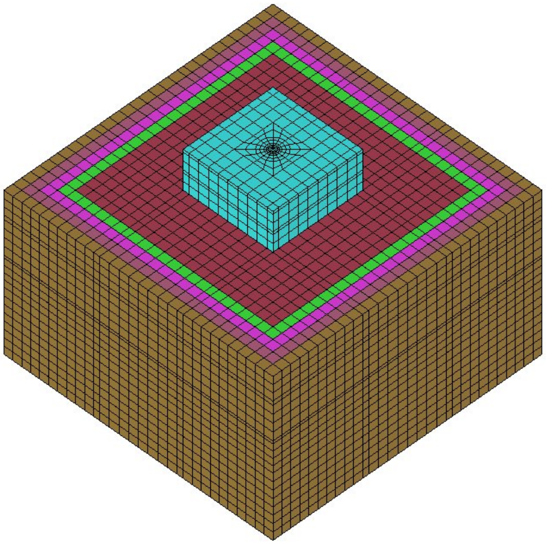

Figure 504.56: Small Modular Reactor model, top (surface) view.

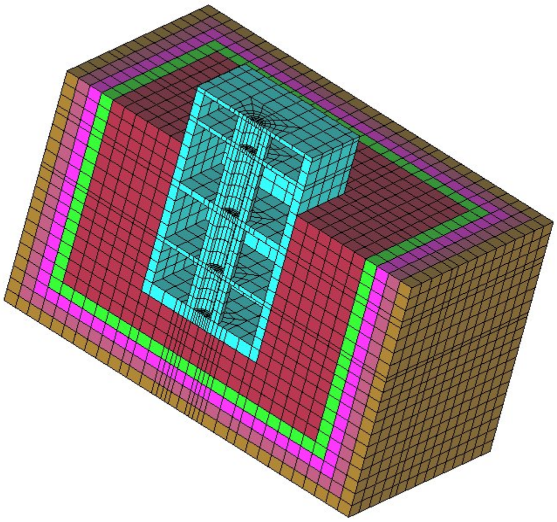

Figure 504.57: Small Modular Reactor model, cross section (half model) view.

504.4 3C (6C) vs 1C Seismic Motions

Realistic seismic wave fields are fully three dimensional, consisting of a body and surface waves, and featuring translational and rotational components of motions at and near the surface. However, current focus of various seismic analysis standards is on 1C motions. These 1C motions are representing one component of a full 3C wave field. More recently, use of 3×1C wave fields have been advocated, where 1C wave motions are replicated in other horizontal and a vertical direction with certain scaling factors. Use of 3×1C motions makes an implicit assumption that vertical motions are resulting from 1C compressional waves. This assumption is usually not true, as most of the vertical motions are a result of surface wave motions.

504.4.1 Appropriate Use of 3C and 3×1C and 1C Seismic Motions

We start by pointing out one of the biggest simplifying assumptions made, is that of a presence and use of 1C seismic waves. As pointed out in section 4.2.1 above, worldwide records do not show evidence of 1C seismic waves. It must be noted, that an assumption of neglecting full 3C seismic wave field and replacing it with a 1C wave field can sometimes be appropriate. However, such assumption should be carefully made, taking into account possible intended and unintended consequences.

A brief discussion on 1C, 3×1C and 3C seismic wave modelling and effects on SSI is provided below:

- 1C modelling of seismic waves is possible if material modelling for soil is linear or equivalent linear elastic. In this case, 1C motions from different directions (horizontal) can be combined, as superposition principle applies for linear elastic systems (soil in this case). Modeling of vertical motions using 1C approach is abit different as an analysis needs to be performed to decide if the vertical wave is a compressional wave (primary, P wave) or if vertical motions are a consequence of vertical components of surface waves. More on those options is provided below in 3×1C modelling option.

- 3×1C modeling of seismic waves is possible, similarly to the above case, if soil material is linear or equivalent linear elastic. SAs noted above, superposition principle can be applied and motions from each direction can be superimposed to obtained 3C motions at the surface. Since most of the time vertical motions are a results (consequence) of Rayleigh surface waves, it is important to analyze vertical motions and decide if modelling motions as 1C is appropriate. To this end, a wave length of surface wave plays an important role. If the Rayleigh surface wave length (which features both horizontal and vertical components) is longer than 12 times the dimension of the object (NPP), than object rotations, due to differential vertical displacements at object ends, are indeed fairly small and object does move up and down as if excited with a vertical wave. This is shown in Figure 504.58 as the upper case. On the other hand, if the wave is long less than 12 object dimensions, then vertical motions are gradually replaced by object rotations, while vertical motions are reduced. Case in the lower left corner of Figure 504.58 shows a limiting case where seismic wave is 4 times longer than object dimension, which results in minimal vertical motions of the object, and maximum rotations, due to differential motions of object ends. For shorter surface waves, as shown in Figure 504.58, lower right case, waves might not even be exciting any significant dynamic behavior of the object (except local deformation) as their wave lengths are shorter than twice object length.

- 3C modelling, when done properly will capture all the body and surface wave effects for SSI analysis of NPPs.

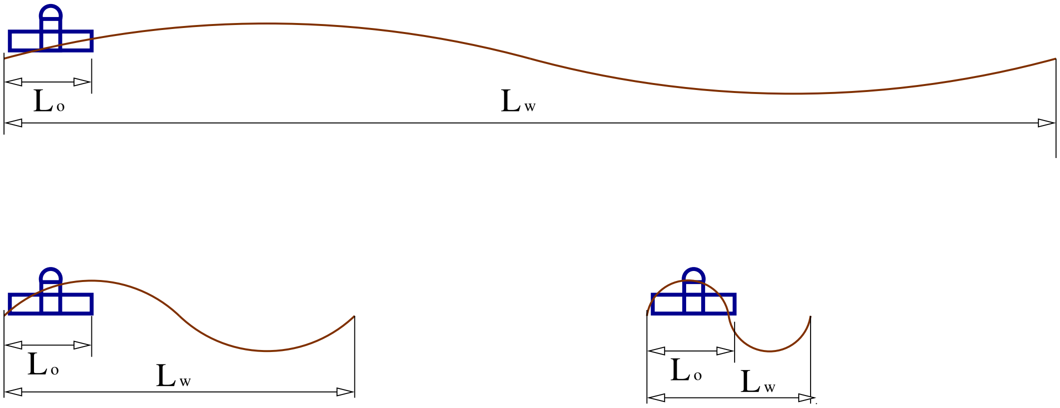

Figure 504.58: 1C vs 3×1C vs 3C. Three different cases of surface wave wave length. Upper case is where the surface wave length is 12 or more times longer than the object (NPP) dimension). Lower left case is where the surface wave length is only four times longer than the wave length, and lower right case is where the surface wave length is only two times longer than the object length.

504.4.2 Illustration of Use of 3C and 1C Seismic Motions

A simple example can be used to illustrate differences in 1C vs 3C seismic motions. Assume that a full 3C (6C, 3 translational components and 3 rotational components) motions at the surface are only recorded in one horizontal direction. From a 1C recorded component one can develop a vertically propagating shear wave in 1C, that exactly models 1C recorded motion. This is usually done using de-convolution Kramer (1996a). Figure 504.59 illustrates the idea of using a full 3C seismic wave field to develop a reduced, 1C wave field

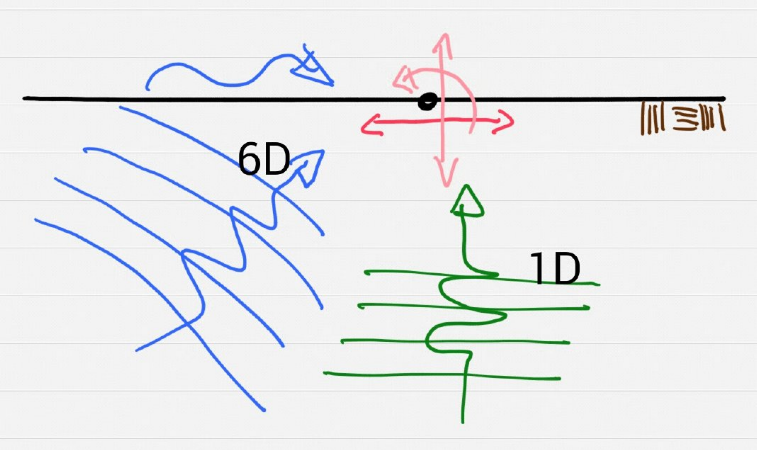

Figure 504.59: Illustration of the idea of using a full 3C (6C) seismic motion field to develop a 1C seismic motion field.

Two seismic wave fields, the original wave field and a subset 1C wave field now exist. The original wave field includes body and surface waves, and features translational and rotational motions. On the other hand, subset 1C wave field only has one component of motions, usually an SV component (vertically polarized component of S (Secondary) body waves).

Figure 504.61 shows a snapshot of a full 3C wave field, resulting from a large scale regional simulation, from a point source (simplified), propagating P and S waves through layers.

Figure 504.62 shows a snapshot of the same wave field as in Figure 504.61, now focused on an immediate viscinity of location of interest, where blue stick is positioned.

It should be noted that regional simulation model shown in Figures 504.62 and 504.61 is rather simple, consisting of a point source at shallow depth in a 3 layer elastic media. Waves propagate, refract at layer boundaries (turn more "vertical") and, upon hitting the surface, create surface waves (in this case, Rayleigh waves). In our case (as shown), out of plane translations and out of plane rotations are not developed, however this simplification will not affect conclusions that will be drawn. A seismic wave field with full 3 translations and 3 rotations (6C) will only emphasize differences that will be shown later.

Figures 504.63 and 504.64 show local free field model with 3C and 1C wave fields respectively.

Please note that seismic motions are input in an exact way, using the Domain Reduction Method Bielak et al. (2003a); Yoshimura et al. (2003a) and how there are no waves leaving the model out of DRM element layer (4th layer from side and lower boundaries). It is also important to note that horizontal motions in one direction at the location of interest (in the middle of the model) are exactly the same for both 3C motions case and for a 1C motions case.

Figure 504.65 shows a snapshot of an animation (available through a link within a figure) of difference

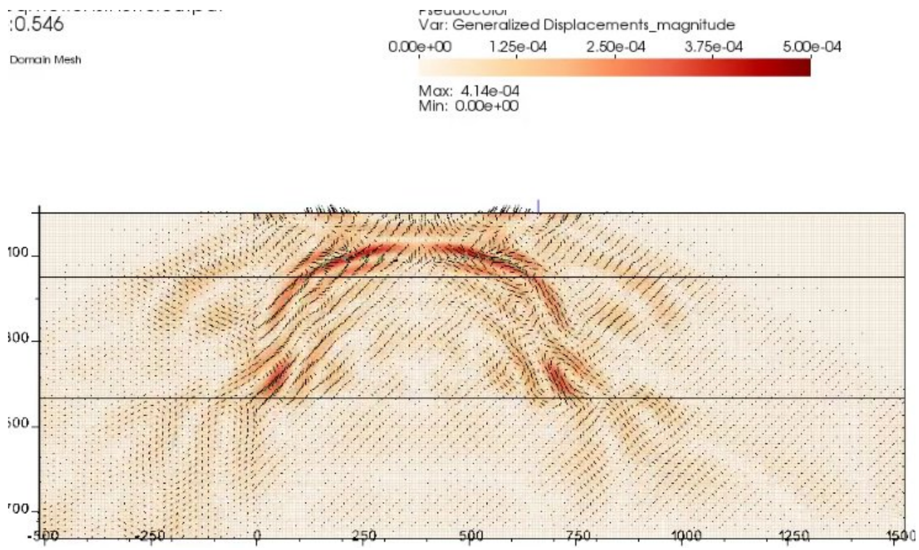

Figure 504.60: Snapshot of a full 3C wave field

in response of an NPP excited with full 3C (6C) seismic wave field, and a response of the same NPP to 1C seismic wave field.

Figures 504.66 and 504.67 show displacement and acceleration response on top of containment building for both 3C and 1C seismic wave fields.

Figures ?? and ?? show displacement and acceleration response on top of containment building for both 3C and 1C seismic wave fields.

A number of remarks can be made:

- Accelerations and displacements (motions, NPP response) of 6C and 1C cases are quite different. In some cases 1C case gives bigger influences, while in other, 6C case gives bigger influences.
- Differences are particularly obvious in vertical direction, which are much bigger in 6C case.
- Some accelerations of 6C case are larger that those of a 1C case. On the other hand, some displacements of 1C case are larger than those of a 6C case. This just happens to be the case for given source motions (a Ricker wavelet), for given geologic layering and for a given wave speed (and length). There might (will) be cases (combinations of model parameters) where 1C motions model will produce larger influences than 6C motions model, however motions will certainly again

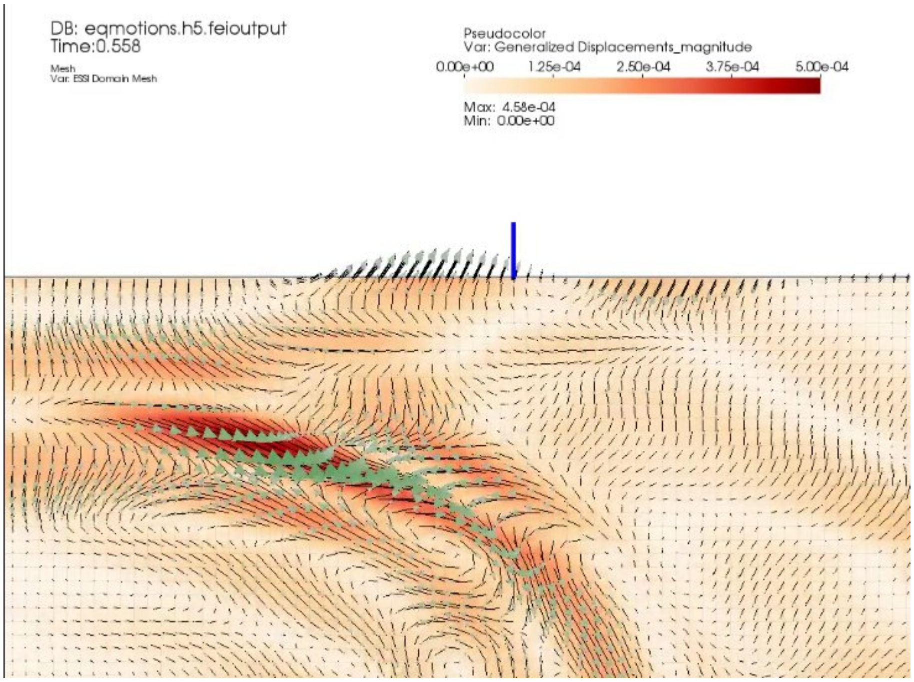

Figure 504.62: Snapshot of a full 3C wave field, with body and surface waves, resulting from a point source at 45^o at depth, down-left. This is a large regional scale model of a (simplified) fault with soil layers. Figure is a link to an animation of a full wave propagation.

be quite different. There will also be cases where 6C motions will produce larger influences than 1C motions. These differences will have to be analyzed on a case by case basis.

In conclusion, response of an NPP will be quite different when realistic 3C (6C) seismic motions are used, as opposed to a case when 1C, simplified seismic motions are used.

504.6 3D Nonlinear Modeling for Nuclear Power Plants

This section is based on Sinha et al. (2017).

It noted that input files for these models are available at this LINK, and can be directly simulated using Real-ESSI Simulator, `http://real-essi.us/`, that is available on Amazon Web Services, `https://aws.amazon.com/`.

504.6.1 Introduction

Seismic simulations to structures are often done by 1-D input excitations defined from a family of damped response spectra. These input motions are applied uniformly to the entire base of the structure regardless of its dimension and dynamic characteristics of the soil, foundation and motion itself. This not only ignores the foundation and its contact/interface with soil, soil-structure interaction (SSI) but also the 3C nature and variability of seismic waves.

Interest to study SSI effects has grown significantly in recent years. However Tyapin (2007) and Lou et al. (2011) note that even after four decades of extensive SSI research, there still exists a large gap. Lou et al. (2011) notes that spatial analysis of full model in 3D is hardly done. To reduce the amount of calculations, many existing publications simplify extremely the super-structure to spring mass damper model or consider only limited interaction. Elgamal et al Elgamal et al. (2008) performed a 3D analysis of a full soil–bridge system, focusing on interaction of liquefied soil in foundation and bridge structure. Jeremić et al. (2009) showed a full 3D soil-structure interaction of a prototype bridge, devised as a part of grand challenge, pre-NEESR project.

Investigations of SSI have shown that the dynamic response of a structure supported on elastic-plastic soil may differ significantly from the response of the same structure when supported on a rigid base Chopra and Gutierrez (1974); Bielak (1978). The difference comes because of the dissipation of part of the vibrational energy (seismic energy) by hysteresis action of the soil or structure itself. This results in damping of high frequency components, which could potentially prove quite useful for equipment that are prone to damage from high frequencies. On the other hand Jeremić et al. (2004) found that SSI can have detrimental effects on structural behavior as well and is dependent on the dynamic characteristics of the earthquake motion, the foundation soil and the structure.

Dissipation of energy during seismic events is another important factor to consider in design for its safety and economy. Dissipating energy in structure can lead to material degradation and damage. It is desired to dissipate most of the energy in soil with acceptable level of deformations in structure. A common neglect of plastic free energy has been observed in many publications, which results in clear violation of the second law of thermodynamics. A thermomechanical framework that can correctly evaluate energy transformation and dissipation in dynamic SSI simulation was presented by Yang et al. (2018, 2019a) based on works of Rosakis et al. (2000); Dafalias et al. (2002). This framework is applied to the prototype NPP model that is being analyzed in this paper. Locations with high possibility of damage are identified and insights on design improvement are discussed.

Only a few full 3D SSI interactions have been studied that too mainly focusing on bridges or small soil-foundation system. However, as per author's knowledge a full 3D non-linear analysis for a structure with soil-foundation-structure and contact/interface effects have not been investigated. Purpose of this paper here is to present a methodology for high fidelity modeling of seismic soil–foundation-structure (SFSI) interaction for a prototype of Nuclear Power Plant (NPP) with surface (shallow) foundation. Presented methodology employs the currently best available models and simulation procedures. In addition to presenting such state-of-the-art modeling, simulation results are used to illustrate non-linear-effects on seismic response of a prototype NPP model.

504.6.2 Model Development and Simulation Details

The Nuclear Power Plant (NPP) modeled here is a symmetric structure with shallow foundation of thickness $3.5m$ and size $100m$. Figure 504.70 shows a slice view of the model in normal y direction (perpendicular to plane of the paper). Solid brick elements were used to model soil and foundation. The NPP structure was modelled by elastic shell elements. This section describes the material and modeling parameters summarized in Table 504.5, foundation, structure, and contact. Given also is a brief description of staged loading and seismic force application using domain reduction method (DRM).

504.6.2.1 Structure Model

The NPP structure consists of auxiliary building, containment building and shallow foundation as shown in Figure ??. The auxiliary building consists of 4 floors of $0.6m$ thickness, ceiling floor of $1m$ thickness, exterior wall of $1.6m$ thickness and interior walls of $0.4m$ thickness. The exterior and interior walls are embedded down to the depth of the foundation. The containment building is a cylinder of diameter $20m$ and height $40m$ with wall thickness of $1.6m$. There is a gap of $0.2m$ between the containment and auxiliary building. Top of the containment building is covered by semi-spherical dome of radius $20m$. The foundation is square shallow footing of size $100m$ and thickness $3.5m$. The containment building and the auxiliary building were modelled as shell elements and foundation as linear brick elements, both having the properties of concrete of elastic Young's modulus $20GPa$, poison's ratio 0.21 and density $2400kg/m^3$. The containment building which is more flexible than the auxiliary building had its first mode as bending with fundamental frequency at $4Hz$.

504.6.2.2 Soil Model

The depth of the soil modelled below the foundation was 120 m, which is also the depth of DRM layer Sec 504.6.2.5. It is assumed that within this range the soil will plastify because of its self-weight, structure and seismic motions. The soil is assumed to be a stiff saturated-clay with undrained behavior having shear velocity of 500 m/s, unit weight of 21.4 kPa and Poisson's ratio of 0.25. To represent the travelling wave accurately for a given frequency, about 10 nodes per wavelength i.e. about 10 linear or 3 quadratic brick elements are required. Here, the seismic waves are analyzed up to $f_{max} = 10Hz$. The smallest wavelength λ_{min} to be captured thus, can be estimated as

$$\lambda_{min} = v/f_{max} \qquad (504.2)$$

where, v is the smallest shear wave velocity of interest. For $v = 500m/s$ and $f_{max} = 10Hz$ the minimum wavelength λ_{min} would be $(500m/s)(10/s) = 50m$. Choosing 10 nodes/elements per wavelength the element size would be 5m. Jeremić et al. (2009); Watanabe et al. (2017) state that even by choosing mesh size $\Delta h = \lambda_{min}/10$, smallest wavelength that can be captured with confidence is $\lambda = 2\Delta h$ i.e. a frequency corresponding to $5f_{max}$. Based on the above analysis, soil was modeled as linear 8-node brick elements with grid spacing of $\Delta h = 5m$.

Because of the complex plastic-behavior of the soil many sophisticated models Yang et al. (2003); Dafalias and Manzari (2004b) have been developed to capture the non-linear response of soil. Wair et al. (2012) provides an empirical correlation to predict the shear strength of soil for given shear velocity V_s. Dickenson (1994) proposed the following relationship Eq 504.3 between V_s and undrained strength S_u for cohesive soils in San Francisco Bay Area.

$$V_s[m/s] = 23(S_u[kPa])^{0.475} \tag{504.3}$$

Thus, for $V_s = 500m/s$, the undrained strength S_u would be $650kPa$. Here, two scenarios of soil properties were considered in analysis. One linear elastic and the other as von-Mises with non-linear kinematic hardening of Armstrong – Frederick type. For S_u of $650kPa$ and $E = 1.3Gpa$, the non-linear inelastic model was calibrated for yield strength achieved at 0.01% shear strain with linear kinematic hardening rate (h_a) as $30MPa$ and non-linear hardening rate (c_r) as 25. The soil properties is summarized in Table 504.5. The stress-strain response for the non-linear material model is shown in Figure ??

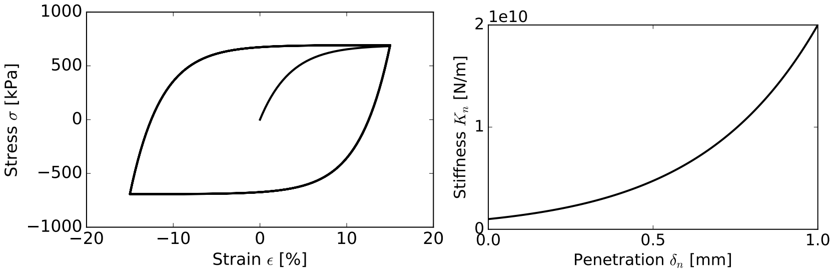

Figure 504.72: Soil and contact/interface modeling.

504.6.2.3 Interface/Contact Modeling

Node-to-node penalty based soft contact/interface element Sinha and Jeremić (2017) was used to model the interaction between foundation and soil as they are not one continuum material. In soft contact, normal contact/interface force F_n from soft-soil is assumed to increases exponential with penetration δ_n

as shown in Eq 504.4. The normal force F_n and stiffness K_n in defined as

$$\begin{aligned} F_n &= k_n^{init} * exp(S_r * \delta_n) * \delta_n \\ K_n &= max(k_n^{init} * exp(S_r * \delta_n) * (1 + k_n^{init} * \delta_n), k_n^{max}) \end{aligned} \tag{504.4}$$

where δ_n refers to the relative displacement between contact/interface node pairs in normal contact direction, k_n^{init} refers to the normal stiffness in normal contact/interface direction, S_r refers to the stiffening rate in normal contact direction. k_n^{Max} refers to maximum normal stiffness and provides a cap on exponentially increasing stiffness to make the solution numerically stable. The soft contact/interface was implemented to capture the phenomenon of increasing stiffness of soil with increasing penetration. Figure ?? shows the stiffness curve with penetration for the chosen contact/interface parameters also shown in Table 504.5.

Contact elements were applied all around the foundation connecting to the soil as shown in Figure ?? in red color zone. To ensure the stability of the numerical solution, the penalty stiffness in normal direction was chosen $2-3$ order magnitude greater than the stiffness of the soil. The Coulomb's friction coefficient μ between the soil and the foundation was chosen as 0.25. Viscous damping of $100 Ns/m$ in normal and tangential damping was provided to model viscous damping arising from water.

504.6.2.4 Seismic Motions

3C seismic motions were developed by Rodgers (2017) using SW4 (Serpentine Wave Propagation of 4^{th} order) Petersson and Sjögreen (2018) for an earthquake of magnitude (M_w) of 5.5 modelled with a point source on a fault of dimension $5.5 \times 5.6 km$ with up-dip rupture slip model. The ESSI (Earthquake Soil Structure Interaction) box to capture the free-field motion was located on the foot-wall of the reverse thrust fault. The generated motion had a directivity effect as the fault slips and propagates in x-direction. Also, since the ESSI box was located perpendicular to the fault, strong motions in y-direction was expected.

Acceleration and displacement time-series of the motion at the center of ESSI box is shown in Figure 504.86. The peak ground acceleration (PGA) in x and y direction is about $0.5g$. Significant amount of vertical motions PGA of $0.2g$ can be observed which is neglected in many conventional seismic simulations. Since, the fault is located at foot-wall side of reverse thrust fault, there is permanent subsidence of about $50mm$ in z-direction at the end of shaking event. Fourier transform and response spectrum of the motions are shown in Figure 504.87. The frequency range of the motion is within $20Hz$. Response spectrum plot shows amplification for natural frequency greater than $2Hz$. Since, many equipments in nuclear industry operate at high frequencies, determination of high frequency excitation of NPP building is critical for design.

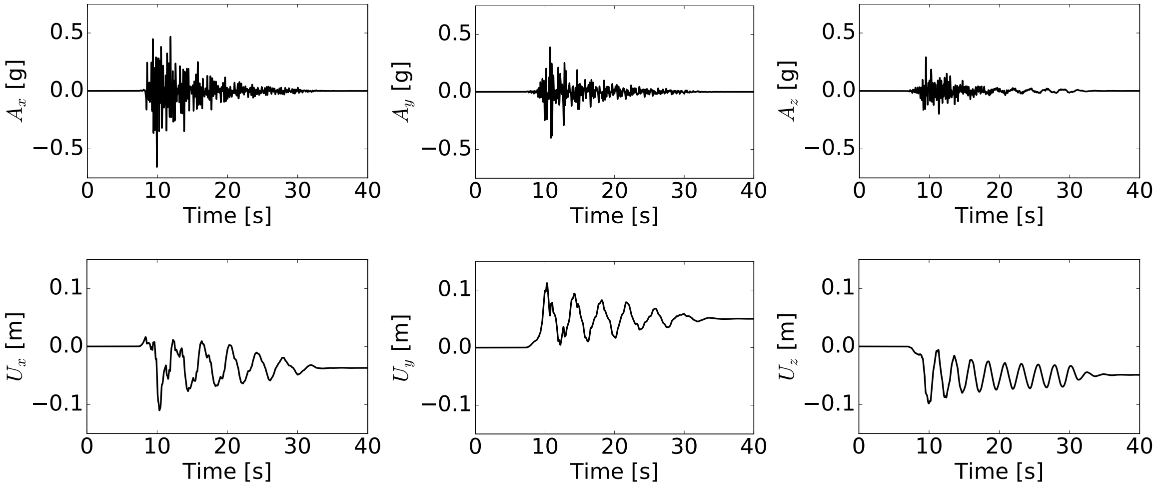

Figure 504.73: Acceleration and displacement time series.

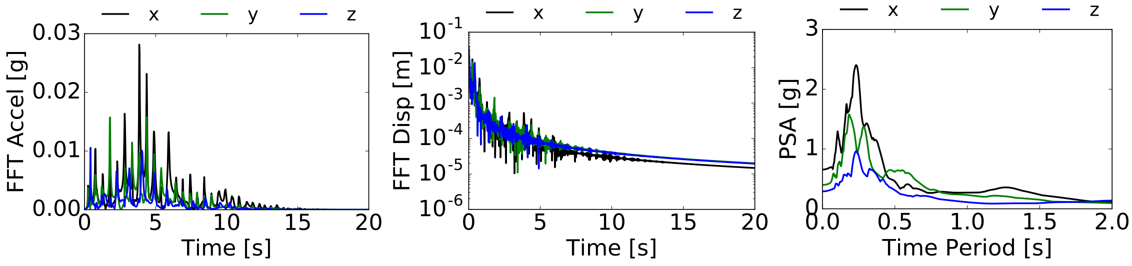

Figure 504.74: Strong motion Fourier transform and response spectrum.

504.6.2.5 Domain Reduction Method

Domain Reduction Method (DRM) Bielak et al. (2003a) was used to apply 3C seismic motions generated from SW4 all around the model as shown in Figure ??. DRM is one of the best methods that can apply free field 3C ground motions to a finite-element model. It features a two-stage strategy for a complex, realistic 3D earthquake engineering simulation. First, is the generation of free field model with correct geology and second is the application of the generated free-field to the structure of interest. The DRM layer here is modeled as a single layer of elastic soil. Three damping (absorbing) layers adjacent to DRM layer were modeled to prevent incoming of reflected waves. For this analysis, 60% Rayleigh damping was applied in each of the damping and DRM layers. The Rayleigh damping was applied in the frequency range of 1-5Hz.

504.6.2.6 Staged Simulation

The whole analysis was simulated with two loading stages. First stage was static self-weight to get the initial stress state of the soil and contact/interface elements. In second stage, seismic motion was applied using DRM method. For each stage, equilibrium was achieved using full Newton-Raphson method with a small tolerance of $1e^{-4}N$ on second-norm of unbalanced force. For dynamic analysis, Newmark integration method with numerical damping $\gamma = 0.7$ was used. Rayleigh damping of 2% in structure and 30% in soil was applied. The time step considered here was 0.02 seconds with simulation running in total for 40 seconds.

The analysis was run in parallel in Real-ESSI Simulator Jeremić et al. (1988-2025), `http://real-essi.info`. on eight CPUs. The model consisted of about $300k$ degrees of freedoms (dofs). Four scenarios (a) elastic no contact/interface (b) elastic with contact (c) elastic-plastic no contact and (d) elastic-plastic with contact/interface were performed. In this paper, unless specified *elastic* means elastic without contact/interface and *inelastic* means elastic-plastic with contact.

504.6.3 Simulation Results

Due to the space restriction, only few locations are selected to study the non-linear effects on NPP structure. The selected locations are shown in Figure 504.75. Since the containment building is more flexible than auxiliary building, location (D) in Figure 504.75 located on the top of the containment building is naturally the point of interest as it describes maximum drift during shaking. Three locations (A), (B) and (C) located at center of foundation is also selected to study the slip at interface during shaking.

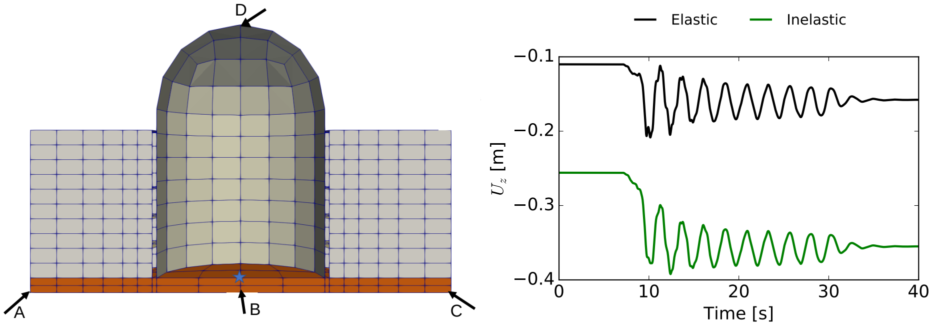

Figure 504.75: Locations selected to study non-linear effects and plot of total displacement at center of model *Elastic* (elastic with contact) and *Inelastic* (Elastic-Plastic with contact).

Since the site is located on the foot wall, during seismic shaking the whole structure along with soil subsides down by about $50mm$ in elastic and $100mm$ in inelastic case. Overall, if self-weight stage is also included, the soil settles by $150mm$ in elastic and $350mm$ in inelastic case as shown in Figure ??.

It is important to predict the development of high frequency excitation during shaking because it can prove to be alarming (when close to fundamental frequency) for nuclear-equipment. These high frequencies are thus, important to be monitored, predicted during earthquakes, for design of nuclear building to ensure the safety of equipment. Figure 504.76 plots the acceleration and its Fourier amplitude for the location (D). It is interesting to observe, the elastic-plastic analysis kills high frequency excitations in the structure which are persistent in elastic analysis. Elastic-plastic soil shows natural damping to some high frequencies because of dissipation of energy in form of heat by hysteresis loop.This can prove to be bigly useful for safe operation of nuclear equipments even at strong seismic events. The effects of contacts coupled with elastic-plastic material leads to huge dissipation of energy reducing the high frequency modes. In Z-direction, very little significant excitation was observed.

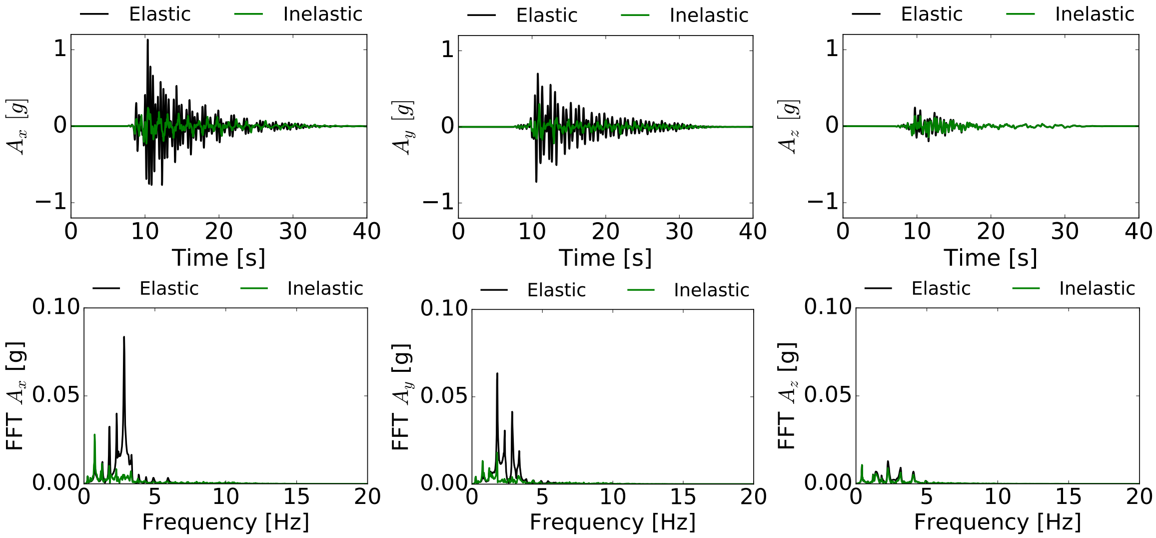

Figure 504.76: Seismic response at top of containment building *Elastic* (elastic without contact) and *Inelastic* (elastic-plastic with contact).

The introduction of contact/interface can result in opening and closing of gaps at the soil-foundation interface for stronger earthquakes. However, here for the considered seismic motion for both elastic and inelastic case with contact, no uplift was observed. Figure 504.77 shows the relative displacement of NPP structure for elastic and inelastic analysis at 11 seconds. In elastic case, the structure drifts a lot while the deformation in soil remains small. Whereas, in the inelastic case, the soil deforms and plastify in z-direction keeping the structure deformation small. Thus the elasto-plastic soil acts as a natural base isolators material. This demonstrates that for the considered earthquake motions, the elastic-plastic soil can prove to quite beneficial because of small deformation and excitation in structure.

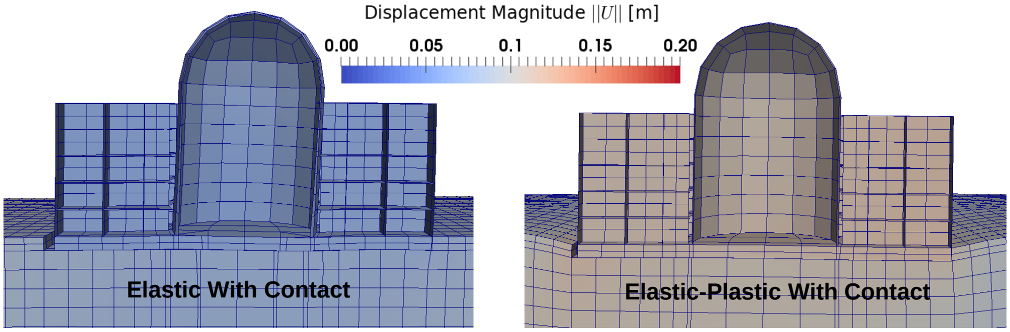

Figure 504.77: Deformation of the NPP structure at 11 seconds (scaled 100 times).

Figure 504.78 plots the inter-slip of foundation with respect to soil at location (A), (B) and (C) for elastic and elastic-plastic case with contact. It can be observed that point (A) and (B) slips both relatively towards each other describing the presence of surface waves. The center of the foundation (B) bends and slides comparatively less than the exterior ends. This also strongly shows the directivity effects of the motion coming from the $-x$ to $+x$ direction. The directivity effect is more pronounced in inelastic analysis resulting in comparatively more slip and permanent deformation. Careful observation of sliding in x-direction, shows a permanent slip of $18mm$ for elastic-plastic soil. Although not shown in figure, the whole NPP structure show tendency of rotation about its center of mass during the DRM stage.

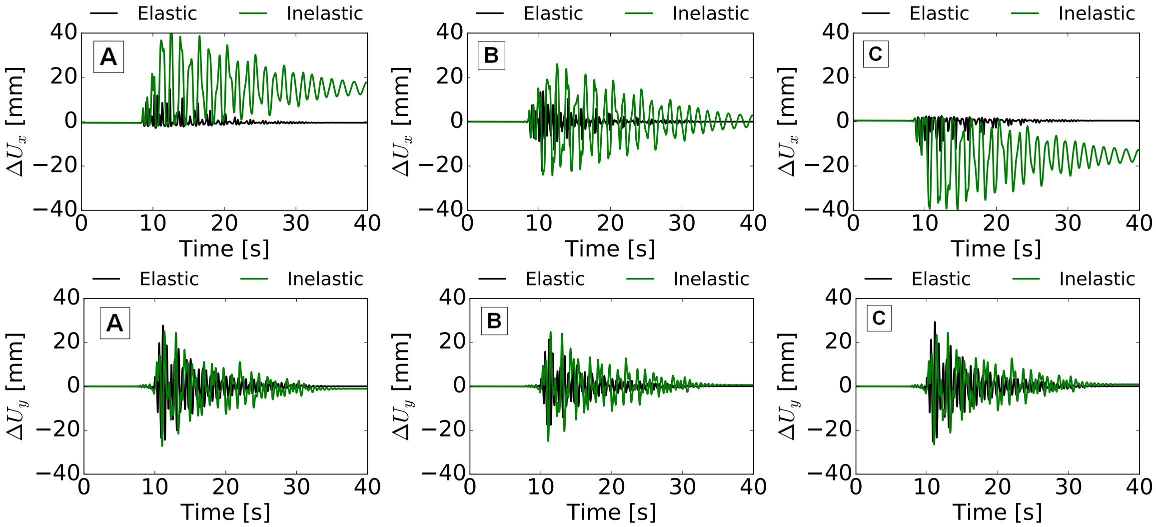

Figure 504.78: Slip of foundation with respect to soil beneath it in x-y slice plane for *Elastic* (elastic with contact) and *Inelastic* (Elastic-Plastic with contact).

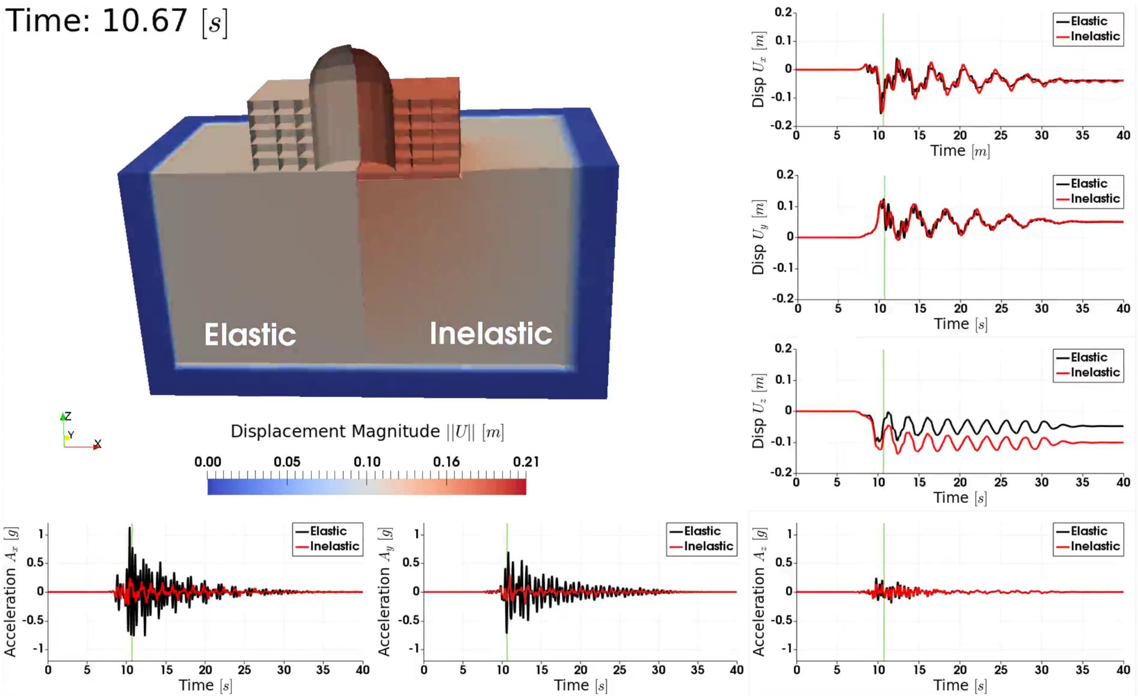

Figure 504.79: Animation of a linear elastic vs inelastic response of an NPP.

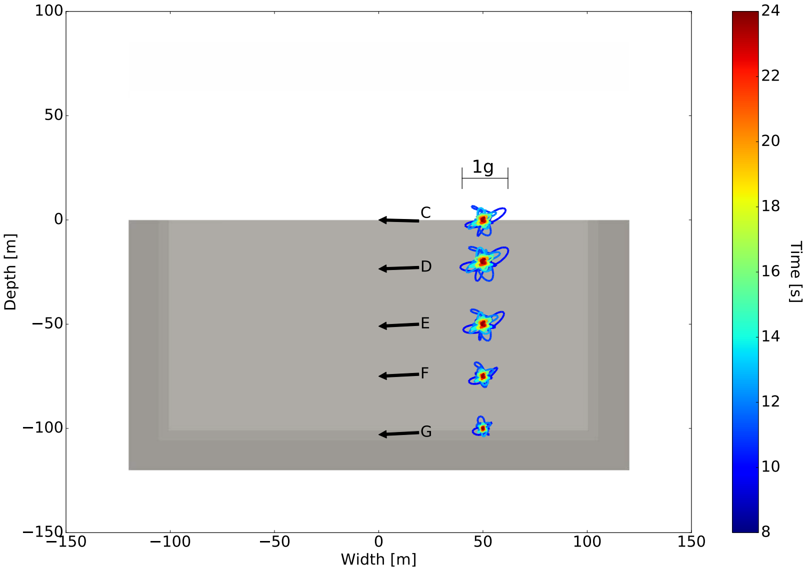

Figure 504.80: Free Field.

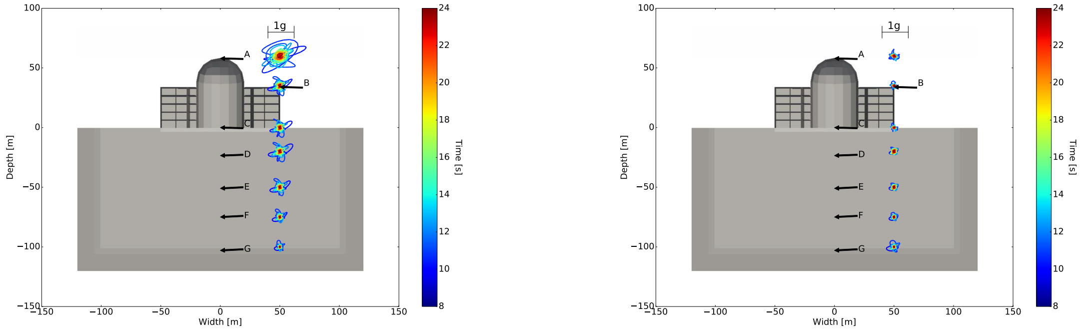

Figure 504.81: Acceleration traces, elastic vs inelastic.

504.6.4 Energy Dissipation

The energy dissipation in decoupled elastic plastic material under isothermal condition is given by Yang et al. (2019a):

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij} - \sigma_{ij}\dot{\epsilon}_{ij}^{el} - \rho\dot{\psi}_{pl} \geq 0 \tag{504.5}$$

where Φ is the rate of change of energy dissipation per unit volume (or dissipation density), σ_{ij} and ϵ_{ij} are the stress and strain tensors respectively, ϵ_{ij}^{el} is the elastic part of the strain tensor, ρ is the mass density of the material, and ψ_{pl} is the plastic free energy per unit volume (or plastic free energy density). Note that Equation 504.8 is derived from the first and second laws of thermodynamics, which indicate the conditions of energy balance and nonnegative rate of energy dissipation, respectively. Considering all possible forms of energy inside SSI system, the energy balance between input mechanical work W_{Input} and the combination of internal energy storage E_{Stored} and energy dissipation $E_{Dissipated}$ can be expressed as:

$$W_{Input} = E_{Stored} + E_{Dissipated} = KE + SE + PF + PD \tag{504.6}$$

where KE is the kinetic energy, SE is the elastic strain energy, PF is the plastic free energy, and PD is the energy dissipation due to material plasticity. Equations for each energy component can be found in Yang et al. (2018). Note that the plastic dissipation term PD includes energy dissipated in both elastic plastic solids (soil) and contact/interface elements.

Figure ?? shows the accumulated plastic dissipation density field of the NPP model at the end of seismic event. The super-structure does not dissipate energy since it is modeled as a linear elastic material. Significant amount of seismic energy is dissipated in the contact/interface zone between the structure and underlying soil, especially at regions around the corners and edges of the foundation.

An arch-shaped elastic region is formed under the structure, where the soil moves together with the foundation and dissipates little energy. Such observation is consistent with classic bearing capacity analysis, which also indicates the formation of a relatively undeformed "active zone" beneath foundation.

As can be observed in Figure ??, the plastic dissipation density at location (A) is the highest. From Figure ??, it can be observed that more than 80% of the total input work is dissipated due to material plasticity or contact slipping. About 70% of the energy dissipation happens due to contact/interface slipping, which indicates that the property and behavior of the interface between foundation and soil is crucial in SSI system. It is worth pointing out that there is about 10% of the input work transformed into plastic free energy, which falls in the typical range reported by Taylor and Quinney (1934).

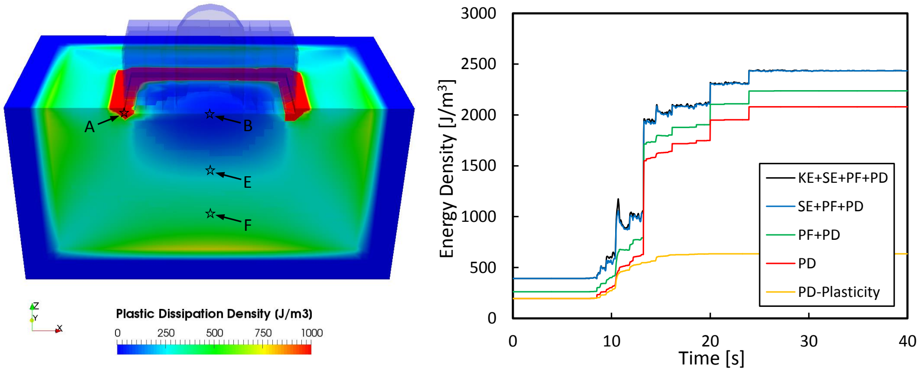

Figure 504.82: Energy dissipation in SMR model for inelastic (elastic-plastic soil with contact).

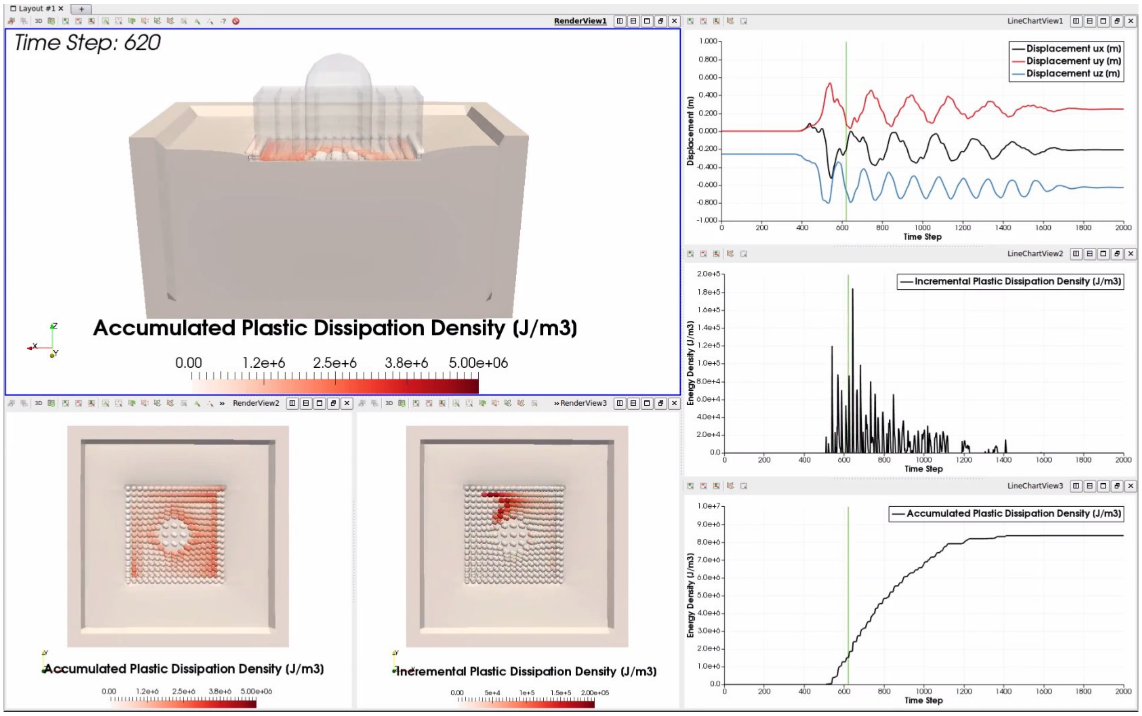

Figure 504.83: Animation of energy dissipation for an NPP.

504.6.5 Conclusion

Presented was a high fidelity seismic simulation methodology for investigating non-linear SSI effects on NPP structures. The site being in foot-wall of the reverse thrust fault, results in permanent subsidence in vertical direction. Due to plastification, elastic-plastic soil produces comparatively more vertical settlement than linear elastic soil. It also leads to damping of some higher frequency waves. This effect of non-linear material could be beneficial to the machines which are fatal to high frequency waves. It was found that with elastic-plastic soil, there was comparatively less seismic excitation and deformation in the NPP structure for the considered seismic motion. This illustrates that the stiff soil does not necessarily help in seismic behavior of structure. This also emphasizes the fact that linear elastic modeling of soil can lead to wrong conclusions resulting in huge capital loss. With the advancement of super-computers, uncertainty in modeling can be significantly reduced by following the high-fidelity modelling techniques discussed in this paper.

The non-linear effect studied here is with respect to the specific motion (Mw 5.5 up-dip slip fault). The non-linear effect cannot be fully described using this motion itself. More similar kind of research studies using different motions and geology needs to be carried out to find out the overall non-linear and geology effects on soil-structure interaction. The author also feels that new quantities needs to be formulated to study and compare different models to categories and unify the nonlinear effects on Soil Structure Interaction (SSI) effects. Energy dissipation analysis showed that the soil close to the corners and edges of the NPP structure dissipates large amount of seismic energy. An arch-shaped elastic region was identified where design can be improved so that soil strength at these locations can contribute to the overall safety of the SSI system.

504.7 3D Nonlinear Modeling for Small Modular Reactors (SMRs)

Figure 504.84 shows a generic model (half is only shown, full model is simulated) of an SMR. It is important to note extensive contact/interface zone of SMR walls with surrounding soil. This brings forward a number of modeling and simulation issues for SMRs:

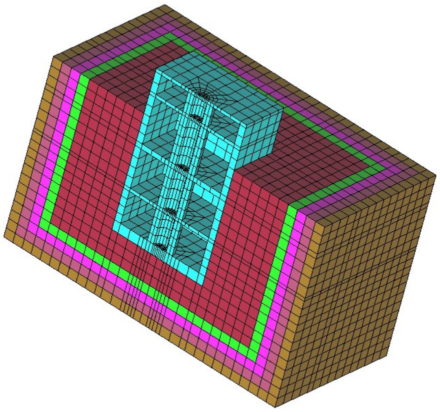

Figure 504.84: Generic model of a Small Modular Reactor (SMR).

- Seismic Motions: There will be a difference in seismic wave fields at the surface and at depth. Surface waves do extend somewhat into depth (about two wave lengths at most Aki and Richards (2002)), so different motion frequencies, wave lengths, and depending on soil stiffness, SMR will experience very different motions at tha surface and at the base. This seismic motion incoherence will affect seismic response of an SRM.
- Nonlinear/Inelastic Contact: Large contact/interface zone, with its nonlinear/inelastic behavior will have significant effect on dynamic response of a deeply embedded SMR.
- Nonlinear/Inelastic Soil Behavior: With deep embeddement, dynamic behavior an SMR is significantly influenced by the nonlinear/inelastic behavior of adjacent soil.
- Buoyant Forces: With deep embeddement, and (a possible) presence of underground water (water table that is within depth of embeddement), water pressure on walls of SMR will create buoyant forces. During earthquake shaking, those forces will change dynamically, with possibility of cyclic mobility and liquefaction (even for dense soil, due to water pumping during shaking).
- Uncertainty in Motions and Material: Due to large contact/interface area and significant embeddement, significant uncertainty and variability (incoherence) in seismic motions will be present.

Moreover, uncertainties in properties of soil material surrounding SMR will add to uncertainty of the response.

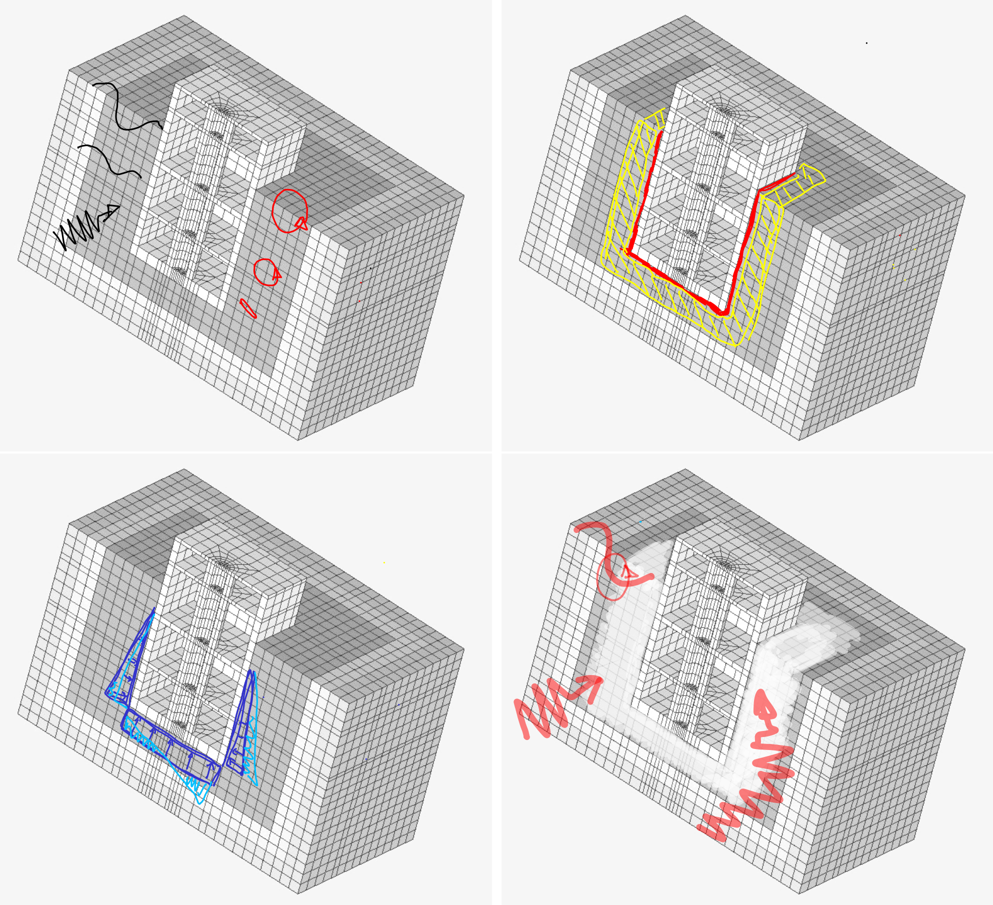

Figure 504.85: Four main issues for realistic modeling of Earthquake Soil Structure Interaction of SMRs: variable weave field at depth and surface, inelastic behavior of contact/interface and adjacent soil, dynamic buoyant forces, and uncertain seismic motions and material.

Writeup that follows is based on Wang et al. (2017).

It noted that input files for this model are available at this LINK, and can be directly simulated using Real-ESSI Simulator, `http://real-essi.info/`, that is available on Amazon Web Services, `https://aws.amazon.com/`.

504.7.1 Introduction

Seismic performance of nuclear facilities is carefully analyzed considering the significant problems that damage of such structures can bring. The structure investigated here is a deeply embedded Small

Modular Reactor (SMR). Model SMR structure analyzed here is deeply embedded (36 meters) with only 14 meters of structure above ground.

In recent years, many researchers (Spyrakos et al. (1989); El Ganainy and El Naggar (2009); Iida (2012)) made efforts to perform realistic modeling of dynamic SSI system and seismic response of underground structure. Romero et al. (2013) coupled FEM and BEM method to model wave propagation in elastic foundation and corresponding dynamic response of the structure. Fatahi and Tabatabaiefar (2013) investigated the seismic performance of mid-rise buildings on soft soils using existing earthquake records. An elastoplastic SSI analysis was conducted by Shahrour et al. (2010) to explore the seismic response of tunnels in soft soils. However, some inherent modeling uncertainties still existed in these previous studies and were not well addressed:

- A very important modeling uncertainty comes from the ground motion. For surface structures, it is common to use historical earthquake records and simplified 1C seismic wave propagation models (Paolucci et al. (2008)). Vertical ground motion are usually neglected. However, Oprsal and Fäh (2007) has emphasized the necessity to use 3C ground motion by showing the big difference between 1C and 3C computation result. The modeling uncertainty of input motion for seismic modeling of underground structure is even higher. Due to the lack of ground motion observations along the depth, deconvolution method is usually adopted in many studies (Elgamal et al. (2008)) to get the excitation motion at certain depth. The deconvolution procedure represents a 1C linear inverse analysis. This inverse analysis is seemingly simple but it can introduce considerable confusion and uncertainties to the modeling system (Mejia and Dawson (2006)).

- Another uncertainty comes from the method that is used to input seismic motion into SSI system. Usually free field motion are directly imposed to the structure without considering ESSI effects. This is especially common for underground structures where simplified static loads are directly imposed and these structures are simply designed to accommodate the estimated free field deformation(Hashash et al. (2001)).

- Nonlinear ESSI effects are also important factor that is neglected or simplified in many existing studies. There are three sources of significant nonlinearity in an ESSI system: (a) Inelastic (elastic-plastic) behavior of soil, (b) inelastic (elastic-plastic) behavior of the contact/interface zone, and (c) inelastic (elastic-damage-plastic) behavior of the structure. Early works found that structural response can be quite different when elastoplasticity of surrounding soil is considered (Bielak (1978); Iguchi and Luco (1981)). In addition to that Jeremić et al. (2004) reported that ESSI behavior can have both beneficial and detrimental effects on structural behavior. The nonlinear contact (interface) was analyzed by Hu and Pu (2004) and it was shown that its accurate modeling is a key part to realistic modeling of ESSI systems.

Due to computational limitations and complicated nature of ESSI problems mentioned above, there exist only few high-fidelity ESSI simulations, for bridges (Jeremić et al. (2009)) and tunnels (Corigliano et al. (2011)). To the Author's knowledge, there is no high fidelity (realistic 3C motions, realistic elastic plastic soil modeling, and realistic contact/interface modeling) for a deeply embedded SMR structure. In this paper, we present high fidelity modeling of SMR using state-of-the-art ESSI methodology. Realistic 3C free field seismic motions are modeled using regional scale wave propagation models. Developed free field motions are then input into ESSI system using Domain Reduction Method (Bielak et al. (2003a)). Modeling description section presents inelastic/nonlinear modeling details for elastic-plastic models of surrounding soils and nonlinear interface/contact behavior. The inelastic/nonlinear modeling result are compared with linear elastic in Simulation Results section.

In addition to accurate modeling of 3C motions and nonlinear effects, energy propagation through the model is also accurately modeled. Energy dissipation is a widely used indicator of material damage in elastic plastic materials. A common misconception does exist, however, on the meaning of plastic work and plastic energy dissipation, as observed in a number of publications. Correct evaluation of energy dissipation should follow the principles of thermodynamics that incorporated plastic free energy (Rosakis et al., 2000; Dafalias et al., 2002). The thermodynamics framework presented by Yang et al. (2018, 2019a) is implemented in the Real-ESSI Simulator Jeremić et al. (1988-2025), and is used to perform energy analysis on the SMR model in this paper. Energy dissipation in the SMR model is discussed in some detail.

504.7.2 Domain Reduction method

Input seismic motions into finite element model is an indispensable step for the simulation of soil structure interaction. The method we used here is called Domain Reduction Method, developed by Bielak et al. (2003a). It is a modular, two-step dynamic procedure aimed at reducing the large computation domain to a more manageable size. Firstly, large scale regional free field model is developed encompassing causative fault and location of SMR structure (however SMR structure is not present, it is a free field model). Time series of free field motions (displacements and accelerations) are recorded at locations of DRM elements, a single layer of finite elements encompassing soil structure SMR model. Those motions are then used in the second step, to develop effective forces that are used to input free field motions into ESSI SMR model.

504.7.3 3C Free Field Motions

Development of free field motions was done using a fourth order finite difference program SW4 (Petersson and Sjögreen (2018) developed at LLNL. Modeled was propagation of fault rupture in a model with dimensions $9km \times 6km \times 20km$. The magnitude of simulated earthquake is 5.5. The shear wave velocity of soils in surface layer (500 meters thick) is V_s = 500m/s. Motions were recorded in a box with dimensions $300m \times 300m \times 200m$

The characteristic ground motions recorded by ESSI nodes are plotted in Figure 504.86. The peak ground acceleration (PGA) in x and y direction is about 1g. Apart from that, significant amount of vertical motions with PGA $0.5g$ is also observed. The peak ground displacement (PGD) is about 0.1m in horizontal direction. Since ESSI box is located in the foot wall of the reverse fault, the permanent ground subsidence of about 6cm is recorded. Fourier transformation and response spectrum of the motions are shown in figure 504.87. The frequency range of the motion is within 15Hz. The dominant frequency of the motion is around 5 Hz. In response spectrum, we also see significant resonance effects for structure whose fundamental period is around 0.2s corresponding to 5 Hz fundamental frequency.

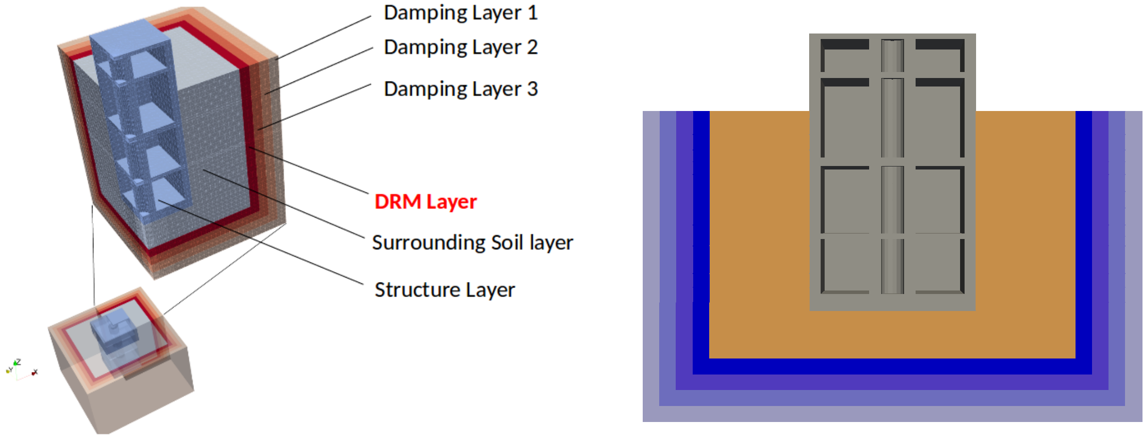

Figure 504.88: FEM model for an SMR.

504.7.4 Model Description

In order to reduce model size using DRM method, we develop our target model with 6 layers. As shown in figure 504.88, the innermost part is a structure layer, which is surrounded by a soil layer. Following that, there is a DRM layer used to apply equivalent earthquake force. Outside DRM layer, there are three damping layers. These damping layers are designed to add high Rayleigh damping so that the outgoing wave (vibrations of structure, radiation damping) can be adsorbed. Table 504.5 shows the material used. The size of whole FEM model is 72m×72m×56m. There are 177,806 nodes, 20172 27-node brick elements, 3,177 contact/interface elements (modeling the interface between soil and embedded structure), with a total of over 533 thousand degrees of freedom (DoFs)l. The average mesh size is 3 meters. Newmark time integration method is used in this study with parameters γ =0.7 and β=0.36 addingl numerical damping that reduces high frequency motions that were introduced by SW4. In order to capture the wave propagation in FEM model, mesh size should be controlled so that there is no artificial filtering to motions above certain frequency (Watanabe et al., 2017). As pointed out by Hughes (1987), 10 linear interpolation finite elements and 2 quadratic interpolation elements are needed per wave wavelength. Since second order 27 node brick element are used here, the minimum wave length captured is 6 meters. Considering shear wave velocity $v_s = 500 m/s$, the maximum frequency calculated by equation 504.7 is 83 Hz. Even when material plasticifies (becomes softer), model is still propagating high frequencies of up to required $f_{max} \leq$ 15Hz.

$$f_{max} = v_s/\lambda_{min} \tag{504.7}$$

504.7.4.1 Embedded Nuclear Structure

Small Modular Reactor (SMR) analyzed here is a 4 storied reinforced concrete structure with total height 50 meters and 36 meters embedded in the ground. The length and width of the structure is 30 meters. The whole structure is modeled using 27-node solid brick element with linear elastic material. The Young's modulus is selected as $E = 30\text{GPa}$ and Poisson's ratio $\nu = 0.2$. Single layer of 27 node bricks can accurately model (beam and plate) bending, and is hence chosen for structural model.

504.7.4.2 Soil Model

The depth of the model surrounding the structure is 45m. The soil is assumed to be saturated soil with undrained behavior during the earthquake. In order to considering nonlinear site effects, the soil is modeled with elastoplastic material. In the past 20 years, many 3D constitutive models Yang et al. (2003); Dafalias and Manzari (2004b); Park and Byrne (2004); Pisanò and Jeremić (2014) have been developed. Undrained behavior can be approximately modeled using von Mises material model (Yang and Jeremić, 2003). Elastic plastic von Mises material model with linear kinematic hardening rule is used here. The material parameters are presented in table 504.5. Backward Euler implicit algorithm (Jeremić and Sture (1997)) is used for the equilibrium iterations at constitutive level.

504.7.4.3 Soft Contact Element

Model for contact/interface (axial contact, gap opening and closing and slip behavior) of the interface between structure and surrounding soil, relies on a node-to-node soft contact/interface element (Sinha and Jeremić (2017)). In soft contact, the normal stiffness exponentially grows as the relative displacement between two contact/interface nodes increases and finally reaches maximum normal stiffness. 3,177 contact elements are placed at the soil-structure interface. Contact/Interface parameters are shown in Table 504.5.

504.7.4.4 Simulation Procedure

The nonlinear ESSI analysis was conducted using Real-ESSI Simulator (Jeremić et al. (1988-2025)) developed at UC Davis and LBNL. Two SMR simulation models were simulated. First model uses linear elastic soil without contact element and second model uses inelastic/nonlinear soil with inelastic/nonlinear contact. In both cases, two loading stages were modeled: First loading stage is a self weight, developed by adding a uniform gravity field. This is a necessary stage for inelastic analysis in order to develop initial stress state of structure and surrounding soil before earthquake comes. Self weight was also applied to the elastic model, just so that we have comparable displacement results. Then second loading stage

Table 504.5: Modeling parameters

Material parameters	shear wave velocity [m/s]	500
	Young's modulus [GPa]	1.25
	Poisson ratio	0.25
	von Mises radius [kPa]	60
	kinematic hardening rate [MPa]	0
Contact parameters	initial normal stiffness [N/m]	1e9
	hardening rate [/m]	1000
	maximum normal stiffness [N/m]	1e12
	tangential stiffness [N/m]	1e7
	normal damping [N/(m/s)]	100
	tangential damping [N/(m/s)]	100
	friction ratio	0.25
Damping parameters	structure layer	5%
	surrounding soil	15%
	DRM layer	20%
	outside layer 1	20%
	outside layer 2	40%
	outside layer 3	60%

is an earthquake load. Simulations were performed on a local parallel computer with parallel version of the Real-ESSI Simulator using 10 CPUs. It is noted that Real-ESSI Simulator is also available on Amazon and Google cloud parallel computers as well as on large national parallel compters at the LBNLf (EDISON and CORI). Local parallel computer (a workstation) was used in order to illustrate versatility of Real-ESSI Simulator and to show that high fidelity parallel computations do not need to require high price parallel computers.

504.7.5 Simulation Results

Figure 504.89 shows time series acceleration response of top center of SMR.

The elastic results represent simulation case where the surrounding soil is modeled using linear elastic material and no contact elements in soil-structure interface. The inelastic results represent simulation case where the surrounding soil is modeled using inelastic soil material and an inelastic contact. Signifi-

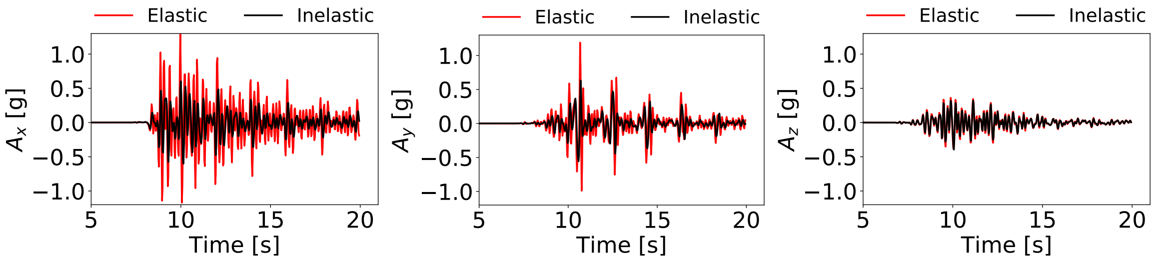

Figure 504.89: Time Series Acceleration Response.

cant acceleration decreases can be seen in the inelastic case. The horizontal peak acceleration values is reduced by almost 40%. This is due to plastification of soil and inelastic response of the contact/interface zone. Moreover significant seismic energy is dissipated, so that inelastic soil and inelastic contact/interface act as seismic dissipators and isolators during seismic event. The acceleration difference in vertical, z direction is less significant than horizontal direction.

Figure 504.90 shows Fourier magnitude that high frequency component of horizontal acceleration was significant decreased in inelastic case.

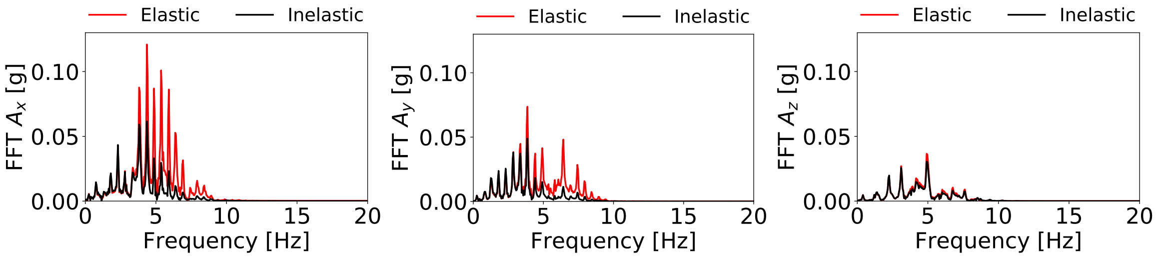

Figure 504.90: Acceleration Response in frequency domain

Material Modeling Influence on Results is Shown in Figure 504.91.

SMR: Variation of Acceleration with Depth is Shown in Figures 504.92 and 504.93.

SMR: PGA and PGD Depth Variation is Shown in Figure 504.94.

- The PGA & PGD of SSI systems are (very) different from free field motions,

- Material nonlinearity has significant effect on acceleration response.

SMR: Elastic vs Inelastic response is shown in Figure 504.95.

Figure 504.96 shows the distribution of plastic strain in surrounding soil. There are two main plastic zones near two bottom corners of the structure. Also the plastic strain at the soil-structure interface is higher than adjacent area. It is interesting to note that there is an elastic zone beneath structure. The

504.7.6 Energy Dissipation

According to the thermodynamics framework presented by Yang et al. (2019a), the energy dissipation in any decoupled material undergoing isothermal process can be expressed as:

$$\Phi = \sigma_{ij}\dot{\epsilon}_{ij} - \sigma_{ij}\dot{\epsilon}^{el}_{ij} - \rho\dot{\psi}_{pl} \geq 0 \tag{504.8}$$

where Φ is the rate of change of energy dissipation per unit volume (or dissipation density), σ_{ij} and ϵ_{ij} are the stress and strain tensors respectively, ϵ^{el}_{ij} is the elastic part of the strain tensor, ρ is the mass density of the material, and ψ_{pl} is the plastic free energy per unit volume (or plastic free energy density). Equation 504.8 ensures the energy balance and nonnegative energy dissipation conditions that correspond to the first and second law of thermodynamics.

With Equation 504.8, the energy balance of a SSI system is simply given by:

$$W_{Input} = E_{Stored} + E_{Dissipated} = KE + SE + PF + PD \tag{504.9}$$

where W_{Input} is the input work due to external loading, KE is the kinetic energy, SE is the elastic strain energy, PF is the plastic free energy, and PD is the energy dissipation due to material plasticity. Formulation for each energy component can be found in Yang et al. (2018). Note that in Equation 504.9, it is assumed that no other forms of energy dissipation exists in the system.

Figure 504.97 (a) shows the distribution of plastic dissipation density in the SMR model at the end of simulation. The case presented in this section is elastic plastic soil without contact/interface element. Note that the structure is modeled with elastic material, so they do not dissipate any energy. As expected, more seismic energy is dissipated around the corners and edges of the structure due to stress concentration. It can be observed that there are several elastic regions around the boundaries of the structure, which means that the soil there does not plastify much and moves together with the structure. Economy of the design can be improved by better utilizing the strength of soil around these locations.

Figure 504.97 (b) show the evolution of energy components at location A. It can be observed that the amount of plastic energy dissipation is much larger than the other forms of energy, indicating that the nonlinear effect is quite significant in deeply embedded structure. Another interesting observation is the small amount of plastic free energy whose quantity largely depends on material hardening parameters and loading conditions. It should be pointed out that even if it is small, plastic free energy should never be neglected so that the condition of nonnegative incremental energy dissipation can be upheld Rosakis et al. (2000); Taylor and Quinney (1934).

504.7.7 SMR Inelastic Modeling Conclusions

The seismic response of an embedded SMR has been modeled with high fidelity. Using state-of-the-art nonlinear ESSI simulation techniques, many modeling uncertainties have been eliminated. The methodology shown here is also applicable to many other ESSI problems (buildings, bridges, dams, etc.). The simulation result of SMR shows that the acceleration response of the structure decreases with nonlinear effects properly modeled. In addition, the high frequency component of acceleration is significantly damped out in inelastic case due to soil plastification.

Energy dissipation analysis shows that the soil close to the edge of the SMR structure dissipates large amount of seismic energy during shaking. Such observation also indicates significant nonlinear effect when elastoplastic material is used for soil modeling. Several elastic regions are identified where design can be improved so that soil strength at these locations can contribute to the safety of the SSI system.

504.8 Inclined Waves, Free Field and SMR Modeling

Methodology developed by Wang et al. (2020a) and presented in section 109.2.5 on page 557 is illustrated here. This is really a repeat of results from Wang et al. (2020a).

Input files for these models are available HERE.

Presented WPF-DRM method is implemented in the Real-ESSI Simulator (Jeremić et al., 1988-2025). Described examples and publicly available executables for the Real ESSI sequential and parallel programs are available through Real ESSI Simulator web site `http://real-essi.info/`. All numerical examples presented here are analyzed using Real-ESSI Simulator version 20.01, in parallel computing mode, on UC Davis and Amazon Web Services parallel computers.

504.8.1 Free Field Modeling and Verification

Free field response of layered ground excited by an inclined incident seismic wave is used to illustrate and verify developed methodology. Analytic solutions based on Thomson-Haskell propagation matrix technique (Thomson, 1950; Haskell, 1953; Silva, 1976) are used for verification.

A finite element model for the free field, that is 300m wide and 200m deep, consisting of three layers, as described in Table 504.6, is used.

It is noted that dimension of analyzed model is 300m × 200m, however there exist additional finite elements outside this domain: DRM layer is a single layer of finite elements that surround the interior domain. Beside the DRM layer, there are absorbing layers consisting of multiple layers of finite elements with high viscous damping. These damping layers should be thick enough to absorb the outgoing waves.

Table 504.6: Properties of layers: thickness d, density ρ, shear wave velocity V_s, compressional wave velocity V_p and Poisson's ratio ν.

Layer	d [m]	ρ [kg/m^3]	V_s [m/s]	V_p [m/s]	ν
1	50	2100	500	816.5	0.2
2	100	2300	750	1403.1	0.3
3	∞	2500	1000	2081.7	0.35

The thickness and damping parameters of these absorbing layers are determined such that the response of exterior damping layer given by earthquake soil structure interaction analysis is negligible compared to the inner part. A fixed boundary condition is applied to the outer boundary. It is also noted that theoretically there should be no waves propagating outside of the DRM layer for a free field response. Additional damping layers are added in order to accommodate further, non-free field model expansions and additions. Finite element size is set to 5m, and with 10 finite elements per wave length, this mesh can accurately propagate waves of up to $f = 10\text{Hz}$, for surface soil with shear wave velocity of $V_s = 500\text{m/s}^2$, as per Lysmer and Kuhlemeyer (1969); Watanabe et al. (2017).

A number of monochromatic, single frequency plane SV wave, represented by a cosine function, with variable inclinations $\theta = 10^o, 45^o, 60^o, 80^o$ and variable frequencies, $f = 1.0, 2.5, 5.0, 10.0\text{Hz}$, are applied to the layered ground model using developed methodology. The incident SV wave magnitude from the depth is 0.06m and is kept the same for all the analyzed cases. It is noted that inclination angle θ is measured between a wave propagation direction vector and vertical axes. The wave inclination θ depends on many factors, e.g., source focal mechanism and radiation pattern, wave propagation path and local site geology and topography. The typical range of inclination is $0^\circ \sim 40^\circ$ (Tabatabaie et al., 1986; Sigaki et al., 2000). For example, Tabatabaie et al. (1986) estimated that the incidence angle of shear waves at the SMART-1 array site is around 20 degrees using the recorded motions from 1981 Taiwan earthquake. For far-field, flat engineering site with large impedance contrast (e.g., soft soil overlying stiff bedrock), the assumption of vertical wave propagation can be adopted due to very small inclination of incident seismic waves. However, for near-field, hard rock site with low impedance contrast or engineering site with significant topography, incidence angle of seismic waves tends to be large and inclined wave propagation should be carefully modeled.

Free field motions are developed and introduced into the model through WPF-DRM. Figure 504.99 shows snapshots of wave displacements in the model, for a wave frequency of $f = 5\text{Hz}$, for different input plane wave inclinations, $\theta = 10^o, 45^o, 60^o, 80^o$. Figure 504.100 shows snapshots of wave displacements in the model, for a wave that is inclined at $\theta = 60^o$, for variable input plane wave frequencies $f = 1.0, 2.5, 5.0, 10.0\text{Hz}$.

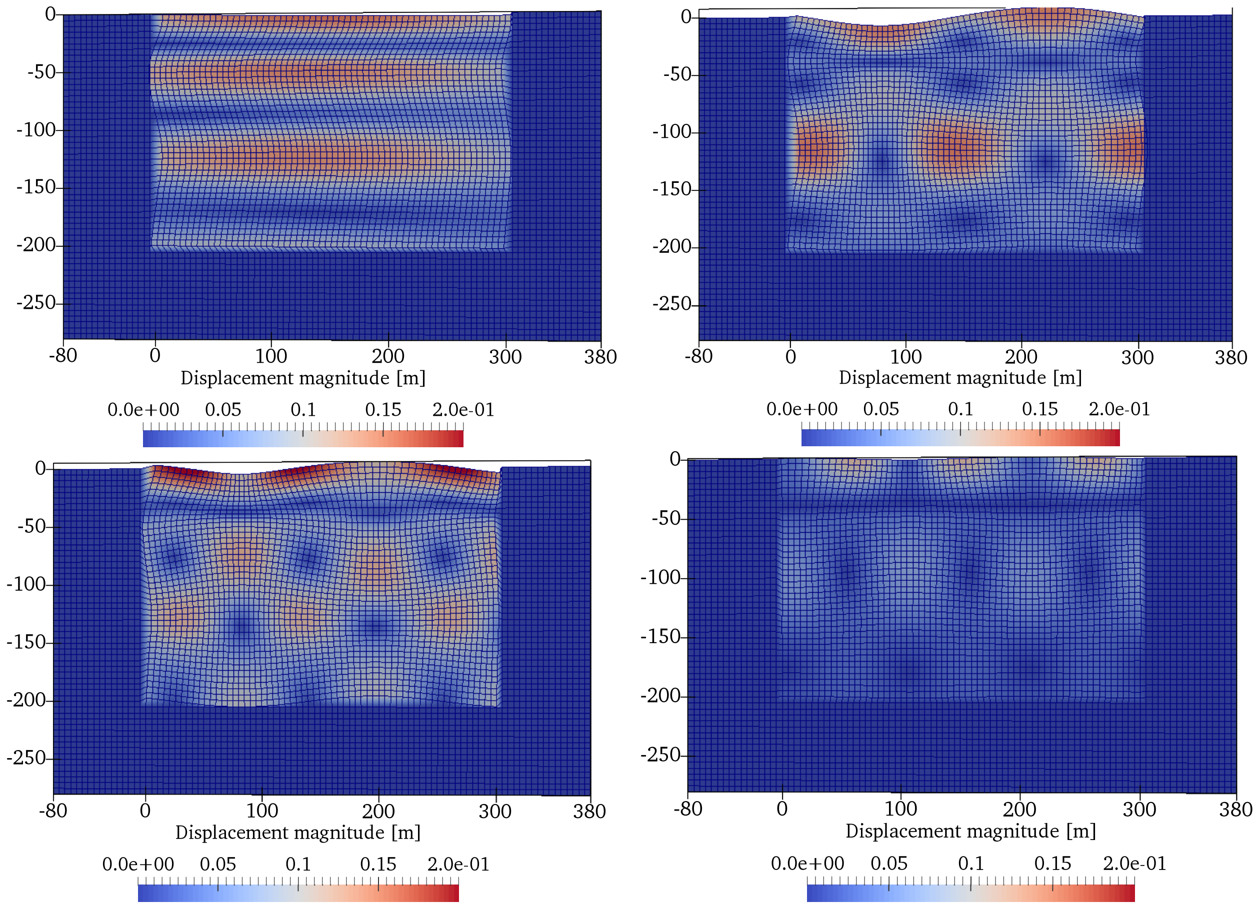

Figure 504.99: Displacement magnitudes for a free field response under incident SV wave, frequency $f = 5$Hz, with different incident wave inclinations: (a) $\theta = 10^\circ$ (b) $\theta = 45^\circ$ (c) $\theta = 60^\circ$ (d) incident angle $\theta = 80^\circ$.

Few notes are in order upon visual inspection of results in Figures 504.99 and 504.100. The outgoing waves in exterior region, outside DRM layer, are negligibly small, almost zero for all the cases. This is indeed expected, as it follows from the theory of the domain reduction method (Bielak et al., 2003a; Yoshimura et al., 2003a), whereby the so called residual field (w_e) should be non-existent for free field motions, that were used to develop effective DRM forces.

Comparing free field responses for SV wave with different incident angles, Figure 504.99, the $\theta = 10^\circ$ case behaves very similar to 1D vertically propagating motion field that is commonly used in engineering practice. It is noted, however that there are still vertical motions at the surface due to such almost vertical SV wave interacting with the free surface. For cases where wave inclination is more significant, for $\theta = 45^\circ$ and $\theta = 60^\circ$, significant surface motions are observed, with pronounced vertical and horizontal motions. When the incident wave inclination is $\theta = 80^\circ$, seismic wave propagates almost horizontally

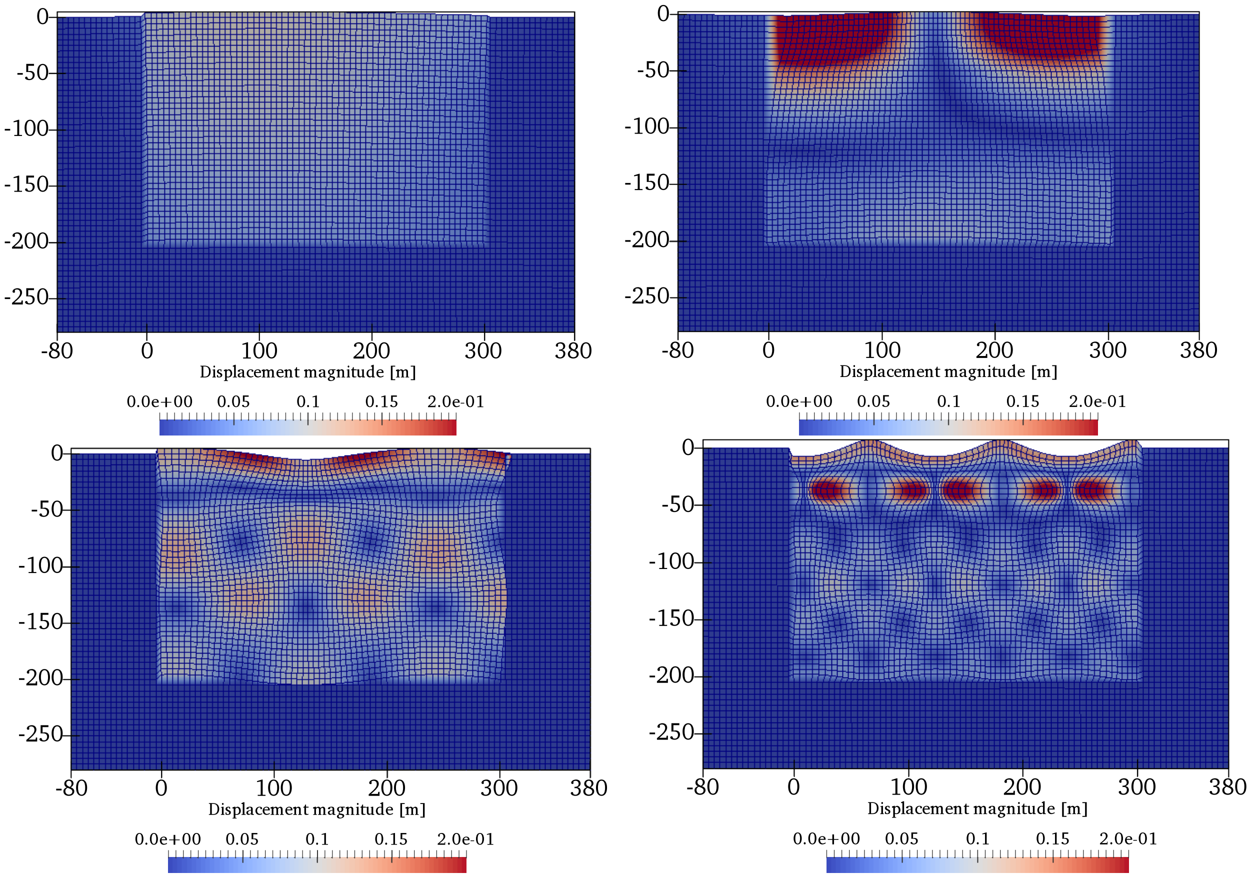

Figure 504.100: Displacement magnitudes for a free field response under incident SV wave at an angle of $\theta = 60^o$, with different frequencies: (a) $f = 1.0$Hz (b) $f = 2.5$Hz (c) $f = 5.0$Hz (d) $f = 10.0$Hz.

without generating significant surface motions. It is also noted that the displacement magnitude of the seismic wave field for wave inclination case $\theta = 80^{\circ}$ is much smaller than for the other cases. This is reasonable considering the site amplification for other free field cases comes, in part, from the impedance contrast of vertical wave propagation.

Results, snapshots of displacement field magnitudes for wave fields of different frequencies are shown in Figure 504.100 for seismic motion inclined SV wave field at $\theta = 60^{\circ}$. It is noted that layer boundaries, impedance contrasts, are at -50m, and at -150m. Those layer boundaries can be visually identified from distribution of waves through model depth with positive and negative interference reflected and refracted waves within different layers of the domain.

Figures 504.101 and 504.102 compare simulated free field horizontal and vertical displacement magnitudes against corresponding analytical solutions along the depth. It is noted that acceleration magnitudes can be obtained by multiplying displacement magnitudes with w^2. Very good agreement is observed

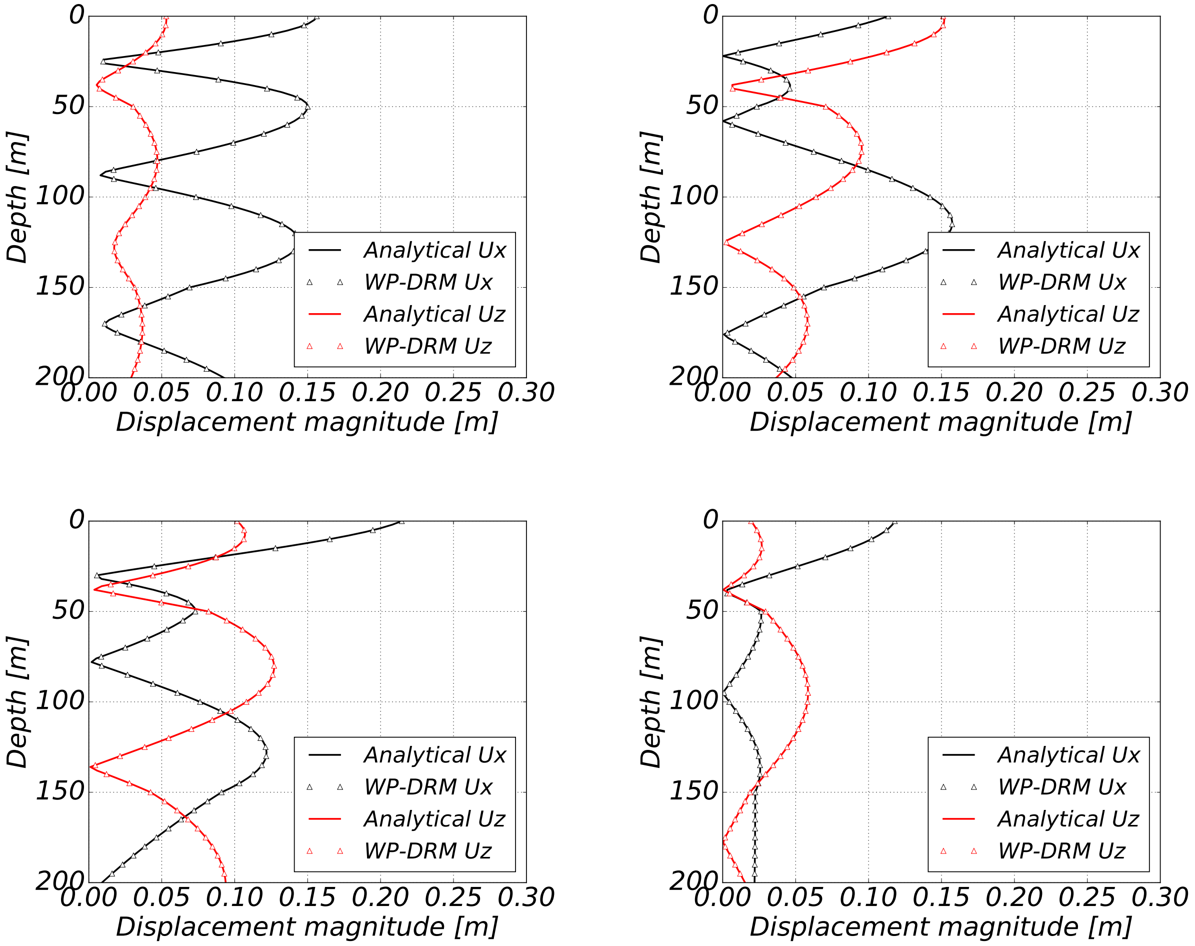

Figure 504.101: Verification of free field modeling under incident SV wave $f = 5Hz$ with different incident angles θ: (a) $\theta = 10°$, (b) $\theta = 45°$, (c) $\theta = 60°$ (d) $\theta = 80°$.

between results given by WPF-DRM simulation and analytical solutions. Several interesting observations can also be made:

1. Along with the increase in frequencies, the vertical wave length becomes shorter, and that results in more wave interferences along the depth.
2. The existence of layers and interfaces at $z = -50$m and $z = -150$m complicates the spatial variation of wave field along the depth, especially for higher frequencies, $f = 5Hz$ and $10Hz$. The response curves at depths $0 \sim 50$m and $50 \sim 150$m are quite different in both amplitude and variation pattern.

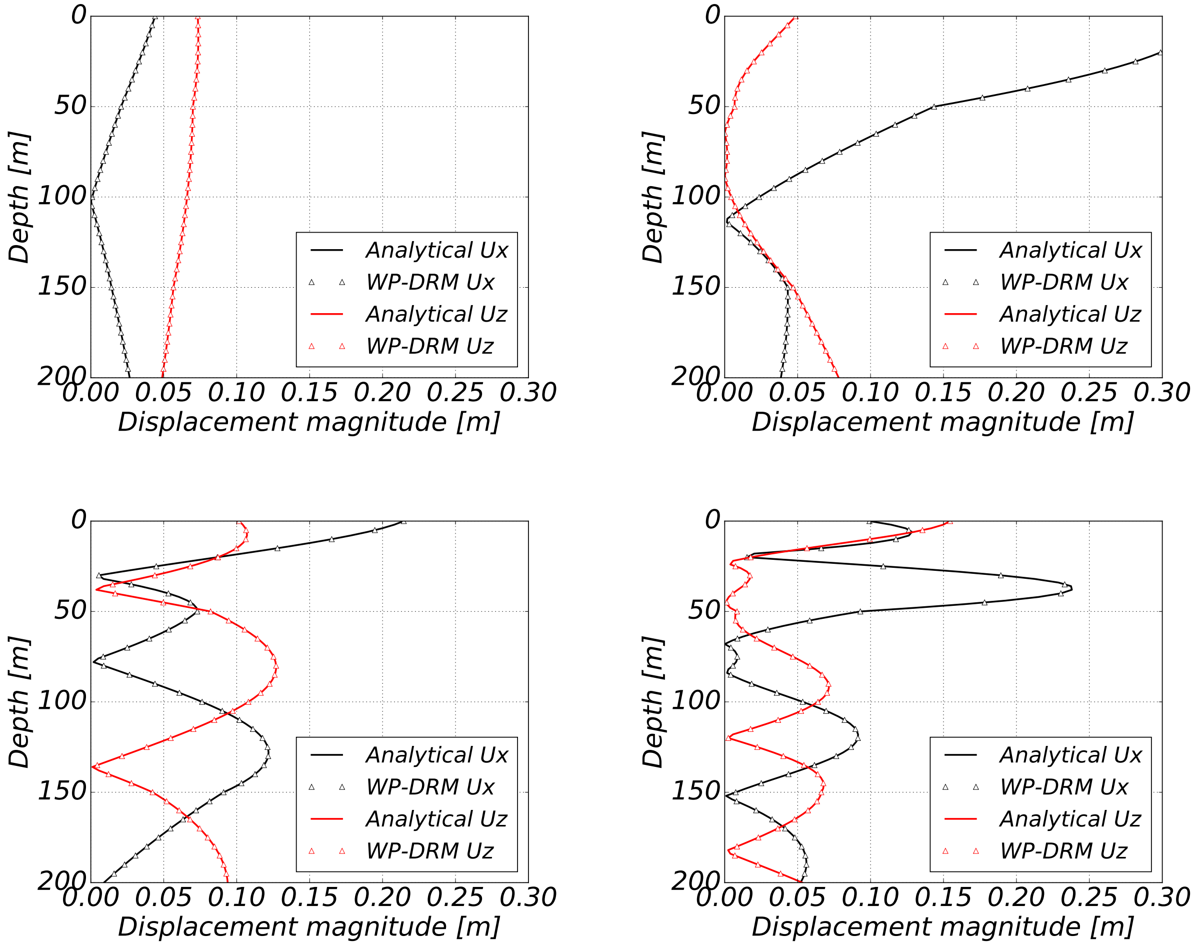

Figure 504.102: Verification of free field modeling under incident $\theta = 60^o$ SV wave with different frequencies f: (a) $f = 1.0$Hz, (b) $f = 2.5$Hz, (c) $f = 5.0$Hz, (d) $f = 10.0$Hz.

3. From Fig. 504.101, it can be seen that inclination angle of input SV wave also plays a crucial role in the interference characteristic of inclined wave field. Periodic peaks and troughs shown in the case of 10° inclination are typical interference characteristics of 1D homogeneous, vertically propagating wave field. However, the interference characteristics given by other wave inclinations show significant differences. These different variation patterns along the depth, that might not make much difference for shallow founded surface structures, can result in very different seismic response for deeply embedded structures.

504.8.2 Deeply Embedded Soil-Structure Model

Deeply embedded structural model, a model of a Small Modular Reactor (SMR) is analyzed and used to illustrate developed methodology. The FEM model of an SMR structure embedded in layered ground is shown in Figure 504.103(a). The embedment depth is 36m, while the height of SMR structure above ground is 14m. The structure width is 30m and the whole model width of SSI system is 150m. It is noted that the lateral extent of soil domain should be large enough such that the outgoing waves passing through DRM layer are insignificant. These waves can then be damped out through the absorbing layer and would have negligible influence on the dynamic response of SMR. Key factors to determine the model width of SSI system include structural width, intensity of seismic excitations, etc. Detailed discussions regarding the required lateral extent of soil domain for dynamic SSI analysis can be found in Sharma et al. (2020). Eleven representative points, point A to point K in Figure 504.103(b), are selected to monitor the dynamic response of SMR. The layered ground parameters are the same as those used in free field study given in Table 504.6.

To proper model wave propagation, the finite element size and time step should be carefully controlled to reduce discretization errors. For linear displacement approximation within finite element, in this case eight-node brick elements, at least 10 nodes per wavelength should be used (Watanabe et al., 2017). The time step length Δt is limited by Courant-Friedrichs-Lewy condition (Courant and Hilbert, 1989) for stability. In addition, following requirement needs to be met to accurately capture the propagation of wave front (Jeremić et al., 2009), where Δh is the mesh size and v is the highest wave velocity.

$$\Delta t < \frac{\Delta h}{v} \tag{504.10}$$

In this study, eight-node brick element with 4m mesh size is used for spatial discretization. The maximum frequency the model can propagate is about $12.5Hz$ considering the minimum elastic shear wave velocity $500m/s$. Time step is chosen as $\Delta t = 0.005$s. Newmark time integration method (Newmark, 1959) is used with Newmark parameters $\gamma = 0.505$ and $\beta = 0.25(0.5 + \gamma)^2$. Since parameter $\gamma > 0.5$, a small amount of numerical, algorithmic damping is introduced to damp out unrealistic high frequency responses from spatial discretization (Argyris and Mlejnek, 1991). See Yang et al. (2019b,c) for more information about the proper selection of Newmark parameters for dynamic analysis. Gradually increasing Rayleigh damping (7%, 15% and 30%) is assigned to the inner, middle and exterior part of the absorbing layers, outside of the DRM layer, to prevent reflection of radiated outgoing waves (Jeremić et al., 2009; Abell et al., 2018). These damping values are determined such that after dynamic SSI analysis the response of the exterior absorbing layer is negligible compared to the inner part.

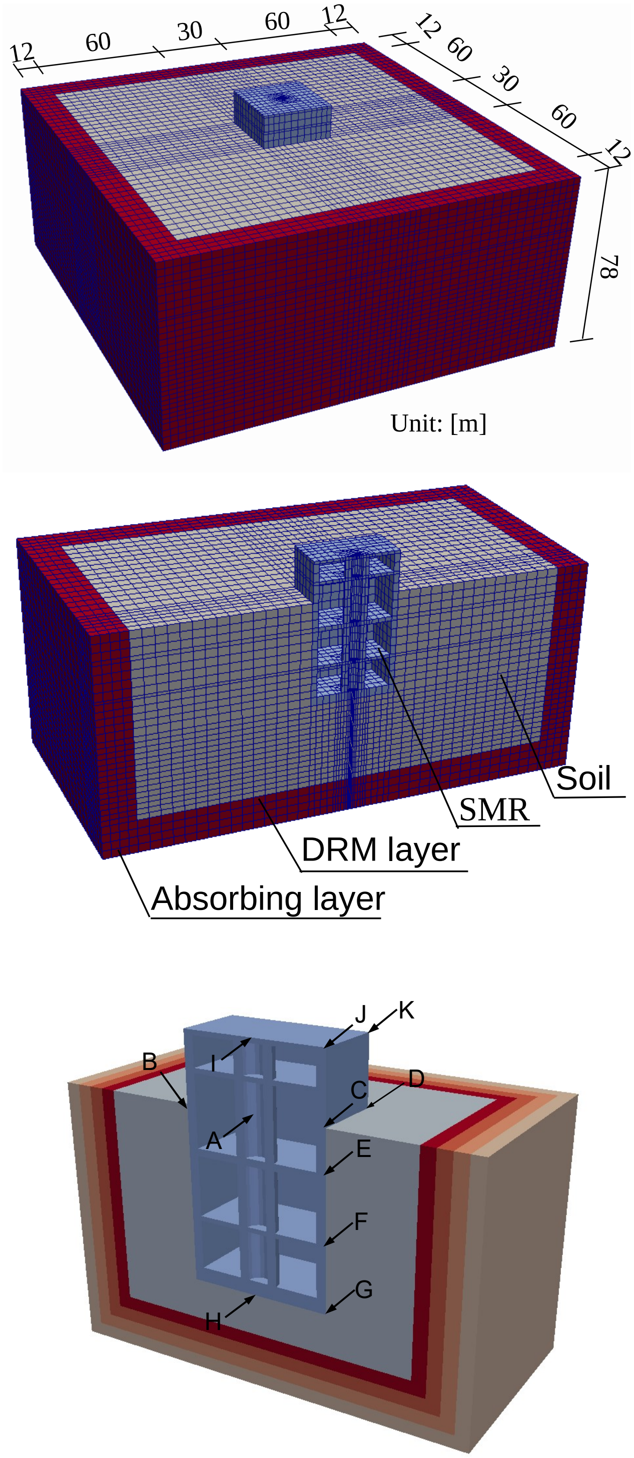

Figure 504.103: FEM model of embedded SMR and representative points.

504.8.3 SMR Excited with Inclined SV Waves

Deeply embedded SMR structure is excited with inclined plane waves, at inclination angles of $\theta = 10^\circ, 45^\circ, 60^\circ$ and 80°. Seismic wave frequency used for this set of numerical test was set at $f = 5Hz$. As described in table 504.6 on page 2544, shear wave velocities of top 50m layer is $V_s = 500$m/s while the lower layer is 100m think and has a shear wave velocity of $V_s = 750$m/s. Due to presence of layers, seismic wave field close to the surface is made up Rayleigh and Stoneley waves (Aki and Richards, 2002; Semblat and Pecker, 2009). It might thus be difficult to separate influence of these different surface waves the response of the SMR. For example, in Figure 504.99 on page 2545, that shows displacement magnitudes at certain time, for different inclination of incident plane wave, Stoneley wave is apparent close to depth of 50m. In addition, Rayleigh wave is also apparent close to free field surface. Those wave fields, when applied to the SMR SSI system, produce response, at location of point A[2] on SMR structure, as shown in Figures 504.104 and 504.105.

It is noted that corresponding free field motions at the same location are also plotted for comparison. Variations of displacement magnitudes caused by different inclinations of incident SV wave are quite noticeable for vertical displacements and accelerations, while influence on horizontal displacements and accelerations is much less significant. The reduction of vertical displacement and accelerations that is observed in all the four cases, is consistent with the concept of "base averaging", "ironing out" of seismic motions by Housner (1957). The most significant reduction occurs for the case of incident wave at an angle $\theta = 45^\circ$ while little reduction is seen in the case of $\theta = 80^\circ$.

The deformed shapes of SMR at $t = 0.4s$ for four scenarios are shown in Figure 504.106. In the cases of seismic waves at inclinations $\theta = 45^\circ$ and $\theta = 60^\circ$, rocking responses of SMR are quite evident when compared with the cases of almost vertical wave propagation ($\theta = 10^\circ$) and almost horizontal wave propagation ($\theta = 80^\circ$).

---

[2] Location of point A is in the middle of SMR structure, where center of the free field model would be, please see Figure 504.103 on page 2550.

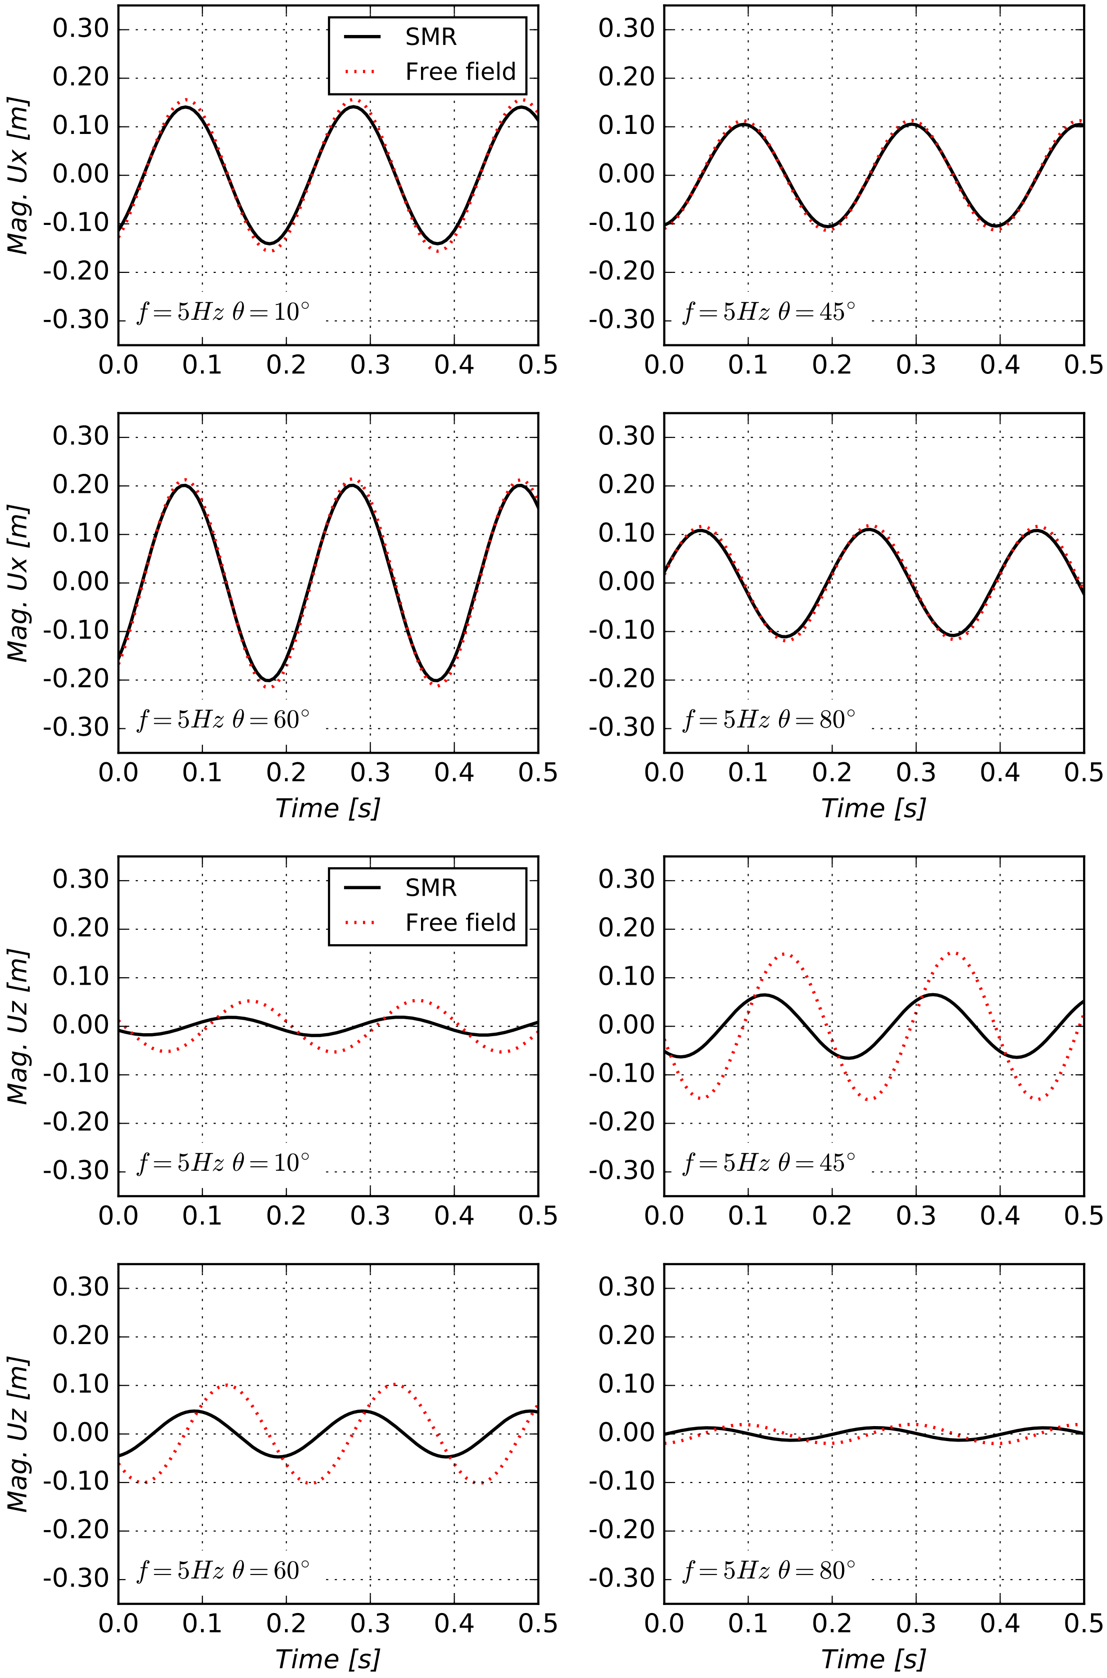

Figure 504.104: Displacement response of point A within embedded SMR, excited by an inclined SV wave with $f = 5Hz$ and different inclination angles, $\theta = 10^\circ, 45^\circ, 60^\circ$ and 80°: (a) horizontal displacement (b) vertical displacement.

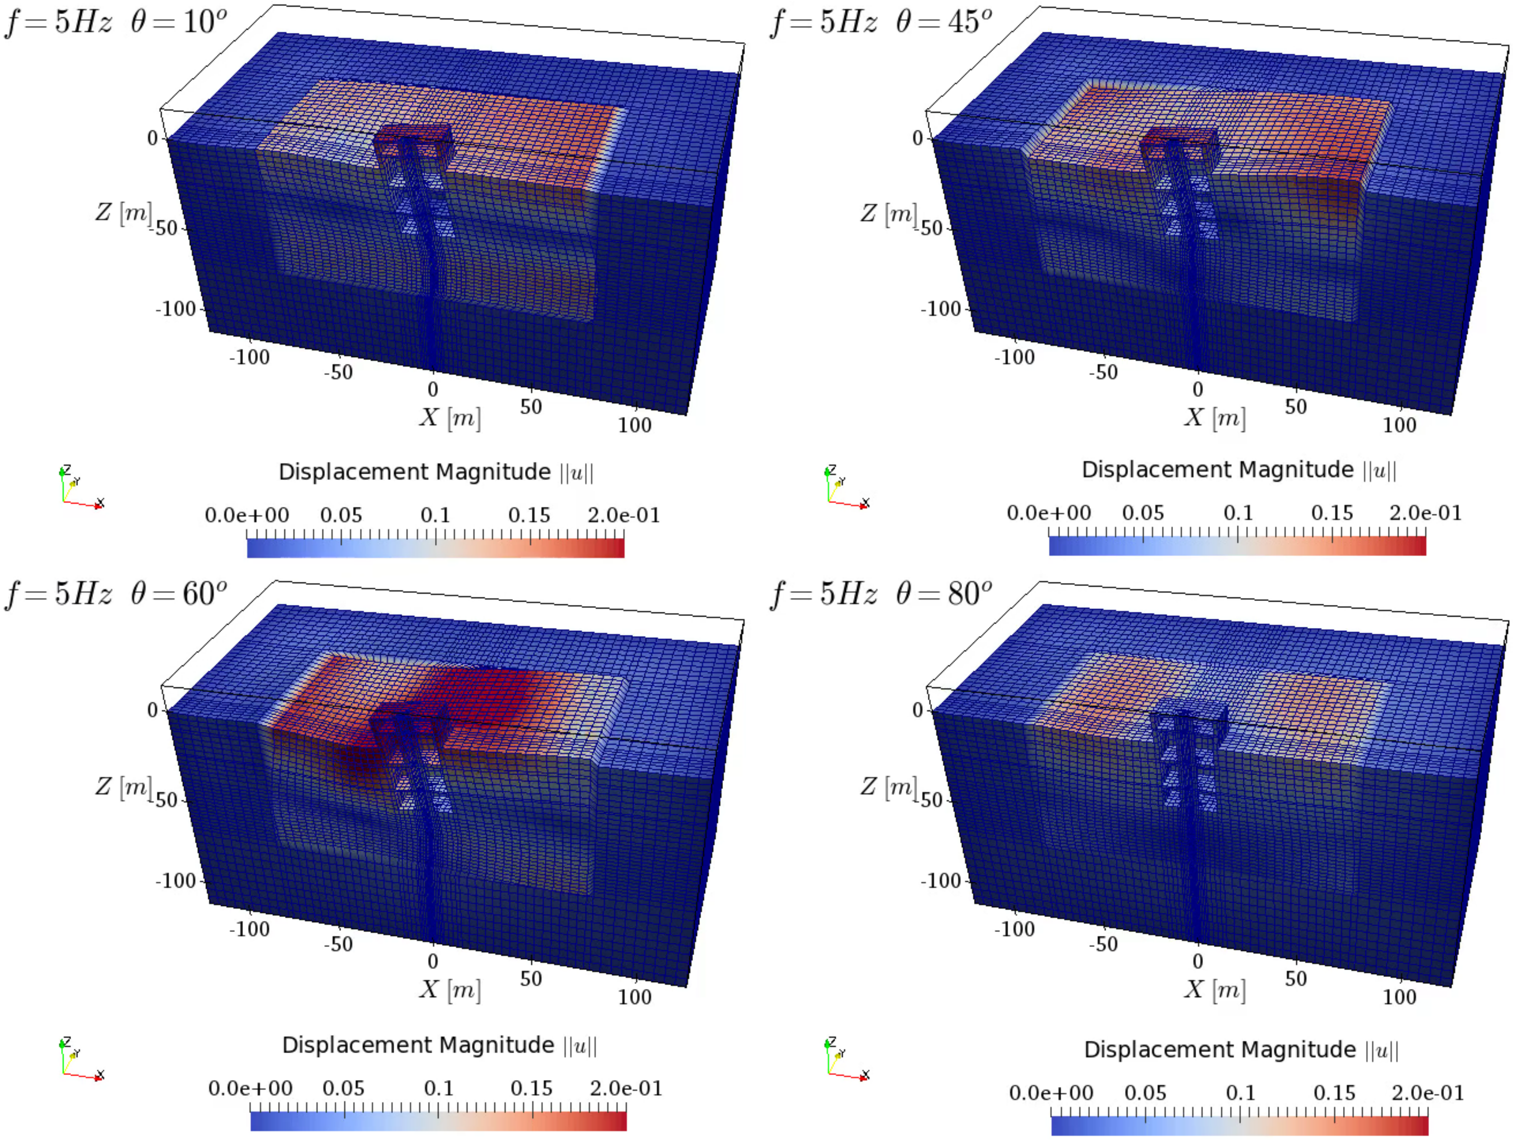

Figure 504.106: The deformed shapes of SMR at $t = 0.4s$ for incident SV wave at different inclinations $\theta = 10^\circ, 45^\circ, 60^\circ$ and 80°.

504.8.4 SMR Excited with Variable Frequency Inclined SV Waves

Keeping incidence angle constant, at $\theta = 60^\circ$, dynamic responses of an SMR under different frequencies of SV wave ($f = 1Hz, 2.5Hz, 5Hz$ and $10Hz$) is investigated next. Figures 504.107 and 504.108, show displacement and acceleration responses at point A of SMR model.

It is noted that, again, free field response at the location of point A is also shown for comparison purposes. Significantly variation in displacement and acceleration responses are produced by incident SV wave at different frequencies. The largest horizontal displacement magnitude 0.30m is observed for the case of frequency of $f = 2.5Hz$ while the smallest horizontal magnitude of 0.047m for $f = 1Hz$. The vertical displacement responses varies from 0.02m for $f = 2.5Hz$ to 0.085m for $f = 10Hz$. SSI effects are almost negligible in the case of $f = 1Hz$ due to long horizontal wave length of 1154m. This observation follows similar observation made many years ago by Housner (1957) for large stiff buildings. Both horizontal and vertical displacements of SMR overlap with corresponding free field response for $f = 1Hz$. Along with the increase of incident frequency, SSI effects become more significant, especially for the vertical components of displacement and acceleration. In the cases of $f = 2.5Hz$ and $f = 5Hz$, horizontal response of SMR is still very close to its free field counterpart, for both displacements and accelerations, however the reduction of vertical response of SMR becomes more significant for frequency of $f = 5Hz$, For relatively high frequency of $f = 10Hz$, both horizontal and vertical response of SMR are significantly different from free field modeling in both displacements and accelerations.

The spatial variation of displacements at the surface of free field model and at the same location within SMR model, along the horizontal line through SMR (i.e. $x \in [-75\text{m}, 75\text{m}], y = 0m, z = 0\text{m}$), at $t = 3.5$s are shown in Figure 504.109. It is noted that SMR structure occupies space for $x \in [-15m, 15m]$, where flat trace of displacements within a stiff structure is observed. The base slab averaging is observed for higher frequency, shorter wave length cases of $f = 5$Hz and $f = 10$Hz, while it is almost negligible for incident waves at frequencies of $f = 1$Hz or $f = 2.5$Hz due to the wavelength being longer that object size for those low frequencies.

Similar spatial variation of displacement along the transverse axis (i.e. $x = 0m, y \in [-75m, 75m], z = 0$m) is shown in Figure 504.110. Since the incident SV wave propagates within the XZ plane, uniform distribution of both horizontal and vertical free field response along the transverse axis (Y axis) is expected and presented in Figure 504.110. However, the existence of SMR alters the original uniform distribution, and a wave field in this, out plane of polarization direction. Significant wave field disturbance effects can be observed within the structure part ($y \in [-15m, 15m]$) in the cases of medium ($f = 5Hz$) to high frequency ($f = 10Hz$). In other words, 3C dynamic response of soils surrounding the structure has been induced from 2C excitation by an SV wave due to SSI and transverse wave field disturbance effects.

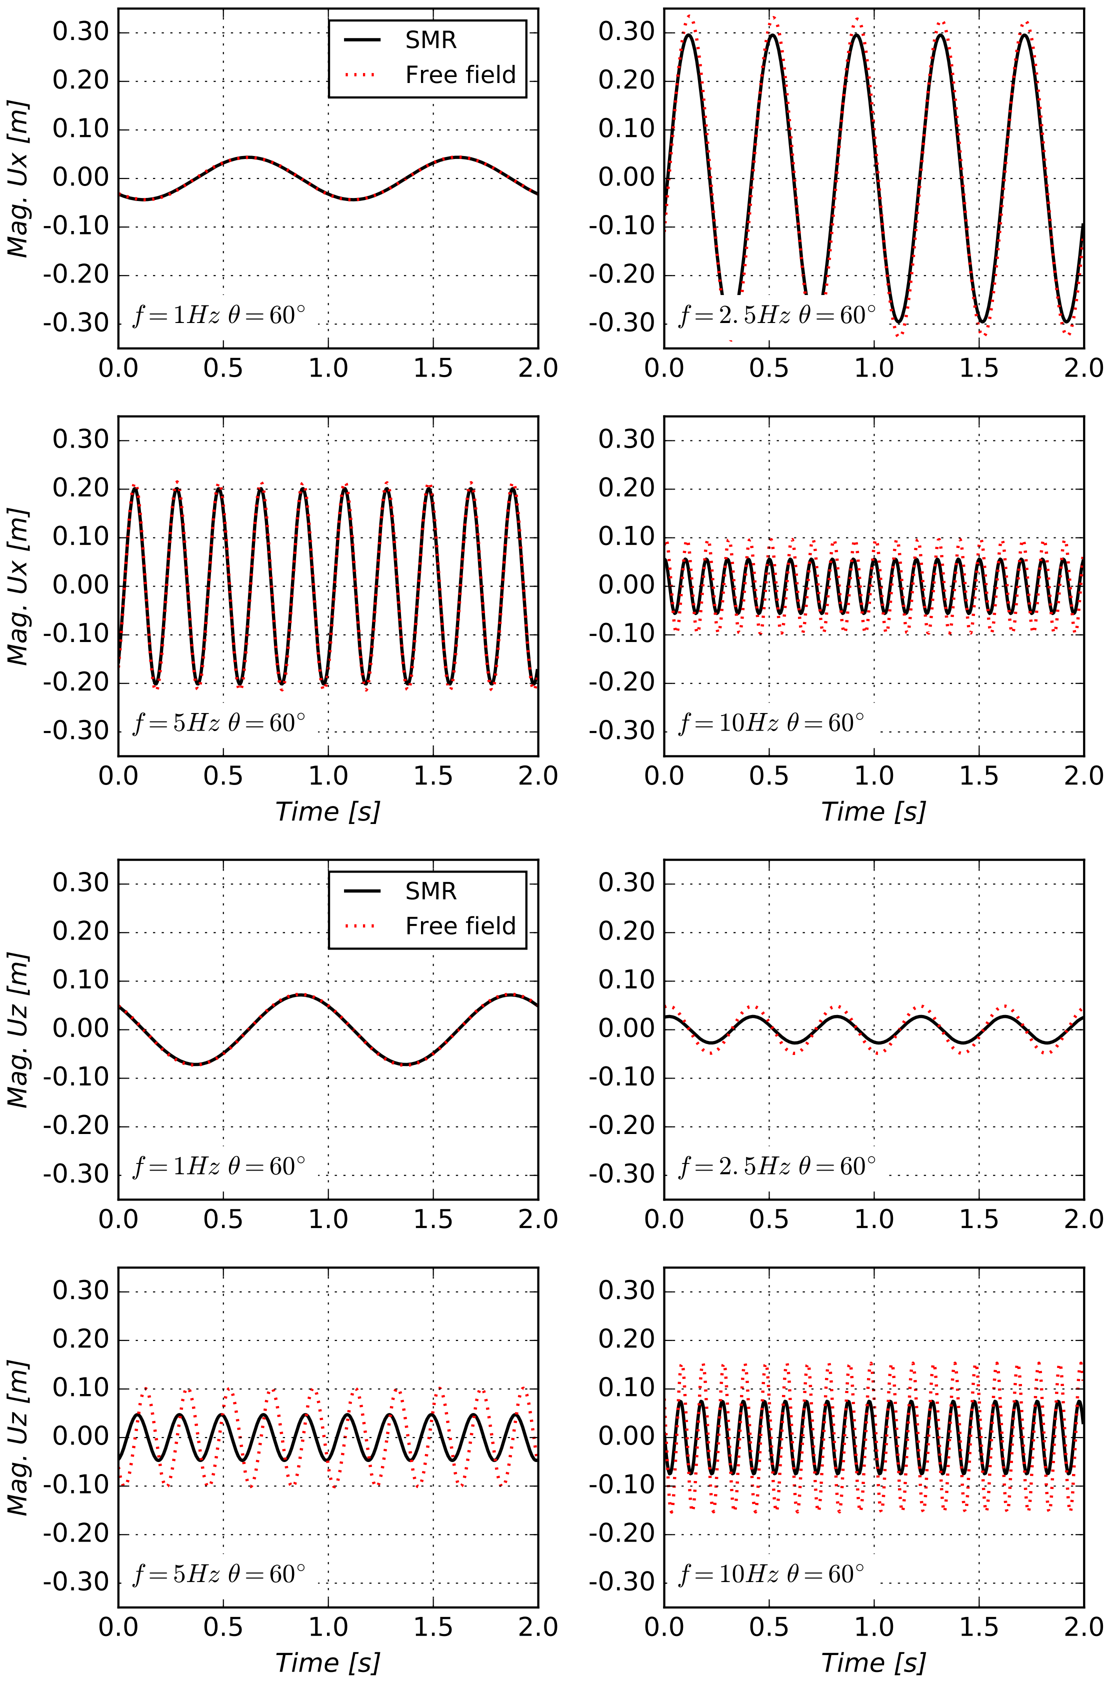

Figure 504.107: Displacement response of point A for scenarios with different frequencies of incident SV wave: (a) Horizontal displacement (b) Vertical displacement.

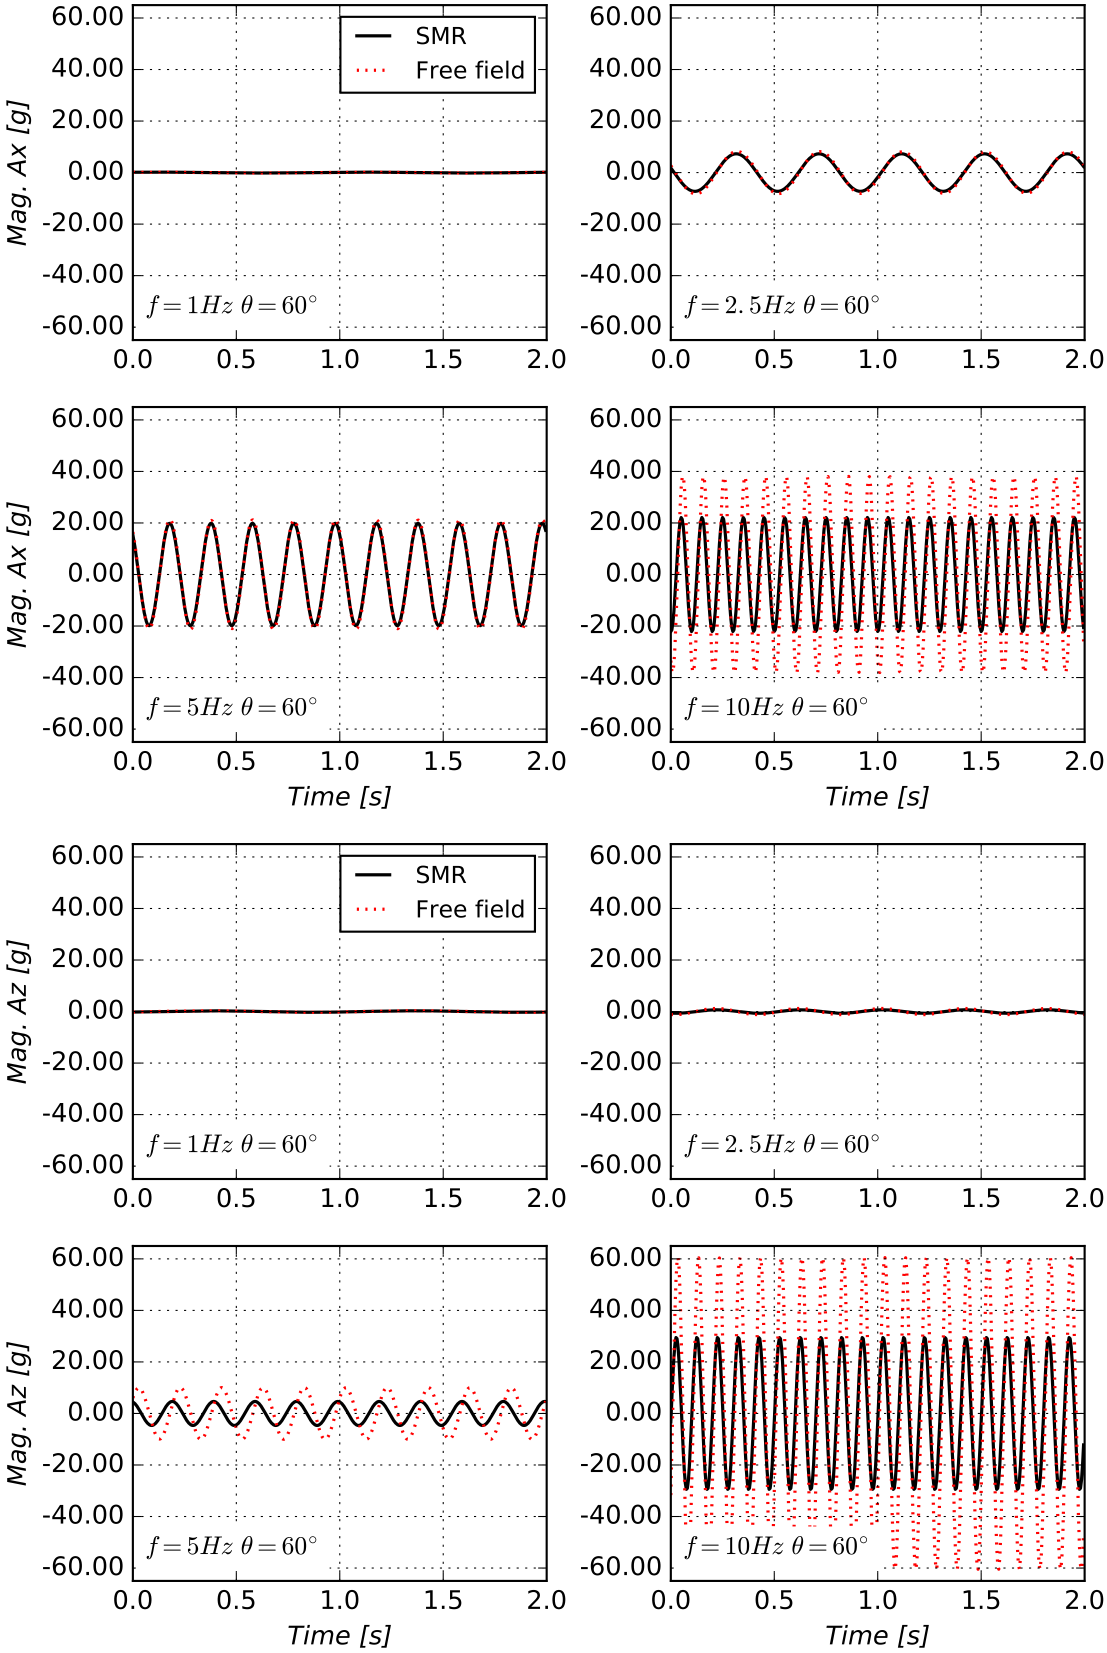

Figure 504.108: Acceleration response of point A for scenarios with different frequencies of incident SV wave: (a) Horizontal acceleration (b) Vertical acceleration.

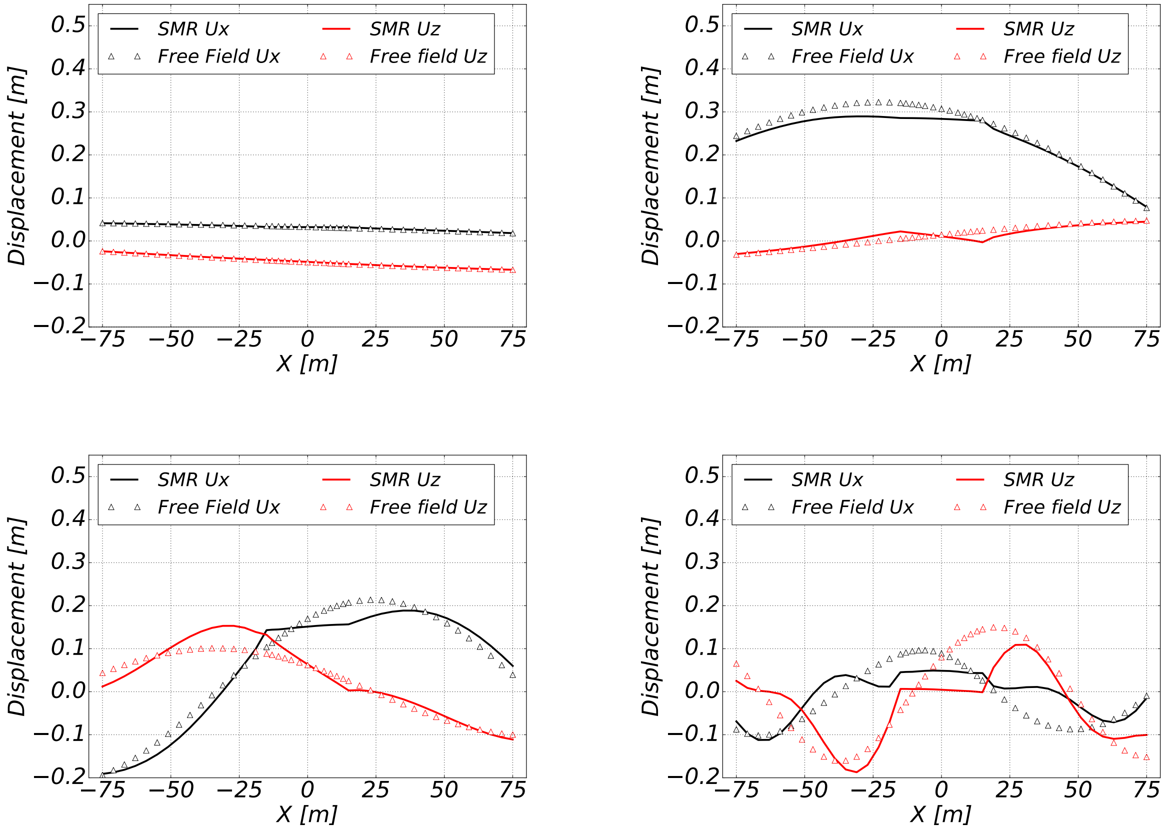

Figure 504.109: Spatial variation of displacement along the horizontal axis at $t = 3.5s$ for a wave at $\theta = 60^o$ different incident wave frequencies (a) f= $1Hz$ (b) f= $2.5Hz$ (c) f= $5Hz$ (d) f= $10Hz$.

Another important observation from Fig. 504.110(d) is that, although the reduction of displacement amplitude is observed within the structure, in locations where $y \in [-15m, 15m]$, near field motions close to the structure can be amplified, for example, motion within region $y \in \pm[25m, 50m]$ in this case. This implies that there are potentially significant structure-soil-structure dynamic effects for closely spaced structures.

The deformed shapes of SMR for four frequency scenarios at $t = 0.3s$ with different frequencies are shown in Fig. 504.111. The aforementioned wave field disturbance effects are clearly visible for the low wave length, high frequency case of $f = 10Hz$. The existence of local structure has significantly altered the near field seismic wave due to strong SSI effect, since wave lengths are shorter than the dominant dimension of the structure.

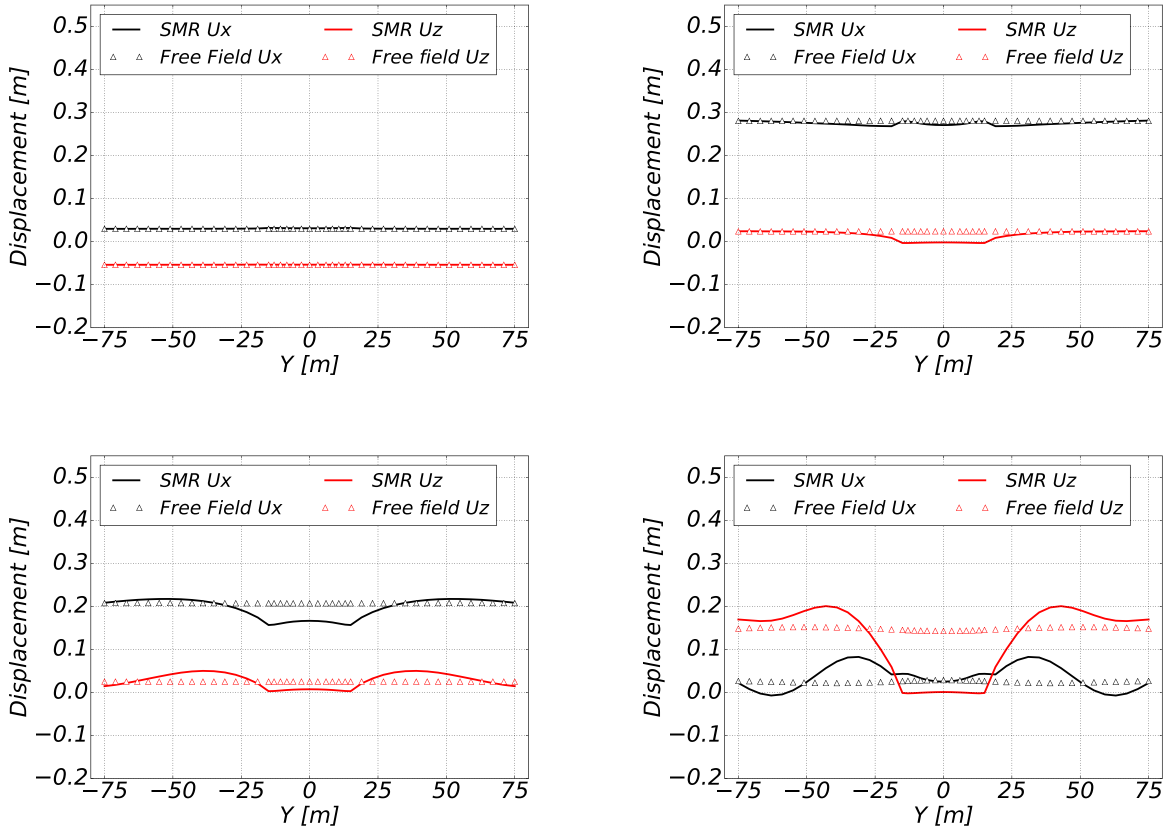

Figure 504.110: Spatial variation of displacement along the transverse axis at $t = 3.5s$ for for a wave at $\theta = 60^o$ at different incident wave frequency (a) f= $1Hz$ (b) f= $2.5Hz$ (c) f= $5Hz$ (d) f= $10Hz$.

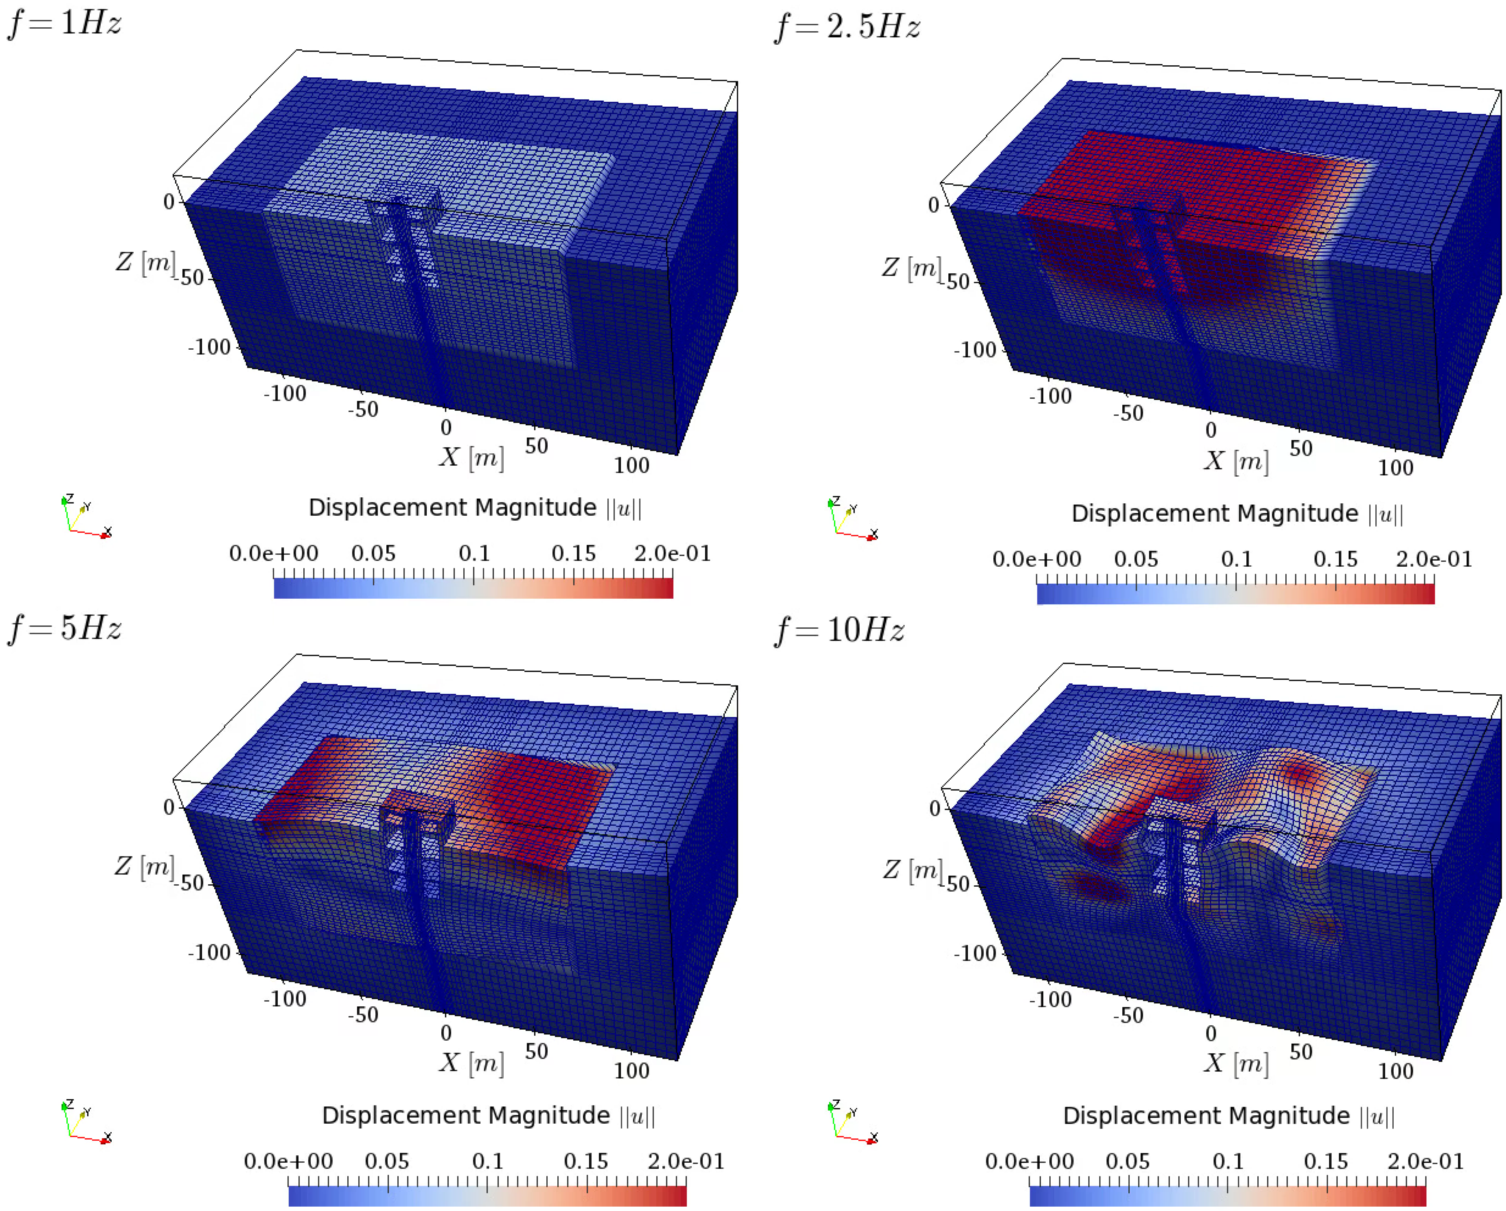

Figure 504.111: The deformed shapes of SMR at $t = 0.3s$ for four scenarios.

504.9 Three Dimensional (3D) Inelastic Modeling for Structure Soil Structure Interaction

504.10 Case Study of Cruas Nuclear Power Plant under Seismic Load from Le Teil Earthquake

504.10.1 Introduction

Seismic hazard in different regions of Central Europe has been recently revised, see, e.g., (Renault et al., 2013). The studies have been based on the historical evidence, like the earthquake in Basel, Switzerland, in 1356 (Mayer-Rosa and Cadiot, 1979). It turns out that quite a few nuclear facilities are located in areas where a weak to moderate seismic activity has been recorded.

Much effort has lately been put into the assessment of existing nuclear stations and into the design of new ones in these earthquake-prone areas. Hence the knowledge on the mechanical behavior of the so-called *earthquake-soil-structure interaction* (ESSI) systems is currently of significant importance in structural and geotechnical engineering.

The nuclear power plant (NPP) in Cruas is located in the south of France, on the right bank of the Rhône River. This NPP was built in the 1970s and it is seismically isolated at the base. On November 11, 2019, the NPP was excited by an earthquake near Le Teil (Viallet et al., 2022). The resulting ground motions were recorded at different locations, both, near Le Teil and at Cruas NPP. The structural vibrations of the NPP were also measured.

Here, simulation of the ground motions and of the mechanical behavior of the NPP under the earthquake load is conducted. For this purpose, the Real-ESSI Simulator (Jeremić et al., 1988-2025) is used. It is a finite element (FE) system developed to reproduce the behavior of soils and structures, and their interaction, under static and dynamic loads. The results obtained in this research are evaluated by comparison with the available field data. In this way, the current design and assessment of ESSI systems can be validated and possibly improved.

This study is conducted within the *SMATCH benchmark*[3] organized by the Institut de Radioprotection et de Sûreté Nucléaire (IRSN), Électricité de France (EDF) and Organisation for Economic Co-operation and Development-Nuclear Energy Agency (OECD-NEA).

---

504.10.2 Notation

Bold-face letters, like $\boldsymbol{\sigma}$, are vectors or second rank tensors. Sans-serif letters, like E, are fourth rank tensors. Gibbs notation, like $\dot{\boldsymbol{\sigma}} = \mathsf{E} : \dot{\boldsymbol{\varepsilon}}$, or index notation, $\dot{\sigma}_{ij} = E_{ijkl}\dot{\varepsilon}_{kl}$, in the Cartesian coordinate system with usual summation over repeated (dummy) indices is used. The mechanical sign convention is applied to stress, $\boldsymbol{\sigma}$, and strain, $\boldsymbol{\varepsilon}$, with compression negative.

The basic Latin variables are explained below.

E	Young modulus
f	frequency
$\mathbf{u}$	displacement
$\mathbf{x}$	location
V_p	primary, compressional, wave velocity
V_s	secondary, shear, wave velocity

The basic Greek variables are given below.

ε	strain
λ, μ	Lamé constants
ν	Poisson ratio
ρ	mass density
$\boldsymbol{\sigma}$	stress, tension positive

The following notation is used.

$\dot{\sqcup}$	material rate of $\sqcup$, $\dot{\sqcup} = \partial \sqcup / \partial t = \sqcup_{,t}$
$\ddot{\sqcup}$	material acceleration of $\sqcup$, $\partial^2 \sqcup / \partial t^2 = \sqcup_{,tt}$

The essential abbreviations are listed below.

DRM	Domain Reduction Method
ESSI	Earthquake-Soil-Structure Interaction
FE	Finite Element
NPP	Nuclear Power Plant
THMM	Thomson-Haskell Matrix Method

504.10.3 Le Teil Earthquake

Some basic knowledge about Le Teil earthquake is indispensable to determine the seismic load in the simulation of the mechanical behavior of Cruas NPP. After a brief introduction of the necessary seismological definitions, a short description of the earthquake in Le Teil is given. It will allow to establish the *seismic input* in Section 504.10.7.

504.10.3.1 A Short Résumé on the Seismological Description of Earthquakes

Origins of Earthquakes Tectonic plates, pieces of the Earth's litosphere, move, due to, i.a., the convection in the Earth's mantel (Andel, 2008; Bragg, 2022), and interact with each other at *interfaces*. An interface, also known as a *fault*, between two tectonic plates is rough, jigsaw-like, and the movement of the plates is hindered. This is similar to shearing along a fault in a rock (Wittke, 2014).

During shearing along an interface, the jigsaw-like boundaries of the plates undergo the plastic deformation. Stress at the interface is being increased, which is known as *hardening*, and the *plastic work* is being done at the interface. A part of the plastic work, the so-called *frozen elastic energy*, also known as the *plastic free Helmholtz energy*, is being accumulated at the fault.

When the stress limit is reached, the peak friction is mobilized, at the fault, a sudden, *dynamic*, brittle *slip* occurs and causes an *earthquake*. A slip is a movement of the plates along the interface. A ductile slip is also possible but it is *aseismic* (Kramer, 1996a) and hence it is not considered here. A brittle slip is also called a *rupture*.
The strain is localized along the fault and the stress decreases, which is known as *softening*. The frozen elastic energy accumulated at the interface is transformed into other forms of energy, like *acoustic energy* or heat. In seismology, the origins of earthquakes are explained with the so-called *elastic-rebound theory* (Kramer, 1996a; Bragg, 2022). It is based on the assumption of repeatable accumulation and release of the frozen elastic energy at a fault.

However, an earthquake may also result from various, natural or anthropogenic, events within a single tectonic plate (Kramer, 1996a; Semblat and Pecker, 2009), for example, from a large underground explosion, a volcanic eruption or a slip triggered by *fracking*. A slip may generally occur along, e.g., an interface between two rock masses and not necessarily along an interface between two tectonic plates.

Here, a shallow earthquake, triggered at a depth of less than 5 km, is examined. It was caused by a slip along a fault in a rock.

Types of Faults A slip is described by jump in displacement $[\![\mathbf{u}]\!]$ between two rock masses, or two tectonic plates. This $[\![\mathbf{u}]\!]$ is measured along the slip plane, π. At a fault, discontinuity, in a rock, $\|[\![\mathbf{u}]\!]\|$ can achieve several kilometers (Wittke, 2014). Two rock masses, or two tectonic plates, can (Wittke, 2014; Bragg, 2022; Andel, 2008):

- slide past each other at a *transform fault*, particularly:
    - in horizontal direction at a *strike-slip fault*, inclined or vertical, Figure 504.112(a)
    - in vertical direction at a *dip-slip fault*, vertical, Figure 504.112(b)
    - in both, horizontal and vertical, directions at an *oblique-slip fault*, vertical, Figure 504.112(c)
- move towards each other, collide, at a *reverse fault*, also called *thrust fault*, inclined or horizontal, Figure 504.112(d)
- move apart from each other at a *normal fault*, inclined or horizontal, Figure 504.112(e).

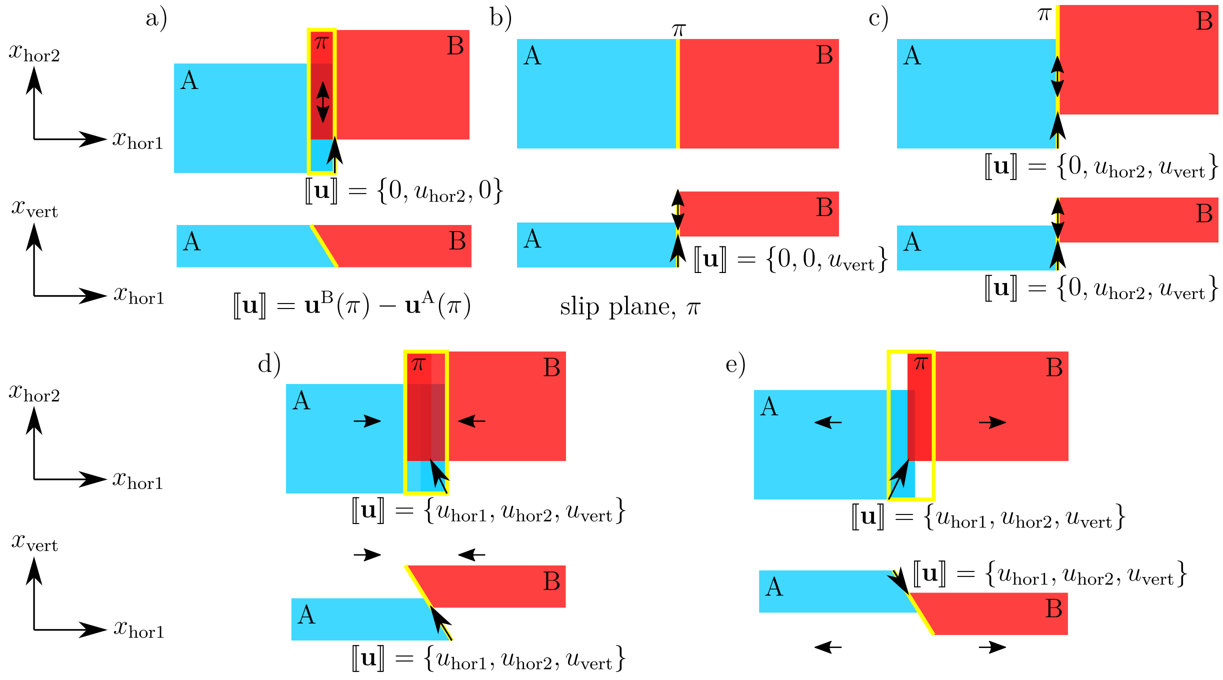

Figure 504.112: Types of faults: a) strike-slip fault, here, inclined; b) dip-slip fault; c) oblique-slip fault; d) reverse fault, here, inclined; e) normal fault, here, inclined.

Mechanism and Orientation of a Slip in a Cartesian Coordinate System Mechanism and orientation of a slip are commonly described in a Cartesian coordinate system using the so-called *focal mechanism*. It is a graphic representation of the slip and it is known in the seismological community as the “beach ball”[4]. A focal mechanism is defined by *strike angle*, *dip angle* and *rake angle* (Aki and Richards, 2002; Wittke, 2014), see Figure 504.113.

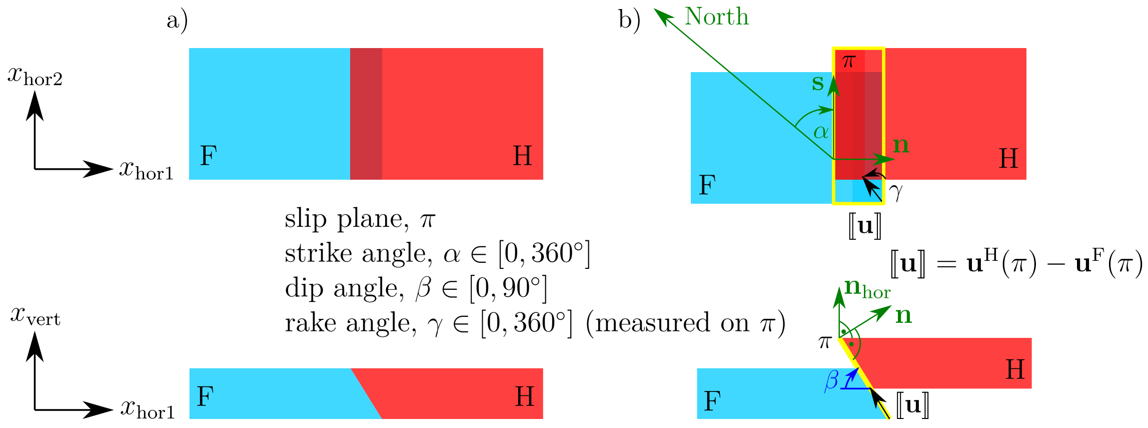

Figure 504.113: a) Inclined fault before a slip; b) Inclined fault after a reverse slip: the slip plane, π, is defined by the unit normal vector, $\mathbf{n}$, that points upwards; $\mathbf{n}_{\mathrm{hor}}$ is a unit vector that is normal to the horizontal plane and points upwards; $\mathbf{s} = (\mathbf{n}_{\mathrm{hor}} \times \mathbf{n})^{\rightarrow}$; strike angle, $\alpha \in \left[0, 360°\right]$, is the azimuth of $\mathbf{s}$; dip angle, $\beta \in \left[0, 90°\right]$, describes the inclination of π; rake angle, $\gamma \in \left[0, 360°\right]$, is measured anticlock-wise from $\mathbf{s}$ to the jump in displacement, $[\![\mathbf{u}]\!]$, on π. F is the so-called *foot wall* and H is the *hanging wall*.

Strike angle, dip angle and rake angle can be found in MATHEMATICA for a slip plane, π, defined by the unit normal vector, $\mathbf{n}$, with given displacement of the foot wall, $\mathbf{u}^{\mathrm{F}}(\pi)$, and of the hanging wall, $\mathbf{u}^{\mathrm{H}}(\pi)$, along π.

```
n = Normalize[{1, 1, 1}]; nhor = {0, 0, 1}; s = Normalize[Cross[nhor, n]]; north = {0, 1, 0};
rotclockwise = {{Cos[a], Sin[a], 0}, {-Sin[a], Cos[a], 0}, {0, 0, 1}};
solua = Solve[rotclockwise.north == s, a][[1]] /. C[1] -> 0; (* solve for strike angle *)
rotanticlockwise = {{Cos[a], -Sin[a], 0}, {Cos[a], Sin[a], 0}, {0, 0, 1}}; nprime = (rotanticlockwise.n) /. solua;
solub = Solve[Tan[b] == nprime[[3]]/nprime[[1]], b][[1]] /. C[1] -> 0; (* solve for dip angle *)
uF = {0, 0, 0}; uH = {1, 1, -2}; jump = uH - uF;
solug = Solve[((rotclockwise /. a -> g).jump/Norm[jump])[[1]] == 1, g][[1]] /. C[1] -> 0; (* solve for rake angle *)
```

---

[4] Focal mechanism is briefly explained under `https://www.iris.edu/hq/inclass/animation/focal_mechanisms_explained`. Knowing the strike, dip and slip angle, one can easily plot the focal mechanism in MATHEMATICA using the code by Prof. Scherbaum from the University of Potsdam, available on the Internet, `https://demonstrations.wolfram.com/EarthquakeFocalMechanism/`.

```
{a //. solua, b /. solub, Re[g /. solug]} // N (* strike angle, dip angle, rake angle *)
```

504.10.3.2 Slip along Rouvière Fault near Le Teil

Le Teil earthquake was recorded on November 11, 2019 (Marconato et al., 2022; Ritz et al., 2020; Viallet et al., 2022). This earthquake resulted from a slip along Rouvière fault within the existing les Cévennes faults system in Southern France, near Le Teil, Figure 504.114. The slip might have been caused by a reduction of the effective stress at Rouvière fault either due to the increase in the ground water level, caused by a heavy rain, (Burnol et al., 2023) or due to the progressive unloading of the ground in the nearby quarry (Novellis et al., 2020).

Basic characteristics of the slip that caused shallow Le Teil earthquake are given in Table 504.7 and explained in Figure 504.113. The location of the source of the earthquake is shown in Figure 504.114.

Table 504.7: Basic characteristics of the slip along Rouvière fault

Latitude	Longitude	Depth	Mw	Dip angle	Strike angle	Rake angle	Velocity
°	°	km	-	°	°	°	m/s
44.5188 ± 0.01	4.6694 ± 0.01	1 ± 0.5	4.9 ± 0.1	55 ± 5	45 ± 5	90 ± 10	1800

504.10.3.3 Site Description

A number of free-field and in-structure instruments were used to record the seismic motions at Cruas NPP, the local site, and near Le Teil. The data are accessed via the SMATCH project. Unfortunately, the elastic soil and rock parameters are available at the epicenter of the earthquake and at two locations at the local site only.

Locations of the Free-field Recordings Locations of the free-field instruments are given in Table 504.8 and shown in Figure 504.114. In-structure recordings are discussed in Section 504.10.6.

Elastic Soil and Rock Parameters The elastic soil and rock parameters at station 1 and station 2, at Cruas NPP, and at the epicenter of the earthquake are given in Table 504.9. The elevations at station 1 and 2 are given in Table 504.8. The elevation of the epicenter, ≈ 260 m, can be estimated using, e.g., an online map with elevation contours.

Table 504.8: Locations of the free-field instruments at Cruas NPP and near Le Teil

504.10.4 FE Simulation of Ground Motions from Le Teil Earthquake

Ground motions from Le Teil earthquake had been intensively studied within the SIGMA2 project[5] (Viallet et al., 2022). Two kinds of methods for the simulation of seismic motions had been used, that is, the empirical ones and the physically based ones. The latter include both 1D (Fasan, 2016; Fasan et al., 2016; Hassan et al., 2020; Magrin et al., 2016; Magrin, 2012; Panza et al., 2012) and 3D (Mazzieri et al., 2013; Paolucci et al., 2020, 2021) simulations. Some recent 3D numerical calculations of seismic motions from Le Teil earthquake are reported in (Lehmann et al., 2023; Smerzini et al., 2023).

Elastic soil and rock parameters are available at three locations only, see Table 504.9. This scarcity of data alone precludes a realistic FE reproduction of Le Teil earthquake. Different assumptions about the regional geology could be made, of course. Then, a parametric back-analysis of the earthquake could be conducted to match the measured ground motions. However, such analysis would require a very large FE domain to avoid the corruption of the obtained results by an unreal behavior at the model boundaries, which generally cannot be avoided, see, e.g., (Baffet et al., 2012). It is well-known that in dynamics a parametric FE calculation with a large spatial domain involves a considerable computation time.

Here, we aim to save the computation time. For this purpose, we make a few physically justified simplifying assumptions about the ground motions from Le Teil earthquake. Based on these assumptions, the seismic input will be determined and used in a computationally efficient simulation of the mechanical behavior of Cruas NPP, Section 504.10.7. To establish the necessary assumptions, we first conduct a preliminary FE calculation of the seismic wave field from Le Teil earthquake using the Real-ESSI Simulator (Jeremić et al., 1988-2025).

504.10.4.1 Preliminary 2D Simulation of Le Teil Earthquake

In the case of a shallow earthquake, the incident angle larger than the critical angle, $\alpha_i > \alpha_{ic}$, see (504.13) and (504.14), should be expected at the ground surface. Such $\alpha_i > \alpha_{ic}$ results in a *Rayleigh wave*, see, e.g., (Nowacki, 1974).

A preliminary simulation of the earthquake in Le Teil is performed and used to examine the possible presence of a Rayleigh wave. The calculated ground motions will be validated by a qualitative comparison with the field measurements.

---

[5] `https://www.sigma-2.net/`

The geometry, geology, material description and mechanism of the slip are simplified. The FE model represents $2000 \times 1 \times 300$ m^3 ground with a 280 m thick rock that is overlayed by a 20 m thick soil, see Figure 504.115, cf. Table 504.9.

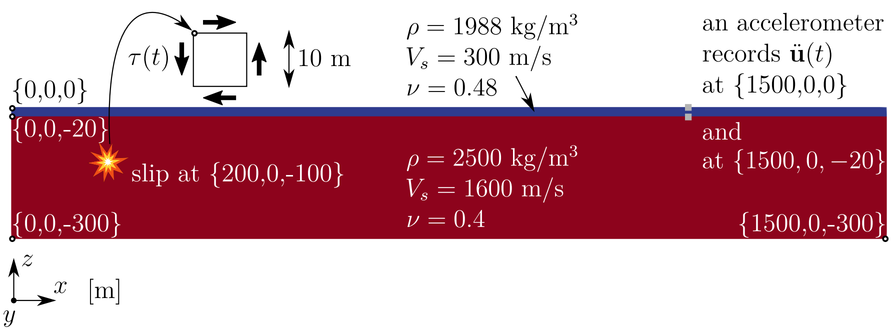

Figure 504.115: FE model used in the preliminary 2D simulation of Le Teil earthquake

Both materials are isotropic linear elastic with parameters given in Table 504.10 (with Young modulus $E = 2\rho V_s^2(1+\nu)$).

Table 504.10: Material properties in preliminary 2D simulation of Le Teil earthquake

Material	z m	ρ kg/m^3	V_s m/s	ν
Soil	$[0, -20]$	1988	300	0.48
Rock	$[-20, -300]$	2500	1600	0.4

The ground is discretized into a single layer (in y direction, Figure 504.115) of 6000 `27NodeBrick` elements. The size of the element is 10 m.

The slip is simulated as the *pure shear* of an element at $\boldsymbol{x} = \{200, 0, -100\}$. The dynamic disturbance is introduced onto faces of the element in the form of a shear load, $\tau(t) = \tau^{\text{ampl}} \sin(2\pi f t)$ with $\tau^{\text{ampl}} = -60$ GPa and the frequency $f = 1$ Hz.

`Newmark` integration procedure is used in search of the dynamic equilibrium. Numerical damping is introduced using parameters $\gamma = 0.6$ and $\beta = 0.3025$ in the `Newmark` algorithm.

Time functions of the horizontal displacement, $u_x(t)$, and the vertical displacement, $u_z(t)$, at the ground surface, $\boldsymbol{x} = \{1500, 0, 0\}$ m, and at the top of the rock layer, $\boldsymbol{x} = \{1500, 0, -20\}$ m, are plotted in Figure 504.116(a) and in Figure 504.117(a), respectively. Additionally, the corresponding hodographs, $u_z(u_x)$, are shown in Figure 504.116(b) and in Figure 504.117(b). The horizontal ground acceleration, $\ddot{u}_x(t)$, and the vertical ground acceleration, $\ddot{u}_z(t)$, at $\boldsymbol{x} = \{1500, 0, 0\}$ m and at $\boldsymbol{x} = \{1500, 0, -20\}$ m are plotted in Figure 504.118(a) and in Figure 504.119(a). The corresponding diagrams $\ddot{u}_z(\ddot{u}_x)$ are shown in Figure 504.118(b) and in Figure 504.119(b).

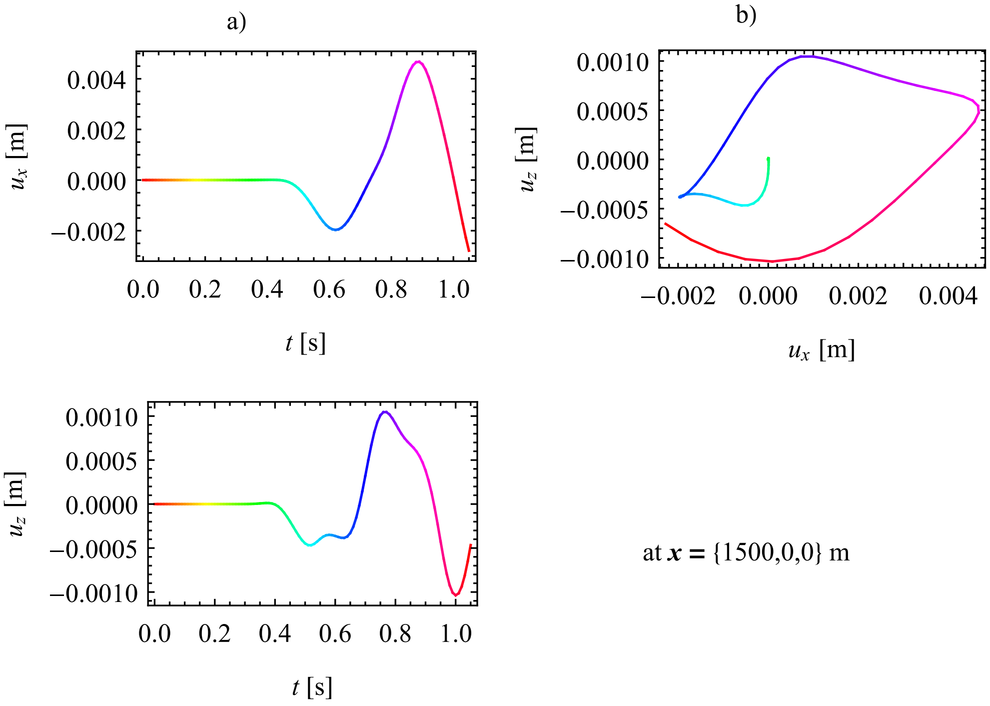

Figure 504.116: Preliminary 2D simulation of Le Teil earthquake: a) $u_x(t)$ and $u_z(t)$, and b) $u_z(u_x)$ at the ground surface, $\boldsymbol{x} = \{1500, 0, 0\}$ m

Judging by the hodograph from Figure 504.116(b), the motions at the ground surface can be interpreted as a Rayleigh wave, a surface wave. It is probably overlapped by the Stoneley wave from Figure 504.117(b) which propagates along the interface between the soil and the rock.

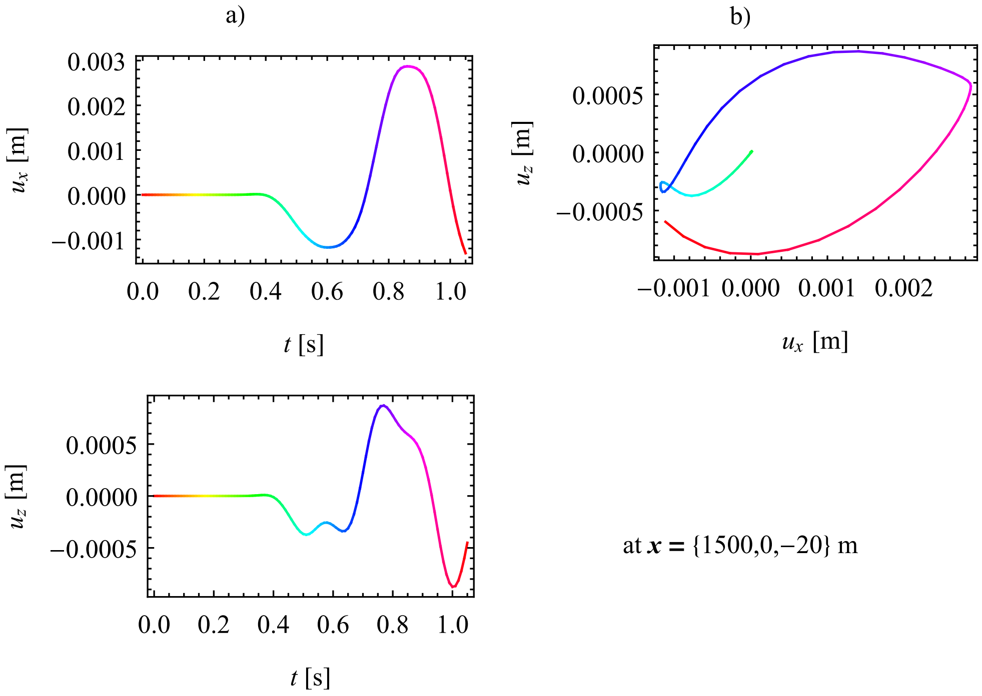

Figure 504.117: Preliminary 2D simulation of Le Teil earthquake: a) $u_x(t)$ and $u_z(t)$, and b) $u_z(u_x)$ at the top of the rock layer, $\boldsymbol{x} = \{1500, 0, -20\}$ m

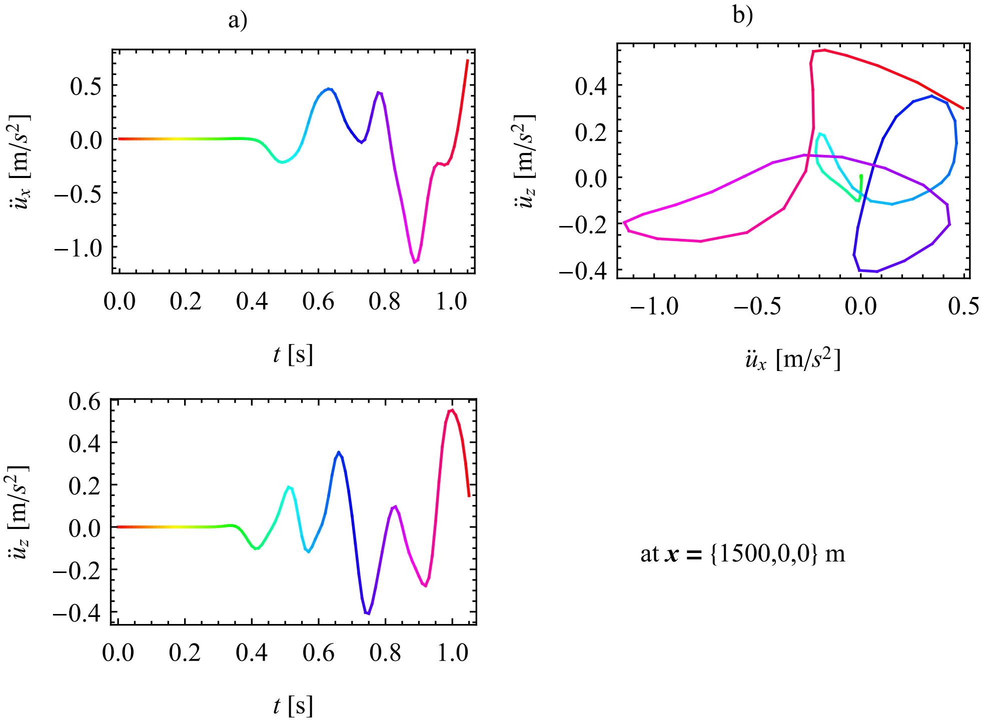

Figure 504.118: Preliminary 2D simulation of Le Teil earthquake: a) $\ddot{u}_x(t)$ and $\ddot{u}_z(t)$, and b) $\ddot{u}_z(\ddot{u}_x)$ at the ground surface, $\boldsymbol{x} = \{1500, 0, 0\}$ m

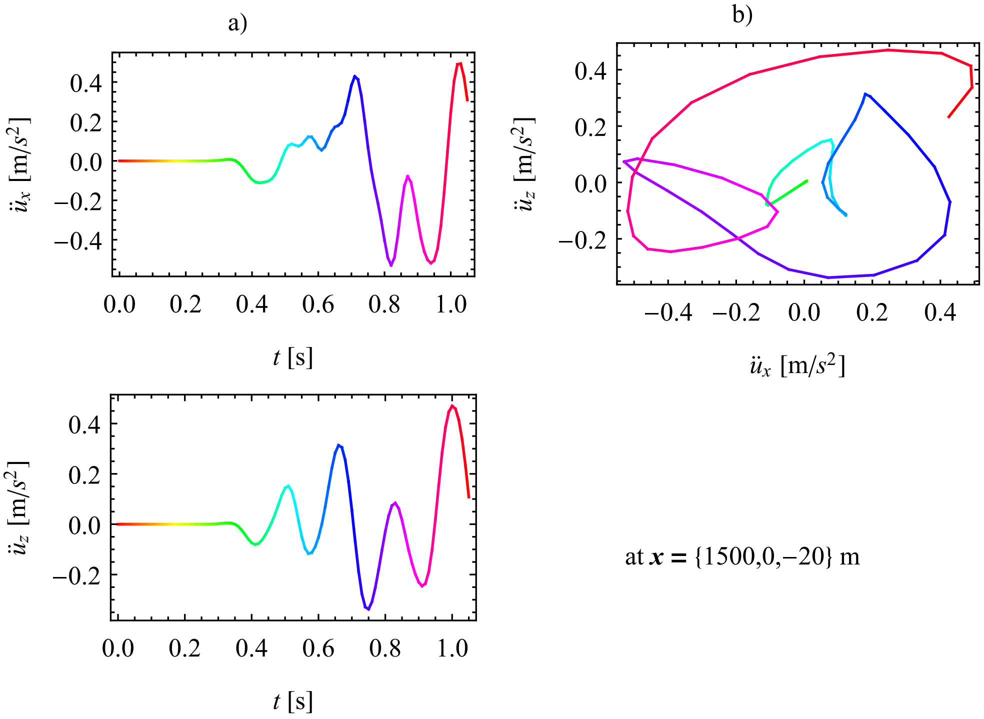

Figure 504.119: Preliminary 2D simulation of Le Teil earthquake: a) $\ddot{u}_x(t)$ and $\ddot{u}_z(t)$, and b) $\ddot{u}_z(\ddot{u}_x)$ at the top of the rock layer, $\boldsymbol{x} = \{1500, 0, -20\}$ m

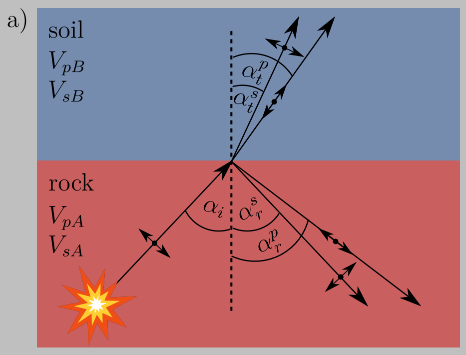
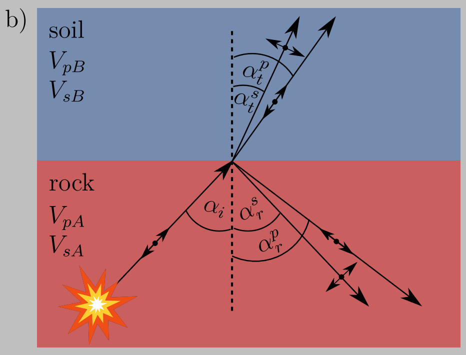
Some "unreal" *reflections* and *refractions* of the waves, at the bottom and side boundaries of the model, are present in the simulation due to the very small size of the model. Reflection and refraction of a wave is governed by the *Snell law*. It is assumed that the "unreal" waves do not corrupt the preliminary results significantly.

Let us consider a 2D S-wave, see Figure (a) below, or a 2D P-wave, Figure (b) below, that travels from the source, through the rock.





The incident wave arrives at the interface between the rock and the soil at an incident angle, $\alpha_i \in [0, 90^\circ)$, and it is *reflected* and *refracted*. Component of the wave that is normal to the interface is reflected back into the rock at α_r^p and transmitted, refracted, into the soil at α_t^p as a P-wave. Component tangent to the interface is reflected back into the rock at α_r^s and transmitted into the soil at α_t^s as a S-wave.

According to the Snell law, the following holds

$$\begin{aligned}
\frac{\sin\alpha_i}{V_{sA}} = \frac{\sin\alpha_r^p}{V_{pA}} = \frac{\sin\alpha_r^s}{V_{sA}} = \frac{\sin\alpha_t^p}{V_{pB}} = \frac{\sin\alpha_t^s}{V_{sB}} \quad &\text{for the incident wave being a S-wave and} \\
\frac{\sin\alpha_i}{V_{pA}} = \frac{\sin\alpha_r^p}{V_{pA}} = \frac{\sin\alpha_r^s}{V_{sA}} = \frac{\sin\alpha_t^p}{V_{pB}} = \frac{\sin\alpha_t^s}{V_{sB}} \quad &\text{for the incident wave being a P-wave}\,,
\end{aligned} \tag{504.11}$$

wherein

$$V_p = \sqrt{\frac{\lambda}{\rho} + 2V_s^2} \quad \text{with} \quad \lambda = \frac{E\nu}{(1+\nu)(1-2\nu)} \tag{504.12}$$

and V_{pA}, V_{sA} denote the wave velocities in material from which a wave arrives at the interface and V_{pB}, V_{sB} denote the wave velocities in material into which the wave is transmitted.

Additionally, one defines the so-called *critical angle*, α_{ic}. It is the incident angle for which the incident wave is transmitted or reflected parallel to the interface between two layers, here, rock and soil,

$$\begin{aligned}
\sin\alpha_{ic}^{srp} &= \frac{V_{sA}}{V_{pA}} \quad \text{with} \quad \alpha_r^p = 90^\circ \quad \text{and} \quad V_{sA} < V_{pA} \quad \text{for an incident S-wave reflected as the P-wave} \\
\sin\alpha_{ic}^{stp} &= \frac{V_{sA}}{V_{pB}} \quad \text{with} \quad \alpha_t^p = 90^\circ \quad \text{and} \quad V_{sA} \leq V_{pB} \quad \text{for an incident S-wave transmitted as the P-wave} \\
\sin\alpha_{ic}^{sts} &= \frac{V_{sA}}{V_{sB}} \quad \text{with} \quad \alpha_t^s = 90^\circ \quad \text{and} \quad V_{sA} \leq V_{sB} \quad \text{for an incident S-wave transmitted as the S-wave}
\end{aligned} \tag{504.13}$$

and

$$\begin{aligned}
\sin\alpha_{ic}^{ptp} &= \frac{V_{pA}}{V_{pB}} \quad \text{with} \quad \alpha_t^p = 90^\circ \quad \text{and} \quad V_{pA} \leq V_{pB} \quad \text{for an incident P-wave transmitted as the P-wave} \\
\sin\alpha_{ic}^{pts} &= \frac{V_{pA}}{V_{sB}} \quad \text{with} \quad \alpha_t^s = 90^\circ \quad \text{and} \quad V_{pA} \leq V_{sB} \quad \text{for an incident P-wave transmitted as the S-wave.}
\end{aligned} \tag{504.14}$$

If the incident angle, α_i, exceeds the critical angle, α_{ic}, it follows that

$$\sin\alpha_i > \sin\alpha_{ic} \quad \text{with} \quad V_A \leq V_B \qquad \frac{V_A}{V_B}\sin\alpha_t > \frac{V_A}{V_B} \qquad \sin\alpha_t > 1 \tag{504.15}$$

for transmission of the incident wave from layer A to layer B or, analogously,

$$\sin\alpha_i > \sin\alpha_{ic} \quad \text{with} \quad V_{sA} < V_{pA} \qquad \frac{V_{sA}}{V_{pA}}\sin\alpha_r^p > \frac{V_{sA}}{V_{pA}} \qquad \sin\alpha_r^p > 1 \tag{504.16}$$

for reflection of the incident S-wave as the P-wave in layer A. If (504.15) or (504.16) holds, then an interface wave is present, e.g., the *Rayleigh wave*.

504.10.5 Validation of the Preliminary 2D Simulation of Le Teil Earthquake

Ground accelerations at station 1, at Cruas NPP, see Table 504.8 and Figure 504.114, are plotted as time functions, $\ddot{u}_{\mathrm{NS}}(t), \ddot{u}_{\mathrm{EW}}(t), \ddot{u}_{\mathrm{UD}}(t)$, in Figure 504.120(a). Indices NS, EW and UD denote the North-South, East-West and up-down components of $\ddot{\mathbf{u}}$, respectively. Accelerations $\ddot{u}_{\mathrm{NS}}(t), \ddot{u}_{\mathrm{EW}}(t), \ddot{u}_{\mathrm{UD}}(t)$ were integrated over time t into displacements $u_{\mathrm{NS}}, u_{\mathrm{EW}}, u_{\mathrm{UD}}$. Functions $u_{\mathrm{NS}}(t), u_{\mathrm{EW}}(t), u_{\mathrm{UD}}(t)$ are given in Figure 504.120(b).

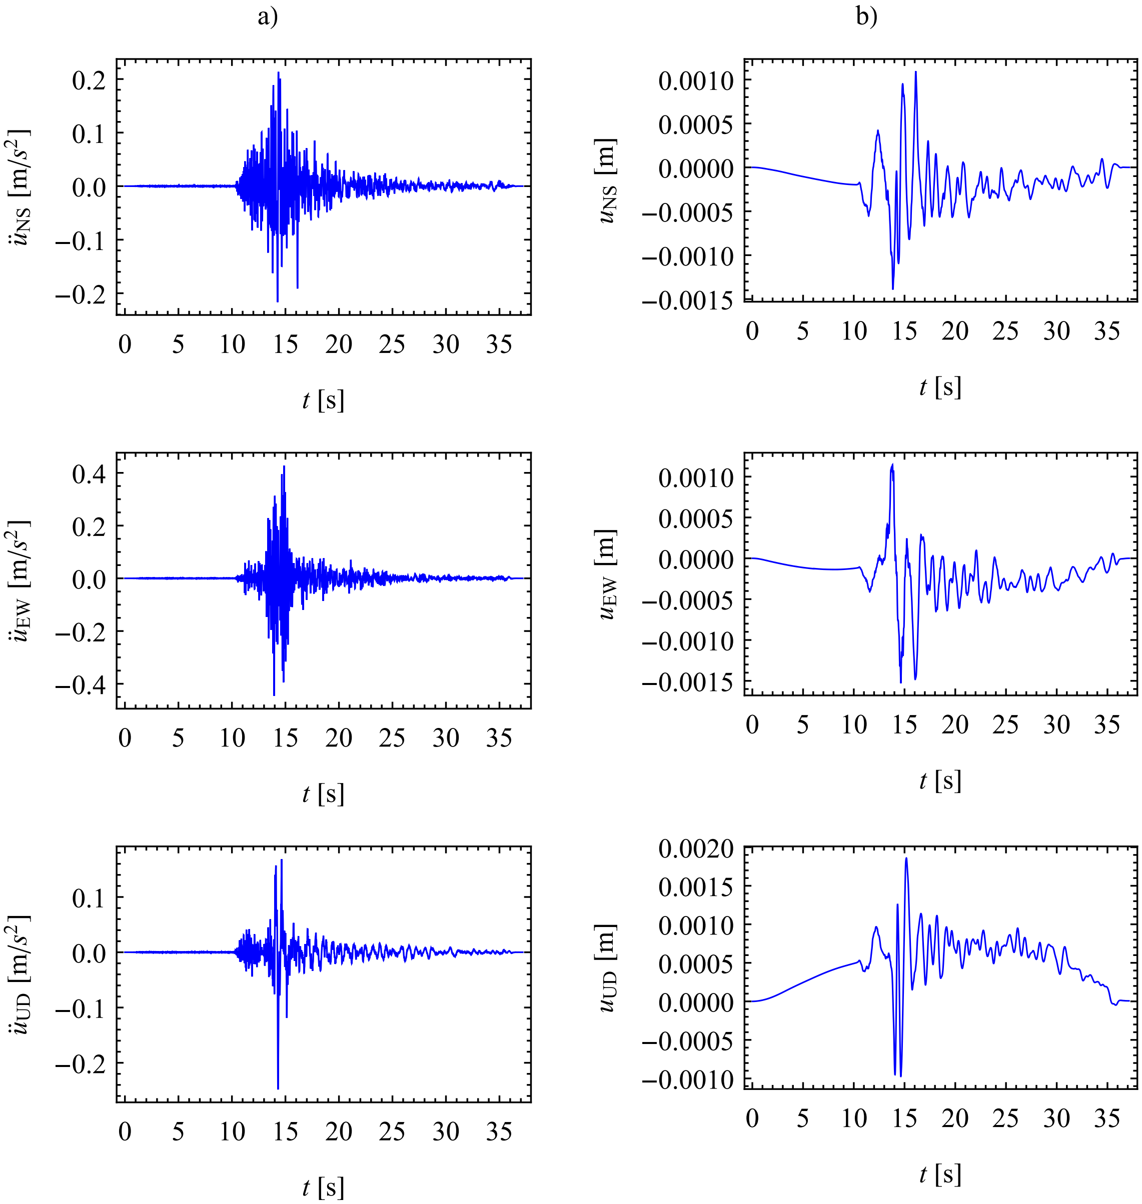


Figure 504.120: Ground motions from Le Teil earthquake recorded at station 1, at Cruas NPP: a) accelerations $\ddot{u}_{\rm NS}(t), \ddot{u}_{\rm EW}(t), \ddot{u}_{\rm UD}(t)$ and b) displacements $u_{\rm NS}(t), u_{\rm EW}(t), u_{\rm UD}(t)$.

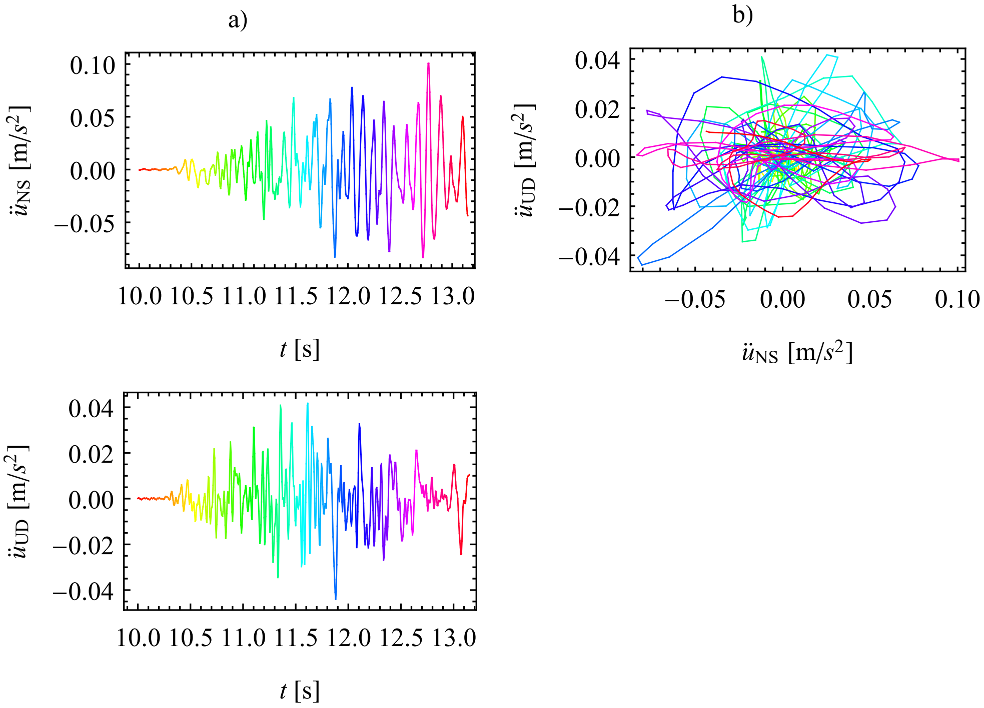

Figure 504.121: Ground accelerations from Le Teil earthquake recorded at station 1, at Cruas NPP, for $t \in [10, 13.15]$ s: a) $\ddot{u}_{NS}(t), \ddot{u}_{UD}(t)$ and b) $\ddot{u}_{UD}(\ddot{u}_{NS})$.

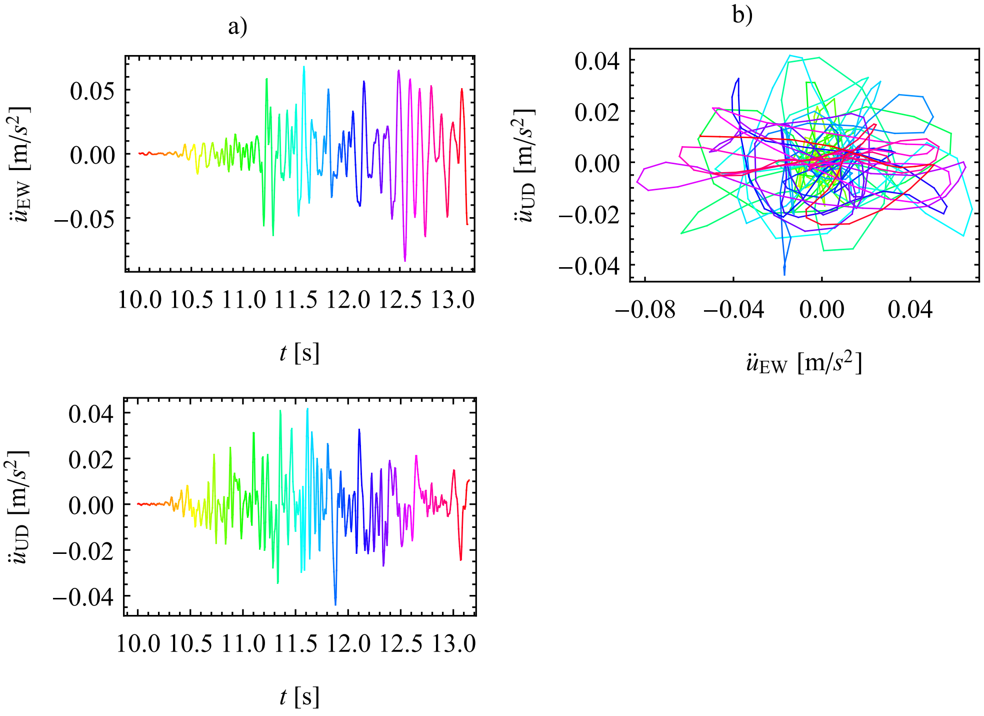

Figure 504.122: Ground accelerations from Le Teil earthquake recorded at station 1, at Cruas NPP, for $t \in [10, 13.15]$ s: a) $\ddot{u}_{\mathrm{EW}}(t), \ddot{u}_{\mathrm{UD}}(t)$ and b) $\ddot{u}_{\mathrm{UD}}(\ddot{u}_{\mathrm{EW}})$.

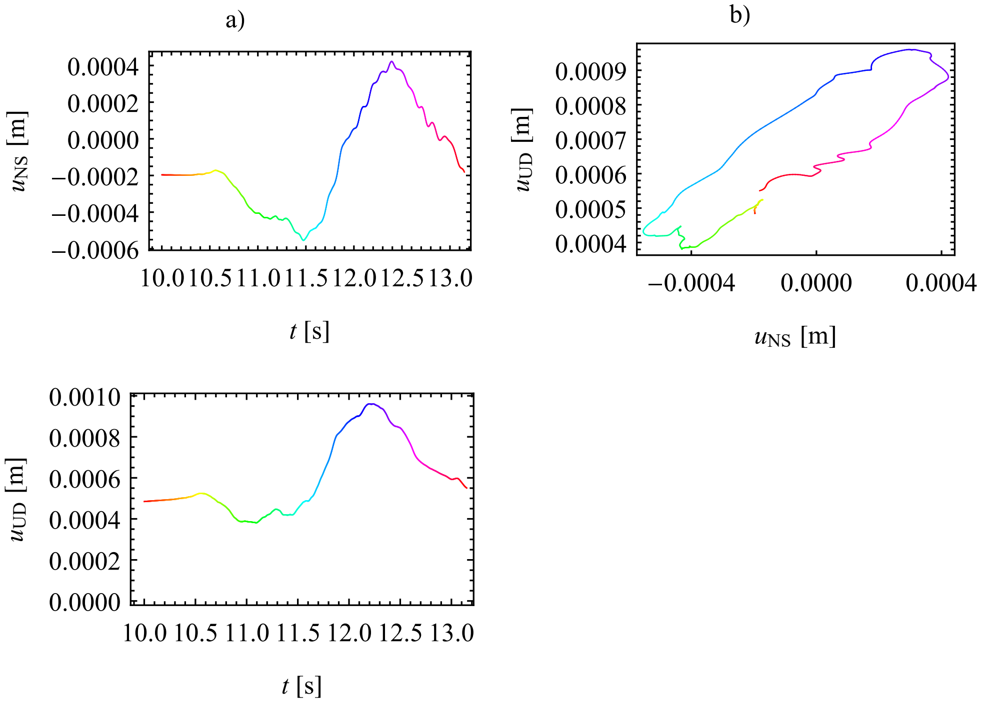

Figure 504.123: Ground displacements from Le Teil earthquake recorded at station 1, at Cruas NPP, for $t \in [10, 13.15]$ s: a) $u_{\mathrm{NS}}(t), u_{\mathrm{UD}}(t)$ and b) $u_{\mathrm{UD}}(u_{\mathrm{NS}})$.

504.10.5.1 Estimation of the Seismic Input

Seismic loads on ESSI systems are generally uncertain. Different earthquake scenarios and regional geology are probable. A parametric FE simulation of the mechanical behavior of an ESSI system using models at the regional scale would be required. It is usually quite problematic due to large computation time, however. Apart from that, unrealistic reflections of the waves at the model boundaries cannot be avoided (Baffet et al., 2012). Even larger FE models, and computation time, would be needed to ensure that the obtained results are not corrupted by the resulting so-called spurious waves. Hence it is advantageous to test ESSI systems parametrically using models at the local scale.

Different simplified approaches have been used in the literature (Semblat and Pecker, 2009; Zienkiewicz et al., 1999b) in order to shorten the computation time in FE solutions of the seismic wave propagation in ESSI systems. These methods rely on reduction of the size of the model and replacement of the distant earthquake load with a *proxy seismic load* applied at the local scale using some simplifying assumptions. Here, the *domain reduction method* (DRM) (Bielak et al., 2003a) is adapted. The proxy seismic input, also called the *DRM load*, will be used to "stress"-test Cruas NPP efficiently and fairly realistically.

An earthquake load usually arrives at the local site in the form of a plane seismic wave. This is due to the large distance between the source and the local site. The inclination of this incident plane wave has been shown, e.g., in (Hori, 2006; Teisseyre et al., 2006; Trifunac, 1982), to have significant influence on the mechanical behavior of ESSI systems. For this reason, Cruas NPP will be tested under an inclined plane wave, an incoherent wave. The DRM load will be obtained using the *Thomson-Haskell matrix method* (THMM) (Haskell, 1953). It is a closed-form solution of the propagation of an inclined monochromatic plane wave in a 3D linear elastic medium with horizontal isotropic layers.

Domain Reduction Method (DRM) The DRM (Bielak et al., 2003a; Yoshimura et al., 2003a) allows to significantly shorten the computation time in a FE solution of the seismic wave propagation in an ESSI system. However, some simplifying assumptions are needed. It is assumed that the real seismic ground motions do not differ significantly from the approximate ground motions. These approximate seismic ground motions correspond to:

- the *far field* simplified into the linear elastic medium and
- the *local site* simplified into the linear elastic *free field*, i.e., without the structure.

The earthquake load at the source is replaced by a proxy load at the local site. This proxy load is also called the DRM load. It can be calculated analytically, possibly with additional simplifying assumptions. Here, a plane wave is assumed to arrive at Cruas NPP, the local site, and the THMM is used.

It will be shown sufficient to apply the proxy load to solely a single layer of elements around the FE domain at the local scale. In this way, the regional domain can be remarkably reduced. The single layer of elements is called the *DRM layer*. The formulation of the DRM is given in what follows.

Global System of Equations We recall the global system of equations for dynamics, here, without an artificial damping,

$$K_{\alpha i\beta j}\, U_{\beta j} + M_{\alpha i\beta j}\, \ddot{U}_{\beta j} = F^{\text{ext}}_{\alpha i} \quad \text{at given } t\,. \tag{504.17}$$

Eq. (504.17) describes the discretized, in space only, weak form of the dynamic equilibrium equation (EE) and it is solved numerically in a FE calculation for a given time, t. The global tangent stiffness matrix is $K_{\alpha i\beta j}$. It stores the contributions from all elements and, generally, it can be either elastic, $K^{\text{el}}_{\alpha i\beta j}$, or elasto-plastic, $K^{\text{el-pl}}_{\alpha i\beta j}$. The Greek indices, $\alpha, \beta = 1, 2, \ldots, N$, correspond to the global node numbers and the Latin indices, $i, j = 1, 2, 3$, denote the degrees of freedom (DOFs). The displacement at node β in direction j is $U_{\beta j}$. Analogously, $M_{\alpha i\beta j}$ is the constant global mass matrix that stores the contributions from all elements. The acceleration at node β in direction j is $\ddot{U}_{\beta j}$. The external force at node α in direction i is $F^{\text{ext}}_{\alpha i}$.

Global System of Equations in the Regional Model The regional domain includes the source of the earthquake and it is denoted as R. The local-site domain, with the structure, is denoted as L, Fig. 504.129(a). Let us write (504.17) for R, L and the boundary, Γ, between R and L,

$$\begin{bmatrix} K^{\text{el}}_{\alpha i\beta j} & K^{\text{el}}_{\alpha i\mathsf{b}j} & 0_{\alpha i\mathsf{B}j} \\ K^{\text{el}}_{\mathsf{a}i\beta j} & K^{\text{R el}}_{\mathsf{a}i\mathsf{b}j} + K^{\text{L el--pl}}_{\mathsf{a}i\mathsf{b}j} & K^{\text{el--pl}}_{\mathsf{a}i\mathsf{B}j} \\ 0_{\mathsf{A}i\beta j} & K^{\text{el--pl}}_{\mathsf{A}i\mathsf{b}j} & K^{\text{el--pl}}_{\mathsf{A}i\mathsf{B}j} \end{bmatrix} \cdot \begin{Bmatrix} U_{\beta j} \\ U_{\mathsf{b}j} \\ U_{\mathsf{B}j} \end{Bmatrix} + \begin{bmatrix} M_{\alpha i\beta j} & M_{\alpha i\mathsf{b}j} & 0_{\alpha i\mathsf{B}j} \\ M_{\mathsf{a}i\beta j} & M^{\text{R}}_{\mathsf{a}i\mathsf{b}j} + M^{\text{L}}_{\mathsf{a}i\mathsf{b}j} & M_{\mathsf{a}i\mathsf{B}j} \\ 0_{\mathsf{A}i\beta j} & M_{\mathsf{A}i\mathsf{b}j} & M_{\mathsf{A}i\mathsf{B}j} \end{bmatrix} \cdot \begin{Bmatrix} \ddot{U}_{\beta j} \\ \ddot{U}_{\mathsf{b}j} \\ \ddot{U}_{\mathsf{B}j} \end{Bmatrix} = \begin{Bmatrix} F^{\text{ext}}_{\alpha i} \\ 0_{\mathsf{a}i} \\ 0_{\mathsf{A}i} \end{Bmatrix}, \tag{504.18}$$

wherein $K^{\text{R el}}_{\mathsf{a}i\mathsf{b}j}, M^{\text{R}}_{\mathsf{a}i\mathsf{b}j}$ correspond to the elements in R and $K^{\text{L el--pl}}_{\mathsf{a}i\mathsf{b}j}, M^{\text{L}}_{\mathsf{a}i\mathsf{b}j}$ correspond to the elements in L. The Greek indices, $\alpha, \beta = 1, 2, \ldots, N$, denote the nodes in R. The lower-case sans-serif letters, $\mathsf{a}, \mathsf{b} = 1, 2, \ldots, N$, denote the nodes at Γ and the upper-case ones, $\mathsf{A}, \mathsf{B} = 1, 2, \ldots, N$, denote the nodes in L. Domain R is much, say, $10^3\times$, larger than domain L. The Neumann BC, $F^{\text{ext}}_{\alpha i}$, is prescribed to the nodes in R only. The materials in R are assumed to be linear elastic. The material behavior in L may be strongly non-linear. Hence L may require some sophisticated constitutive description and a fine discretization, both, in space and time. Computational cost of this regional model is mainly related to the size of domain R and to the material non-linearity inside domain L.

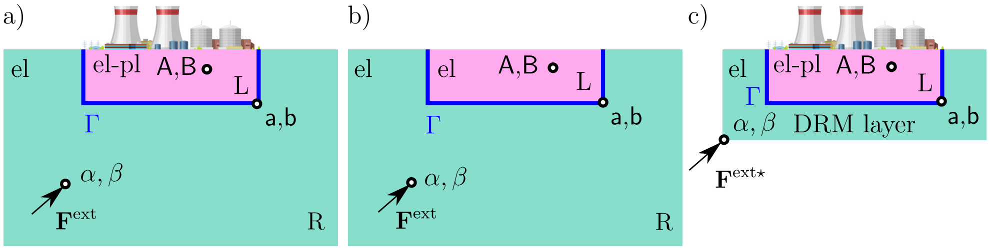

Figure 504.129: DRM: a) regional model, b) regional model with the simplified local site and c) reduced model. L is the local-site domain, R is the regional domain and Γ is the boundary between L and R. The BC, $\mathbf{F}^{\text{ext}}$, is replaced by the proxy load, $\mathbf{F}^{\text{ext}\star}$, applied to the DRM layer only.

Global System of Equations in the Regional Model with the Simplified Local Site Let us temporarily remove the structure from domain L, Fig. 504.129(b), and assume the linear elastic behavior within L. We rewrite (504.18) using index $\sqcup^{\star}$ for a quantity, $\sqcup$, that corresponds to the regional model with the simplified local site. The following holds.

$$\begin{bmatrix} K^{\text{el}}_{\alpha i\beta j} & K^{\text{el}}_{\alpha i\mathsf{b}j} & 0_{\alpha i\mathsf{B}j} \\ K^{\text{el}}_{\mathsf{a}i\beta j} & K^{\text{R el}}_{\mathsf{a}i\mathsf{b}j}+K^{\text{L el}}_{\mathsf{a}i\mathsf{b}j} & K^{\text{el}}_{\mathsf{a}i\mathsf{B}j} \\ 0_{\mathsf{A}i\beta j} & K^{\text{el}}_{\mathsf{A}i\mathsf{b}j} & K^{\text{el}}_{\mathsf{A}i\mathsf{B}j} \end{bmatrix} \cdot \begin{Bmatrix} U^{\star}_{\beta j} \\ U^{\star}_{\mathsf{b}j} \\ U^{\star}_{\mathsf{B}j} \end{Bmatrix} + \begin{bmatrix} M_{\alpha i\beta j} & M_{\alpha i\mathsf{b}j} & 0_{\alpha i\mathsf{B}j} \\ M_{\mathsf{a}i\beta j} & M^{\text{R}}_{\mathsf{a}i\mathsf{b}j}+M^{\text{L}\star}_{\mathsf{a}i\mathsf{b}j} & M^{\star}_{\mathsf{a}i\mathsf{B}j} \\ 0_{\mathsf{A}i\beta j} & M^{\star}_{\mathsf{A}i\mathsf{b}j} & M^{\star}_{\mathsf{A}i\mathsf{B}j} \end{bmatrix} \cdot \begin{Bmatrix} \ddot{U}^{\star}_{\beta j} \\ \ddot{U}^{\star}_{\mathsf{b}j} \\ \ddot{U}^{\star}_{\mathsf{B}j} \end{Bmatrix} = \begin{Bmatrix} F^{\text{ext}}_{\alpha i} \\ 0_{\mathsf{a}i} \\ 0_{\mathsf{A}i} \end{Bmatrix} \tag{504.19}$$

The simplification of L does not influence either the stiffness matrices or the mass matrices corresponding to the elements in R. Neither the BC, $F^{\text{ext}}_{\alpha i}$, is affected.

Material in the far field is assumed linear elastic independently of the temporary simplification of L, so the displacement and its time derivates are additive, that is,

$$\Delta U_{\beta j} = U_{\beta j} - U^{\star}_{\beta j} \quad \text{and} \quad \Delta \ddot{U}_{\beta j} = \ddot{U}_{\beta j} - \ddot{U}^{\star}_{\beta j} \tag{504.20}$$

hold in R.

Global System of Equations in the Reduced Model The force

$$F^{\text{ext}}_{\alpha i} = K^{\text{el}}_{\alpha i\beta j} U^{\star}_{\beta j} + K^{\text{el}}_{\alpha i\mathsf{b}j} U^{\star}_{\mathsf{b}j} + M_{\alpha i\beta j} \ddot{U}^{\star}_{\beta j} + M_{\alpha i\mathsf{b}j} \ddot{U}^{\star}_{\mathsf{b}j} \tag{504.21}$$

from (504.19) can be substituted together with (504.20) into (504.18) and one obtains the following system of equations.

$$\begin{bmatrix} K^{\mathrm{el}}_{\alpha i\beta j} & K^{\mathrm{el}}_{\alpha i\mathrm{b}j} & 0_{\alpha i\mathrm{B}j} \\ K^{\mathrm{el}}_{\mathrm{a}i\beta j} & K^{\mathrm{R\,el}}_{\mathrm{a}i\mathrm{b}j} + K^{\mathrm{L\,el-pl}}_{\mathrm{a}i\mathrm{b}j} & K^{\mathrm{el-pl}}_{\mathrm{a}i\mathrm{B}j} \\ 0_{\mathrm{A}i\beta j} & K^{\mathrm{el-pl}}_{\mathrm{A}i\mathrm{b}j} & K^{\mathrm{el-pl}}_{\mathrm{A}i\mathrm{B}j} \end{bmatrix} \cdot \begin{Bmatrix} \Delta U_{\beta j} \\ U_{\mathrm{b}j} \\ U_{\mathrm{B}j} \end{Bmatrix} + \begin{bmatrix} M_{\alpha i\beta j} & M_{\alpha i\mathrm{b}j} & 0_{\alpha i\mathrm{B}j} \\ M_{\mathrm{a}i\beta j} & M^{\mathrm{R}}_{\mathrm{a}i\mathrm{b}j} + M^{\mathrm{L}}_{\mathrm{a}i\mathrm{b}j} & M_{\mathrm{a}i\mathrm{B}j} \\ 0_{\mathrm{A}i\beta j} & M_{\mathrm{A}i\mathrm{b}j} & M_{\mathrm{A}i\mathrm{B}j} \end{bmatrix} \cdot \begin{Bmatrix} \Delta \ddot{U}_{\beta j} \\ \ddot{U}_{\mathrm{b}j} \\ \ddot{U}_{\mathrm{B}j} \end{Bmatrix} = \begin{Bmatrix} K^{\mathrm{el}}_{\alpha i\mathrm{b}j} U^{\star}_{\mathrm{b}j} + M_{\alpha i\mathrm{b}j} \ddot{U}^{\star}_{\mathrm{b}j} \\ -K^{\mathrm{el}}_{\mathrm{a}i\beta j} U^{\star}_{\beta j} - M_{\mathrm{a}i\beta j} \ddot{U}^{\star}_{\beta j} \\ 0_{\mathrm{A}i} \end{Bmatrix} \tag{504.22}$$

The RHS of (504.22),

$$\begin{Bmatrix} F^{\mathrm{ext}\star}_{\alpha i} \\ F^{\mathrm{ext}\star}_{\mathrm{a}i} \\ 0_{\mathrm{A}i} \end{Bmatrix} = \begin{Bmatrix} K^{\mathrm{el}}_{\alpha i\mathrm{b}j} U^{\star}_{\mathrm{b}j} + M_{\alpha i\mathrm{b}j} \ddot{U}^{\star}_{\mathrm{b}j} \\ -K^{\mathrm{el}}_{\mathrm{a}i\beta j} U^{\star}_{\beta j} - M_{\mathrm{a}i\beta j} \ddot{U}^{\star}_{\beta j} \\ 0_{\mathrm{A}i} \end{Bmatrix}, \tag{504.23}$$

can be used as the BC instead of $\mathbf{F}^{\mathrm{ext}}$ from (504.18).

It is evident in (504.23) that the proxy forces, $\mathbf{F}^{\mathrm{ext}\star}$, take on non-zero values for elements with nodes a, b, in domain R, or both, a, b, in domain R, and α, β, at boundary Γ, only. This means that $\mathbf{F}^{\mathrm{ext}\star}$ can be applied to solely the single layer of elements adjacent to Γ, namely, the DRM layer, and hence the model can be reduced, Fig. 504.129(c).

The discrete proxy load, $\mathbf{F}^{\mathrm{ext}\star}$, is only a rough estimation of the real seismic load because it corresponds to the simplified local site. Hence using the DRM, one saves the computation time at the cost of the reliability of the obtained results.

This $\mathbf{F}^{\mathrm{ext}\star}$ is obtained in Real-ESSI Simulator from an inclined plane wave in horizontally layered soil using the THMM.

Thomson-Haskell Matrix Method (THMM) The propagation of an inclined plane wave in a linear elastic ground with horizontal isotropic layers is solved analytically using the Thomson-Haskell matrix method (THMM) (Haskell, 1953; Thomson, 1950). In this way, reflections and refractions of the wave at interfaces between the layers are captured. Also, the Rayleigh wave is taken into account. The use of a closed-form solution eliminates the problem of unrealistic reflections of the wave at the boundaries of the FE model.

The THMM holds for monochromatic waves only. If the wave is non-monochromatic, it can be decomposed into harmonic components with the Fourier analysis. The THMM is then used for each monochromatic component and the solutions are synthesized using, again, the Fourier analysis.

The analytical solution of the wave propagation is generally established from the boundary conditions at the interfaces between the layers and at the surface. The Helmholtz decomposition theorem is incorporated and the wave field is separated into two parts, i.e., the part pertaining to the purely volumetric deformation and the part related to the pure rotation of material particles (Nowacki, 1974). The Snell law describes reflections and refractions of the waves at the interfaces between the layers and at the surface. In the THMM, the governing equations are conveniently rewritten into a matrix form to ease the computation of the wave propagation.

A comprehensive description of the implementation of the THMM into Real-ESSI Simulator is given in (Wang et al., 2021).

504.10.5.2 Preliminary 2D Simulation of Le Teil Earthquake using DRM with THMM

Rock is isotropic, linear elastic, E, ν with $E = 2\rho V_s^2(1+\nu)$, Table 504.11.

Table 504.11: Material properties in preliminary 2D simulation of the earthquake in Le Teil using DRM with THMM

Material	z m	ρ kg/m^3	V_s m/s	ν
Rock	$[0, -\infty]$	2500	1600	0.4

Time functions of the horizontal ground acceleration, $\ddot{u}_x(t)$, and the vertical ground acceleration, $\ddot{u}_z(t)$, at $\boldsymbol{x} = \{140, 0, 0\}$ m is plotted in Figure 504.130(a). The corresponding hodograph, $u_z(u_x)$, is shown in Figure 504.130(b).

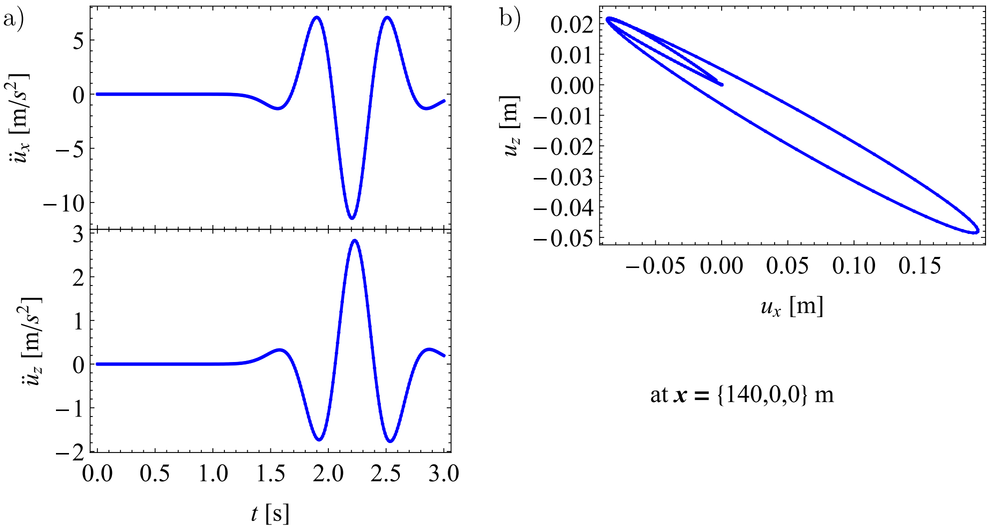

Figure 504.130: Preliminary 2D simulation of the earthquake in Le Teil using DRM with THMM: a) $\ddot{u}_x(t)$ and $\ddot{u}_z(t)$, and b) $u_z(u_x)$ at $\boldsymbol{x} = \{140, 0, 0\}$ m.

504.10.6 Cruas Nuclear Power Plant (NPP)

Base isolators are located at approximately -9.0 to -12.0 m. This means that the NPP is founded on rock, see the soil profile from Table 504.9 on page 2570.

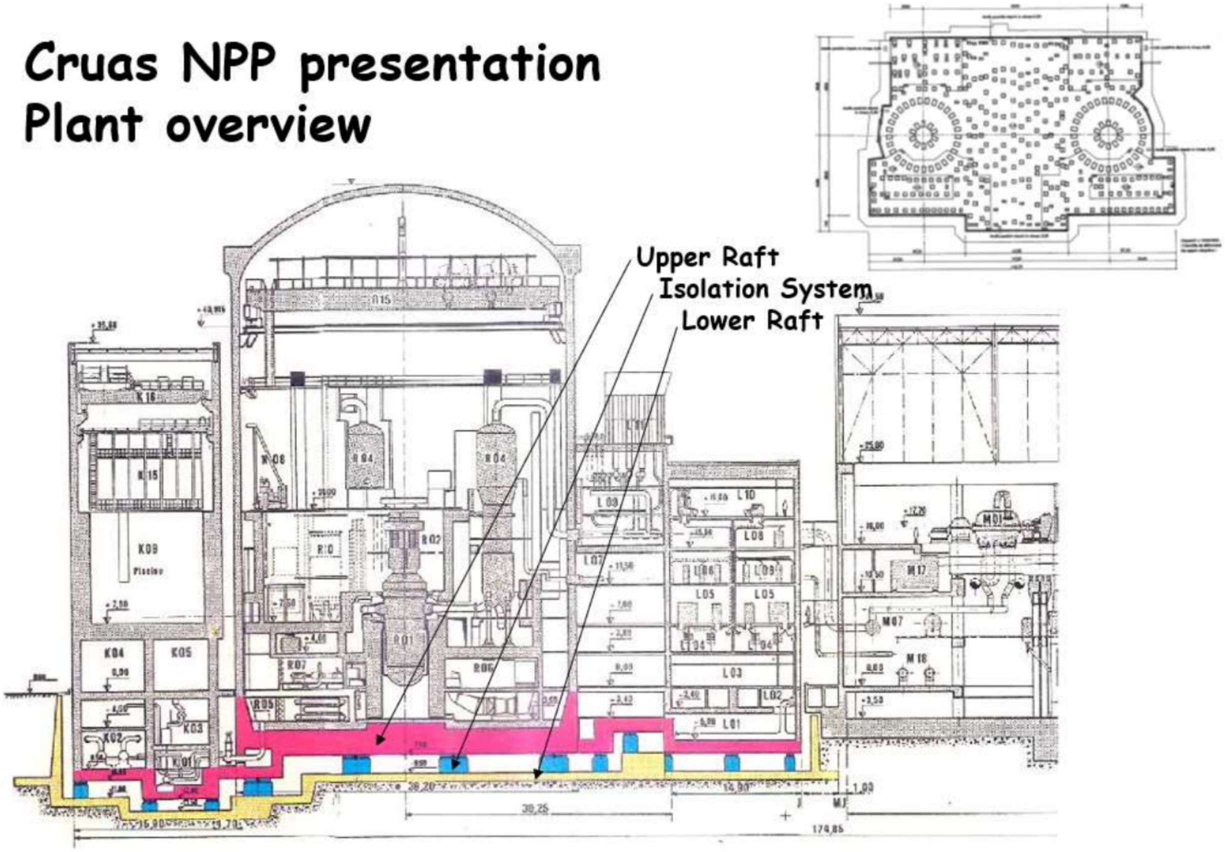

Figure 504.131: Cruas NPP, section 01, according to Viallet et al. (2022).

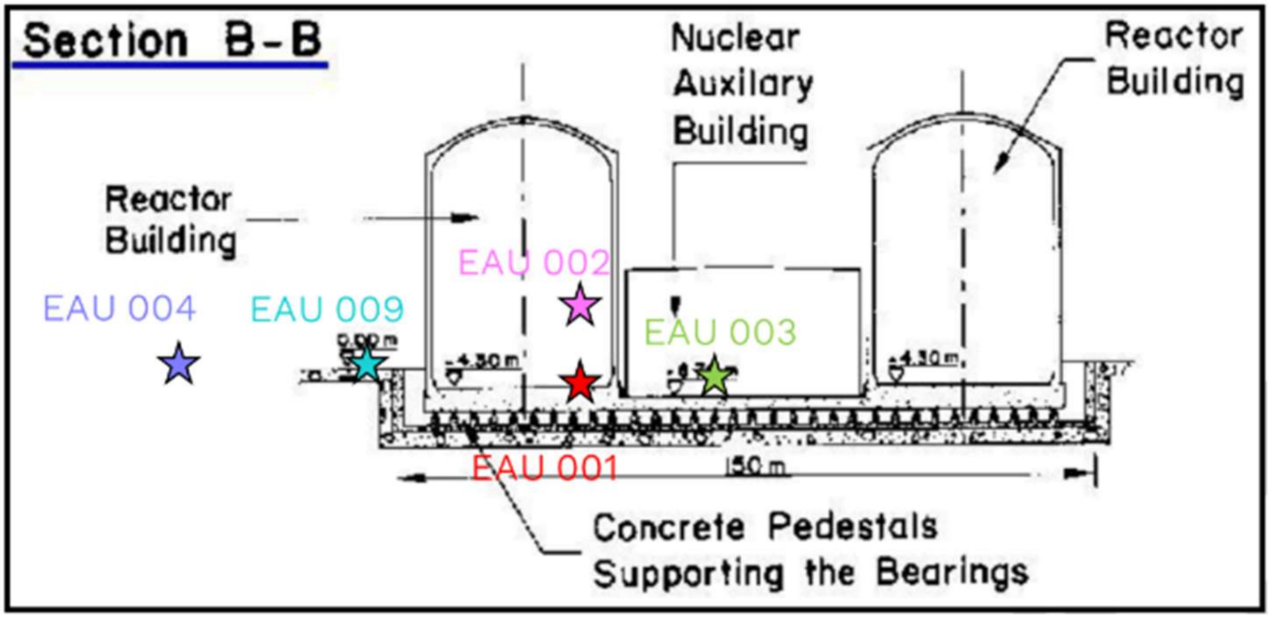

Figure 504.132: Cruas NPP, section 02, according to Viallet et al. (2022).

504.10.7 FE Simulation of Cruas NPP under Seismic Load from Le Teil Earthquake

...

504.10.7.1 Verification of the Simulation

FE simulation of an ESSI system requires one to specify:

- the domain of simulation (both, in space and in time)
- the boundary conditions (BCs)
- the initial conditions (ICs)
- the material laws
- the material parameters
- the discretization (in space and in time) and
- the numerical procedures used in the calculation,

wisely. A parametric study using a simple FE model may be helpful in understanding the influence of the above aspects on the results of the simulation. This influence can be additionally quantified in a sensitivity study (Sobol, 2001). Also, in the case of a simple model, the numerical solution can be compared with the corresponding analytical one. In this way, a complex FE model can be verified.

Element Tests The mechanical behavior of chosen critical parts of Cruas NPP (being an ESSI system) is investigated in suitable element tests. They are conducted on different structural materials and on different soils with various:

- BCs (displacement, seismic load)
- ICs (initial stress and strain)
- material laws
- material parameters.

The resulting evolution of the stress, $\boldsymbol{\sigma}(\mathbf{x},t)$, and strain, $\varepsilon(\mathbf{x},t)$, fields is examined.

Beam Element Tests on Reinforced Concrete A cantilever beam is tested on reinforced concrete with different material laws for concrete and for steel in:

- uniaxial compression or extension, Figure ...
- uniaxial bending, Figure ...
- biaxial bending, Figure ...
- torsion, Figure ....

A (displacement-based) *fiber beam-column element* similar to the one from (Taucer et al., 1991) is used. It is called `BeamColumnDispFiber3d_Corotational`. The co-rotational formulation by (Crisfield, 1990) is implemented. The local coordinate system co-rotates with the element during a rigid body rotation and hence `BeamColumnDispFiber3d_Corotational` is applicable also in the case of the *geometric non-linearity*, i.e., when *large deformations* are involved. Otherwise, during a large deformation with a significant rigid body rotation, an excessive stiffness might be obtained in such beam element.
The element has two nodes and the user defines the number of Gauß points along the element.

`BeamColumnDispFiber3d_Corotational` may represent multiple 1D so-called *fibers*. They are simply connected in parallel, Figure 504.133. A fiber is defined by its cross-section, A, and location in the element cross-section, $\{y, z\}$. The cross-section is constant along the beam.

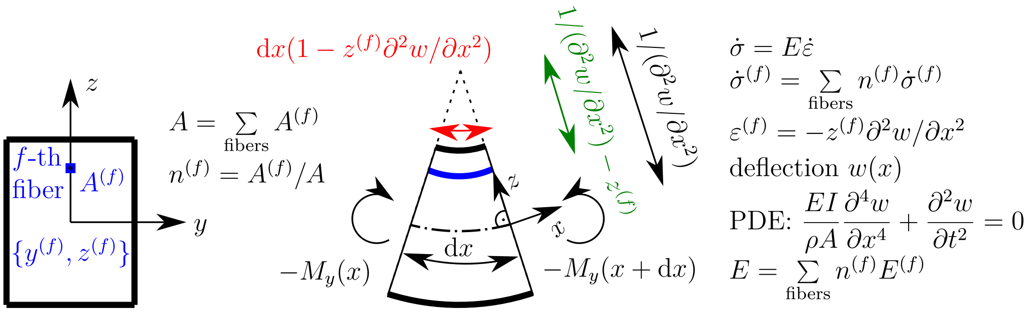

Figure 504.133: Fiber beam-column element in uniaxial bending: The second moment of area, I, pertains to the whole cross-section and the density, ρ, describes the average density of the material.

Each fiber has a prescribed material law. Different material laws can be prescribed to different fibers. The strain in a single fiber is obtained assuming that the cross-section remains plane and normal to the beam axis during the deformation. This means that `BeamColumnDispFiber3d_Corotational` is an *Euler-Bernoulli beam*. The shear stress is neglected which is allowed in beams for which the cross-sectional dimensions are much smaller than the length, see, e.g., (Nowacki, 1974).

However, the cross-section is additionally (independently of the fibers) described by the product, GJ, of the shear modulus, G, and the torsional constant, J. Hence the element has four nodal degrees of freedom (DOFs) altogether, i.e., three translations and the angle of twist due to the torsional moment, M_x.

Shell Element Tests on Concrete ...

Solid Element Tests on Concrete Different constitutive laws for concrete are tested in:

- triaxial compression, Figure 504.134(a),
- simple shear, Figure 504.134(b),
- pure shear (here, understood as isochoric shear with no rotation of the principal stress and strain directions), Figure 504.134(c).

The 3D solid brick element, `8NodeBrick`, is used.

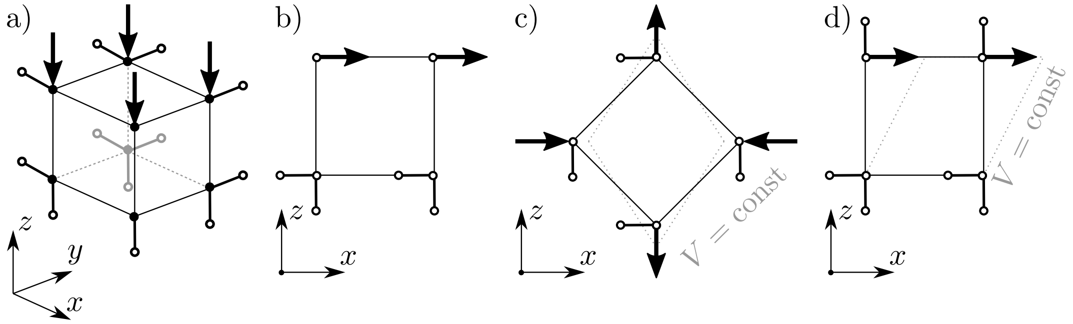

Figure 504.134: Solid element tests: a) triaxial compression, b) simple shear, c) pure shear (isochoric with no rotation of the principle stress and strain directions), d) pure shear (in soil mechanics, commonly understood as isochoric shear).

Solid Element Tests on Soil Similarly as in the case of the solid element tests on concrete, different constitutive laws for soils are tested in:

- triaxial compression, Figure 504.134(a),
- simple shear, Figure 504.134(b),

- pure shear (here, understood as isochoric shear with no rotation of the principal stress and strain directions), Figure 504.134(c).

The 3D solid brick element, `8NodeBrick`, is used.

Seismic Isolator and Dissipator Element Tests …

Report for Phase 2 of Stage 1, Simulation of the Ground Motions

Ground motions from the Le Teil earthquake had been intensively studied within the SIGMA2 project[6] (Viallet et al., 2022). Two types of methods for the simulation of seismic motions had been used, the empirical methods and the physically based methods. The latter include both, 1D (Fasan, 2016; Fasan et al., 2016; Hassan et al., 2020; Magrin et al., 2016; Magrin, 2012; Panza et al., 2012) and 3D (Mazzieri et al., 2013; Paolucci et al., 2020, 2021) simulations. Some recent 3D numerical calculations of seismic motions from the Le Teil earthquake are reported in (Lehmann et al., 2023; Smerzini et al., 2023).

Seismic input due to the Le Teil earthquake is needed to simulate the inelastic behavior of the Cruas NPP. A FE simulation of the wave field from the earthquake is conducted using the Real-ESSI Simulator (Jeremić et al., 1988-2025). Unfortunately, the knowledge about the local and regional geology is very limited. Soil and rock profiles are available at three locations only. This scarcity of data precludes the preparation of a realistic model at the regional scale. Hence an accurate reproduction of the seismic wave field from the earthquake in Le Teil is impossible.

Based on a preliminary simplified FE simulation and the recent work by Viallet et al. (2022), some important observations are made about the studied seismic wave field.

- The preliminary simulation using a simple 2D model with a shallow point source reveals a possible occurence of the Stoneley wave and the Rayleigh wave. This should, indeed, be expected from a shallow earthquake, particularly with the rupture that achieves the surface.
- Based on Viallet et al. (2022), the horizontal and vertical components of ground motions at the Cruas NPP occur almost simultaneously. We interprete these motions as the overlapping Rayleigh and Stoneley waves.
- Earthquake loads are usually simulated as one dimensional (1D), one component (1C) waves, possibly superposed, wherein 1D pertains to the direction of propagation, either vertical or horizontal, while 1C corresponds to the direction of polarization, analogously, either vertical or horizontal. The probable presence of the Rayleigh wave and the Stoneley wave excludes this common approach to modelling of seismic loads. In the case of the surface and interface waves, the simulated seismic wave field is shown to be significantly different than the one obtained using the common approach. The seismic response of a structure will also be different depending on the seismic input. The difference is most evident in the case of shorter wave lengths, that is, for higher wave frequencies.

Chapter 505

Liquefaction and Cyclic Mobility

(2002-2006-2009-2021-)

(In collaboration with Dr. Zhao Cheng, and Dr. Panagiota Tasiopoulou)

505.1 Chapter Summary and Highlights

505.2 Introduction

Liquefaction is one of the most complex phenomena in earthquake engineering. Liquefaction also represents one of the biggest contributors to damage of constructed facilities during earthquakes (Kramer, 1996a). Prediction of behaviors of liquefiable soils is difficult but achievable. There are number of methods that can be utilized to predict such behaviors. Methods currently used can have varying prediction accuracy and certainty. Of particular interest in this paper is the description of verified and validated numerical simulation methodology based on rational mechanics that is used to model, simulate and predict behavior of a single pile in liquefiable soil subjected to seismic loading. Both level and sloping ground pile systems are modeled and simulated. Detailed description of background theory, formulation and implementation were recently given by Cheng et al. (2007) and Jeremić et al. (2008).

It should be noted that presented development does show great promise in analyzing a myriad of liquefaction related problems in geotechnical and structural engineering. The effectiveness and power of numerical simulation tools for analyzing liquefaction problems becomes even more important and prominent in the light of potential disadvantages of models used in experimental simulations. These disadvantages, related to proper scaling (Wood, 2004) and problems in maintaining appropriate similarities (Harris and Sabnis, 1999) for first order important phenomena, can render scaled models ineffective, when used for physical simulations (under one-step or multiple-step gravity loading).

In what follows, a brief literature review is provided. The literature review comprises sections on observations of liquefaction behavior in case studies, non–continuum modeling efforts, review of redistribution of voids and pore fluid volume/pressures phenomena and continuum modeling efforts.

Observation of Behavior. Liquefaction behavior was observed during a number of earthquakes in the past. During Alaskan Earthquake (1964), liquefaction was the main cause of severe damage to 92 highway bridges, moderate to light damage to another 49 highway bridges, and moderate to sever damage to 75 railroad bridges (Youd and Bartlett, 1989). During Niigata Earthquake (1964) liquefaction induced damage to foundation piles under Yachiya bridge (Hamada, 1992). During that same earthquake, girders of Showa Bridge toppled as the support structure and piles moved excessively due to liquefaction (Japanese Society of Civil Engineers, 1966). During Kobe Earthquake (1995), liquefaction was the primary cause of damage to many pile supported or caisson supported bridges and structures. For example, Shin–Shukugawa bridge was subjected to excessive pile foundation movement due to liquefaction (Yokoyama et al., 1997).

Opposed to these failures and collapses, there were a number of bridges with pile foundations that did not suffer much or even minor damage even though there was liquefaction around foundations. For example, pile foundations of the Landing Road Bridge in New Zealand performed quite well during Edgecumbe earthquake (1987) even with a significant liquefaction recorded (Berril et al., 1997; Dobry and Abdoun, 2001). In addition to that, Second Maya Bridge piles (large steel pipes) were not damaged during Kobe earthquake despite significant liquefaction in surrounding soils (Yokoyama et al., 1997).

Non–Continuum Modeling Efforts. Modeling and simulation of piles in liquefied grounds has been focus of a number of recent studies. The simple approach, based on scaling of p-y springs has been suggested early by Japanese Road Association (1980), Architectural Institutive of Japan (1988), Liu and Dobry (1995), Miura et al. (1989) and O'Rourke (1991). However, large inconsistencies with material parameter selection are present when p-y spring approach is used for piles in liquefied soils. Since p-y methodology for liquefied soils is not based on rational mechanics, appropriate choice of material parameters is primarily based on empirical observations of behaviors of piles in liquefied soils in experimental studies. A number of experimental studies have carefully examined pile behaviors in liquefiable soils. We mention Tokida et al. (1992), Liu and Dobry (1995), Abdoun et al. (1997), Horikoshi et al. (1998) and Boulanger and Tokimatsu (2006). Studies using physical model can be used to obtain very high quality data on behavior of piles in liquefied soils, provided that similarity of important physical phenomena is maintained (Wood, 2004; Harris and Sabnis, 1999). Some of the recent papers that discussed use of these models and gave recommendations about parameter choices are listed for reference: Tokimatsu and Asaka (1998), Martin et al. (2002), Dobry et al. (2003), Liyanapathirana and Poulos (2005), Rollins et al. (2005), Čubrinovski and Ishihara (2006), Brandenberg et al. (2007).

Redistribution of Voids and Pore Fluid Volume/Pressures. Mechanics of pile behavior in liquefiable grounds is based on the concept of redistribution of voids and pore fluid volume/pressures (RVPFVP). It should be emphasized that geomechanics phenomena of redistribution of voids – pore fluid volume/pressure is used here in purely mechanistic way. That is, RVPFVP is a phenomena that occurs in saturated soils and that phenomena is responsible for (is manifested in) liquefaction related soil behaviors with or without piles. This is noted as in some recent publications, RVPFVP terminology is explicitly used for problems of liquefaction induced failures of sloping grounds without piles. Our understanding of the RVPFVP phenomena is that RVFVP is responsible for many more facets of behavior of liquefied soils, rather than only failure of liquefied slopes.

The early investigation of the RVPFVP phenomena was related to the behavior of infinite slopes. For example, loss of shear strength in infinite slopes is one of the early understood manifestations of RVPFVP (Whitman, 1985; National Research Council, 1985; Malvick et al., 2006). Laboratory investigation of sand was also used to observe the RVPFVP phenomena (Casagrande and Rendon, 1978; Gilbert, 1984)

Continuum Modeling Efforts. Continuum based formulations for modeling liquefaction problems have been present for over two decades. In a landmark paper, Zienkiewicz and Shiomi (1984) presented three possible coupled formulations for modeling of soil skeleton – pore fluid problems. The most general and complete one is the so called u-p-U formulations while the other two, the u-p and the u-U have a number of restrictions on the domain of application. Here, the unknowns are the soil skeleton displacements u; the pore fluid (water) pressure p; and the pore fluid (water) displacements U. The u-p formulation captures the movements of the soil skeleton and the change of the pore pressure, and is the most simplistic one of the three mentioned above. This formulation neglects the differential accelerations of the pore fluid (it does account for acceleration of pore fluid together with soil skeleton, but not the differential one if it exists), and in one version neglects the compressibility of the fluid (assuming complete incompressibility of the pore fluid). In the case of incompressible pore fluid, the formulation requires special treatment of the approximation function (shape function) for pore fluid to prevent the volumetric locking (Zienkiewicz and Taylor, 2000). The majority of the currently available implementations are based on this formulation. For example Elgamal et al. (2002) and Elgamal et al. (2003) developed an implementation of the u-p formulation with the multi-surface plasticity model by Prevost (1985b), while Chan (1988) and Zienkiewicz et al. (1999a) used generalized theory of plasticity Pastor et al. (1990).

The u-U formulations tracks the movements of both the soil skeleton and the pore fluid. This formulation is complete in the sense of basic variables, but might still experience numerical problems (volumetric locking) if the difference in volumetric compressibility of the pore fluid and the solid skeleton is large.

The u-p-U formulation resolves the issues of volumetric locking by including the displacements of both the solid skeleton and the pore fluid, and the pore fluid pressure as well. This formulation uses additional dependent unknown field of pore fluid pressures to stabilize the solution of the coupled system. The pore fluid pressures are connected to (dependent on) displacements of pore fluid. With known (given) volumetric compressibility of the pore fluid, pore fluid pressure can be calculated. Despite it's power, the u-p-U formulation has rarely been implemented into finite element code, and has never (at least to our knowledge) been used to analyze pile – liquefied soil interaction. This can be attributed in part to a sophistication of implementation that is required, and to a sizable increase in computational cost for u-p-U elements.

505.3 Liquefaction of Level and Sloping Grounds

Material presented here is from Cheng et al. (2007); Jeremić et al. (2008).

Liquefaction of level and sloping grounds represents a very common behavior during earthquakes. Of interest is to estimate settlement for level ground, and horizontal movements for sloping grounds. In next few sections, presented are results for a 1D, vertical (level ground) and sloping ground cases for dense and loose sand behavior during seismic shaking.

505.3.1 Model Description

Vertical soil column consists of a multiple-elements subjected to an earthquake shaking. The soil is assumed to be Toyoura sand and the calibrated parameters are from Dafalias and Manzari (2004a), and are given in the Table (505.1).

Table 505.1: Material parameters of Dafalias-Manzari model.

material parameter		value	material parameter		value
Elasticity	G_0	125 kPa	Plastic modulus	h_0	7.05
	v	0.05		c_h	0.968
Critical sate	M	1.25		n_b	1.1
	c	0.712	Dilatancy	A_0	0.704
	λ_c	0.019		n_d	3.5
	ξ	0.7	Fabric-dilatancy	z_{max}	4.0
	e_r	0.934		c_z	600.0
Yield surface	m	0.01			

The other parameters, related to the boundary value problem are given in table (505.2).

For tracking convenience, the mesh elements are labeled from E01 (bottom) to E10 (surface) and nodes at each layers are labeled from A (bottom) to K (surface).

A static application of gravity analysis is performed before seismic excitation. The resulting fluid hydrostatic pressures and soil stress states along the soil column serve as initial conditions for the subsequent dynamic analysis.

It should be noted that the self weight loading is performed on an initially zero stress (unloaded) soil column and that the material model and numerical integration algorithms are powerful enough to follow through this early loading with proper evolution. The boundary conditions are such that the soil and water displacement degree of freedom (DOF) at the bottom surface are fixed, while the pore pressure

Table 505.2: Additional parameters used in boundary value problem simulations (other than material parameters from the Table (505.1)).

Parameter	Symbol	Value
Solid density	ρ_s	$2700\ kg/m^3$
Fluid density	ρ_f	$1000\ kg/m^3$
Solid particle bulk modulus	K_s	$3.6 \times 10^7\ kN/m^2$
Fluid bulk modulus	K_f	$2.2 \times 10^6\ kN/m^2$
permeability	k	$5.0 \times 10^{-4}\ m/s$
HHT parameter	α	-0.2

DOFs are free; the soil and water displacement DOFs at the upper surface are free upwards to simulate the upward drainage. The pore pressure DOFs are fixed at surface thus setting pore pressure to zero. On the sides, soil skeleton and water are prevented from moving in horizontal directions while vertical movement of both is free. It is emphasized that those displacements (of soil skeleton and pore fluid) are different. In order to simulate the 1D behavior, all DOFs at the same depth level are connected in a master–slave fashion. Modeling of sloping ground is done by creating a constant horizontal load, sine of inclination angle, multiplied by the self weight of soil column, to mimic sloping ground. In addition to that, for a sloping ground, there should be a constant flow (slow) downhill, however this is neglected in our modeling. The permeability is assumed to be isotropic $k = 5.0{\times}10^{-4}$ m/s. The input acceleration time history (Figure (505.1)) is taken from the recorded horizontal acceleration of Model No.1 of VELACS project Arulanandan and Scott (1993) by Rensselaer Polytechnic Institute, `http://geoinfo.usc.edu/gees/velacs/`. The magnitude of the motion is close to 0.2 g, while main shaking lasts for about 12 seconds (from 1 s to 13 s). For the sloping ground model a slope of % 3 was considered.

It should be emphasized that the soil parameters are related to Toyoura sand, not Nevada sand which is used in VELACS project. The purpose of presented simulation is to show the predictive performance using verified and validated formulation, algorithms, implementation and models.

505.3.2 Behavior of Saturated Level Ground

Figure (505.2) describes the response of the sample with loose sand $e_0 = 0.85$. This figure shows the typical mechanism of cyclic decrease in effective vertical stress due to pore pressure build up as expected for the looser than critical granular material. The lower layers show only the reduction of effective vertical stress from the beginning. Once the effective vertical (and therefore confining) stress

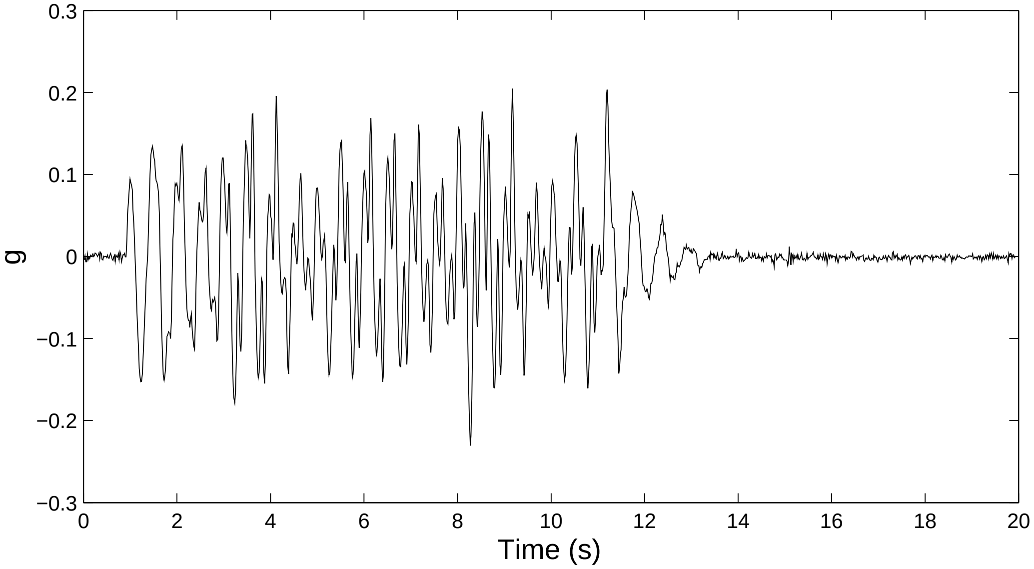

Figure 505.1: Input earthquake ground motion for the soil column.

approaches the smaller values, signs of the so-called butterfly shape can be observes in the stress path. Similar observation can made in the upper layers which have the smaller confining pressure comparing to the lower layers from the very beginning due to lower surcharge. The upper layers have lower confining pressure (lower surcharge) at the beginning of the shaking, hence less contractive response is expected in these layer; however, soon after the initiation of the shaking these top layers start showing the liquefaction state and that type of response continues even after the end of the shaking. The top section of the model has remained liquefied well past the end of shaking. This is explained by the large supply of pore fluid from lower layers, for which the dissipation starts earlier. For example, for the lowest layer, the observable drop in excess pore pressure start as soon as the shaking ends, while, the upper layers then receive this dissipated pore fluid from lower layers and do liquefy (or continue being liquefied) well past end of shaking (which happens at approximately 13 seconds). It is very important to note the significance of this incoming pore water flux on the pore water pressure of the top layers. Despite the less contractive response of soil skeleton at the top elements, the transient pore water flux, that enters these elements from the bottom, forces those to a liquefaction state. In other words, the top elements have not liquefied only due to their loose state but also because of the water flow coming from the bottom layers. The maximum horizontal strains can be observed in the middle layers due to liquefaction and prevents upper layers from experiencing larger strains. The displacements of water and soil are presented in the last column. It shows that in all layers the upward displacement of water is larger than the downward displacement of soil. This behavior reflects soil densification during shaking.

Figure (505.3) describes the response of the sample with dense sand ($e_0 = 0.75$). This figure also shows the typical mechanism of cyclic decrease in effective vertical stress. However, in case of this dense sample the decreasing rate of the effective confining pressure is much smaller than what was observed in the loose sample. Signs of the partial butterfly shape in the effective stress path can be observed from early stages of shaking. The butterfly is more evident in the upper layers with the lower confining pressure, i.e. more dilative response. In later stages of the shaking, i.e. when the confining pressure reduces to smaller value the butterfly shape of the stress path gets more pronounced due to having more dilative response in the lower confining pressure based on CSSM concept. In comparing this dense case to the case of shaking the loose sand column, the current case does not show any major sign of liquefaction (when stress ratio $r_u = 1$). This is due to the less contractive (more dilative) response of the sand in this case, which is coming from the the denser state of the sample. Because of having partial segments of dilative response, the whole column of the sand has not loosed its strength to the extent that happened for the case of loose sand and therefore smaller values of horizontal strains has been observed in the results. The absolute values of soil and water vertical displacements are also smaller than the case of loose sand which can be again referred to the less overall contractive response in this case.

Overall, it can be noted that the response in the case of loose sand ($e_0 = 0.85$) is mainly below the dilatancy surface (phase transformation surface) while the denser sand sample with $e_0 = 0.75$ shows partially dilative response referring to the denser than critical state.

505.3.3 Behavior of Saturated Sloping Ground

Figures (505.4) and (505.5) present the result of the numerical simulations for shaking the inclined soil columns (toward right) with loose and dense sand samples, respectively. The inclination of the soil column results in presence of the offset shear stress to the right side. This essentially poses asymmetric horizontal shear stresses (toward the direction of inclination) during cycles of shaking. On one hand, this offset shear stress makes the sample more dilative in the parts of shaking toward the right side (think about the state distance from the phase transformation line or dilatancy line in the $p-q$ space). As a result asymmetric butterfly loops will be induced causing the soil to regain its stiffness and strength (p) in the dilative parts of the corresponding cycles, therefore only instantaneous spikes of $r_u = 1$ can be observed in case of the sloped columns of soil. There is also a permanent liquefaction in terms of having stationary portions of $r_u = 1$ in this case. On the other hand, the offset shear stress results generation of more horizontal strains in the portions of loading which are directed toward the right side than those which are directed back toward the left side. As a result the horizontal shear strains will accumulative toward the right side and create larger permanent horizontal displacement comparing

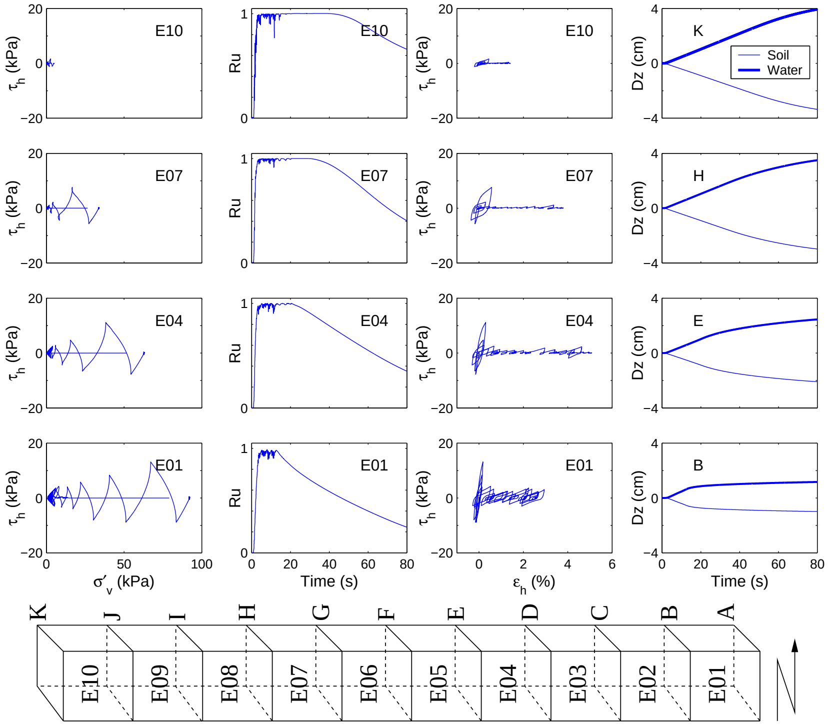

Figure 505.2: Seismic results for (loose sand) soil column in level ground ($e_0 = 0.85$).

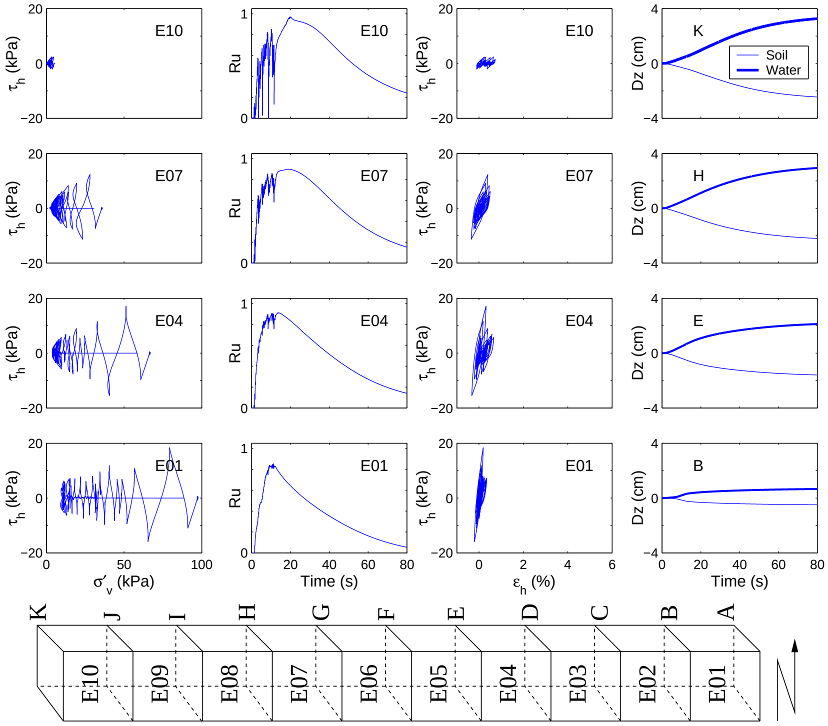

Figure 505.3: Seismic results for (dense sand) soil column in level ground ($e_0 = 0.75$).

to the case of level ground soil column. Since the overall dilative response of the dense sample, i.e. Figure (505.5), is larger than that of the loose sample, i.e. Figure (505.4), the dense sample shows stiffer response and therefore less accumulative horizontal shear strains than the loose sample. The difference in predicted horizontal displacements is almost three times, that is, for the dense sample the final, maximum horizontal displacement is approx. 0.5 m, while for the loose sand sample, it almost 1.5 m,

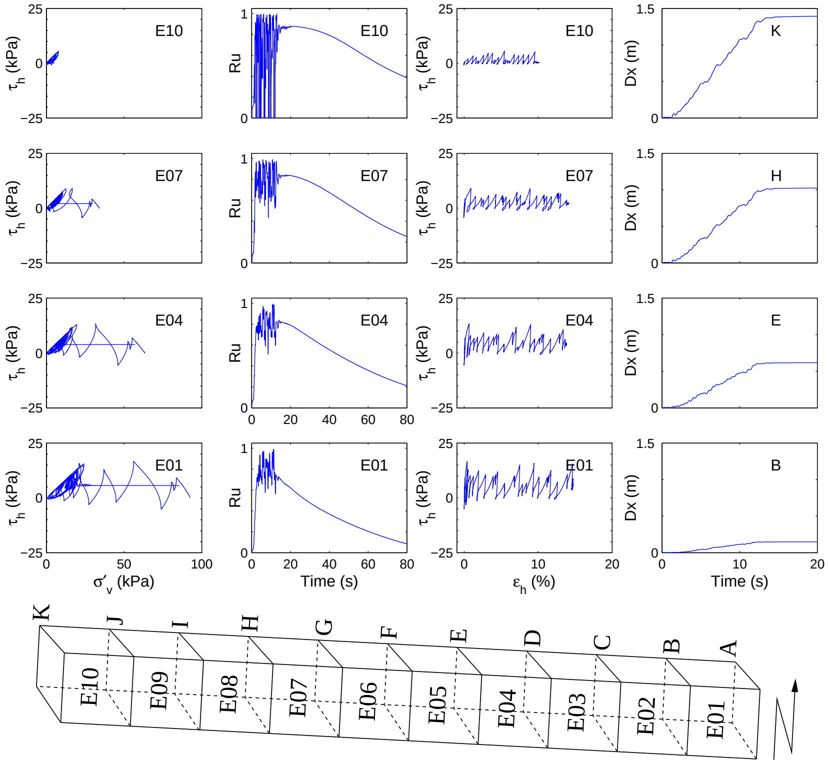

Figure 505.4: Seismic results for (loose sand) soil column in sloping ground ($e_0 = 0.85$).

505.4 Pile in Liquefied Ground, Staged Simulation Model Development

Material presented here is from Cheng and Jeremić (2009a,b) Model development for a pile in the liquefiable soil follows physics (mechanics) of the problem as close as possible. Numerical simulation of such problems in geomechanics is usually based on stages of loading and increments within those stages.

All load stages are applied to a series of finite element models, all of which share features of an initial soil model. This initial soil model consists of a soil block with dimension of $12 \times 12 \times 15$ m (length × width × depth). Due to the symmetry of the model, only half of the block is modeled. Symmetry assumptions is based on assumption that all the loads, dynamic shaking and other influences are symmetric with

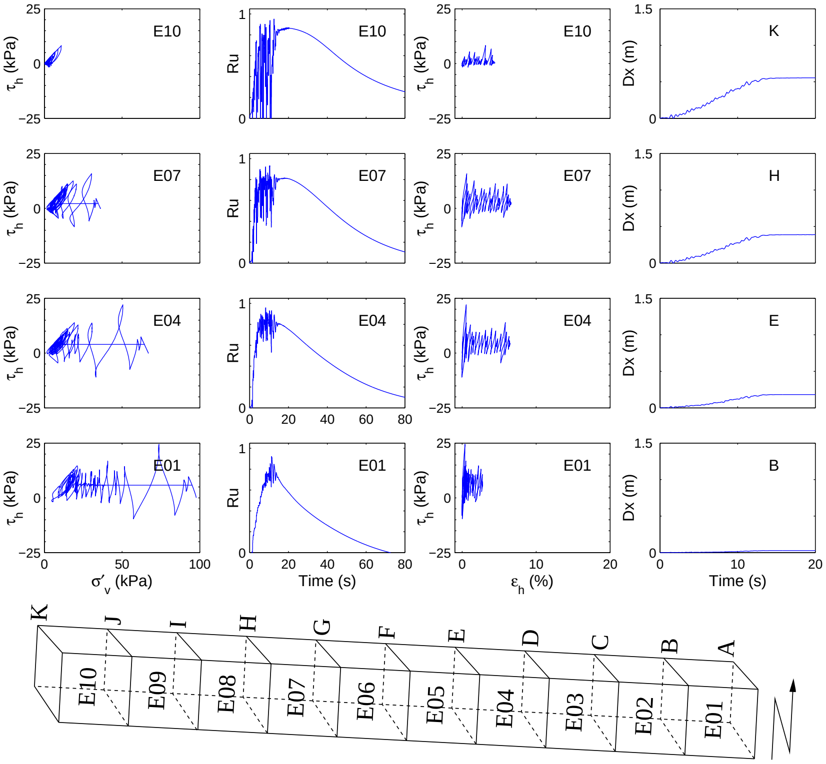

Figure 505.5: Seismic results for (dense sand) soil column in sloping ground ($e_0 = 0.75$).

respect to the plane of symmetry. This specialization to symmetric model reduces model generality (for example this use of symmetry will preclude analysis of dynamic shaking perpendicular to sloping ground dip). However, as our goal is to present a methodology of analyzing behavior of piles in liquefying ground, this potential drawback is not deemed significant in this study. Finite element mesh for the model is presented in Figure (505.6). The initial mesh consists of 160 eight node u-p-U elements.

Each node of the mesh has 7 degrees of freedom, three for soil skeleton displacements (u_i), one for pore water pressure (p), and three for pore water displacement (U_i). While it can be argued that the mesh is somewhat coarse, it is well refined around the pile, yet to be installed, in place of gray region in the middle.

A single set of parameters is used with the Dafalias-Manzari material model. Soil is modeled as Toyoura sand and material parameters (summarized in Table 505.4) are calibrated using tests by Verdugo and Ishihara (1996), while initial void ration was set to $e_0 = 0.80$. It is very important to emphasize that the state of stress and internal variables from initial state (zero for stress and given value for void ratio and fabric) will evolve through all stages of loading by proper modeling and algorithms, by using single set of material parameters. Table 505.4 presents additional parameters, other than material parameters

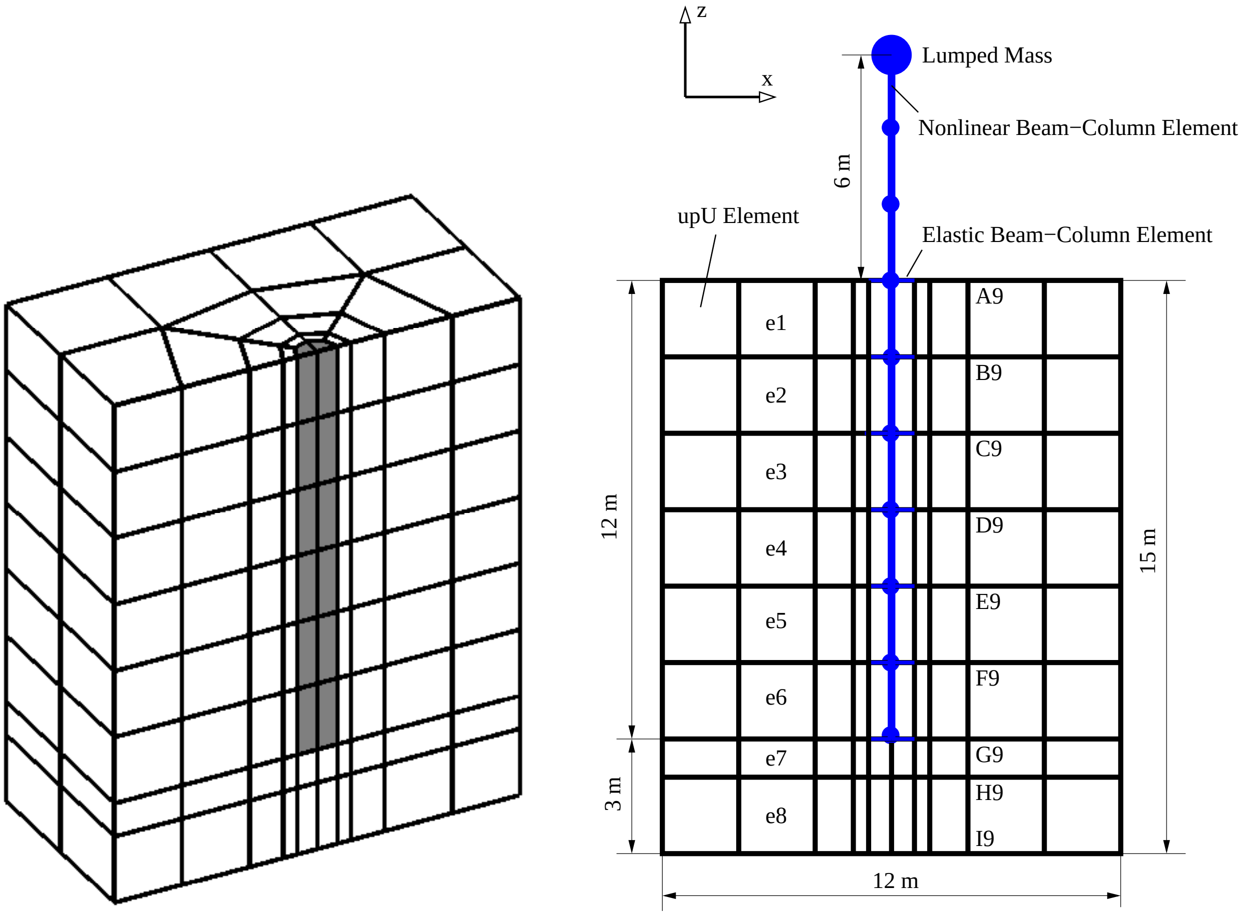

Figure 505.6: Left: Three dimensional finite element mesh featuring initial soil setup, where all the soil elements are present. The gray region of elements is excavated (numerically) and replaced by a pile during later stages of loading; Right: Side view of the pile-soil model with some element and node annotation, used to visualize results.

presented in Table 505.4, used for numerical simulations.

505.4.1 First Loading Stage: Self Weight

The initial stage of loading is represented by the application of self weight on soil, including both the soil skeleton and the pore water. Initial state in soil before application of self weight is of a zero stress and strain while void ratio and fabric are given initial values. The state of stress/strain, void ratio and fabric will evolve upon application of self weight. At the end of self weight loading stage, soil is under appropriate state of stress (K_0 stress), the void ratio corresponds to the void ratio after self weight (redistributed such that soil is denser at lower layers), while soil fabric has evolved with respect to stress

Table 505.3: Material parameters used for Dafalias-Manzari elastic–plastic model.

Material Parameter		Value	Material Parameter		Value
Elasticity	G_0	125 kPa	Plastic modulus	h_0	7.05
	v	0.05		c_h	0.968
Critical sate	M	1.25		n_b	1.1
	c	0.8	Dilatancy	A_0	0.704
	λ_c	0.019		n_d	3.5
	ξ	0.7	Fabric-dilatancy	z_{max}	4.0
	e_r	0.934		c_z	600.0
Yield surface	m	0.02			

Table 505.4: Additional parameters used in FEM simulations.

Parameter		Value
Solid density	ρ_s	$2800\ kg/m^3$
Fluid density	ρ_f	$1000\ kg/m^3$
Solid particle bulk modulus	K_s	$1.0 \times 10^{12}\ kN/m^2$
Pore fluid bulk modulus	K_f	$2.2 \times 10^{6}\ kN/m^2$
permeability	k	$1.0 \times 10^{-4}\ m/s$
Gravity	g	10 m/s^2

induced anisotropy. All of these changes are modeled using Dafalias–Manzari material model and using constitutive and finite element level integration algorithms developed within UC Davis Computational Geomechanics group in recent years.

Boundary conditions (BC) for self weight stage of loading are set in the following way:

- Soil skeleton displacements (u_i), are fixed in all three directions at the bottom of the model. At the side planes, nodes move only vertically to mimic self-weight effect. All other nodes are free to move in any direction.

- Pore water pressures (p), are free to develop at the bottom plane and at all levels of the models except at the top level at soil surface where they are fixed (set to zero, replicating drained condition),

- Pore water displacements (U_i), are fixed in all three directions at the bottom, are free to move only vertically at four sides of the model and are free to move in any direction at all other nodes.

These boundary condition are consistent with initial self-weighting deformation condition for soil and pore water at the site.

For the case of sloping ground, an additional load sub-stage is applied after self weight loading, in order to mimic self weight of inclined (sloping) ground. This is effectively achieved by applying a resultant of total self weight of the soil skeleton times the sine of the inclination angle at uphill side of the model. This load is applied only to the solid skeleton DOFs, and not on the water DOFs. Physically it would be correct to consider the sloping ground effects on the pore water as well. This will create a constant flow field of the water downstream, which, while physically accurate, is small enough that it does not have any real effect on modeling and simulations performed here.

505.4.2 Second Loading Stage: Pile–Column Installation

After the first loading stage, comprising self weight applications (for level or sloping ground, as discussed above), second loading stage includes installation (construction) of the pile–column. Modeling changes performed during loading stage included:

- Excavation of soil occupying space where the pile will be installed. This was done by removing elements, nodes and loads on elements shown in gray in Figure (505.6).
- These elements were replaced by very soft set of elements with small stiffness, low permeability. This was done in order to prevent water from rushing into the newly opened hole in the ground after original soil elements (used in the first loading stage) are removed.
- Installation of a pile in the ground and a superstructure (column) above the ground. Nonlinear bean–column elements were used for both pile and column together with addition of appropriate nodal masses at each beam-column node, and with the addition of a larger mass at the top representing lumped mass of a bridge superstructure. Pile beam-column elements were connected with soil skeleton part of soil elements using a specially devised technique.

As mentioned earlier, the volume that would be physically occupied by the pile in the pile hole, is "excavated" during this loading stage. Beam–column elements, representing piles, are then placed in the middle of this opening. Pile (beam–column) elements are then connected to the surrounding soil elements by means of stiff elastic beam–column elements. These "connection" beam–column elements extend from each pile node to surrounding nodes of soil elements. The connectivity of nodes to soil skeleton nodes is done only for three beam–column translational DOFs, while the three rotational DOFs from the beam–column element are left unconnected. These three DOFs from the beam–column side are connected to first three DOFs of the u-p-U soil elements, representing displacements of the soil skeleton

(u_i). Water displacements (U_i) and pore water pressures (p) are not connected in any way. Rather, these two sets of DOFs representing pore water behave in a physical manner (cannot enter newly created hole around pile beam–column elements) because of the addition of a soft, but very impermeable set of u-p-U elements, replacing excavated soil elements. By using this method, both solid phase (pile with soil skeleton) and the water phase (pore water within the soil) are appropriately modeled. Figure (505.7) shows in some detail schematics of coupling between the pile and soil skeleton part finite elements.

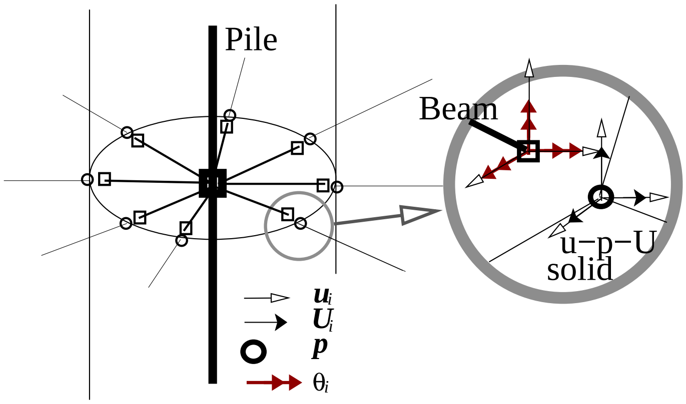

Figure 505.7: Schematic description of coupling of displacement DOFs (u_i) of beam-column element (pile) with displacement DOFs (u_i) of u-p-U elements (soil).

Nonlinear force based beam–column elements (Spacone et al., 1996a,b) were used for modeling the pile–column. Pile was assumed to be made of aluminum. This was done in order to be able to validate simulations with centrifuge experiments (when they become available). Presented models were all done in prototype scale, while for (possible future) validation, select results will be carefully scaled and compared with appropriate centrifuge modeling. Pile and the column were assumed to have a diameter of $d = 1.0$ m, with Young's modulus of $E = 68.5$ GPa, yield strength $f_y = 255$ kPa, and the density $\rho = 2.7\ \text{kg/m}^3$. Wall thickness of prototype pile–column is $t = 0.05$ m. Lumped mass of pile and column was distributed along the beam–column nodes, while an additional mass was added on top $(m = 1200\ \text{kg})$ that represents (small) part of the superstructure mass. This particular mass $(m = 1200\ \text{kg})$ comes from a standard (scaled up in our case) centrifuge model for pile–column–mass used at UCD.

Figure (505.6) (right side) shows side view of the column-pile-soil model after second stage of loading.

505.4.3 Third Loading Stage: Seismic Shaking

After the application of self weight on the uniform soil profile, excavation and construction of the single pile with column and super structure mass on top and application of their self weight, the model is at the appropriate initial state for further application of loading. In this case, this additional loading comprises seismic shaking. For this stage, fixed horizontal DOFs used on the side planes during the first stage are removed (set free).

The input acceleration time history, shown in Figure (505.8) was taken from the recorded horizontal acceleration of Model No.1 of VELACS project Arulanandan and Scott (1993) by Rensselaer Polytechnic Institute, `http::/geoinfo.usc.edu/gees/velacs/`. The magnitude of the motion is close to 0.2 g, while main shaking lasts for about 12 seconds (from 1 s to 13 s). Although the input earthquake motions lasts until approx. 13 seconds, simulations are continued until 120 seconds so that both liquefaction (dynamic) and pore water dissipation (slow transient) can be appropriately simulated during and after earthquake shaking (Jeremić et al., 2008).

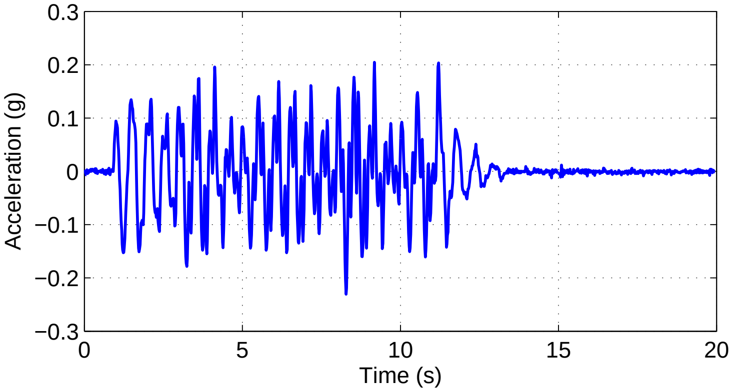

Figure 505.8: Input earthquake ground motions.

505.4.4 Free Field, Lateral and Longitudinal Models

Six models were developed during the course of this study. First three models (model numbers I, II and III) were for level ground, while last three models (model numbers IV, V, and VI) were for sloping ground. First in each series of models (model I for level ground and model IV for sloping ground) were left without the second loading stage, without a pile–column system. Other four models (numbers II, III, V and VI) were analyzed for all three loading stages. Second in each series of models (models number II and V) had all displacements and rotations of pile–column top (where additional mass representing superstructure was placed) left free, without restraints. Thus, these two models represent lateral behavior of a bridge. Third in each series of models (model numbers III and VI) had rotations in y directions fixed at the pile–column top, thus representing longitudinal behavior of a bridge. Modeling longitudinal behavior of a bridge by restraining rotations perpendicular to the bridge superstructure is appropriate if the stiffness of a bridge superstructure is large enough, which in this case it was, as it was assumed to be a post–tensioned concrete box girder, so that realistically, the top of a column does not rotate (much) during application of loads. Table 505.5 summarizes models described above.

Table 505.5: Cases descriptions.

Case	Model sketch	Descriptions
I		horizontal ground, no pile
II		horizontal ground, single pile, free column head
III		horizontal ground, single pile, no rotation at column head
IV		sloping ground, no pile
V		sloping ground, single pile, free column head
VI		sloping ground, single pile, no rotation at column head

505.5 Simulation Results

505.5.1 Pore Fluid Migration

Figures (505.9) through (505.11) show the Ru time history for up to 30 seconds, for elements (at one of Gauss point) e1, e3, e5 and e7 (refer to right side of Figure (505.6)). It is important to note that R_u is defined as the ratio of the difference of initial mean and current mean effective stresses over the initial mean effective stress:

$$R_u = \frac{p'_{initial} - p'_{current}}{p'_{initial}}$$

where mean effective stress is defined as $p' = \sigma'_{kk}/3$. This is different from traditional definition for R_u, that uses ratio of excess pore pressure over the initial mean effective stress ($p'_{initial}$). However, these two definitions are essentially equivalent, as soil is in the state of liquefaction for $R_u = 1$ (so that $p'_{current} = 0$), while there is no excess pore pressure for $R_u = 0$ (so that $p'_{initial} = p'_{current}$). However, the former definition is advocated here as it avoids the interpolation of pore pressure or extrapolation of the stresses (as the latter definition requires), since for the u-p-U element, stresses are available at Gauss points while pore pressures are available element nodes. In particular, Figure 505.9 shows R_u time histories for four points for models I (level ground without pile) and model IV (sloping ground without pile). It is noted that differences are fairly small. It is interesting to observe that lower layers do not liquefy as supply of pore fluid for initial void ratio of $e_0 = 0.8$ is too small, and the pore fluid dissipation upward seems to be to rapid. On the other hand, the upper soil layers do reach close to or liquefaction state ($R_u = 1$). This is primarily due to the propagation of pore fluid pressure/volume from lower layers upward (pumping effect) and, in addition to that, to a local excess pore fluid production. These results can also be contrasted with those of Jeremić et al. (2008), where similar pumping scenario has been observed. The main difference between soil used by Jeremić et al. (2008) and here is in the coefficient of permeability. Namely, here $k = 1.0 \times 10^{-4}$ m/s was used (Čubrinovski et al., 2008; Uzuoka et al., 2008) while Jeremić et al. (2008) used $k = 5.0 \times 10^{-4}$ m/s. It is important to note that other values of permeability for Toyoura sand have also been reported (Sakemi et al., 1995), but current value was

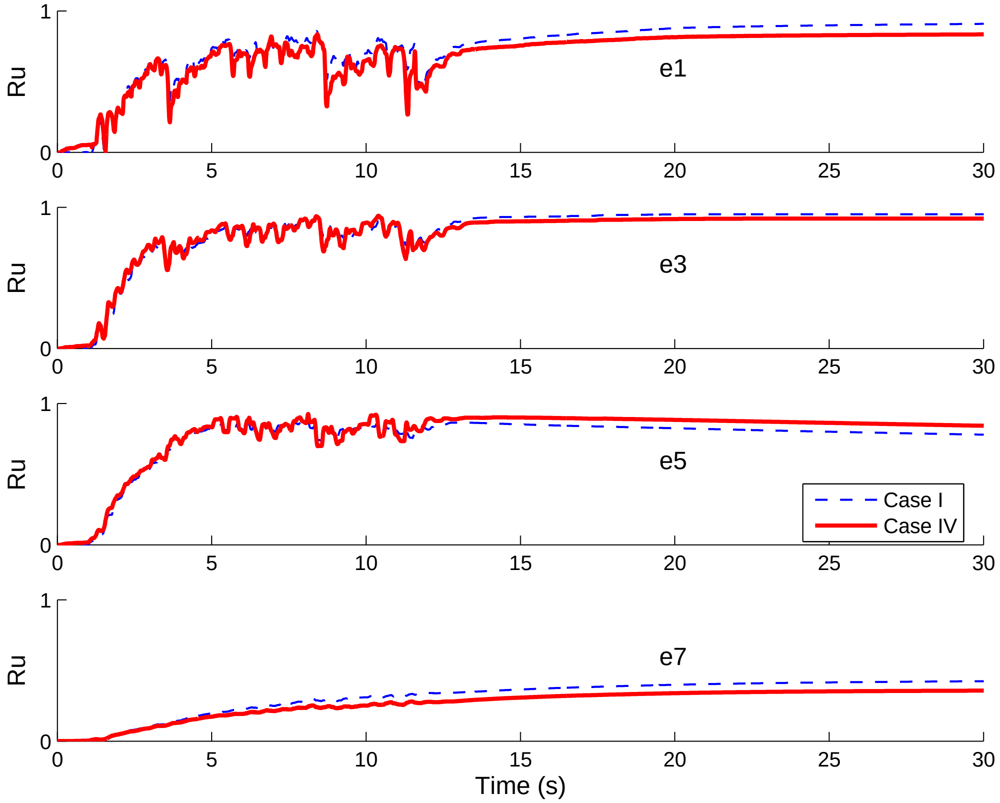

Figure 505.9: R_u times histories for elements e1 (top element), e3, e5, and e7 (bottom element) Gauss point) for Cases I (level ground, no pile) and IV (sloping ground, no pile).

chosen based on Čubrinovski (2007 –).

In addition to that, similar to Jeremić et al. (2008), sloping ground case shows larger R_u spikes, since there is static shear force (stress) that is always present from gravity load on a slope. This static gravity on a slope will result in an asymmetric horizontal shear stresses in the down–slope direction during cycles of shaking. This asymmetric shear stress induces a more dilative response for down–slope shaking which will help soil regain its stiffness in the dilative parts of the loading cycles. This observation can be used to explain smaller R_u spikes for the sloping ground case. Of course, this asymmetry in loading will result in larger accumulation of down–slope deformation.

While R_u ratios for level and sloping ground cases are fairly similar along the depth of the model, the response changes when the pile is present. Figure (505.10) shows R_u responses at four different points (along the depth) approximately midway between the pile and the model boundary, in the plane of shaking (see location of those elements in Figure (505.6) on page 2616). In comparison to behavior without the pile (Figure (505.9)), it is immediately obvious that addition of a pile with a mass on top reduces R_u during shaking for the top element (e1). This is to be expected as presence of a pile–column–mass (PCM) system changes the dynamics of the top layers of soil significantly enough to reduce total amount of shear. This is particularly true for the top layers of soil as effects of column–mass tend to create compressive and extensive movements (compression when the PCM system moves toward soil and extension, and possibly even tension, when PCM system moves away from soil). However, this extension, or possible tension, is not directly observable in presented plots since array of elements where we follow R_u (e1, e3, e5, e7) is some distance away from the pile–soil interface. Middle layers (e3 and e5), on the other hand, display similar response to that of Cases I and IV, as shown in Figure (505.9). It is noted that in a case with of sloping ground with pile, the R_u measurements are always larger that those for level ground (this is also observed for Cases III and VI, as shown in Figure (505.11)). This is expected as presence of a pile in loose sand, and particularly the dynamic movement of a pile during seismic shaking, create an additional shearing deformation field (in the soil adjacent to the pile) that provides for additional (faster) compression of soil skeleton and thus creates additional volume of pore fluid, that is then distributed to adjacent soil (adjacent to the pile).

Particularly interesting are R_u results for soil element e7, which is located below pile tip level (see Figure (505.6)). Observed R_u for Case V in element e7 is significantly larger than for the same element for Case II. Similarly, simulated R_u is larger than what was observed in cases without a pile (see bottom of Figure (505.9)). This increase in R_u for Case V (sloping ground with pile) is explained by noting that the pile "reinforces" upper soil layers and thus prevents excess shear deformation in the upper 12.0 m of soil (above pile tip). The reduction of deformation in upper layers of soil (top 12.0 meters) results in transfer of excessive soil deformation to soil layers below pile tip (where element e7 is located). This,

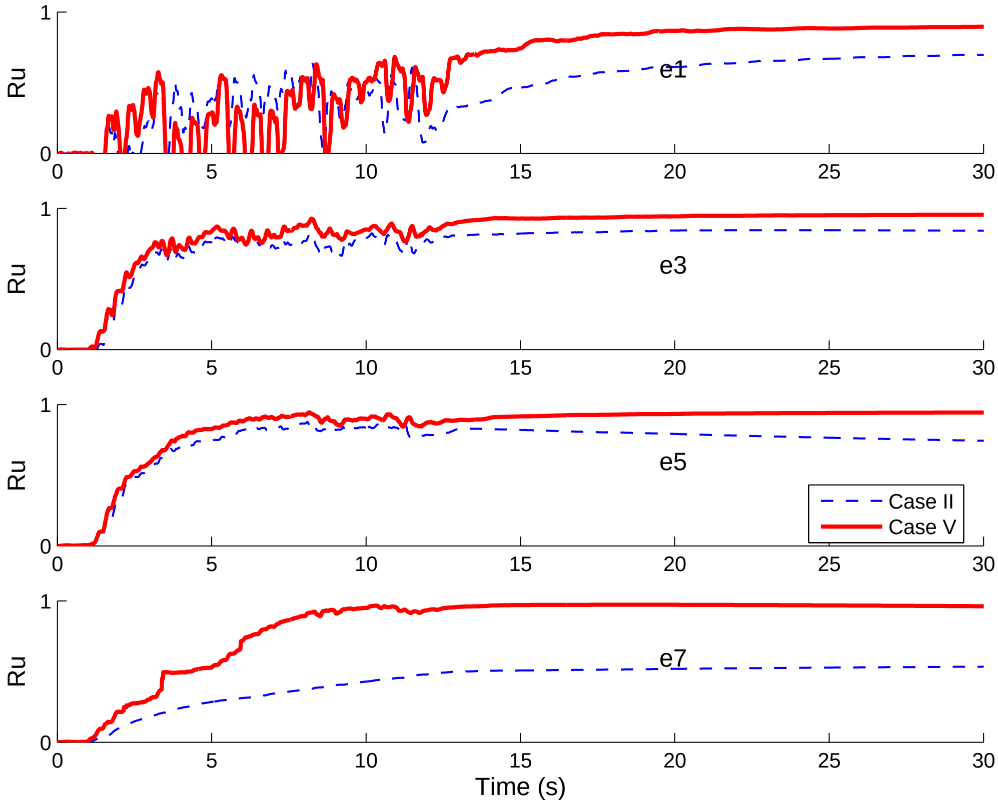

Figure 505.10: R_u times histories for elements e1, e3, e5, and e7 (upper Gauss point) for Cases II (level ground, with pile–column, free column head) and V (sloping ground, with pile–column, free column head).

in turn, results in a much larger and faster shearing of those lower loose soil layers. This significantly larger shearing results in a much higher R_u. Deformed shape, shown in Figure (505.12) for Case V, reinforces this explanation, showing much large shearing deformation in lower soil layers, below pile tip. Same observation can be made for Case VI, shown in Figure (505.12).

Observation similar to the above, for Cases II and V can be made for Cases III and VI, results for which are shown in Figure (505.11). One noticeable difference in R_u results between cases with free column head (Cases II and V) and cases with fixed rotation column head (Cases III and VI) is in significantly larger (and faster) development of R_u close to soil surface for a stiffer, no rotation column cases (Cases III and VI). This much larger R_u observed in a “stiffer” PCM system setup, is due to larger shearing deformation that develops in soils adjacent to the pile during shaking. The stiffer PCM system can displace less (because of additional no rotation condition on column top) while the soil beneath is undergoing shaking (same demand in all cases), thus resulting in larger relative shearing of soil, which then results in larger and faster pore pressure development close to the soil surface, where the column

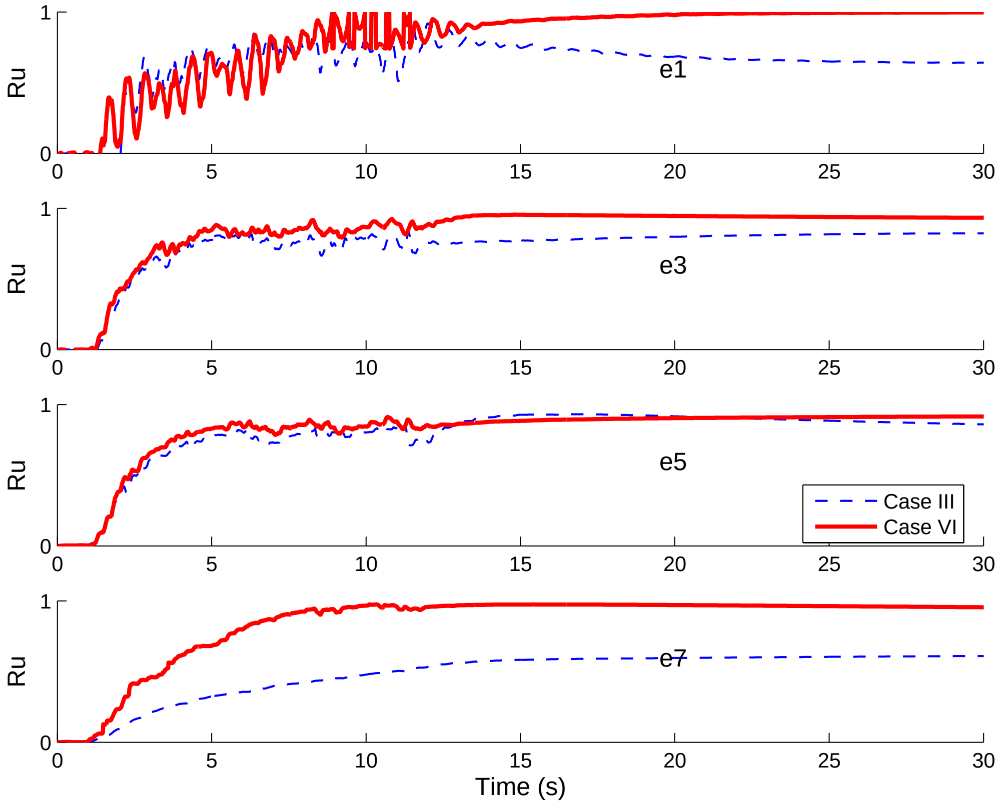

Figure 505.11: R_u times histories for elements e1, e3, e5, and e7 (upper Gauss point) for Cases III (level ground, with pile, no rotation of pile head) and VI (sloping ground, with pile-column, no rotation of column head).

no rotation effect is most pronounced.

505.5.2 Soil Skeleton Deformation

A number of deformation modes is observed for both level and sloping ground cases, with or without PCM system. Figure (505.12) shows deformation patterns and excess pore pressures in symmetry plane for all six cases over a period of eighty seconds. A number of observation can be made on both deformation patterns, excess pore fluid patterns and their close coupling.

Level Ground without Pile (Case I). Excess pore pressures and deformations in symmetry plane for level ground without a pile are shown in Figure (505.12) (I). At the very beginning (at $t = 2$ s) there is initial development of excess pore fluid pressure in the middle soil layers. This expected, as the self weight loading stage has densified lower soil layers enough so that their response is not initially contractive enough to produce excess pore pressure. Top soil layers, on the other hand, have a drainage boundary

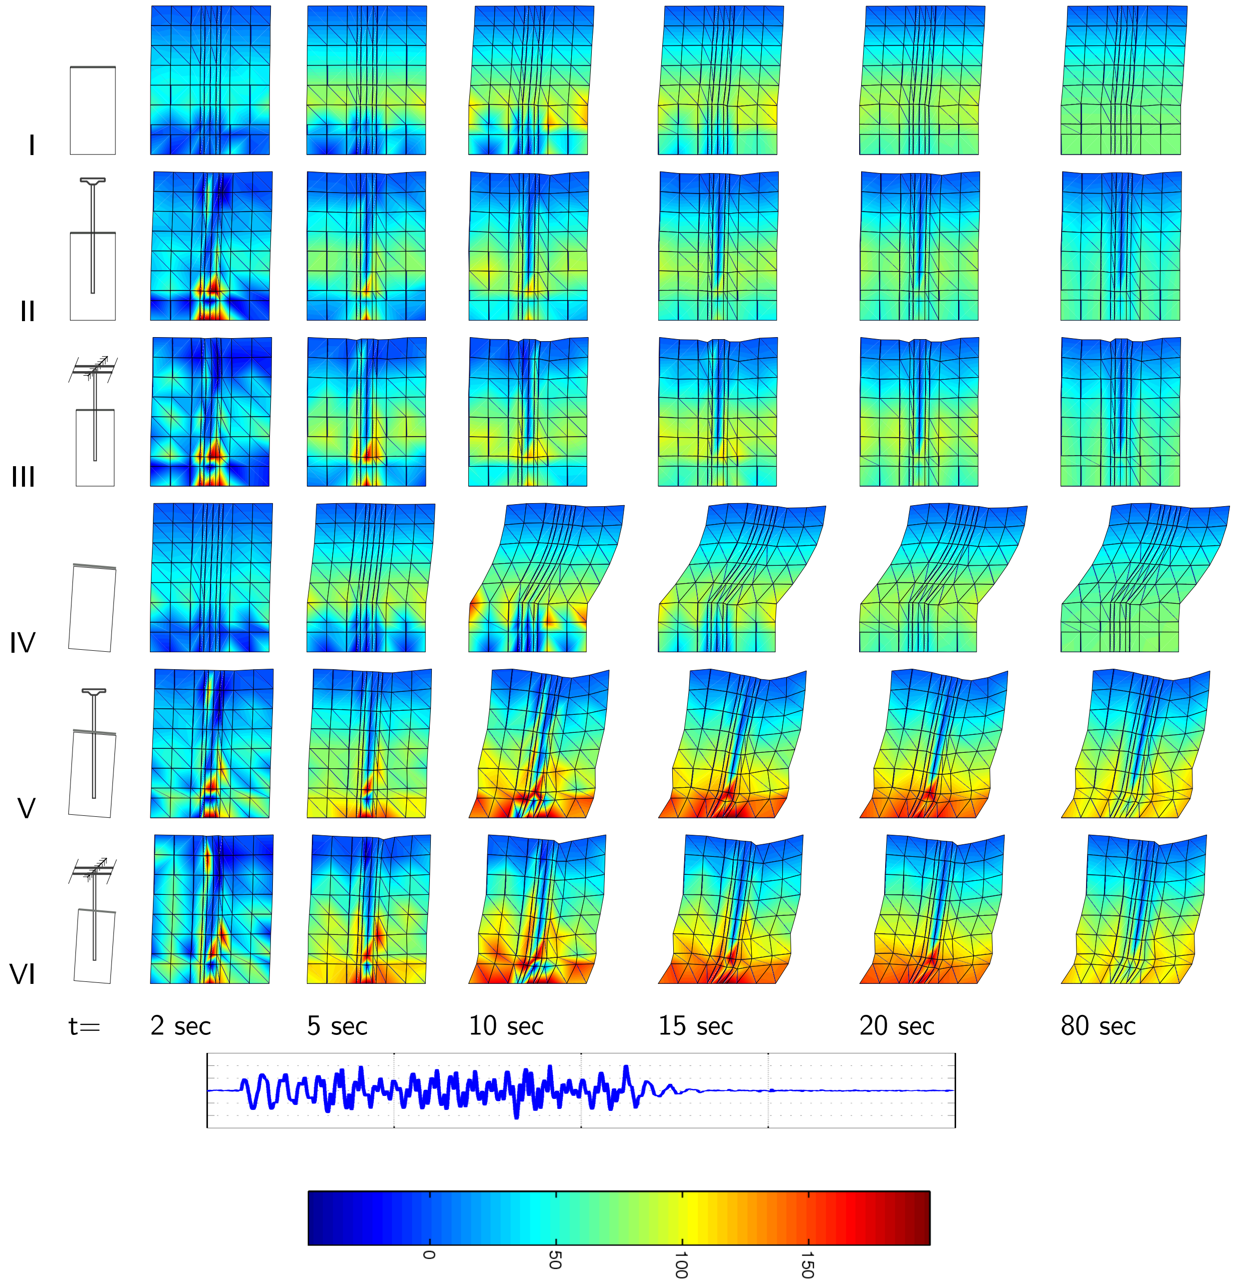

Figure 505.12: Time sequence of deformed shapes and excess pore pressure in symmetry plane of a soil system. Deformation is exaggerated 15 times; Color scale for excess pore pressures (above) is in kN/m^2. Graph of ground motions used (also shown in Figure (505.8)) is placed below appropriate time snapshots and is matching for $t = 2, 5, 10, 15, 20$ seconds while at $t = 80$ seconds there is no seismic shaking.

(top surface) too close to develop any significant excess pore pressures. As seismic shaking progresses (for $t = 5, 10$ s), the excess pore pressure increases, and starts developing in lower soil layers as well. It should be noted that a small non-uniformity in results is present. For example, zones of variable, nonuniform excess pore pressures on the lower mid and right side for Case I at $t = 10$ s develop. Nonuniform mesh (many small, long elements in the middle, large elements outside this middle zone) may introduce small numerical errors in results which can be observed by slightly nonuniform results at $t = 10$ s and $t = 15$ s. It should be noted that results for excess pore pressure shown for first 13 seconds (during shaking) in Figure (505.12) (I) are transient in nature, that is, seismic waves are traveling throughout the domain (model) during shaking (first 13 seconds) and slight oscillations in vertical stresses are possible. This oscillations will contribute to the (small) non-uniformity of excess pore pressure results. After the shaking (after 15 seconds) resulting excess pore pressure field is quite uniform.

Level Ground with Pile (Cases II and III). Excess pore pressures and deformations in symmetry plane for models with PCM system and with two different boundary conditions at top of column (see model description in section 505.4.4) in level ground are shown in Figures (505.12) (II and III). One of the interesting observations is significant shearing and excess pore pressure generation adjacent to the pile tip. The reason for this is that pile is too short, that is, pile tip has significant horizontal displacements during shaking. Those pile tip displacements shear the soil, resulting in excess pore pressure generation. As soon as there is time for dissipation, this localized excess pore pressure dissipates to adjacent soil, and then, after shaking has ceased (at $t = 13$ s and later), it slowly dissipates upward. Addition of pile into the model (construction), with a highly impermeable elements (that mimic permeability of concrete) is apparent as there is a low excess pore pressure region in the middle of model, where pile is located.

Sloping Ground without Pile (Case IV). Excess pore pressures and deformation in symmetry plane for sloping ground without pile is shown in Figures (505.12) (IV). It is noted that initially the excess pore pressure starts developing in middle soil layers,similar to the Case I above. Bottom layers start developing excess pore pressure only after significant shear deformation occurs (at $t = 10$ s) at approximately $2/3$ of the model depth. Lower layers have densified enough during self weight stage of loading that initial shaking is not strong enough to create excess pore water pressure, rather, those layers are fed by the excess pore pressure from above. Lower soil layers also do not develop much deformation, while middle and upper layers together develop excessive horizontal deformation.

Sloping Ground with Pile (Cases V and VI). Excess pore pressures and deformation in symmetry plane for sloping ground with PCM system are shown in Figures (505.12) (V and VI). Similar to the above cases

(II and III), pile is too short and there is again excessive shearing of soil at the pile tip, suggesting large movement of that pile tip. In addition to that, pile introduces significant stiffness to upper 12 meters of soil (along the length of pile) and helps reduce deformation of those upper soil layers. Down-slope gravity load is thus transferred to lower soil layers (below pile tip) which exhibit most of the deformation. It should be noted that soil in middle and upper layers (adjacent to pile) does deform, just not as much as the soil below pile tip. The predominant mode of deformation of middle soil layers is shearing in horizontal plane, around the pile. Deformation in horizontal plane is not significant as the pile is short in this examples (as mentioned above) and does not have enough horizontal support at the bottom. The deformation pattern of a soil – pile system is such that pile experiences significant rotation, and deforms with the soil that moves down-slope. If the pile was longer, and if it had significant horizontal support at the bottom, the middle and upper soil layers would have showed more significant flow around the pile in horizontal planes.

Upper layers undergo significant settlement, as seen in Figure (505.13). This settlement is mainly caused by the above mentioned rotation of pile–soil system, where soil in general settles (compacts) but also undergoes differential settlement, between left (up–slope from pile) and right (down–slope from pile) side of the model. As significant shearing with excess pore pressure generation develops in lower soil layers, below pile tip, those lower layers contribute to most of down–slope horizontal deformation. In a sense, all the demand from down-slope gravity forces and seismic shaking is now responded to by lower soil layers, which contribute to most of the excess pore pressure generation and consequently, to most of the soil deformation. Soil surface horizontal deformation is thus strongly influenced by significant shearing of the bottom layers and by rotation of the middle and upper soil layers with the pile. It is interesting to note that the largest settlement is observed just down-slope from pile for Cases V and VI.

505.5.3 Pile Response

Figure (505.14) shows bending moment envelops for pile–column–mass (PCM) system for all four cases (II, III, V and VI). It should be noted that bending moment diagrams are plotted on compression side of the beam–column. A number of observations can be made about bending moment envelopes. For cases with free pile head (shaking transverse to the bridge main axes, Cases II and V) the maximum moments are attained in soil, at depths of approximately $0.6D - 1.2D$, where D (= 1.0 m in this case) is the pile diameter. Opposed to that are cases for PCM systems with restricted rotations at the pile top which (Cases III and VI), which, of course feature largest moment at the column top. Maximum bending moments for section of PCM system in soil (pile) in these two cases are now attained at the depth of approximately $1.8D - 2.0D$.

It is noted that bending moment envelopes are mostly symmetric. Slight non–symmetry is introduced

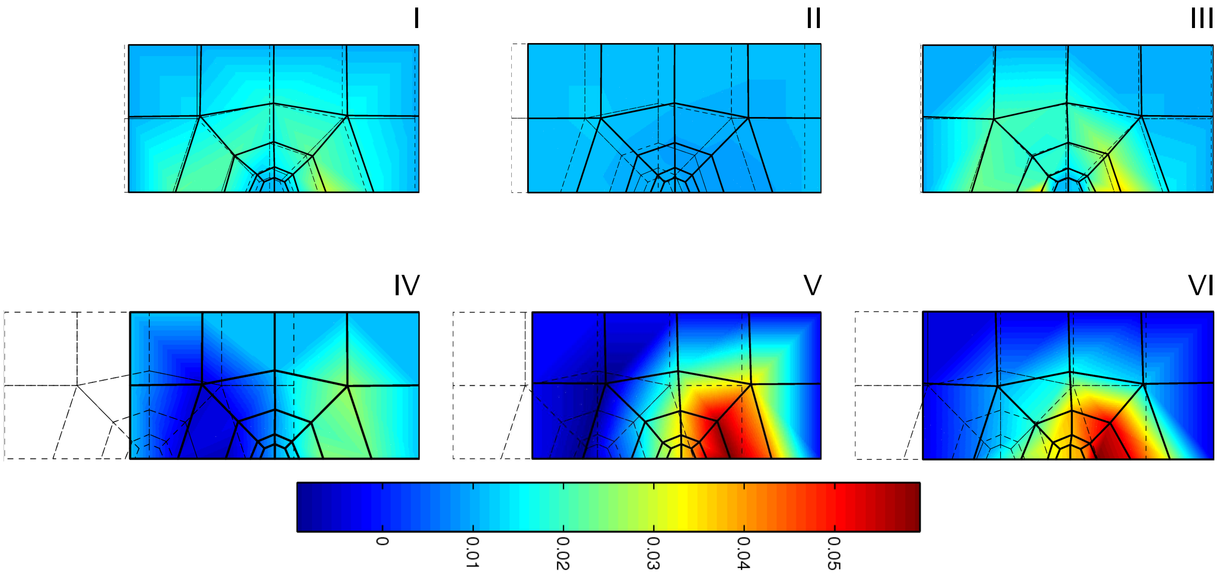

Figure 505.13: Soil surface settlements at 120 s for all six cases. Color scale given in meters

for cases on sloping ground (Case V and VI). It is also noted that moments do exist (are not zero) all the say to the bottom of the pile. Theoretically, moments should be zero at the pile tip, but since physical volume of the pile is considered (see note on that in section 505.4.2 and Figure (505.7)), differential pressure on pile bottom from soil will produce small (non–zero) moments even at the pile tip. More importantly, non–zero moments at the bottom and along the lower part of the pile show that pile is indeed too short, and thus changing curvatures are present along the whole length of the pile.

505.5.4 Pile Pinning Effects

Piles in sloping liquefying ground can also be used to resists movement of soil (all liquefied or liquefied with hard crust on top) down–slope. For models developed in this paper, pile pinning effect can be investigated for Cases IV, V and VI. In particular, deformation of sloping ground without the pile (Case IV) can be compared with either of the cases of piles in sloping ground, Cases V and VI. It is very important to note, again, that models developed here had relatively short pile, and that major soil shearing developed below the pile tip. This apparent shortcoming of a short pile results in reduced pile pinning capacity, thus reducing the down–slope movement by only approximately half, from 0.35 m (Case IV) to 0.22 m (Case V) and to 0.18 m (Case VI) as seen in Figure (505.15). It would have been expected that, had the pile been longer and had it penetrated in deeper, non-liquefiable layers, it would have reduced down–slope movement of the soil to a much larger extent. However, had the pile been longer and had it penetrated non-liquefiable layers, it would have had a much firmer horizontal support

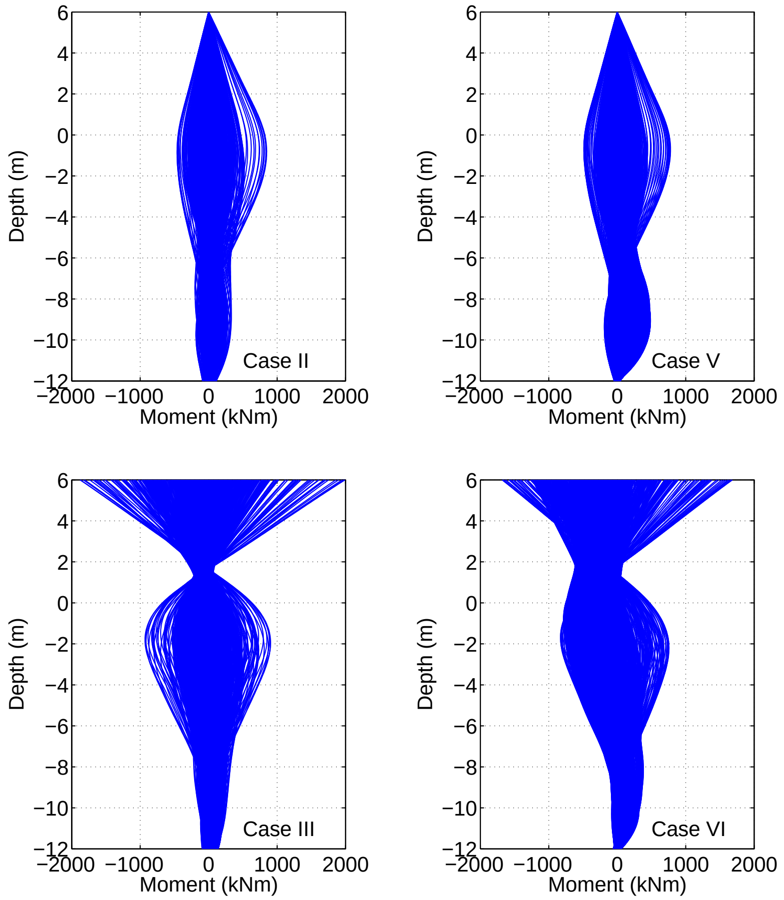

Figure 505.14: Envelope of bending moments for pile–column system for Cases II, III, V and VI.

at the bottom and would have thus attracted much larger forces too, potentially leading to pile damage and yielding.

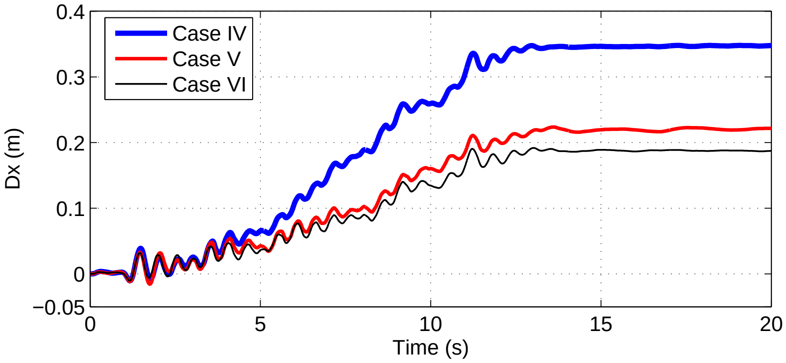

Figure 505.15: Down–slope movement at the ground surface (model center) for Cases IV (no pile), V and VI (with pile–mass system).

Chapter 506

Slope Stability in 2D and 3D

(1999-2010-)

(In collaboration with Dr. Nima Tafazzoli)

506.1 Chapter Summary and Highlights

506.2 Introduction

Presented here is a brief overview of a work on determining factors of safety for a 3D slope for one of the prominent dams in the midwest, for different saturation and water level conditions.

506.3 Dam Section Geometry

Figures 506.1 and 506.2 shows the satellite picture of location

Figure 506.1: Dam satellite picture. Upstream (south facing) three dimensional slope at connection of the embankment and concrete gravity dam is evaluated for potential stability problem.

Figure 506.3 shows the sonar data for water depth measurements at the location of a 3D slope in question.

An interesting topographical feature resembling a valley should be noted at the toe of (beginning of) wrap around section of upstream section of the embankment. That topographical feature is also apparent in a photo taken during Wold Creek Dam construction in 1948, show in Figure 506.4. Figure 506.5 shows rock surface under the embankment and alluvial fill, that serves as base rock foundation for both the alluvial fill and the embankment above. Figures 506.6, 506.7 and 506.8 show sections of the curved, 3D slope of the upstream embankment next to the concrete dam section. In particular, Figure 506.6 shows a dam section perpendicular to the dam axes. Note a significant extent of the alluvium that was left in place during dam construction. Similarly, the alluvium is present in both section inclined at 45^o to dam axes (Figure 506.7) and a section parallel to the dam axes (Figure 506.8).

Analyzed 3D, curved section of the upstream embankment is also shown in a photograph in Figure 506.9, taken on morning of April 21st, 2010. Note a significant length/extent of the two sheet pile walls (one running along the length of work platform and the other one at the end of work platform, next to

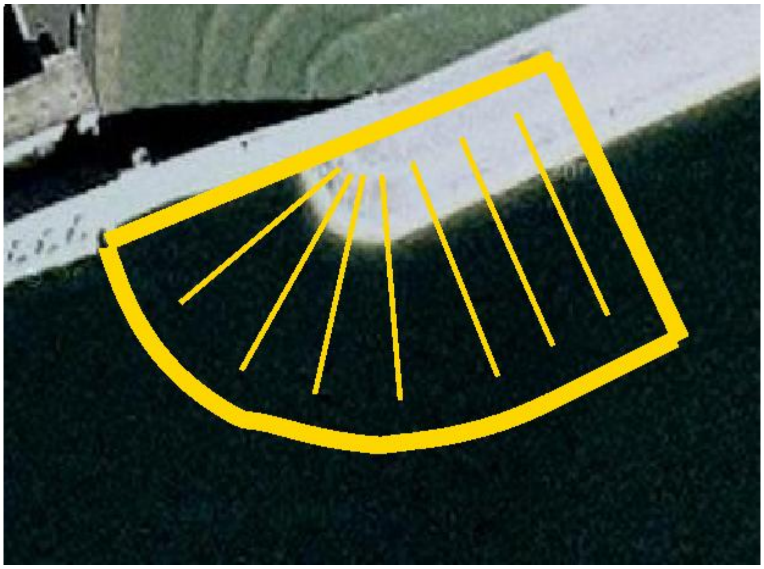

Figure 506.2: Dam satellite picture with location of 3D slope under consideration for potential stability problem.

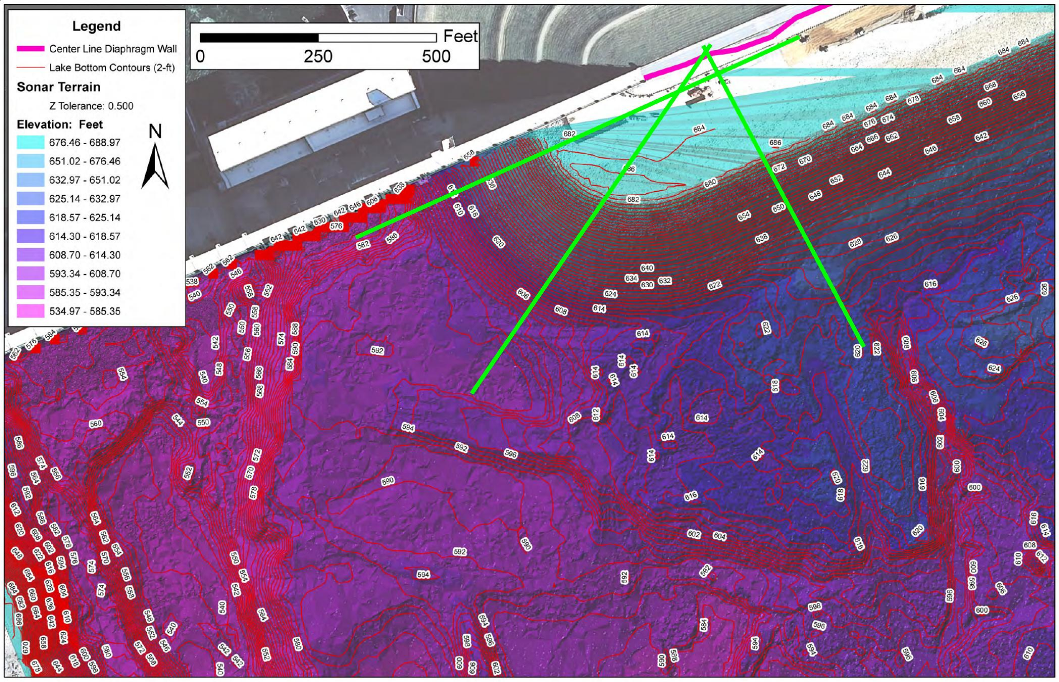

Figure 506.3: Dam sonar data for water depth for the analyzed 3D slope.

concrete dam section).

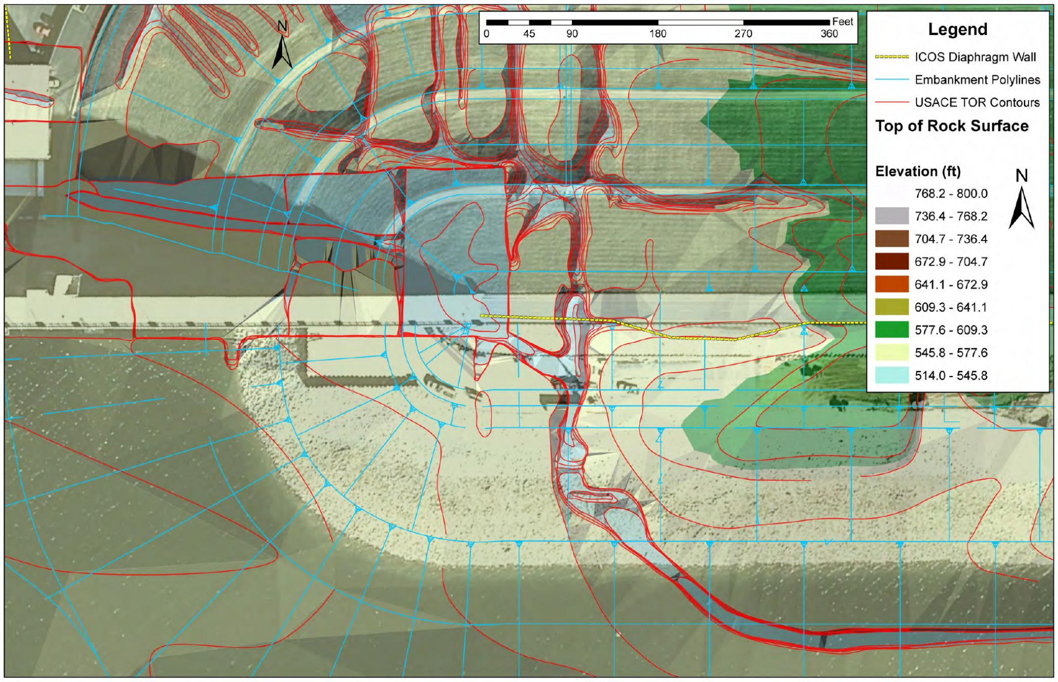

Figure 506.5: Dam rock surface data under the embankment and alluvial fill (under analyzed 3D slope), used for defining FEM model boundary conditions.

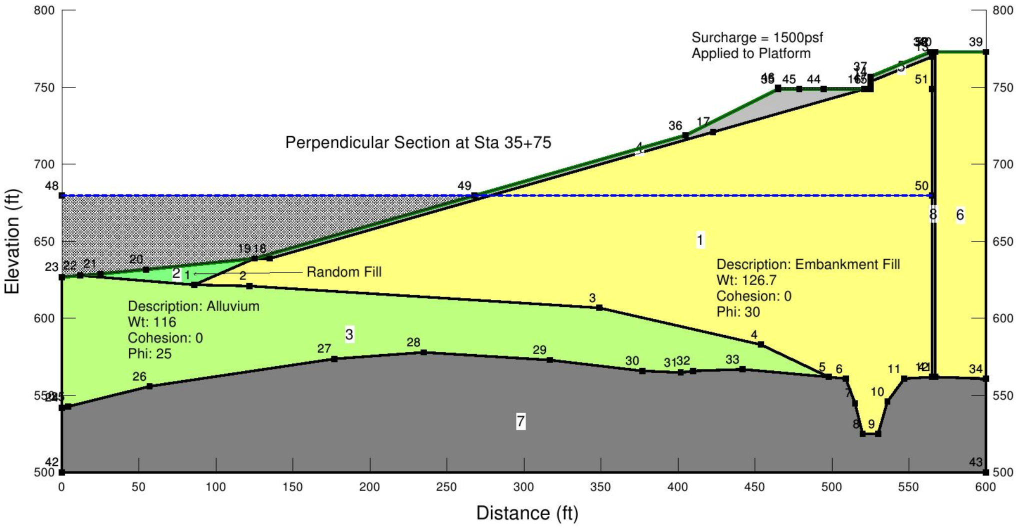

Figure 506.6: Dam section perpendicular to the dam axes for analyzed 3D slope.

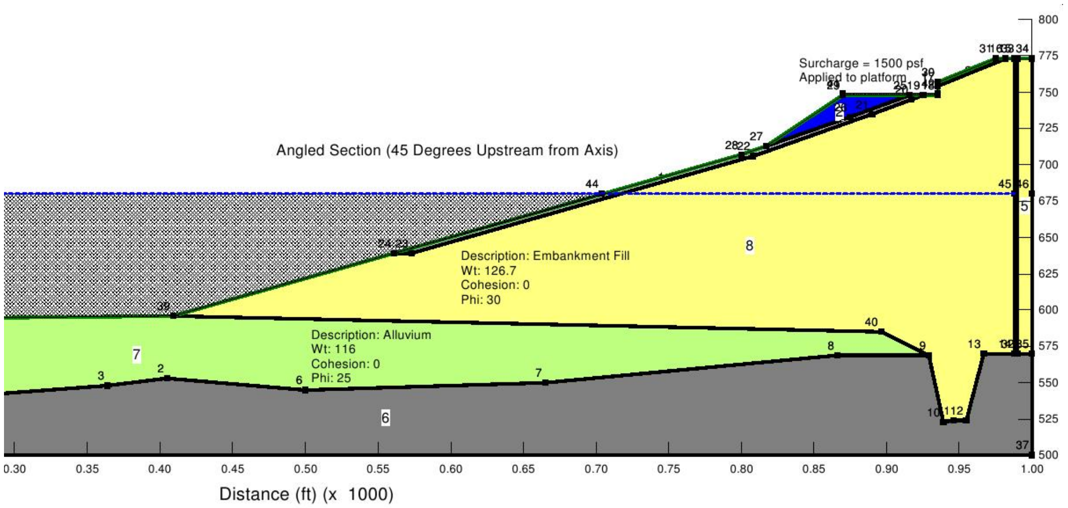

Figure 506.7: Dam section inclined at 45^o to dam axes for analyzed 3D slope.

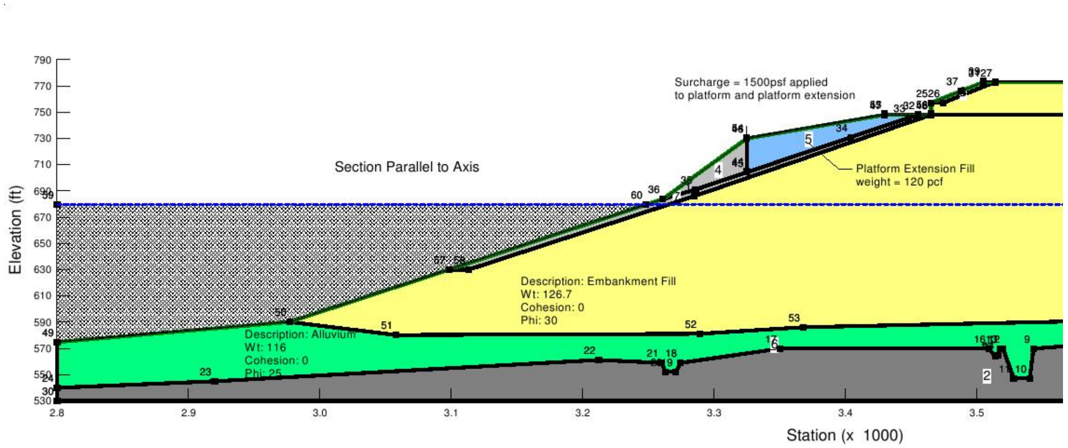

Figure 506.8: Dam section parallel to the dam axes for analyzed 3D slope.

Figure 506.9: Dam view toward the curved, "wrap" section, upstream side.

506.4 Finite Element Modeling

Analysis of 2D and 3D slope stability problem was performed using finite element method. In particular, the strength reduction method was used in conjunction with 2D and 3D finite element models to assess factors of safety. Main focus was on determining the difference between 2D and 3D factors of safety.

506.4.1 Material Models

During initial teleconference, in early April, it was decided to perform two dimensional and three dimensional analysis using finite element method for two limiting cases of material behavior:

- fully drained material behavior, with material defined by a friction angle and no cohesion,
- fully undrained material behavior, with material defined by an undrained shear strength.

Parameters for drained material modeling are given in table 506.1 below. In addition to that table 506.2 below, defines parameters for undrained material modeling. Those material parameters were agreed upon after few and a discussion. It should be noted that USACE has initiated a testing program that will determine material parameters of the embankment and the alluvium with higher certainty.

Table 506.1: Drained strength material parameters.

Material	Unit Weight [pcf]	ϕ [deg]	S_u [psf]
Embankment Fill	126.7	30	0
Alluvial Soil	116	25	0
Random Fill	120	20	0
Riprap	110	40	0
Shot Rock Fill	145	45	0
Platform Extension Fill	120	20	0

Two material models were used for analysis. For drained analysis, a Drucker Prager material model was used. This model is described in some detail in Section 3.5.7 of my lecture notes Jeremić et al. (1989-2025) (available online through my web site). It is important to note that single value of friction angle was used, thus rendering friction angle for both compression and extension the same. While there might be an influence of the difference of friction angle for compression and extension, such difference was not analyzed here. For undrained analysis a total stress, von Mises model was used. This model is also described in some details in Section 3.5.6 of my lecture notes Jeremić et al. (1989-2025). Both models used here feature perfectly plastic behavior after yielding, with associated plastic flow.

Table 506.2: Revised undrained strength material parameters.

Material	Unit Weight [pcf]	ϕ [deg]	S_u [psf]
Embankment Fill	126.7	0	2000
Alluvial Soil	116	0	1000-1500
Random Fill	120	0	500
Riprap	110	40	0
Shot Rock Fill	145	45	0
Platform Extension Fill	120	20	0

506.4.2 Two Dimensional Models

Three two dimensional (2D) models were developed in order to test the effects mesh size has on quality of simulations. Developed 2D mesh was based on perpendicular cross section, shown in Figure 506.6. Mesh for a 2D model, shown in Figure 506.10, represents a very coarse mesh, which, if higher order elements are used (with displacement interpolation higher than linear) might actually work quite well. However, with linear interpolating displacements, this mesh is clearly of low quality. However, this mesh was used as a first iteration, and to gain initial insight into 2D behavior.

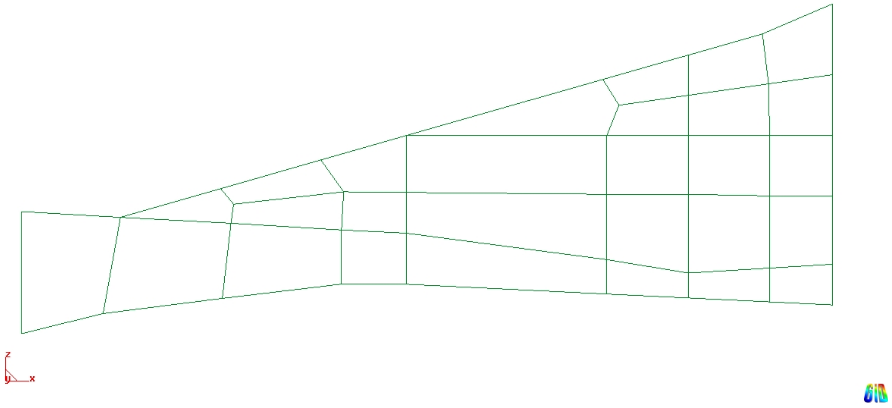

Figure 506.10: Coarse mesh model used for the 2D upstream section of the Dam.

Meshes shown in Figures 506.11 and 506.12, represent a refinement of the first mesh. Models using both meshes were tested for both drained and undrained material models. Results for both fine mesh (Fig. 506.11) and finest mesh (Fig. 506.12) were the same for all practical purposes (differences were negligible for the purpose of analysis), hence it was decided to use fine mesh (Fig. 506.11) for all

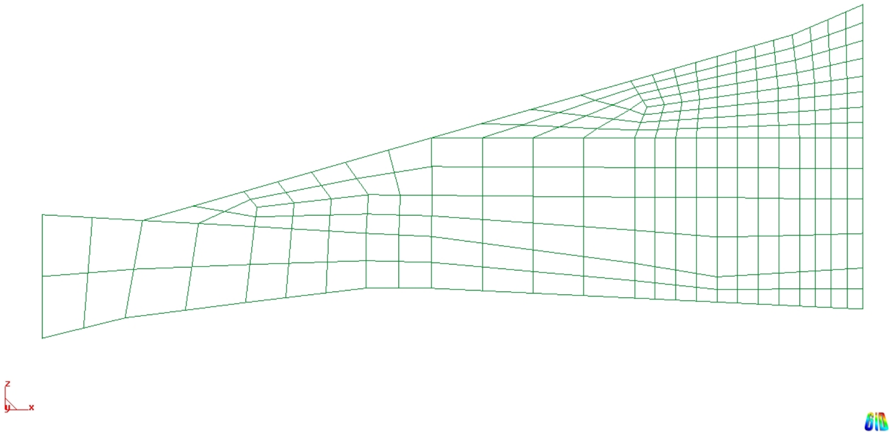

Figure 506.11: Fine mesh model used for the 2D upstream section of the Dam. This mesh was chosen as appropriate enough for all subsequent 2D analysis.

subsequent analysis in 2D.

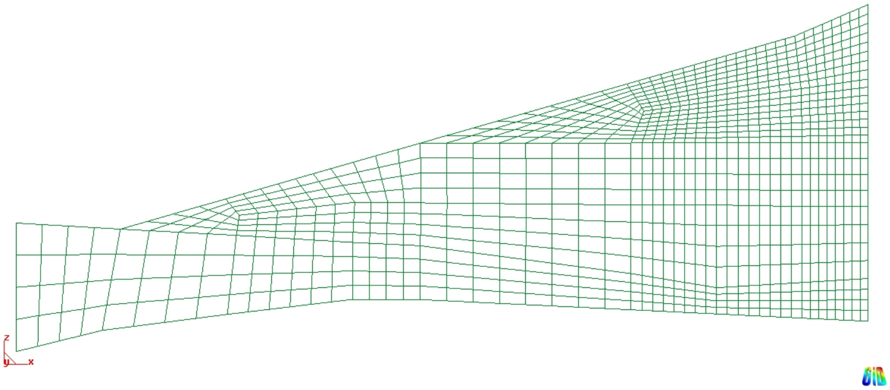

Figure 506.12: Much finer mesh model used for the 2D upstream section of Dam. Results obtained this mesh were the same as previous mesh (shown in Figure 506.11), leading to the choice of the previous mesh (Figure 506.11) for all 2D analysis.

It is important to note that all 2D meshes were actually developed using 3D, brick elements (in this case a linear interpolation, 8 node bricks). Appropriate boundary conditions were used to prevent out of plane displacements. While this approach uses extra resources (use of 3D element for a 2D problem) it allowed us to use the very same element and material models for both 2D and 3D problems, thus removing modeling uncertainty and emphasizing accuracy of determination of differences between 2D and 3D slope stability. The finite element used for analysis in 2D (and later in 3D) was based on an eight node brick element, described in some more details in Section 2.3 of my lecture notes Jeremić et al. (1989-2025).

Mesh in Figure 506.11 has 250 brick finite elements while finest mesh in Figure 506.12 has 1000 brick finite elements. Boundary conditions for the 2D mesh were such that right vertical boundary (at the current Barrier wall) was allowed to move down but not horizontally. Lower mesh boundary (contact with base rock) was fully supported, while left vertical boundary (far into alluvium) was also allowed to move vertically but not horizontally. Work platform was modeled using loads, instead of extending the mesh to include the shape of the platform. This allowed for additional modeling flexibility, without the loss of accuracy. Loading tests with and without the work platform show that its influence on calculated factors of safety is negligible. Figure 506.13 shows a 2D model with location of work platform, water level at 680 ft, boundary conditions and the extent of alluvium layer.

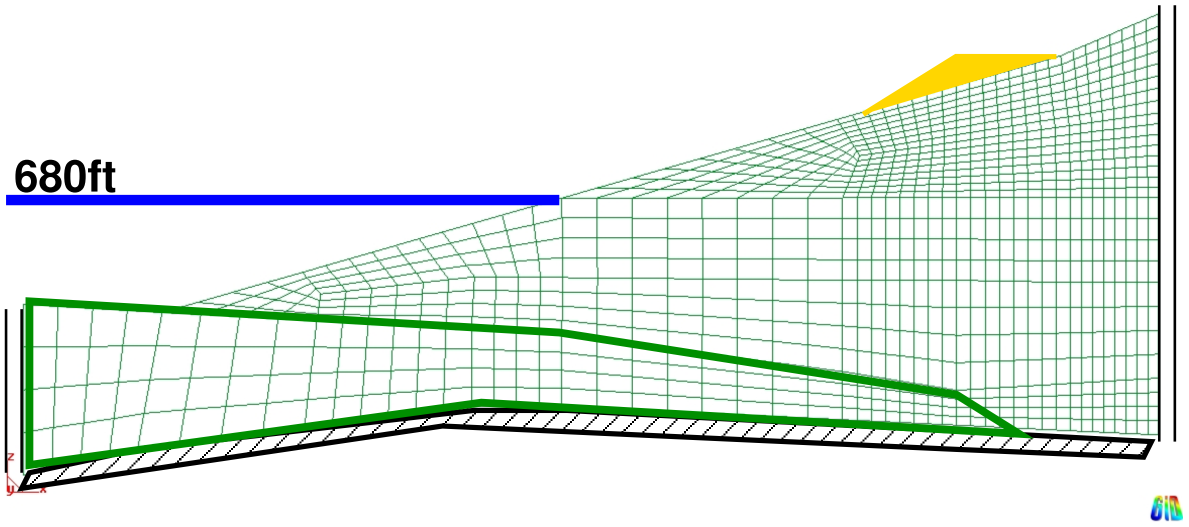

Figure 506.13: A 2D model with boundary conditions, water level at 680 ft and the work platform as load.

506.4.3 Three Dimensional Models

The Dam is a full three dimensional solid, consisting of foundation rock, concrete section and soil embankment section with barrier wall(s) (old and new one when finished). Ideally we would model the complete foundation-concrete-embankment-wall system with porous solid (soil skeleton), pore fluid (water in fully and partially saturated pores), structural components (barrier walls) as well as solid concrete section.

Particular focus on assessing 2D versus 3D slope stability for the upstream, curved (wrap around) section, as well as the very short time frame for this project, dictated development of small part of the complete model. The most important feature of the 3D model was to use optimal model size (extent) so that all important features are properly captured. This was done by developing 3D model for upstream curved, wrap slope in two stages. First stage comprised development of the conical portion of mesh, which was then extended, using a straight second stage, extending the model into the embankment by 200 ft (60 meters).

Conical Section of a 3D Slope Three sections shown in Figures 506.6, 506.7 and 506.7 were used to develop three dimensional mesh. Conical wrap around part of the mesh features 1344 brick elements and is shown in Figure 506.14.

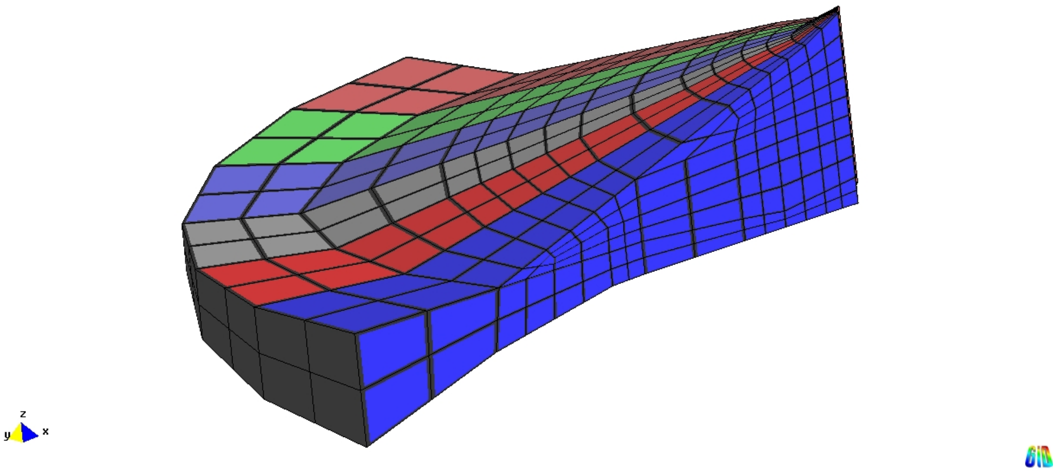

Figure 506.14: Conical section of the 3D upstream slope of the Dam, 3D mesh.

Boundary conditions are such that two vertical sections (one adjacent to the concrete monolith and the one adjacent to straight embankment sections have free vertical and in plane horizontal displacements while no out of plane displacement. A small quarter cylinder boundary was also developed at the top of the curved, wrap around section. This small part of boundary (radius of 2 meters) was necessary to properly mesh radial directions of the 3D model. Boundary conditions at that location are such that they prevent radial deformation while allowing vertical and tangential movement. This is achieved using short, stiff truss elements.

At the lower end of the model (well into alluvium), curved, radial section of the model is supported in such a way that radial deformation is prevented while vertical and horizontal tangential movement is allowed, again achieved using short, stiff truss elements.

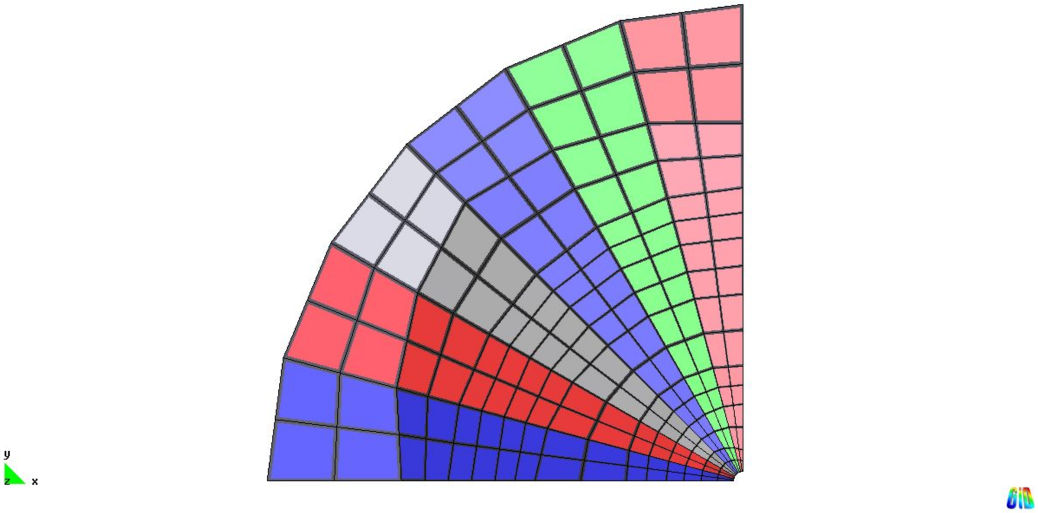

Figure 506.15: Curved section of the 3D upstream slope of the Dam, 3D mesh, top view. Note the difference in extent of the actual embankment (slightly different color of elements, alluvium is represented by last two layers of elements on the outskirts of model. Also note a small cylindrical section close to center of conical slope, that was used to control meshing.

Conical and Straight Section of a 3D Slope While conical section of the slope represent accurately the curved section of the dam, influence of the straight section cannot be neglected. A section (200 ft, 60 meters) of a straight embankment was added to a curved section in order to have a more realistic modeling of the complete upstream 3D embankment. Figures 506.16 and 506.17 show extended 3D mesh for curved and part of straight section of the upstream slope.

Boundary conditions were similar to the previous case for conical part of mesh, except where mesh extension was applied. Extended mesh was fully supported at the bottom, while vertical faces were supported in such a way not to have out of plane displacements while in plane (horizontal and vertical) displacements were left free. Loads from work platform and from water in the lake were applied as appropriate nodal forces.

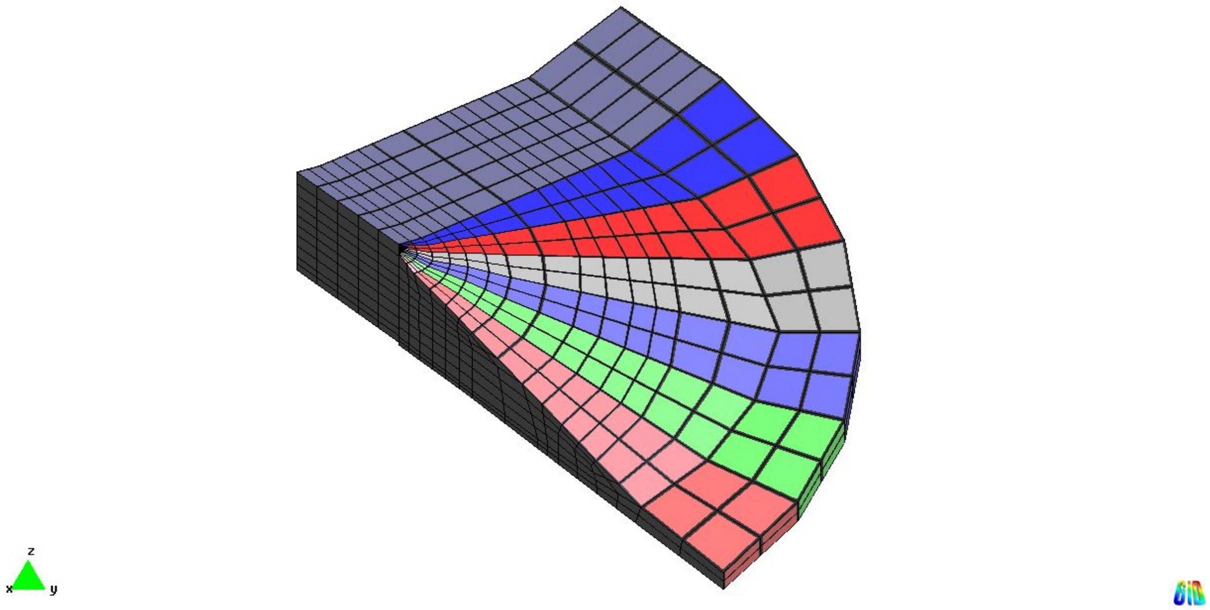

Figure 506.16: Curved and straight section of the 3D upstream slope of the Dam, 3D mesh.

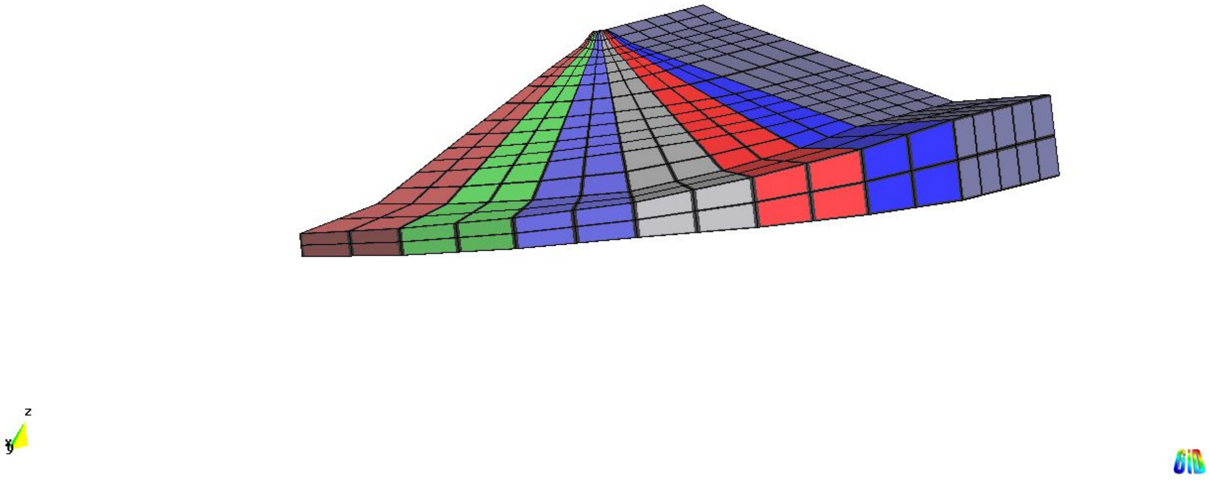

Figure 506.17: Curved and straight section of the 3D upstream slope of the Dam, 3D mesh.

506.4.4 Modeling Issues

Mesh Size Multiple mesh sizes were tested to alleviate any mesh dependency of the computed solution close to stability loss (close to but not into the development of localized deformation).

Following the Equilibrium Path Numerical integration of elastic-plastic constitutive equations was performed using both explicit and implicit algorithms (see Jeremić et al. (1989-2025), Sections 3.3 and 3.4). This was necessary in order to verify the solution accuracy. For explicit constitutive computations, explicit global solution scheme was used (see more detailed description of equilibrium following path algorithms in my lecture notes Jeremić et al. (1989-2025), Chapter 7). For implicit constitutive integrations, Newton method (cf. Dennis and Schnabel (1983), and Jeremić et al. (1989-2025), Chapter 7) was used on both constitutive and global solution levels. Global solution advancement was constrained using both load control (appropriate for factor of safety stability simulations) as well as displacement control (in order to validate load control solutions). Detailed discussion on both load and displacement control algorithms is given in lecture notes Jeremić et al. (1989-2025), Sections 7.3. and 7.4.

Strength Reduction Method Strength reduction method is often used with finite elements to assess factors of safety for slopes, foundations and other problems in geotechnical engineering where elastic-perfectly plastic failure is expected Duncan (1996) Griffiths and Lane (1999). Strength reduction method can be performed in two ways:

- Apply self weight to a model where strength parameters are reduced by Factor of Safety (FS). Perform analysis number of times for larger and larger FS, until the finite element system is not in equilibrium, that is external forces cannot be balanced by internal forces (see Section 7.1 in Jeremić et al. (1989-2025)). This approach has the benefit of not being mesh dependent, that is, for elastic – perfectly plastic material models (without softening), dependence of solution on mesh refinment does not become an issue (Lu et al., 2009). One potential drawback is that since there is no softening involved, deformation will not localize into localized zone, rather failure mode is somewhat diffuse, however still following proper displacement of blocks of material as system becomes unbalanced.
- Apply self weight to a model with full strength material parameters, and then gradually start softening the material parameters, by dividing them with FS. Perform reduction in parameters, until there is loss of equilibrium, that is until external forces cannot be balanced by internal forces (again see Section 7.1 in Jeremić et al. (1989-2025)). This approach might have a potential problem in that the mesh size/refinment will affect the solution, as material models involved are

softening, and different meshes will create different localization patterns and hence lead to different solutions. The benefit of this approach is that deformation will indeed localize in a very thin band, thus resembling the limit equilibrium approach that is popular for slope stability problems, however, such deformation patterns are mesh size/refinment dependent and thus not unique.

In this work, the first approach is used, that is self weight computations are performed for a number of models where strength parameters are reduced by FS, until such FS for which equilibrium between external and internal forces cannot be achieved.

Variable Water Levels Comparison of 2D vs 3D stability for two water elevation was originally suggested. Discussions during a meeting at a Dam site, further clarified conceptual problems with two water elevation, namely lake at 680 ft and water table in the embankment at 720 ft. For any water table that is above the lake level, there will exist a water flow (seepage) within the embankment toward the (lower level) lake water. Such seepage will create a seepage force $f_s = \gamma_w (dh)/(dl) = \gamma_w i$ where, γ_w is the unit weight of water, and $i = (dh)/(dl)$ is the hydraulic gradient. Clearly, with seepage from embankment toward the lake, such force destabilizes the embankment (slope). Finite Element formulation and tools that can model and simulate such fully coupled system (transient analysis of deforming porous soil with moving pore fluid) are available (Cheng et al., 2007; Jeremić et al., 2008; Cheng and Jeremić, 2009a,b), however material parameters for soil permeability as well as the extent of phreatic surface need to be determined. Due to unavailable test data for permeability of embankment soil and due to (high) uncertainty in the extent of phreatic surface (number of piesometric measurements placing the water table in the embankment at 720 ft were highly questionable, as discussed by the panel), only single phase soil (either effective stress or total stress) analysis were performed. This decision has no effect on analysis for cases where both lake and phreatic line in the embankment are at 680 ft. However, such decisions affects cases with different water levels (lake at 680 ft, phreatic line at):

- Fully undrained case with lake level at 680 ft, embankment phreatic level at 720 ft, was analyzed and in fact provides (based on theory of undrained soil behavor) the same factors of safety as no seepage case, that is, same water level in lake and embankment. This is due to the fact that for total stress analysis, pore fluid pressure does not influence the shear strength. In addition to that, with the assumption of fully undrained conditions, coefficient of permeability is nonexistent, there is no seepage, and hence there is no seepage force. In reality coefficient of permeability for soil is never really zero, however this case was treated as an extreme case, used purely for checking differences in factors of safety between 2D and 3D slope stability.
- Fully drained case with lake level at 680 ft, embankment phreatic level at 720 ft, was not analyzed

as neglecting seepage force would place calculated factors of safety on the *unsafe* side. While such analysis can be run using either buoyant weight approach (however somewhat inconsistent as noted by Duncan (1996)) or by mixing total stress and effective stress approach (more inconsistent) it was decided not to simulate this case.

506.5 Results: Factors of Safety

A large number of computations on a number of models were performed.

Factors of Safety for 2D Models

- Drained, Lake/Embankment at 680 ft,
  $FS_{2D} = 1.89$
- Undrained, Lake/Embankment at 680 ft, alluvium weak of most likely $(S_u = 1000 \text{ psf})$,
  $FS_{2D} = 2.22$
- Undrained, Lake/Embankment at 680 ft, alluvium at most likely value $(S_u = 1500 \text{ psf})$,
  $FS_{2D} = 2.50$

Factors of Safety for Extended 3D Models

- Drained, Lake/Embankment at 680 ft,
  $FS_{3D} = 1.78$
- Undrained, Lake/Embankment at 680 ft, (alluvium weak of most likely $S_u = 1000\text{psf}$),
  $FS = 2.0$

Comparison of 2D vs 3D Factors of Safety

- Drained, lake/water in embankment at 680 ft,
  $FS_{2D} = 1.89$ vs $FS_{3D} = 1.78$
  FS reduced by 5.8 %.
- Undrained, Lake at 680 ft, embankment at 680 ft
  (alluvium weak of most likely $S_u = 1000\text{psf}$),
  $FS_{2D} = 2.22$ vs $FS_{3D} = 2.00$
  FS reduced by 9.91 %.

- Undrained, Lake at 680 ft, embankment at 720 ft
  (alluvium weak of most likely $S_u = 1000\mathrm{psf}$),
  $FS_{2D} = 2.22$ vs $FS_{3D} = 2.00$
  FS reduced by 9.91 %.

506.6 Uncertainty of Results

Full probabilistic analysis for large scale, elastic-plastic finite element models is currently within reach (Sett et al., 2011a) and will probably become a standard simulation tool within next 5 to 10 years. However, for such an analysis, a(n) (extensive) site characterization program is necessary, if probabilistic simulations are to be useful (Sett and Jeremić, 2009). Alternatively, one can use a simplified methodology, described in detail by Duncan (2000a), that can give sensible estimates of mean and standard deviation of common results obtained in soil mechanics. However, in view of lack of consistent material properties for the embankment further work on estimating uncertainty of factors of safety was discontinued. It is important to note that a program was initiated by the USACE to perform extensive testing of embankment soil and upon completion of that program, it will be possible to perform a simplified (and even a more accurate, full probabilistic analysis, as mentioned above) estimation of influence of material uncertainty on obtained factors of safety.

506.7 Conclusion

The main purpose of this study was to investigate changes in factors of safety for failure between 2D and 3D slope problems for curved part of the upstream section of a Dam embankment. Detailed models (both 2D and 3D) were developed for the upstream section of Wold Creek Dam and were analyzed. Strength reduction method was used to assess factors of safety in both 2D and 3D. It was shown that for a number of different cases (drained or undrained soil, lake at 680 ft and water table in the embankment either at 680 ft or at 720 ft for undrained case) the factor of safety is reduced in 3D when compared to 2D. Such reduction, however was not significant (up to approx. 10 %).

Of particular importance for this factor of safety comparison (2D vs 3D) was the robustness of simulations and a number of methods were used to ensure that obtained factors of safety, determined as failure to converge upon strength reduction, were due to loss of equilibrium, and not due to numerical problems leading to loss of convergence.

Appendix given below, contains two additional sections, describing numerical tool used in factor of safety computations (available in public domain) and deformation patterns close to failure for select cases.

506.8 Displacement Patterns

Hypothetical displacement patterns are presented below in Figures 506.18, 506.19 and 506.20. It should be noted that displacements that results from simulations of stability by strength reduction method are not necessarily the failure modes, rather, they are just a side-product of simulation. However, it is instructive to inspect those displacements just before equilibrium is lost in order to gain a better understanding of potential failure patterns.

Figure 506.18 shows a 2D displacement pattern for a drained case with lake and embankment water level at 680 ft where $FS_{2D} = 1.89$. Noted is a clear rotating pattern of the slope just before loss of equilibrium.

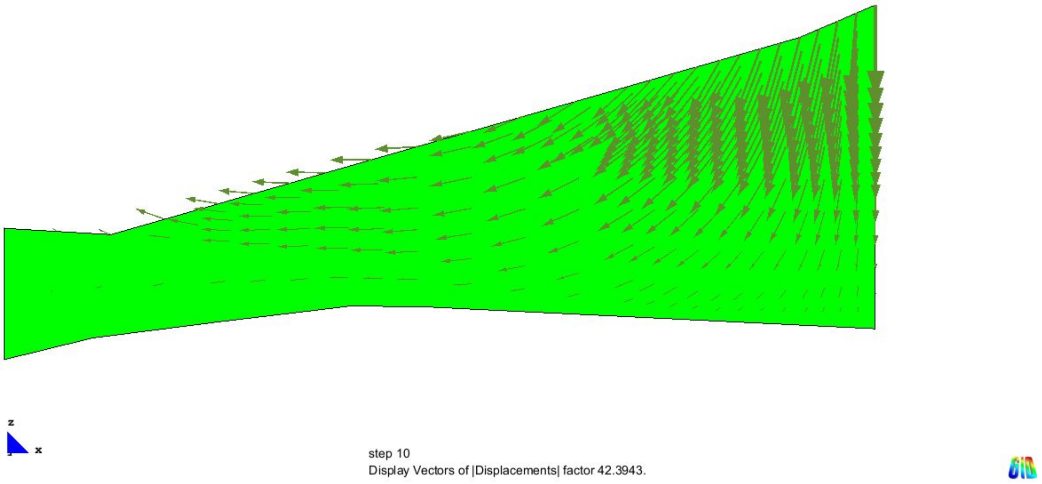

Figure 506.18: Drained case, lake and embankment water lever 680 ft, $FS_{2D} = 1.89$.

Figure 506.19 shows a 2D displacement pattern for an undrained case with more likely (stronger) alluvium ($S_u = 1000 \text{psf}$). Note that while displacement pattern is somewhat similar to the previous case, the block movement on top of alluvium is much reduced, and main failure is through rotation mechanism.

Figure 506.20 shows a plan view of a 3D displacement pattern (vectors) for an undrained case with limiting weak alluvium and lake at 680 ft. Noted is the dominant 3D deformation pattern by which the curved and straight sections of the slope rotate around vertical axes and move toward the lake with direction biased toward dam axes. It is important to note that there is no single 2D section of the 3D

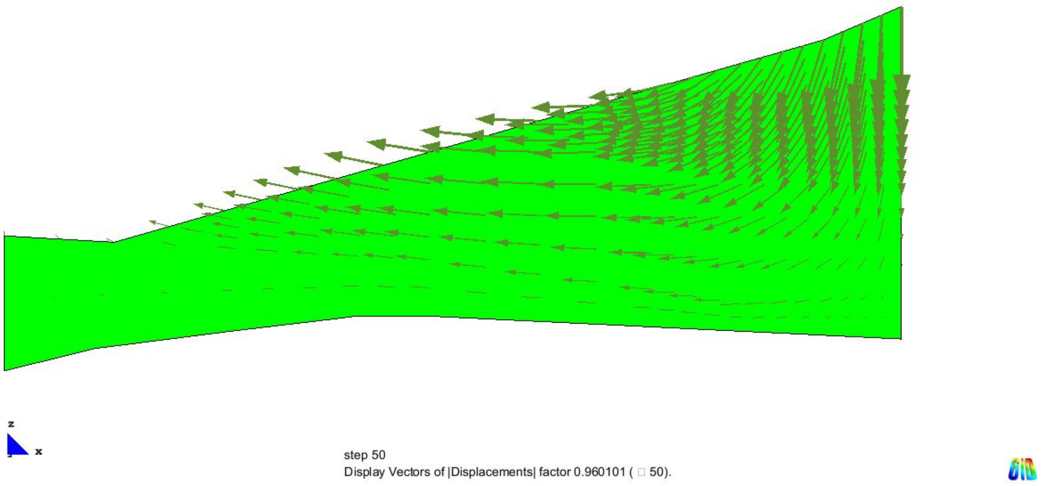

Figure 506.19: Undrained, L680 E680, Most Likely to Weak Alluvium, $FS_{2D} = 2.22$.

slope that can be used to model such failure as failure mode is fully three dimensional.

Figure 506.20: Plan view of a 3D undrained case, displacement vectors, lake and embankment at 680 ft, $FS_{3D} = 2.00$.

Chapter 507

Concrete Structures

(1989-2017-2018-2019-2020-2021-)

(In collaboration with Prof. Han Yang and Dr. Hexiang Wang)

507.1 Chapter Summary and Highlights

507.2 Concrete Wall/Membrane

507.2.1 Introduction

OECD organized project to investigate modeling of concrete walls that have alkali - silica reaction (ASR) has been going on for few years. Our modeling and simulation group, based at the University of California at Davis, in California, USA, and at the Lawrence Berkeley National Laboratory at Berkeley, in California, USA, has joined this effort only at the beginning of 2018. We have gotten project description and already existing reports from participants, in January/February of 2018. We managed to quickly make a model of the wall and to calibrate parameters for a concrete model that we use in our modeling and simulation program.

We rely on and used our program, called the Real-ESSI Simulator (Realistic Modeling and Simulation of Earthquakes, and Soils, and Structures and their Interaction), that is also known as the MS ESSI Simulator[1] (Jeremić et al., 1988-2025) (`http://real-essi.info/`). Real-ESSI Simulator is a software, hardware and documentation system for high fidelity, high performance, time domain, nonlinear/inelastic, deterministic or probabilistic, 3D, finite element modeling and simulation of (a) statics and dynamics of soil, (b) statics and dynamics of rock, (c) statics and dynamics of structures, (d) statics of soil-structure systems, and (e) dynamics of earthquake-soil-structure system interaction.

The Real-ESSI Simulator systems is used for the design and assessment of static and dynamic behavior of infrastructure objects, including buildings, bridges, dams, nuclear installations, tunnels, etc. For design, multiple linear elastic load cases can be combined and design quantities, sectional forces exported for design and cross section dimensioning. For assessment, realistic inelastic load staged analysis is performed, with all the inelastic components properly modeled, as listed below, and with all the simulation, algorithmic features available, as listed below. Analysis is performed in order to assess safety and economy of objects. The work on Real-ESSI Simulator is based on a philosophy that aims to develop modeling and simulations that inform and predict rather than (force) fit.

507.2.1.1 Motivation

The alkali - silica reaction (ASR), is a reaction that occurs over time in concrete, between the alkaline cement paste and the silica found in many common aggregates, triggered by the presence of moisture. The ASR does volumetric expansion of interface between cement paste and the aggregate, thus resulting

---

[1] The Real-ESSI Simulator was developed in collaboration and with financial support from the US-DOE, US-NRC, US-NSF, CNSC-CCSN, Caltrans, etc.

in potentially damaging tensile stress within concrete. A comprehensive study of this effect on concrete properties has been done at University of Toronto, funded by Canadian Nuclear Safety Commission (CNSC). Five shear walls, two regular (REG A, REG B) and three ASR (ASR A1, ASR B1, ASR B2) along with their control specimens were tested as a part of Phase 1, Phase 2, and Phase 3 of the investigation program [ref Prof. Sheikh presentation].

It was proven that ASR causes changes in mechanical properties of the concrete, introducing inaccuracies if conventional analysis is used, without taking into account ASR. Beyond a certain age, modulus of elasticity and tensile strength of ASR concrete decrease, in contrast to regular concrete. Observed is degradation of the ductility in ASR specimens. While concrete expands, the bonding strength between concrete and rebars decreases causing drop in ductility. However, despite these changes in concrete, tested ASR shear wall showed higher peak shear strength compared to regular concrete.

This newly understood behavior of ASR concrete necessitates development of reliable numerical simulation, to be used for the design of new structures as well as to predict behavior of existing ones.

In order to model behavior of the examined wall specimens, Real-ESSI Simulator, (Jeremić et al., 1988-2025) was used.

Plane stress finite element with an inelastic plane stress material model for concrete was used for modeling of shear wall specimens. All inelastic material models and finite elements inside the Real-ESSI Simulator feature accurate energy dissipation modeling and calculation (Yang et al., 2018, 2019a).

Results from ASCET benchmark tests are used for validation of shear behavior for plane stress inelastic reinforced concrete wall tests.

507.2.2 Model Availability

The Real-ESSI input files for the ASR concrete wall example are available HERE.

507.2.3 Model Development

507.2.3.1 Model Mesh

Finite element model includes all relevant parts of the experimental setup, as shown in Figures 507.3 and 507.2.

Beam slabs and steel plates are modeled using 27NodeBrick element, while steel bolt is represented as a single truss element. The shear wall is modeled using nonlinear layered plane stress elements. For the web part of the wall, the elements have a horizontal rebar layer, a vertical rebar layer, and an unconfined concrete layer. For the flanges (columns) of the shear wall, the elements have an additional layer of confined concrete. It is emphasized that the main wall is really made from unconfined concrete, and the

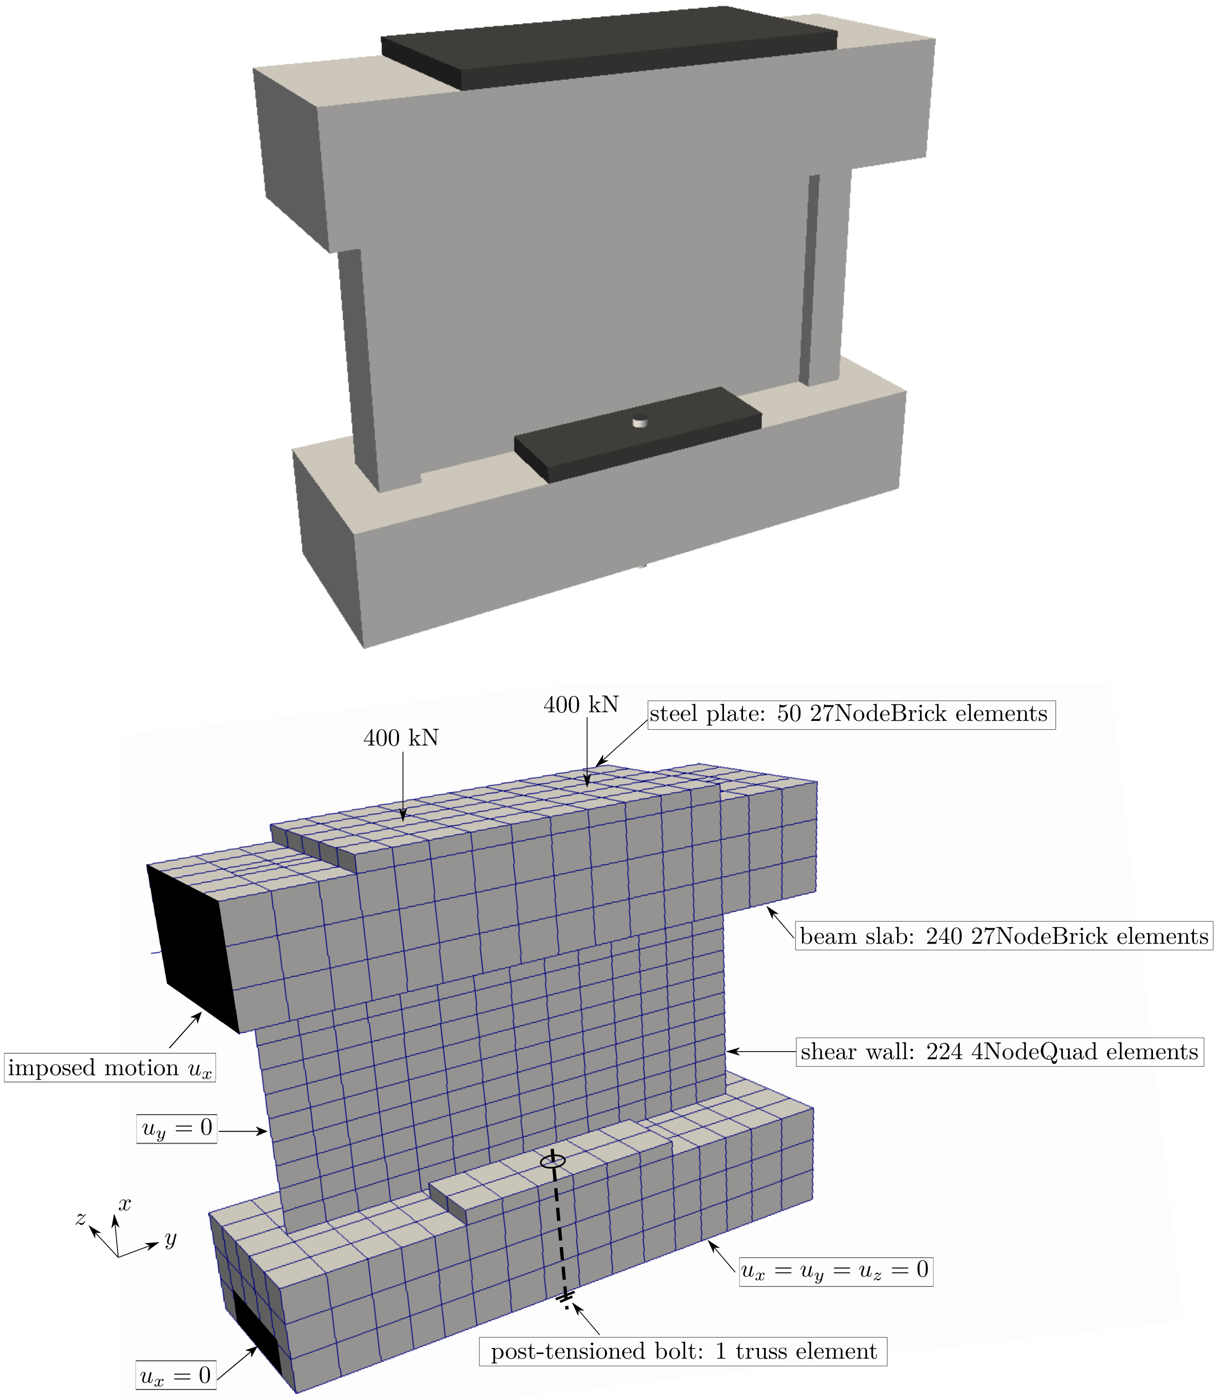

Figure 507.1: 3D rendered view and finite element mesh of the reinforced concrete shear wall model.

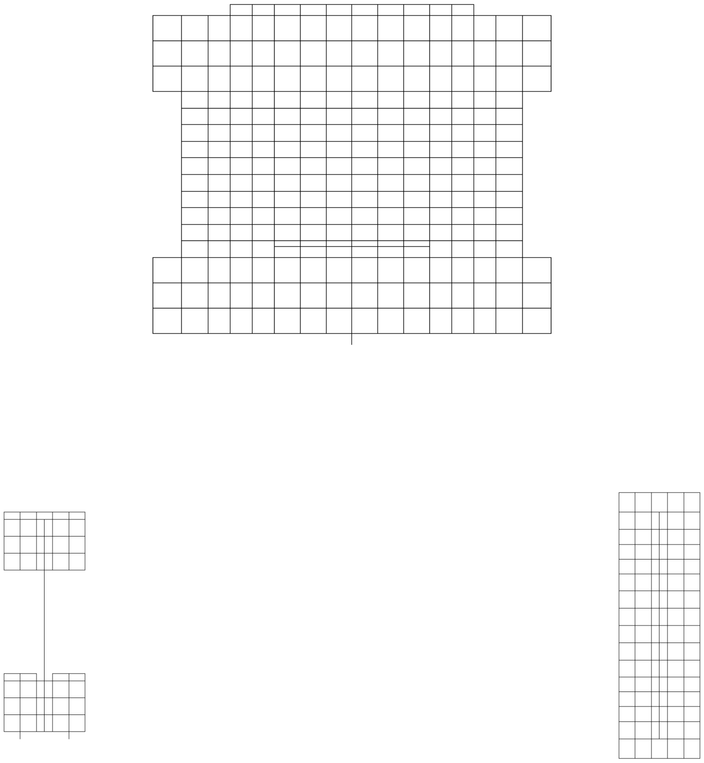

Figure 507.2: Different views of the finite element mesh.

only actually confined concrete is within concrete flanges. Detailed rebar plan and model dimensions are shown in Fig 507.3.

The bottom of the model is restrained in all directions, while the lateral sides of the bottom beam slab are restrained in direction of imposed motion. Since the shear wall consists of 2D plane stress elements the out-of plane displacement is also precluded. The sides of the top beam slab are also restrained to have the same displacement, which is important to represent the boundary conditions of the physical experiment. Initial model included inelastic contact/interface elements (stick-slip and gap open and close) at the bottom boundary. However it was concluded that there will be no slip and there is no gap opening so these elements were removed in order to speed up computations.

To correctly simulate the loading process of the experiment, four loading stages are applied:

1. Self-weight loading is applied to the whole model.

2. To represent post-tensioned force in the truss (bolt) element, the truss is stretched so that an adequate force is obtained and after that the bottom of the bolt is fixed.

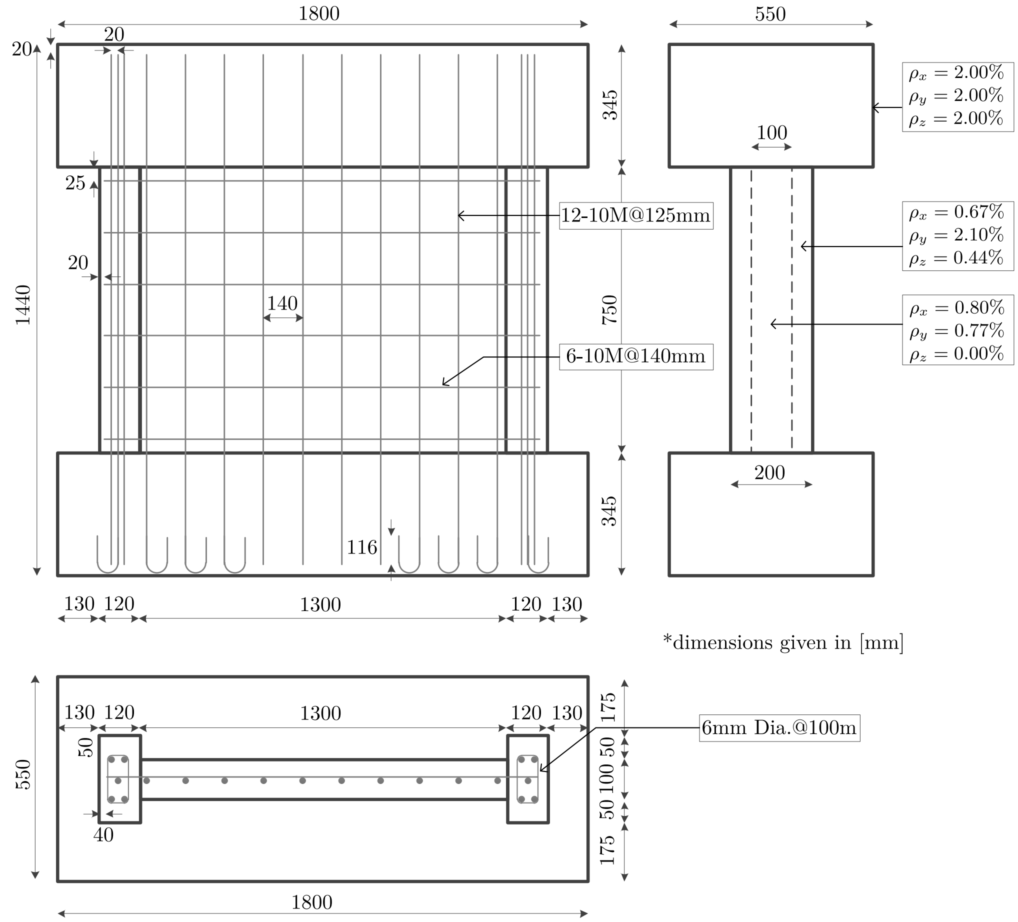

Figure 507.3: Schematics for the rebar plan of the shear wall model.

3. Two-point vertical loading is applied to the top steel plate.

4. Cyclic horizontal loading is applied (using displacement control) to the sides of the top beam slab.

507.2.3.2 Plastic Damage Concrete Material Model

Details for this model are given in Section 104.9.

507.2.3.3 Uniaxial Steel Material Model

Details for this model are given in Section 104.9.

507.2.3.4 Material Model Parameters

There are two approaches to determine the ASR affected concrete model parameters. The first choice is to obtain concrete samples directly from the existing structure. Those samples can be tested in the laboratory to determine mechanical properties of the concrete material. This is a preferred way to obtain material properties.

In this project, the material properties for ASR affected concrete were obtained using laboratory, for concrete aged to 260, 610, and 995 days, as shown in Table 507.1. These values are used in the material models for finite element simulations.

Table 507.1: Mechanical properties for the ASR concrete at 260, 610, and 995 days.

Wall	Age (Days)	Compressive Strength (MPa)	Tensile Strength (MPa)	Elastic Modulus (MPa)	Expansion (%)
ASR A1	260	63.7	3.24	35750	0.190
ASR B1	610	67.1	N/A	32600	0.215
ASR B2	995	63.0	3.18	28100	0.223

The second approach is to estimate change of material properties, future material properties, based on currently measured material properties and empirical correlations. In what follows, it is demonstrated how to predict the mechanical properties of the ASR concrete at 610 and 995 days using the values at 260 days.

First, according to data provided for ASCET II workshop, the maximum ASR expansions of the concrete prisms in longitudinal and transverse directions are approximately 0.25% and 0.28%. For simplicity, an average value of 0.265% is chosen.

Estimations of ASR expansion rates at 260, 610, and 995 days are needed. According to various ASR models (Charlwood et al., 1992; Saouma and Perotti, 2006), the rate of expansion after about 365 days is very small. So it is reasonable to use the maximum value of expansion (0.265%) for estimating mechanical properties of ASR concrete at 610 and 995 days. At 260 days, the expansion is estimated to be 0.23%.

The correlation between normalized mechanical properties of ASR concrete and rate of expansion/swelling from Capra and Sellier (2003) is used. At 0.265% swelling, at 365 days, the normalized compressive strength is 0.60 while the normalized tensile strength is 0.55. The normalized elastic modulus ranges from 0.60 to 0.70.

On the other hand, at 0.23% swelling, at 260 days, the normalized compressive strength is 0.65 while the normalized tensile strength is 0.60. The normalized elastic modulus is approximately 0.70. Therefor, from 260 days to 365 and consequently at 610 and 995 days, the compressive and tensile strengths both decrease approximately 92%. Similarly, the elastic modulus decreases approximately 85%.

Using these values, for ASR concrete older than 365 days , the compressive strength is 58.6MPa, the tensile strength is 2.98MPa, and elastic modulus 30387MPa. Note that these values match well with the experimental results shown in Table 507.1. It is important to note that concrete is a composite material and that expansion of mass of concrete, within confines of reinforcing, can produce increase in confinement, which can have beneficial effects on concrete behavior.

507.2.4 Modeling of Energy Storage and Dissipation

Described in this section is modeling and calculation of energy storage and dissipation within concrete and steel. This section is based on recent work by Yang et al. (2018, 2019a).

507.2.4.1 Plastic Damage Concrete Material

The Helmholtz free energy potential postulated for the plastic damage concrete material has the form:

$$\psi(\epsilon_{ij}, \epsilon^p_{ij}, d^+, d^-) = (1 - d^+)\psi^+_0(\epsilon_{ij}, \epsilon^p_{ij}) + (1 - d^-)\psi^-_0(\epsilon_{ij}, \epsilon^p_{ij}) \tag{507.1}$$

where ψ^+_0 and ψ^-_0 are tensile and compressive parts of the elastic free energy (strain energy), that are defined as:

$$\psi^+_0(\bar{\sigma}_{ij}(\epsilon_{ij}, \epsilon^p_{ij})) = \frac{1}{2}\bar{\sigma}^+_{ij} D^{-1}_{ijkl} \bar{\sigma}_{kl} = \frac{1}{2}\bar{\sigma}^+_{ij}(\epsilon_{ij} - \epsilon^p_{ij}) \tag{507.2}$$

$$\psi^-_0(\bar{\sigma}_{ij}(\epsilon_{ij}, \epsilon^p_{ij})) = \frac{1}{2}\bar{\sigma}^-_{ij} D^{-1}_{ijkl} \bar{\sigma}_{kl} = \frac{1}{2}\bar{\sigma}^-_{ij}(\epsilon_{ij} - \epsilon^p_{ij}) \tag{507.3}$$

The rate of strain energy can be calculated from:

$$\dot{E}_S = \dot{\psi}^+_0 + \dot{\psi}^-_0 = \sigma_{ij}(\dot{\epsilon}_{ij} - \dot{\epsilon}^p_{ij}) \tag{507.4}$$

Taking the time derivative of Equation 507.1 gives the rate form of Helmholtz free energy:

$$\dot{\psi} = \frac{\partial \psi}{\partial \epsilon_{ij}}\dot{\epsilon}_{ij} + \frac{\partial \psi}{\partial \epsilon^p_{ij}}\dot{\epsilon}^p_{ij} + \frac{\partial \psi}{\partial d^+}\dot{d}^+ + \frac{\partial \psi}{\partial d^-}\dot{d}^- = (\sigma_{ij}\dot{\epsilon}_{ij} - \sigma_{ij}\dot{\epsilon}^p_{ij}) + (-\psi^+_0\dot{d}^+ - \psi^-_0\dot{d}^-) \tag{507.5}$$

where the first term is the rate of strain energy given by Equation 507.4.

For a decoupled material model, the Helmholtz free energy can be decomposed into elastic and plastic parts (Collins and Houlsby, 1997). Subtracting the elastic part of the free energy (strain energy) from Equation 507.5 gives the rate form of the plastic free energy:

$$\dot{E}_P = \dot{\psi} - \dot{E}_S = -\psi^+_0\dot{d}^+ - \psi^-_0\dot{d}^- = -\frac{1}{2}(\bar{\sigma}^+_{ij}\dot{d}^+ + \bar{\sigma}^-_{ij}\dot{d}^-)(\epsilon_{ij} - \epsilon^p_{ij}) \tag{507.6}$$

The plastic energy dissipation D_P is defined as the difference between plastic work and plastic free energy (Farren and Taylor, 1925; Taylor and Quinney, 1934). The rate of plastic dissipation can be expressed as:

$$\dot{D}_P = \sigma_{ij}\dot{\epsilon}^p_{ij} - \dot{E}_P = \sigma_{ij}\dot{\epsilon}^p_{ij} + \frac{1}{2}(\bar{\sigma}^+_{ij}\dot{d}^+ + \bar{\sigma}^-_{ij}\dot{d}^-)(\epsilon_{ij} - \epsilon^p_{ij}) \tag{507.7}$$

It can be proven that the rate of plastic dissipation given by Equation 507.7 is always non-negative. This means that the concrete material model used in this study satisfies the Clausius-Duhem inequality, which represents a form of the second law of thermodynamics.

Combining Equation 507.4, 507.6, and 507.7, the rate form of energy balance in this concrete material model is achieved:

$$\dot{E}_S + \dot{E}_P + \dot{D}_P = \sigma_{ij}\dot{\epsilon}_{ij} \tag{507.8}$$

507.2.5 Uniaxial Steel Material

The energy computation procedure for the uniaxial steel model is shown in Figure 507.4. Note that the only difference between the monotonic loading branch (Figure 507.4(a)) and the cyclic loading branch (Figure 507.4(b)) is that the strain reversal point c is at the origin o in the monotonic case. So the following explanation of the proposed energy computation method applies to both monotonic and cyclic loading scenarios.

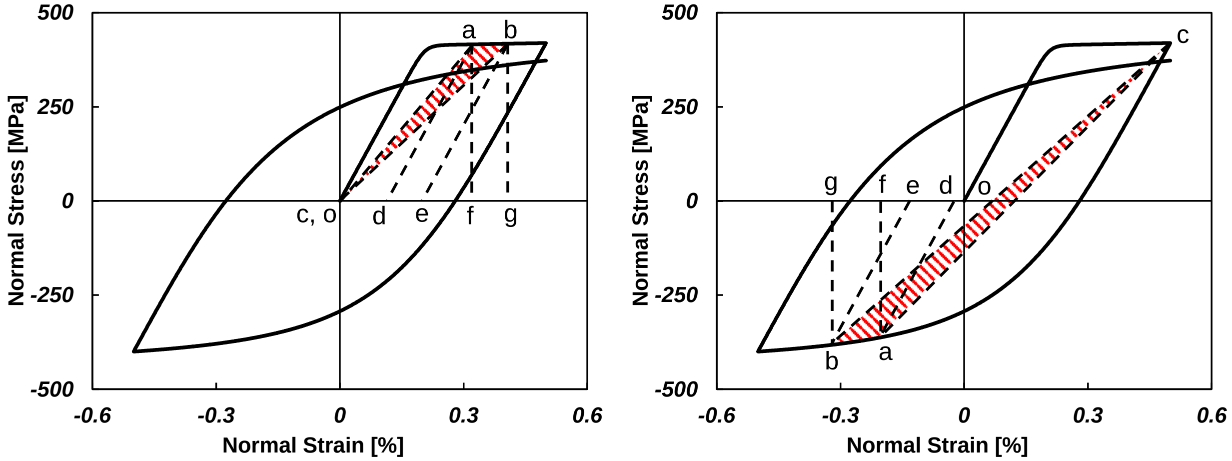

Figure 507.4: Energy computation of uniaxial steel fiber: (a) Monotonic loading branch; (b) Cyclic loading branch.

Firstly, the elastic strain energy density E_S is defined in accordance with the classic assumption that it is only a function of current stress state of the material, which yields:

$$E_S = E_S(\sigma) = \frac{1}{2E_0}\sigma^2 \tag{507.9}$$

where E_0 is the initial stiffness of the material.

Graphically, the elastic strain energy density of the material shown in Figure 507.4 at states a and b are the triangular areas afd and bge. Then the incremental form of Equation 507.9 is simply:

$$dE_S = \frac{1}{E_0}\sigma d\sigma \tag{507.10}$$

Next, the incremental plastic dissipation density D_P from state a to b is assumed to be the triangular area abc:

$$dD_P = \frac{1}{2}[(\sigma - \sigma_r)d\epsilon - (\epsilon - \epsilon_r)d\sigma] \tag{507.11}$$

This assumption ensures that the incremental plastic dissipation is non-negative, and that ensures that the second law of thermodynamics is satisfied.

For general case where the material does exhibit cyclic softening, plastic free energy density E_P is graphically described as the areas $adoc$ and $beoc$ at states a and b, respectively. The formulation for plastic free energy density E_P representing this assumption is given by:

$$E_P = \frac{1}{2}\left[\sigma\left(\epsilon - \frac{\sigma}{E_0} - \epsilon_r\right) + \sigma_r\epsilon\right] \tag{507.12}$$

The incremental form of Equation 507.12 is:

$$dE_P = \frac{1}{2}\left[(\sigma + \sigma_r)\, d\epsilon + \left(\epsilon - \frac{1}{E_0}\sigma - \epsilon_r\right) d\sigma\right] \tag{507.13}$$

Adding Equation 507.10, 507.11, and 507.13, the incremental form of energy balance is achieved:

$$dE_S + dE_P + dD_P = \sigma d\epsilon \tag{507.14}$$

where the increment of three energy components add up to the increment of stress power during any loading step.

507.2.6 Modeling and Simulation Results

In this chapter, the simulation results are presented and compared with corresponding experimental results. Three sets of FEM simulations (Reg A, Reg B, and ASR A1) using the Real-ESSI Simulator system (Jeremić et al., 1988-2025) (`http://real-essi.info/`) are performed. In the following sections, the force–displacement responses of these three sets of simulations are shown and discussed. The strain and stress distributions, that share similar pattern in all three simulations, are also presented. In order to investigate the level of damage in the shear wall, the evolution of concrete damage index as well as the plastic dissipation density are plotted and discussed.

507.2.6.1 Force–Displacement Response

Figures 507.5 and 507.6 present the force–displacement responses of the simulation and experiment results for regular concrete (Reg A and Reg B) and ASR concrete.

The ESSI simulation curves show good matching of experimental results. The differences in the envelopes of the cyclic loading curves, between the numerical and experimental results are within 10%.

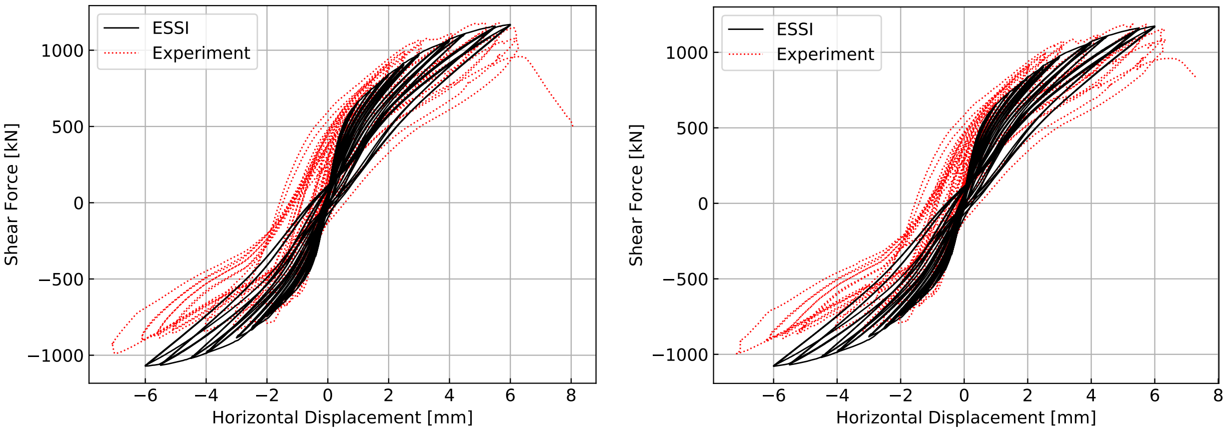

Figure 507.5: Force–Displacement responses of regular concrete tests: (a) Reg A; (b) Reg B.

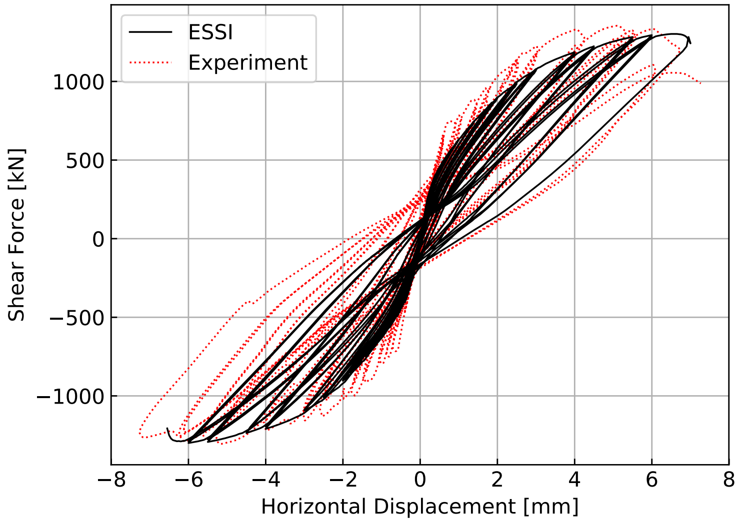

Figure 507.6: Force–Displacement response of ASR concrete test (ASR A1).

The shear strengths and failure loads/displacements given by ESSI simulations match well with the values determined by physical experiments. Note that this particular case with ASR concrete has a much larger unloading-reloading cyclic area, which means that ASR concrete has the capability of dissipating more input energy. It is important to note that this conclusion dos not hold for other ASR concrete walls that were tested. This might indicate that for some structures with the ASR concrete, it is possible to dissipate more seismic energy if the structure is under earthquake cyclic loading. On the other hand, for some other structure with the ASR concrete, such conclusion might not hold as other test data suggests reduction of seismic energy dissipation capacity. This leads to the conclusion that variability of ASR concrete quality and material behavior can be significant.

507.2.6.2 Strain and Stress Distribution

Due to the fact that the stress, strain, and damage patterns in all three cases are very similar, only plots for the Reg A case is presented and discussed in the following sections.

Figure 507.7 shows the distribution of displacement components in the shear wall model at $u_y = 6$ mm. The vertical displacement distribution is almost symmetric. The left part of the shear wall is compressed down while the right part is extended up. It is noted that the upper support beam is thus not remaining horizontal, rather, it is applying bending load to the shear wall. The horizontal displacement in the top beam slab is almost uniform.

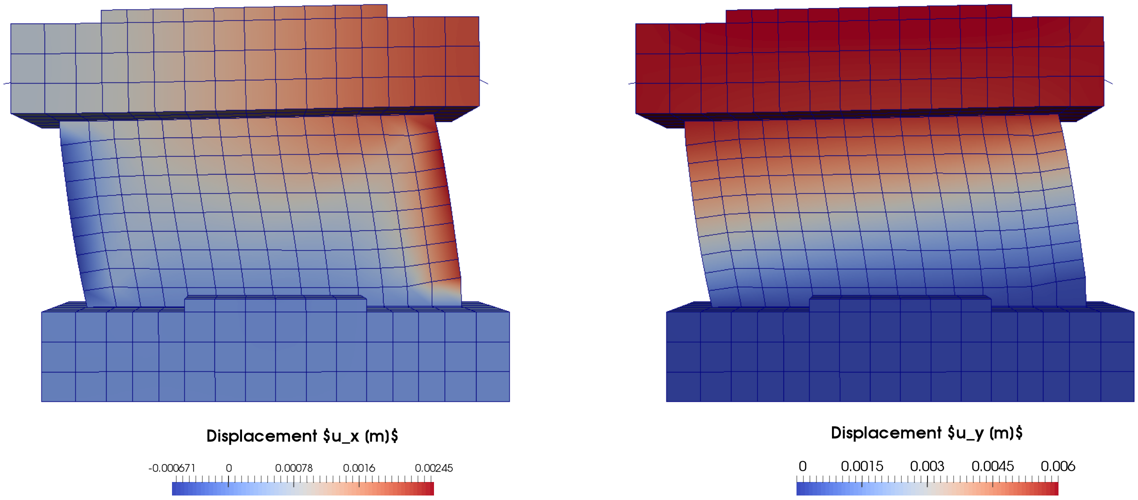

Figure 507.7: Distribution of displacement components in the shear wall model at $u_y = 6$ mm: (a) Vertical displacement u_x; (b) Horizontal displacement u_y.

Figure 507.8 shows the distribution of strain components in the shear wall model at $u_y = 6$ mm. The dominant components of the strains are the vertical normal strain ϵ_{xx} due to the vertical loading, and the shear strain ϵ_{xy} due to the horizontal loading. As can be seen in the distribution of ϵ_{xx}, the maximum tensile strain is much larger than the maximum compressive strain. Tensile strain actually means that there is a crack that opened at the location. This is expected since the compressive strength of concrete is higher than the tensile strength.

A 45^o shear zone can be observed in the shear wall, with significant amounts of tensile and shear strains. In addition, large tensile strains are developing around the top-left and bottom-right corners. As will be shown in the following section, the concrete in these areas is significantly damaged during the test.

Figure 507.9 shows the distribution of stress components in the shear wall model at $u_y = 6$ mm. To

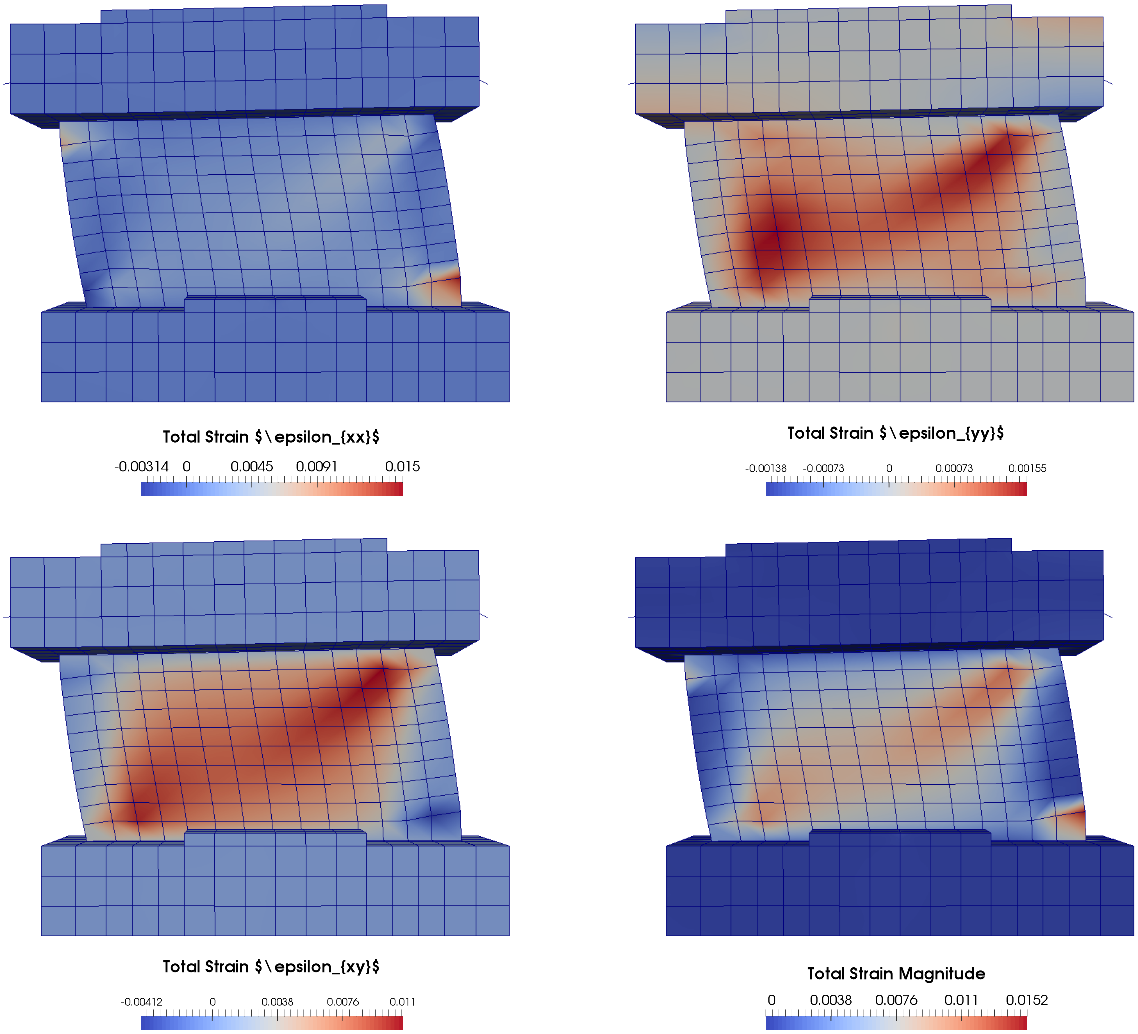

Figure 507.8: Distribution of strain components in the shear wall model at $u_y = 6$ mm: (a) Vertical normal strain ϵ_{xx}; (b) Horizontal normal strain ϵ_{yy}; (c) Shear strain ϵ_{xy}; (d) Strain magnitude $|\epsilon|$.

make the plots more clear, only stresses in the shear wall is plotted. Again, a 45^o shear zone can be observed, that is consistent with the pattern in the strain plots.

Large compressive normal stresses are developed around the top-right and bottom-left corners, while large tensile normal stresses are observed around the top-left and bottom-right corners. The shear stresses at all four corners are significant.

Stress/force and strain/deformation distributions are not enough to directly quantify the level of damage in structures, especially in the case of cyclic loading. In order to analyze damage conditions, the concrete damage index and plastic energy dissipation are calculated and plotted, as shown in the next section.

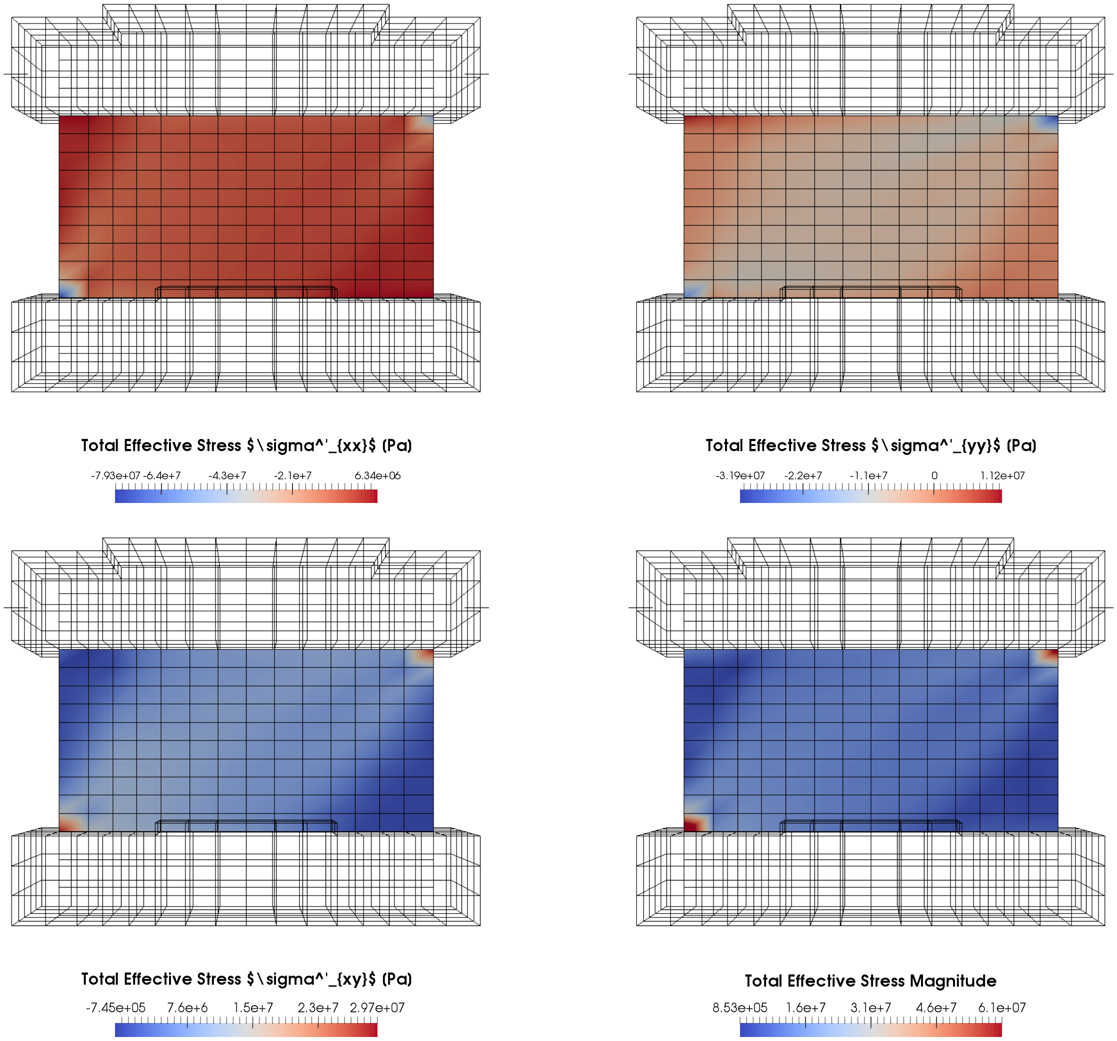

Figure 507.9: Distribution of stress components in the shear wall model at $u_y = 6$ mm: (a) Vertical normal stress σ_{xx}; (b) Horizontal normal stress σ_{yy}; (c) Shear stress σ_{xy}; (d) Stress magnitude $|\sigma|$.

507.2.6.3 Concrete Damage and Energy Dissipation

Figure 507.10 shows the evolution of shear wall concrete damage index d^+, defined in Equation 104.622, at different levels of deformation during cyclic loading. Only tensile damage index is presented in Figure 507.10 as no compressive damage occurs in the wall. It is noted that, according to damage evolution from Figure 507.10, three damage/cracks zones are observed in the wall for load/displacement cycles of $u_y = \pm 1.4$mm. Two 45^o tensile/shear zones with opposite directions as well as a tensile failure zone along the bottom of the wall are developing. Note that the flanges experience damage at the bottom due to tension, which indicates that wall-flange system experiences bending, and not pure shear as intended.

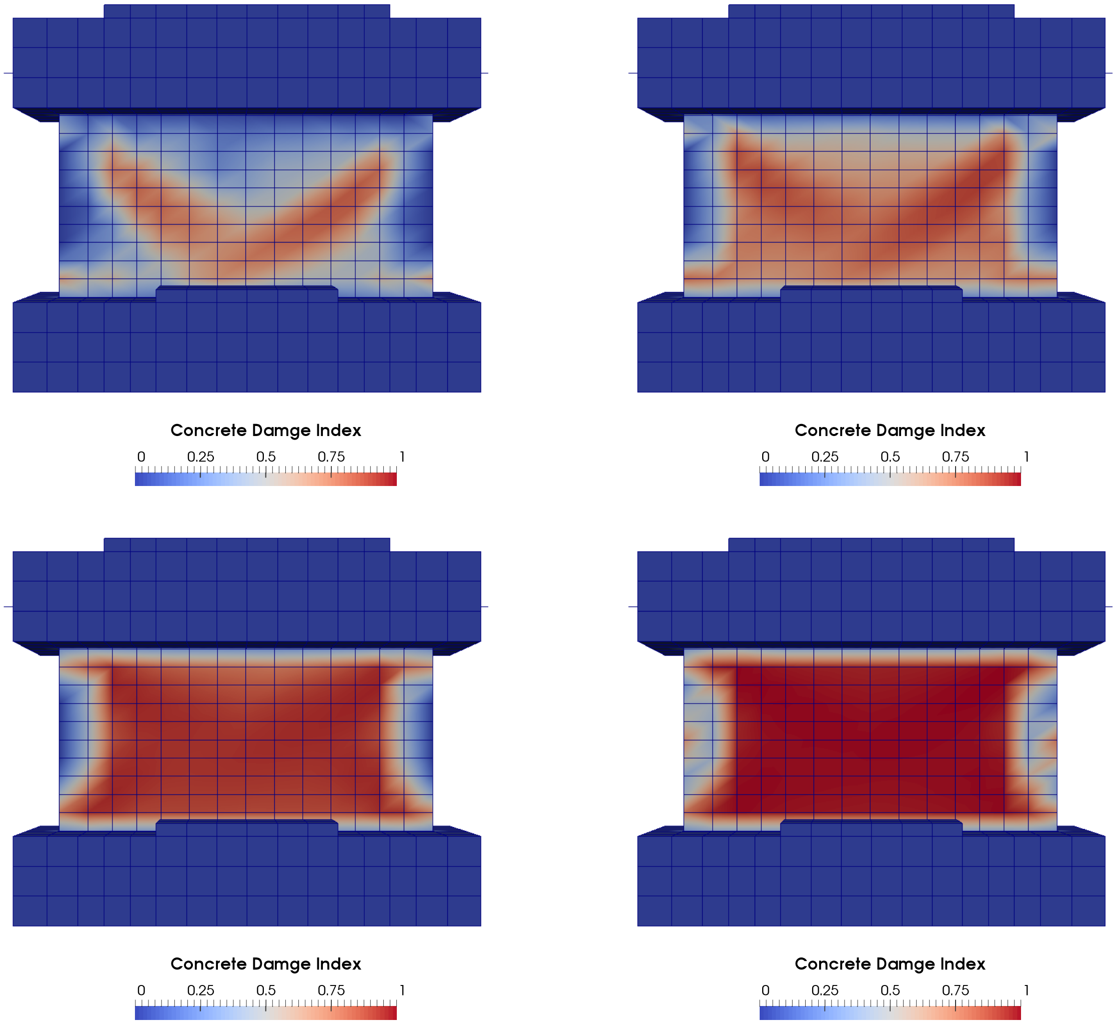

Figure 507.10: Evolution of concrete damage index in the shear wall model for different levels of cyclic loading: (a) At $u_y = \pm 1.4$mm; (b) At $u_y = \pm 1.8$mm; (c) At $u_y = \pm 3.0$mm; (d) At $u_y = \pm 5.0$mm.

As the loading/deformation cycles increase, the damage zones extends and the level of damage increases. At the end, the entire wall is damaged. In reality, due to variability of material properties, some wall regions will experience localization of deformation, as observed in experiments. Modeling of localization of deformation suffers from mesh dependency effects. It is noted that localization of deformation zones, as seen in Figures 507.10 and 507.11 are about the size of single finite element. It is likely that upon mesh refinement these zones would change (Lu et al., 2009), however this type of sensitivity study was not done here due to time constraints. We also note that a more sound approach to modeling localized deformation behavior would be through the use of Cosserat continuum (Cosserat, 1909; de Borst, 1987). Cosserat continuum finite element and micropolar elastic and elastic-plastic models are available within the Real-ESSI Simulator, however calibration of material parameters for those models from current test results is beyond the scope and time frame of this study, and was not done.

Other than damage index, plastic energy dissipation density can also be used to illustrate damage in structures. The main difference between damage index and plastic energy dissipation is that the plastic energy dissipation increases even after an element is completely damaged, that is when $d^+ = 1.0$. [2]

Figure 507.11 shows the evolution of plastic energy dissipation density in the shear wall model at different stages of loading. At the beginning of the test, Figure 507.11(a), the distribution of plastic energy dissipation density is very similar to the distribution of a damage index (d^+). However, as the load cycles progress and displacement increase, Figure 507.11(b), significant amount of energy is dissipated at bottom corners of both flanges. Most of that plastic dissipation happens due to opening of gaps, tensile cracking, and some shear. Plastic dissipation due to tensile cracking can happen only once, as cracks will not "heal", hence there is a redistribution of loads and deformation within flange-wall system. Once flange cannot dissipate any more energy, only wall is left to pick up loads and dissipate energy due to tension and shear. It is noted again that there was no observed development of compression damage, hence there is no plastic dissipation in compressed concrete. Toward the end of simulation, Figure 507.11(c), a failure zone that is X shaped, with distinct 45^o tensile plastic dissipation zones in the wall, and the plastic dissipation zone at the corners, bottom and top of flanges, is observed. At the end of the simulation, Figure 507.11(d), a failure zone due to tension and shear, encompasses flange corners and most of the wall.

Figure 507.12 shows animation of plastic dissipation development in the wall/membrane.

---

[2] Plastic dissipation is also very important for following seismic energy as it propagates through the soil structure system during earthquakes (Sinha et al., 2017; Wang et al., 2017). If seismic energy, and plastic dissipation can be accurately followed and its path even directed, during earthquake soil structure interaction (ESSI), soil structure systems can be optimized for safety and economy.

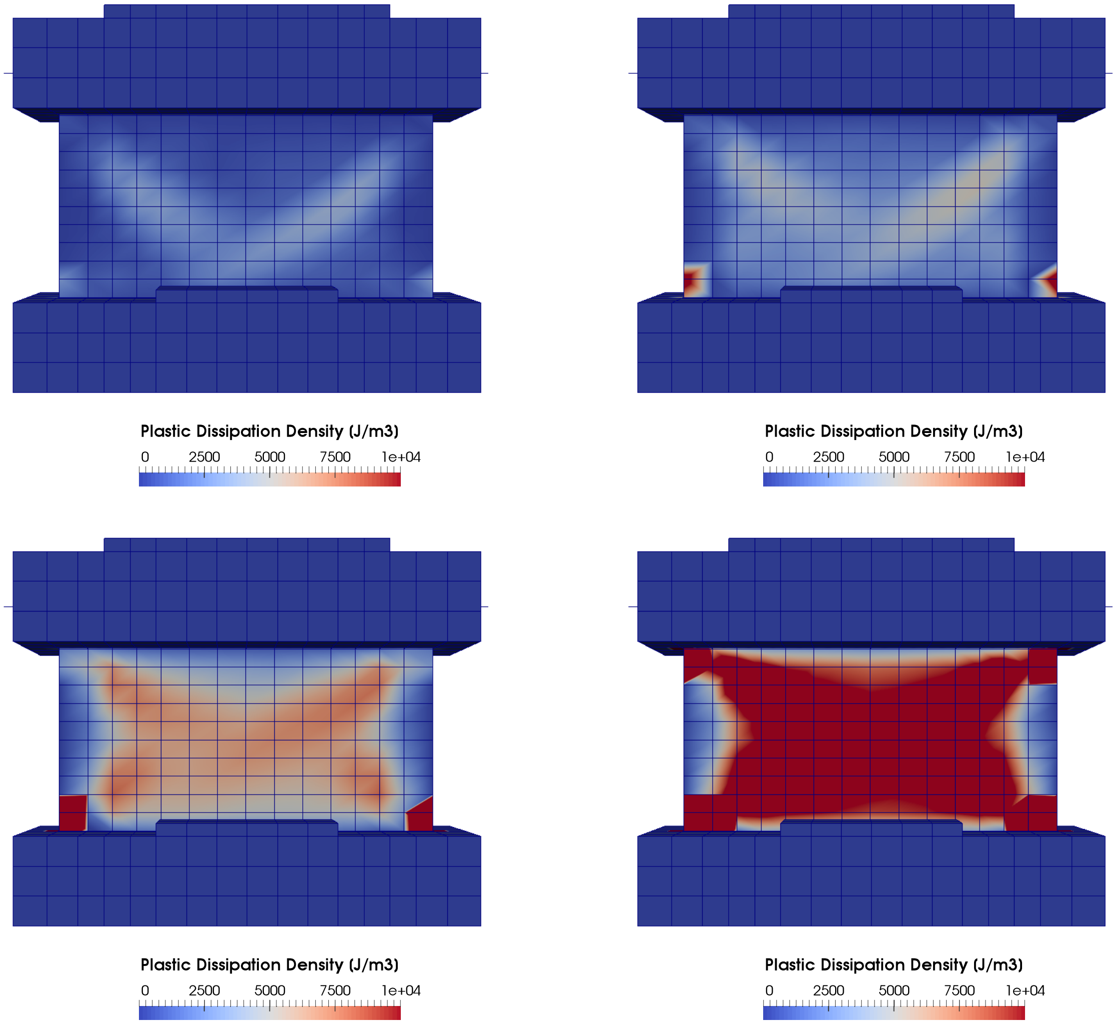

Figure 507.11: Evolution of plastic energy dissipation density in the shear wall model: (a) At $u_y = \pm 1.4\text{mm}$; (b) At $u_y = \pm 1.8\text{mm}$; (c) At $u_y = \pm 3.0\text{mm}$; (d) At $u_y = \pm 5.0\text{mm}$.

NOTE: This model is only 11MB large when compressed. When uncompressed (use `tar -xvf _ASCE-7_tall_concrete_building_Model_.tar.xz`), models files grow to 1.9GB, that is 1,867MB, or 1,911,524Kb, so please be aware of disk space requirements for the model alone.

Chapter 510

Guidebook: Modeling and Simulation of Earthquake-Soil-Structure Interaction for Nuclear Energy Installations, Dams, Buildings, Bridges, Tunnels, &c.

(2016-2017-2018-2019-2020-2021-)

510.1 Motivation: Modeling and Simulation of Earthquake Soil Structure Interaction

Main motivation of this write-up (chapter, guidebook) is to provide a clear, practical, up to date guide on how to perform linear elastic and nonlinear, inelastic Earthquake Soil Structure Interaction (ESSI) modeling and simulations for infrastructure objects, including buildings, dams, bridges, nuclear installations, etc. This is particularly important at this time as a number of endeavors are underway to perform realistic ESSI analysis for a number of important soil, rock – structure systems, including dams, nuclear installations, bridges, buildings, etc.

This write-up is further motivated by the modeling and simulation challenges that are part of any soil, rock – structure system. These challenges are illustrated in Figure 510.1 for a number of soil, rock and soil/rock-structure systems.

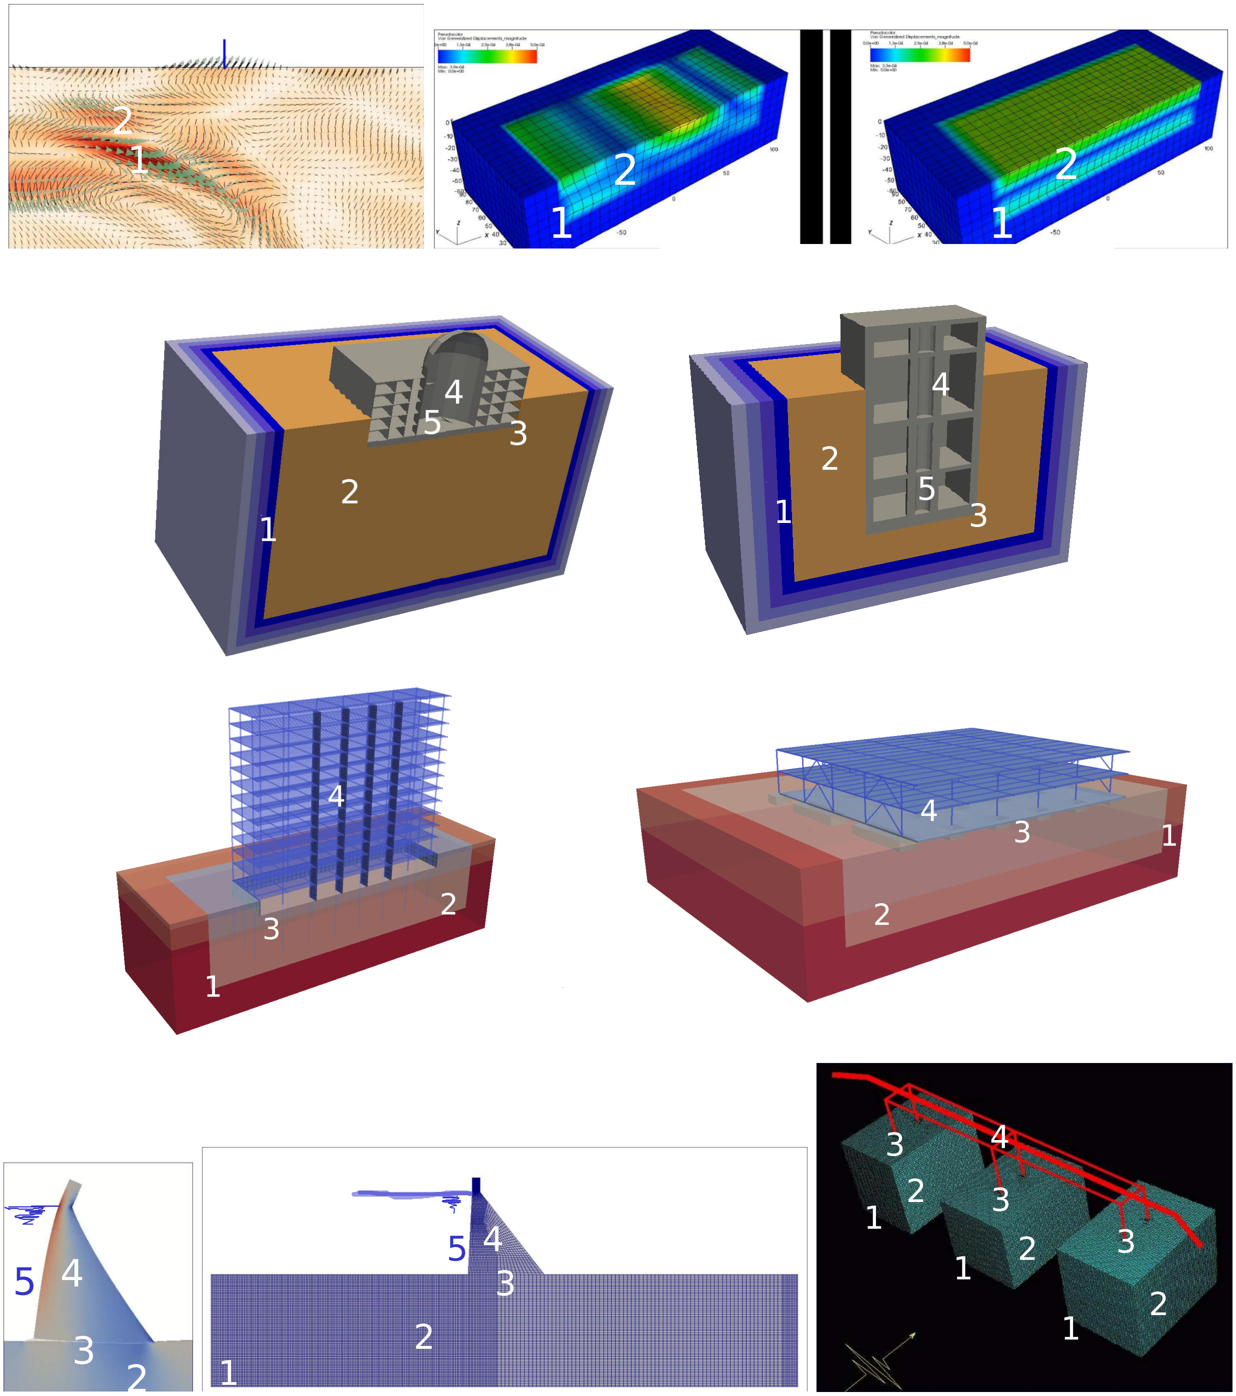

Figure 510.1: ESSI modeling and simulation challenges: Free field motions, 3C/6C vs 3×1C; Nuclear Power Plant structure – soil/rock system, Small Modular Reactor structure – soil/rock system; Low and High Building-foundation-soil system; Dam-Foundation-Fluid system; Bridge-soil system; Aspects of modeling: 1) Seismic motions, 2) Inelastic soil and rock, 3) Inelastic interface/contact/joints, foundation with soil/rock and interfaces/contacts/joints within structure, 4) Inelastic structure, systems and components, 5) Solid, Structure – Fluid interaction, external (reservoirs, fluid pools...) and internal (fully saturated and partially, (un-)saturated soil, rock and concrete).

Challenges for Modeling of Mechanics of Earthquake – Soil/Rock – Structure – Interaction. Presented are challenges related to the modeling of mechanics of ESSI problems.

1 Seismic motions: use of 1C, 3×1C and 3C motions, seismic motions input and radiation damping.

2 Inelastic, elastic plastic modeling of soil and rock, dry and/or partially or fully saturated, and energy dissipation in those soil/rock – structure components,

3 Inelastic, elastic plastic modeling of foundation concrete – soil/rock contacts/interfaces/joints that may be dry and/or partially or fully saturated, and energy dissipation in those parts of soil/rock – structure system,

4 Inelastic, elastic damage plastic modeling of structure, systems and components (SSCs). SSCs: beams, walls, plates, shell made of steel and reinforced concrete, base isolators and dissipators, systems and etc. and energy dissipation in those soil/rock – structure components,

5 Interaction of soil/rock – structure systems with internal, within structure or in pores of porous materials (soil, rock, concrete) and external fluids, reservoirs, pools, etc.

Challenges for Numerical Simulations of Earthquake – Soil/Rock – Structure – Interaction. Presented are challenges related to the numerical simulation of ESSI problems.

A Inelastic simulations on constitutive level, stress-strain, constitutive problem solutions

B Inelastic simulations on finite element level, nonlinear system of equations solutions

C Time marching algorithms, numerical damping

D High performance, parallel computing

510.2 Introduction

Focus is on modeling and simulation of linear elastic and nonlinear, inelastic, elastic-plastic behavior of soil/rock – structure systems during earthquakes.

It is assumed that earthquake motions, earthquake field is known. Earthquake motion or earthquake field, can be given as a simple 1C (1 Component) vertically propagating shear wave, that is obtained from a de-convolution of a given (1C) surface motion, using, for example SHAKE type analysis. Earthquake motion or earthquake field can also be given as a full 3C (3 Component) wave field that is obtained from analytic wave propagation solutions or from a regional geophysical model simulations, using, for example SW4 type analysis. In addition, earthquake motions can be defined in a probabilistic way...

510.3 Seismic Energy Input and Dissipation

Recorded lectures, together with slides, about these topics are available at
`http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/OnlineLectures`

More details about these topics are given in Section 109.2, on page 547 in Jeremić et al. (1989-2025).

510.3.1 Seismic Energy Input

Seismic energy input flux

510.3.2 Seismic Energy Dissipation

510.3.2.1 Seismic Energy Dissipation, Wave Reflection and Wave Radiation

Wave reflection and radiation damping

510.3.2.2 Seismic Energy Dissipation, Viscous Coupling

velocity proportional, viscous damping

510.3.2.3 Seismic Energy Dissipation, Material Inelasticity

Elastic-plastic energy dissipation of material, Displacement proportional

510.3.2.4 Seismic Energy Dissipation, Numerical, Algorithmic Positive and Negative Damping

510.4 Modeling: Seismic Motions

Recorded lectures, together with slides, about these topics are available at

`http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/OnlineLectures`

More details about these topics are given in Section 502.2, on page 2260 in Jeremić et al. (1989-2025).

510.4.1 Seismic Motions: Available Data

Details are given in Section 502.2.1, on page 2262 in Jeremić et al. (1989-2025).

510.4.2 Seismic Motion Development

Details are given in Section 502.2.3, on page 2266 in Jeremić et al. (1989-2025).

510.4.2.1 Seismic Motions from Empirical Models

Details are given in Section 109.2.3, on page 553 in Jeremić et al. (1989-2025).

510.4.2.2 Seismic Motions from Geophysical Models

Details are given in Section 109.2.6, on page 561 in Jeremić et al. (1989-2025).

Small Scale Geophysical Models.

Large Scale Regional Geophysical Models

510.4.2.3 Seismic Motions from 3D/3C Analytic Models

Details are given in Section 109.2.5, on page 557 in Jeremić et al. (1989-2025).

510.4.2.4 Seismic Motions from Full Waveform Inversion

This is based on recent work by Guidio (2020); Guidio et al. (2022b); Guidio and Jeong (2021); Guidio et al. (2022a).

510.4.3 6C vs 3C vs 3×1C vs 1C Seismic Motions

Details are given in Section 504.4.1, on page 2504 in Jeremić et al. (1989-2025).

510.4.4 Incoherent Seismic Motions

Details are given in Section 109.2.8, on page 562 in Jeremić et al. (1989-2025).

510.4.5 Seismic Motion Input into FEM Models

Details are given in Section 109.4.1, on page 568 in Jeremić et al. (1989-2025).

510.5 Modeling: Inelastic, Nonlinear Material Modeling for Solids and Structures

Recorded lectures, together with slides, about these topics are available at
`http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/OnlineLectures`

510.5.1 Inelastic Material Modeling of Rock

Details are given in Section 104.8, on page 329 in Jeremić et al. (1989-2025).

510.5.1.1 Calibration of Inelastic Material Model Parameters for Rock

Details are given in Section 104.10, on page 368 in Jeremić et al. (1989-2025).

510.5.2 Inelastic Material Modeling of Soil

510.5.2.1 Dry Soil

Details are given in Section 104.6, on page 220 in Jeremić et al. (1989-2025).

510.5.2.2 Fully Saturated Soil

Details are given in Section 102.12, on page 137 in Jeremić et al. (1989-2025).

510.5.2.3 Partially Saturated, Unsaturated Soil

Details are given in Section 102.12.2, on page 152 in Jeremić et al. (1989-2025).

510.5.2.4 Calibration of Inelastic Material Model Parameters for Soil

Details are given in Section 104.10, on page 368 in Jeremić et al. (1989-2025).

510.5.3 Inelastic Material Modeling of Steel

Details are given in Section 104.9, on page 363 in Jeremić et al. (1989-2025).

510.5.3.1 Calibration of Inelastic Material Model Parameters for Steel

Details are given in Section 104.10, on page 368 in Jeremić et al. (1989-2025).

510.5.4 Inelastic Material Modeling of Concrete

Solids, Beams, Plates, Walls and Shells

Details are given in Section 104.9, on page 363 in Jeremić et al. (1989-2025).

510.5.4.1 Calibration of Inelastic Material Model Parameters for Concrete

Details are given in Section 104.10, on page 368 in Jeremić et al. (1989-2025).

510.6 Modeling: Inelastic, Nonlinear Material Modeling for Contacts, Interfaces, and Joints

Recorded lectures, together with slides, about these topics are available at
`http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/OnlineLectures`

510.6.1 Material Modeling of Dry Contacts, Interfaces, and Joints (Concrete, Steel – Soil, Rock)

Details are given in Section 104.7, on page 306 in Jeremić et al. (1989-2025).

510.6.1.1 Calibration of Inelastic Material Model Parameters for Dry Contacts, Interfaces, and Joints (Concrete, Steel – Soil, Rock)

510.6.2 Material Modeling of Saturated Contacts, Interfaces, and Joints (Concrete, Steel – Soil, Rock)

Details are given in Section 104.7, on page 306 in Jeremić et al. (1989-2025).

510.6.2.1 Calibration of Inelastic Material Model Parameters for Saturated Contacts, Interfaces, and Joints (Concrete, Steel – Soil, Rock)

510.7 Modeling: Buoyancy

Details are given in Section 502.3.7, on page 2349 in Jeremić et al. (1989-2025).

510.8 Modeling: Base Isolator and Base Dissipator Systems

510.8.1 Base Isolator Systems

Details are given in Section 102.11, on page 136, in Jeremić et al. (1989-2025).

510.8.1.1 Calibration of Elastic/Inelastic Material Model Parameters for Base Isolator Systems

510.8.2 Base Dissipator Systems

Details are given in Section 102.11, on page 136, in Jeremić et al. (1989-2025).

510.8.2.1 Calibration of Elastic/Inelastic Material Model Parameters for Base Dissipator Systems

510.9 Modelling: Finite Element System

510.9.1 Mass Matrix

Details are given in Section 102.4, on page 114, Section 102.6, on page 126, Section 102.7, on page 126, Section 102.8, on page 129, Section 102.9, on page 135, Section 102.10, on page 135, Section 102.11, on page 136, and Section 102.12, on page 137, in Jeremić et al. (1989-2025).

510.9.1.1 Consistent Mass Matrix

510.9.1.2 Lumped Mass Matrix

510.9.2 Viscous Damping Matrix

Details are given in Section 108.4, on page 540, in Jeremić et al. (1989-2025).

510.9.2.1 Rayleigh Damping

510.9.2.2 Caughey Damping

510.9.3 Stiffness Matrix

Details are given in Section 102.4, on page 114, Section 102.6, on page 126, Section 102.7, on page 126, Section 102.8, on page 129, Section 102.9, on page 135, Section 102.10, on page 135, Section 102.11, on page 136, and Section 102.12, on page 137, in Jeremić et al. (1989-2025).

510.9.3.1 Tangent Stiffness Matrix

510.9.3.2 Consistent Stiffness Matrix

510.10 Modeling: Solid, Structure – Fluid Interaction Modeling

Details of OpenFOAM – Real-ESSI Simulator coupling are available starting with Section 111.2, on page 685, in Jeremić et al. (1989-2025).

510.11 Simulation: Nonlinear Finite Elements

Details are given in Section 102.2, on page 100 in Jeremić et al. (1989-2025).

510.11.1 Time Marching Algorithms for Solution of Nonlinear Equations of Motion

Details are given in Section 108.3, on page 538 in Jeremić et al. (1989-2025).

510.11.1.1 Newmark Algorithm

Details are given in Section 108.3.1, on page 538 in Jeremić et al. (1989-2025).

510.11.1.2 Hilber Hughes Taylor α Algorithm

Details are given in Section 108.3.2, on page 539 in Jeremić et al. (1989-2025).

510.11.2 Solution of Elastic-Plastic Constitutive Equations

Details are given in Section 104.2.2, on page 182 in Jeremić et al. (1989-2025).

510.11.2.1 Explicit Integration of Elastic-Plastic Constitutive Equations

Details are given in Section 104.3, on page 206 in Jeremić et al. (1989-2025).

Error accumulation.

510.11.2.2 Implicit Integration of Elastic-Plastic Constitutive Equations

Details are given in Section 104.4, on page 207 in Jeremić et al. (1989-2025).

Iterations and tolerance issues.

510.12 Modelling Guide for ESSI

Recorded lectures, together with slides, about these topics are available at

`http://sokocalo.engr.ucdavis.edu/~jeremic/Real_ESSI_Simulator/OnlineLectures`

More details about these topics are given in Section 502.3, on page 2332 in Jeremić et al. (1989-2025).

510.12.1 Buildings and NPPs on Shallow Foundations, Models

Details are given in Section 504.6, on page 2514 in Jeremić et al. (1989-2025).

510.12.2 Buildings and NPPs on Deeply Embedded Foundation (SMRs), Models

Details are given in Section 504.7, on page 2528 in Jeremić et al. (1989-2025).

510.12.3 Buildings and NPPs on Piles and Pile Group Foundations, Models

Details are given in Section 504.6, on page 2514 in Jeremić et al. (1989-2025).

Chapter 511

ASCE-4, Chapter on Nonlinear ESSI analysis

(2016-2020-2021-)

511.1 Motivation: Modeling and Simulation of Earthquake Soil Structure Interaction

Main motivation of this write-up, chapter is to provide a clear, practical, up to date guide on how to perform nonlinear, inelastic Earthquake Soil Structure Interaction (ESSI) modeling and simulations for nuclear installations. This is particularly important at this time as a number of endeavors are underway to perform realistic ESSI analysis for a number of nuclear installations.

This write-up is further motivated by the modeling and simulation challenges that are part of any soil, rock – structure system. These challenges are illustrated in Figure 511.1 for a number of soil, rock and soil/rock-structure systems.

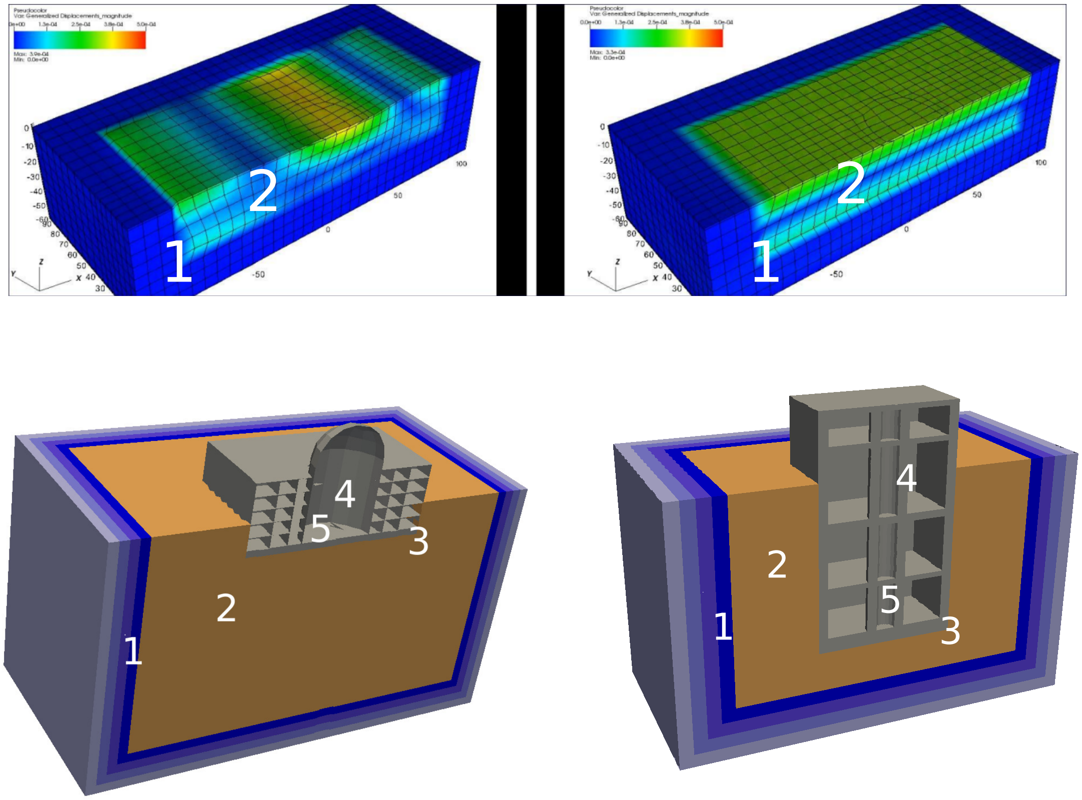

Figure 511.1: ESSI modeling and simulation challenges: Free field motions, 3C vs 3×1C; Nuclear Power Plant structure – soil/rock system, Small Modular Reactor structure – soil/rock system. Aspects of modeling: 1) Seismic motions, 2) Inelastic soil and rock, 3) Inelastic interface/contact/joints, foundation with soil/rock and interfaces/contacts/joints within structure, 4) Inelastic structure, systems and components, 5) Interaction with external (reservoirs, fluid pools...) and internal (saturated and un-saturated soil/rock and concrete.

Challenges for Modeling of Mechanics of Earthquake – Soil/Rock – Structure – Interaction. Presented are challenges related to the modeling of mechanics of ESSI problems.

1 Seismic motions: use of 1C, 3×1C and 3C motions, seismic motions input and radiation damping.

2 Inelastic, elastic plastic modeling of soil and rock, dry and/or partially or fully saturated, and energy dissipation in those soil/rock – structure components,

3 Inelastic, elastic plastic modeling of foundation concrete – soil/rock contacts/interfaces/joints that may be dry and/or partially or fully saturated, and energy dissipation in those parts of soil/rock – structure system,

4 Inelastic, elastic damage plastic modeling of structure, systems and components (SSCs). SSCs: beams, walls, plates, shell made of steel and reinforced concrete, base isolators and dissipators, systems and etc. and energy dissipation in those soil/rock – structure components,

5 Interaction of soil/rock – structure systems with internal, within structure or in pores of porous materials (soil, rock, concrete) and external fluids, reservoirs, pools, etc.

Challenges for Numerical Simulations of Earthquake – Soil/Rock – Structure – Interaction. Presented are challenges related to the numerical simulation of ESSI problems.

A Inelastic simulations on constitutive level, stress-strain, constitutive problem solutions

B Inelastic simulations on finite element level, nonlinear system of equations solutions

C Time marching algorithms, numerical damping

D High performance, parallel computing

511.2 Introduction

Focus is on modeling and simulation of linear elastic and nonlinear, inelastic, elastic-plastic behavior of soil/rock – structure systems during earthquakes.

It is assumed that earthquake motions, earthquake field is known. Earthquake motion or earthquake field, can be given as a simple 1C (1 Component) vertically propagating shear wave, that is obtained from a de-convolution of a given (1C) surface motion, using, for example SHAKE type analysis. Earthquake motion or earthquake field can also be given as a full 3C (3 Component) wave field that is obtained from analytic wave propagation solutions or from a regional geophysical model simulations, using, for example SW4 type analysis. In addition, earthquake motions can be defined in a probabilistic way...

Chapter 512

Earthquake-Soil-Structure Interaction, Core Functionality

(2017-2018-2019-2021-)

(In collaboration with Dr. Yuan Feng, Prof. Han Yang and Dr. Hexiang Wang)

512.1 Core Functionality for ESSI Analysis of Nuclear Installations

Presented here are models that represent core functionality for elastic and inelastic analysis of infrastructure objects, including nuclear installations. There exist a number of other models, with different sophistication levels, that can be used, depending on the amount of data available, about the soil, rock, concrete, contacts/interfaces and seismic motions (Jeremić et al., 1989-2025). However, in order to begin to use of inelastic/nonlinear analysis, and assess inelastic/nonlinear effects on a dynamic response of soil structure systems, a set of initial models and analysis parameters are needed. Provided below is a set of models and materials parameters that are recommended for initial use of inelastic/nonlinear analysis of soil structure systems, using the Real-ESSI Simulator system. (`http://real-essi.info/`). It is noted that a detailed description of examples, commands and the Real-ESSI Simulator system is provided by Jeremić et al. (1989-2025, 1988-2025) and is also available at the Real-ESSI Simulator web site `http://real-essi.info/`. In addition, preprocessing, model development and postprocessing, results visualization for the Real-ESSI Simulator system is also described in detail pre and post processing documents that are available at `http://real-essi.info/`.

512.2 Model Setup

Each model has to be named:

```
model name "model_name_string";
```

In addition to that, there are a number of other considerations to be aware of:

- Each command line has to end with a semicolon ";"
- Comment on a line begins with either "//" or "!" and last until the end of current line.
- Units are required (see more below) for all quantities and variables.
- Include statements allow splitting source into several files
- All variables are double precision (i.e. floats) with a unit attached.
- All standard arithmetic operations are implemented, and are unit sensitive.
- Internally, all units are represented in the base SI units (m - s - kg).
- The syntax ignores extra white spaces, tabulations and newlines. Wherever they appear, they are there for code readability only. (This is why all commands need to end with a semicolon).

512.3 Linear Elastic Modeling

for single stage linear elastic modeling, one stage of loading has to be defined

```
new loading stage "self weight loading stage";
```

512.4 Nonlinear/Inelastic Modeling

For inelastic modeling, stages of loading have to be defined in proper sequence.

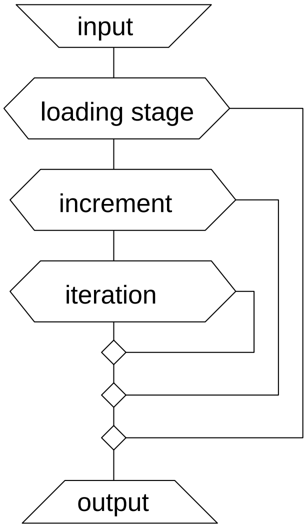

Figure 512.1:

```
new loading stage "self weight loading stage";
```

. . .

```
new loading stage "Seismic Loading";
```

. . .

512.5 Model Domain

Finite element model is developed by defining the finite element mesh which is made of nodes, finite elements, the material, and the loads.

512.5.1 Nodes

For example:

```
add node No 1 at (1.0*m, 2.5*m, 3.33*m) with 3 dofs;
```

adds a node number 1 at coordinates $x = 1.0m$, $y = 2.5m$ and $z = 3.33m$ with 3 dofs. The nodes can be of 3dofs $[u_x, u_y, u_z]$, 4dofs $[]u_x, u_y, u_z, p]$ (u-p elements) , 6dofs $[u_x, u_y, u_z, r_x, r_y, r_z]$ (beams and shells) and 7 dofs $[u_x, u_y, u_z, p, U_x, U_y, U_z]$ (upU element) types.

512.5.2 Boundary Conditions

Example fix translation x and y for node #3 `fix node # 3 dofs ux uy;`

Example fix all appropriate DOFs for node #7. `fix node # 7 dofs all;`

512.5.3 Static Acceleration Field

Example adding acceleration induced loading field for (some) elements

```
add acceleration field # 1
ax = 0*m/s^2
ay = 0*m/s^2
az = -9.81*m/s^2;
```

512.5.4 Dynamic Acceleration Field, Earthquake

One Example of add DRM load from wave fields:

```
add load # 1 type DRM from wave field
  # 1 in direction ux
  # 2 in direction uy
  soil_surface at z = 60.0*m
  hdf5_file = "input.hdf5" ;
```

512.5.5 Super Element

Super element is defined by providing mass and stiffness matrix, together with nodes and DOF numbering. It is assumed that the Super Element is a linear elastic element that is made up of a number of other finite elements. Super Element represents a part of model (structure, solid) that is linear elastic, and that has stiffness and mass matrix already defined using other finite element programs. Other finite element programs export stiffness and mass matrix. In addition, information about Super Element node numbers and degrees of freedom (DOFs) needs to be supplied as well.

512.6 Structural Modeling

Presented in this section are models that are used for modeling and simulation of structural behavior. Following the usually made assumption that structural components will remain linear elastic, only linear elastic material is used for structural modeling. It is noted, that fully nonlinear (inelastic, elastic-damage-plastic) models are also available for modeling of structural components (Jeremić et al., 1989-2025, 1988-2025). However, for the purpose of presenting core functionality features, those models are not covered here.

It is noted that a complete structural model can be replaced with one linear elastic super element, as described in section 512.5.5 on page 2769.

512.6.1 Truss

Truss element represents a 3D two node linear geometry truss member. Real-ESSI command for truss element is given in detail in section ??.

```
add element # 1 type truss
  with nodes (1,2)
  use material # 1
  cross_section = 1*m^2
  mass_density = 2000*kg/m^3;
```

512.6.2 Beam

Beam finite element represents a 3D linear geometry, two node Bernoulli beam member, with 6 DOFs per node. Real-ESSI command for beam element is given in detail in section ??.

```
add element # 1 type beam_elastic
    with nodes (1, 2)
    cross_section = 1*m^2
    elastic_modulus = 2e8*Pa
    shear_modulus = 1e8*Pa
    torsion_Jx = 0.33*m^4
    bending_Iy = 1.0/12*m^4
    bending_Iz = 1.0/12*m^4
    mass_density = 2000*kg/m^3
    xz_plane_vector = (1, 0, 1 )
    joint_1_offset = (0*m, 0*m, 0*m )
    joint_2_offset = (0*m, 0*m, 0*m );
```

512.6.3 Shell

Shell finite element represents a 3D linear elastic geometry, 4 node ANDES shell member with 6DOFs per node, including drilling DOFs (in plane twist). Real-ESSI command for shell element is given in detail in section ??.

```
add element # 1 type 4NodeShell_ANDES
   with nodes (1,2,3,4)
   use material # 1
   thickness = 1*m ;
```

512.7 Solid Modeling

Presented in this section are models that are used for modeling and simulation of soils, using solid and contact/interface elements for interface of foundations and soil. Models for soil can be linear elastic, while they can also be nonlinear/inelastic, mimicking simple G/G_{max} behavior. Models for contact/interface can represent bonded contact, where no slip or gapping is allowed, and also a frictional slip and gapping contact/interface.

It is noted, that a number of more or less sophisticated material models for soil and for contact/interface are also available (Jeremić et al., 1989-2025, 1988-2025). However, for the purpose of presenting core functionality features, those models are not covered here.

512.7.1 Solid Brick

Solid brick finite element with 8 nodes, linear interpolation of displacements between nodes, and three DOFs per node is available. This element is very good for modeling soil volume close to and far away from the structural. Real-ESSI command for 8 node solid brick is given in detail in section ??.

```
add element # 1 type 8NodeBrick
   using 2 Gauss points each direction
   with nodes (1, 2, 3, 4, 5, 6, 7, 8)
   use material # 1;
```

512.7.2 Contact, Interfaces, Joints

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
   with nodes (1, 2)
   initial_axial_stiffness = 5*MPa
   stiffening_rate = 100
   max_axial_stiffness = 800*MPa
```

```
    initial_shear_stiffness = 800*kPa
    axial_viscous_damping = 50*Pa*s
    shear_viscous_damping = 50*Pa*s
    residual_friction_coefficient = 0.68
    shear_zone_thickness = 5e-3*m
    contact_plane_vector = (0, 0, 1 );
```

512.8 Core Material Modeling Parameters for Soil, Rock, Concrete, and Steel

512.8.1 Linear and Nonlinear Elastic Soil, Rock, Concrete, and Steel Modeling

512.8.2 Inelastic/Nonlinear Soil Modeling

Simple modeling of soil can be done using the so called stiffness degradation curves, or G/G_{max} curves, and damping curves, as developed by Seed and Idriss (1970a).

As an example, an elastic plastic material model based on von Mises yield surface with isotropic hardening or softening and Armstrong Frederick nonlinear kinematic hardening can be used to develop such curves. Model parameters are given below:

```
add material # 1 type vonMisesArmstrongFrederick
    mass_density = 2500*kg/m^3
    elastic_modulus = 30 * MPa
    poisson_ratio = 0.3
    von_mises_radius = 300 * Pa
    armstrong_frederick_ha = 150 * MPa
    armstrong_frederick_cr = 25000
    isotropic_hardening_rate = 0*Pa;
```

while the corresponding G/G_{max} and damping curves are given in Figure 512.2.

It is noted that von Mises Armstrong-Frederick Nonlinear Kinematic Hardening material model is a full 3D elastic plastilc material model, that is capable of modeling G/G_{max} and damping behavior, defined in 1D shear testing, fairly well in full 3D.

The command is

```
add material # <.> type vonMisesArmstrongFrederick
    mass_density = <M/L^3>
    elastic_modulus = <F/L^2>
    poisson_ratio = <.>
    von_mises_radius = <.>
    armstrong_frederick_ha = <F/L^2>
    armstrong_frederick_cr = <.>
    isotropic_hardening_rate = <F/L^2> ;
```

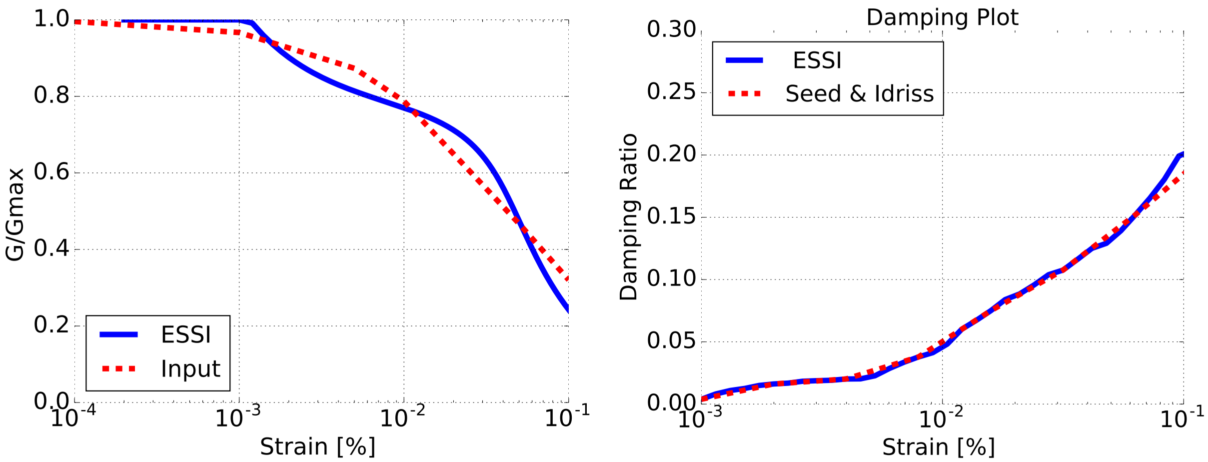

Figure 512.2: Stiffness degradation (G/G_{max}) and damping curves developed using von Mises Armstrong-Frederick Nonlinear Kinematic Hardening material model.

512.8.3 Inelastic/Nonlinear Rock Modeling

512.8.4 Inelastic/Nonlinear Concrete Modeling

512.8.5 Inelastic/Nonlinear Steel Modeling

512.9 Core Material Modeling Parameters for Contacts, Interfaces and Joints

The command for stress based dry soft nonlinear hardening is:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
   with nodes (1, 2)
   initial_axial_stiffness = 5*MPa
   stiffening_rate = 100
   max_axial_stiffness = 800*MPa
   initial_shear_stiffness = 800*kPa
   axial_viscous_damping = 50*Pa*s
   shear_viscous_damping = 50*Pa*s
   residual_friction_coefficient = 0.68
   shear_zone_thickness = 5e-3*m
   contact_plane_vector = (0, 0, 1 );
```

512.9.1 Mass Concrete Against Silt, Sand, Gravel and Clay

A set of initial recommended material parameters for frictional contact/interface are given in Tables 512.1 for contact between mass concrete and sand/gravel. Frictional properties given below are recommended by NAVFAC (1986).

Table 512.1: Friction coefficients for contact/interface of dissimilar materials, mass concrete against soil.

Mass concrete on soil	Friction coefficient ($\tan\phi$)	Friction angle (ϕ)
Clean sound rock	0.70	35^o
Clean gravel, gravel sand mixture, coarse sand	$0.55 – 0.60$	$29^o – 31^o$
Clean fine to medium sand, silty medium to coarse sand	$0.45 – 0.55$	$24^o – 29^o$
Fine sandy silt, nonplastic silt	$0.35 – 0.45$	$19^o – 24^o$
Very stiff clay	$0.40 – 0.50$	$22^o – 27^o$

Example command for a contact/interface element for mass concrete against clean sand, silty sand-gravel mix, single size rock fill (friction coefficient 0.30) is given below:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
   with nodes ( 1, 2)
   initial_axial_stiffness = 10 * MPa
   stiffening_rate = 100
   max_axial_stiffness = 50 * MPa
   initial_shear_stiffness = 40 * kPa
   axial_viscous_damping = 100 * Pa * s
   shear_viscous_damping = 100 * Pa * s
   residual_friction_coefficient = 0.30
   shear_zone_thickness = 5e-3*m
```

```
    contact_plane_vector = (0, 0, 1);
```

Another example, for contact/interface element for mass concrete against clean gravel, gravel sand mixture, coarse sand (friction coefficient 0.55-0.60) is given below:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
    with nodes ( 1, 2)
    initial_axial_stiffness = 20 * MPa
    stiffening_rate = 100
    max_axial_stiffness = 100 * MPa
    initial_shear_stiffness = 80 * kPa
    axial_viscous_damping = 200 * Pa * s
    shear_viscous_damping = 200 * Pa * s
    residual_friction_coefficient = 0.55
    shear_zone_tkness = 1e-2*m
    contact_plane_vector = (0, 0, 1);
```

512.9.2 Steel Sheet Against Sand, Gravel and Rockfill

Recommended material parameters for frictional contact/interface of steel sheets against sand and gravel are given in Tables 512.2. Frictional properties given below are recommended by NAVFAC (1986).

Table 512.2: Friction coefficients for contact/interface of dissimilar materials, steel sheet piles against soil.

Steel sheets against soil	Friction coefficient ($\tan\phi$)	Friction angle (ϕ)
Clean gravel, sand-gravel mix, well graded rock fill	0.40	22^o
Clean sand, silty sand-gravel mix, single size rock fill	0.30	17^o
Fine sandy silt, nonplastic silt	0.20	11^o

Example commands for contact/interface element for steel sheets against clean sand, silty sand-gravel mix, single size rock fill (friction coefficient 0.30) is given below:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
    with nodes ( 1, 2)
    initial_axial_stiffness = 1000 * MPa
    stiffening_rate = 100
    max_axial_stiffness = 5 * GPa
    initial_shear_stiffness = 4 * MPa
    axial_viscous_damping = 100 * Pa * s
    shear_viscous_damping = 100 * Pa * s
    residual_friction_coefficient = 0.30
```

```
   shear_zone_thickness = 5e-3*m
   contact_plane_vector = (0, 0, 1);
```

and for steel sheets against clean gravel, sand-gravel mix, well graded rock fill, with friction coefficient 0.40, command is:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
   with nodes ( 1, 2)
   initial_axial_stiffness = 2000 * MPa
   stiffening_rate = 100
   max_axial_stiffness = 10 * GPa
   initial_shear_stiffness = 8 * MPa
   axial_viscous_damping = 100 * Pa * s
   shear_viscous_damping = 100 * Pa * s
   residual_friction_coefficient = 0.40
   shear_zone_thickness = 5e-3*m
   contact_plane_vector = (0, 0, 1);
```

512.9.3 Formed Concrete Against Sand, Gravel and Rockfill

Recommended material parameters for frictional contact/interface of formed concrete against sand and gravel are given in Tables 512.3. Frictional properties given below are recommended by NAVFAC (1986).

Table 512.3: Friction coefficients for contact/interface of dissimilar materials, formed concrete against soil.

Formed concrete against soil	Friction coefficient ($\tan\phi$)	Friction angle (ϕ)
Clean gravel, sand-gravel mix, well graded rock fill	$0.40 - 0.50$	$22^o - 27^o$
Clean sand, silty sand-gravel mix, single size rock fill	$0.30 - 0.40$	$17^o - 22^o$
Silty sand, gravel or sand mixed with silt and clay	0.30	17^o
Fine sandy silt, nonplastic silt	0.25	14^o

Example command for contact/interface element for formed concrete against clean gravel, sand-gravel mix, well graded rock fill (friction coefficient 0.40-0.50) is given below:

```
add element # 1 type StressBasedSoftContact_NonLinHardShear
   with nodes ( 1, 2)
   initial_axial_stiffness = 30 * MPa
   stiffening_rate = 100
   max_axial_stiffness = 150 * MPa
   initial_shear_stiffness = 120 * kPa
   axial_viscous_damping = 100 * Pa * s
```

```
    shear_viscous_damping = 100 * Pa * s
    residual_friction_coefficient = 0.40
    shear_zone_thickness = 5e-3*m
    contact_plane_vector = (0, 0, 1);
```

512.9.4 Rock or Concrete on Rock or Concrete

More recently, Lei and Barton (2022) presented a very nice set of experiments with data for proper choice of interface parameters for rock on rock interface, that can also be used for concrete as well.

512.10 Earthquake Motion Modeling

512.10.1 One Component (1C) Seismic Motions Defined at Surface or at Depth

DRM...

One can add DRM loading directly, where `input.hdf5` specifies the DRM motions to all DRM nodes.

```
add load # 1 type DRM
    hdf5_file = "input.hdf5"
    scale_factor = 1.0 ;
```

Since the direct specification of DRM motions to all DRM nodes is complicated, alternatively, user is able to specify DRM motion using a surface motion. Internally, wave deconvolution is conducted to specify the DRM motions to all DRM nodes.

```
add wave field # 1 with
    acceleration_filename = "acceleration.txt"
    unit_of_acceleration = 1 * m/s^2
    displacement_filename = "displacement.txt"
    unit_of_displacement = 1 * m
    add_compensation_time = 0.0 * s
    motion_depth = 0 * m
    monitoring_location = within_soil_layer
    soil_profile_filename = "soil_profile.txt"
    unit_of_Vs = 1 * m/s
    unit_of_rho = 1 * kg/m^3
    unit_of_damping = absolute
    unit_of_thickness = 1*m
    ;
```

```
add load # 1 type DRM from wave field # 1 in direction ux
    soil_surface at z = 0.0*m
    hdf5_file = "input.hdf5" ;
```

where `input.hdf5` specifies the HDF5 file which contain the information about the DRM elements and DRM nodes.

512.10.2 3 × 1C Seismic Motions Defined at Surface or at Depth

One Example of add DRM load from wave fields:

```
add load # 1 type DRM from wave field
  # 1 in direction ux
  # 2 in direction uy
  # 3 in direction uz
  soil_surface at z = 0.0*m
  hdf5_file = "input.hdf5" ;
```

512.10.3 Seismic Motions Imposed at Model Base

```
add load # 1 type imposed motion to node # 1 dof ux
    time_step = 0.01*s
    displacement_scale_unit = 1*m
    displacement_file = "displacement.txt"
    velocity_scale_unit = 1*m/s
    velocity_file = "velocity.txt"
    acceleration_scale_unit = 1*m/s^2
    acceleration_file = "acceleration.txt";
```

512.10.4 Eigen Analysis

For structural model alone.

```
simulate using eigen algorithm
    number_of_modes = 3;
```

512.11 Core Modeling and Simulation Commands: Simulation Parameters

Developed model, using core functionality, as described above, numerically simulated using core functionality simulation controls.

Finite element system of equations can be solved in sequential processing mode, for smaller models, on sequential, single CPU computers (laptops, desktops, single CPU Amazon Web Services computers, etc.):

```
define solver sequential umfpack;
```

For larger models, parallel processing mode, on parallel computers ((multi CPU laptops, multi CPU desktops, clusters of PCs, Amazon Web Services parallel computers, Supercomputers, etc.):

Command Example for a direct solver:

```
define solver parallel petsc "-pc_type lu -pc_factor_mat_solver_package mumps" ;
```

For selfweight phase of loading, static solution algorithm is used:

```
 simulate 100 steps using static algorithm;
```

For static loading, for example self weight as described above, load application and the siulation process is controlled trough load control:

```
define load factor increment 0.01;
```

For dynamic loads, simulation process is controlled using Newmark time integration method:

```
define dynamic integrator Newmark with gamma = 0.6000 beta = 0.3025;
```

The dynamic simulation process is performed in a number of steps:

```
 simulate 2000 steps using transient algorithm time_step = 0.01*s;
```

For proper integration of constitutive equations on the integration point (Gauss point) level, within each finite element, constitutive algorithm needs to be defined:

```
define NDMaterial constitutive integration algorithm Forward_Euler;
```

For the finite element level, analysis of nonlinear systems require definition of nonlinear iteration algorithm:

```
define algorithm With_no_convergence_check;
```

701.1 Chapter Summary and Highlights

701.2 Stress and Strain

This section reviews small deformation stress and strain measures used in this report.

701.2.1 Stress

In this work, the tensile stress is assumed positive, and in general we follow classical strength of materials (mechanics of materials) conventions for stress and strain. The stress tensor σ_{ij} is defined as

$$\sigma_{ij} = \lim_{A_i \to 0} \frac{F_j}{A_i} \tag{701.1}$$

where F_j is a traction (force) in the j direction and A_i is an infinitesimal surface area with normal in i direction. Cauchy stress tensor has a total of nine components, six of which are independent (symmetry $\sigma_{ij} = \sigma_{ji}$):

$$\boldsymbol{\sigma} = \begin{pmatrix} \sigma_{xx} & \sigma_{xy} & \sigma_{xz} \\ \sigma_{yx} & \sigma_{yy} & \sigma_{yz} \\ \sigma_{zx} & \sigma_{zy} & \sigma_{zz} \end{pmatrix} = \begin{pmatrix} \sigma_{x} & \sigma_{xy} & \sigma_{zx} \\ \sigma_{xy} & \sigma_{y} & \sigma_{yz} \\ \sigma_{zx} & \sigma_{yz} & \sigma_{z} \end{pmatrix} \tag{701.2}$$

In small deformation theory, this stress is symmetric, that is, $\sigma_{xy} = \sigma_{yx}$, $\sigma_{yz} = \sigma_{zy}$, and $\sigma_{zx} = \sigma_{xz}$. There are only six independent components and sometimes the stress can be expressed in the vector form

$$\boldsymbol{\sigma} = \left\{\sigma_{xx},\ \sigma_{yy},\ \sigma_{zz}, \sigma_{xy},\ \sigma_{yz},\ \sigma_{zx}\right\} \tag{701.3}$$

The principle stresses σ_1, σ_2, and σ_3 ($\sigma_1 \geq \sigma_2 \geq \sigma_3$) are the eigenvalues of the symmetric tensor σ_{ij} in Equation 701.2 and can be obtained by solving the equation

$$\begin{vmatrix} \sigma_{xx} - \sigma & \sigma_{xy} & \sigma_{xz} \\ \sigma_{yx} & \sigma_{yy} - \sigma & \sigma_{yz} \\ \sigma_{zx} & \sigma_{zy} & \sigma_{zz} - \sigma \end{vmatrix} = \mathbf{0} \tag{701.4}$$

or in alternative form

$$\sigma^3 - I_1\sigma^2 - I_2\sigma - I_3 = 0 \tag{701.5}$$

The three first-type stress invariants are then

$$\begin{aligned} I_1 &= \sigma_{ii} \\ &= \sigma_{xx} + \sigma_{yy} + \sigma_{zz} \\ &= \sigma_1 + \sigma_2 + \sigma_3 \end{aligned} \tag{701.6}$$

$$
\begin{aligned}
I_2 &= \frac{1}{2}\sigma_{ij}\sigma_{ji} \\
&= -(\sigma_{xx}\sigma_{yy} + \sigma_{yy}\sigma_{zz} + \sigma_{zz}\sigma_{xx}) + (\sigma_{xy}^2 + \sigma_{yz}^2 + \sigma_{zx}^2) \\
&= -(\sigma_1\sigma_2 + \sigma_2\sigma_3 + \sigma_3\sigma_1)
\end{aligned}
\tag{701.7}
$$

$$
\begin{aligned}
I_3 &= \frac{1}{3}\sigma_{ij}\sigma_{jk}\sigma_{ki} = \det(\sigma_{ij}) \\
&= \sigma_{xx}\sigma_{yy}\sigma_{zz} + 2\sigma_{xy}\sigma_{yz}\sigma_{zx} - (\sigma_{xx}\sigma_{yz}^2 + \sigma_{yz}\sigma_{zx}^2 + \sigma_{zz}\sigma_{xy}^2) \\
&= \sigma_1\sigma_2\sigma_3
\end{aligned}
\tag{701.8}
$$

The stress σ_{ij} can be decomposed into the hydrostatic stress $\sigma_m\delta_{ij}$ and deviatoric stress s_{ij} as $\sigma_{ij} = \sigma_m\delta_{ij} + s_{ij}$, with the definitions

$$
\sigma_m = \frac{1}{3}I_1, \quad s_{ij} = \sigma_{ij} - \frac{1}{3}\sigma_{kk}\delta_{ij}
\tag{701.9}
$$

where δ_{ij} is the Kronecker operator such that $\delta_{ij} = 1$ for $i = j$ and $\delta_{ij} = 0$ for $i \neq j$.

Since both hydrostatic and deviatoric stresses are stress tensors, they have their own coordinate-independent stress invariants respectively. The three invariants of the hydrostatic stress are

$$
I_1 = 3\sigma_m = I_1, \quad I_2 = -3\sigma_m^2 = -\frac{1}{3}I_1^2, \quad I_3 = \sigma_m^3 = \frac{1}{27}I_1^3
\tag{701.10}
$$

Since I_1, I_2 and I_3 are all simple functions of I_1, the hydrostatic stress state can therefore be represented by only one variable I_1.

The three eigenvalues of the deviatoric stresses s_{ij} are called principal deviatoric stresses, with the order $s_1 \geq s_2 \geq s_3$. The three invariants of the deviatoric stress are

$$
J_1 = s_{ii} = 0
\tag{701.11}
$$

$$
\begin{aligned}
J_2 &= \frac{1}{2}s_{ij}s_{ji} \\
&= \frac{1}{3}I_1^2 + I_2 \\
&= \frac{1}{6}[(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2] \\
&= -(s_{xx}s_{yy} + s_{yy}s_{zz} + s_{zz}s_{xx}) + (s_{xy}^2 + s_{yz}^2 + s_{zx}^2) \\
&= \frac{1}{2}(s_1^2 + s_2^2 + s_3^2) = -(s_1s_2 + s_2s_3 + s_3s_1)
\end{aligned}
\tag{701.12}
$$

$$
\begin{aligned}
J_3 &= \frac{1}{3}s_{ij}s_{jk}s_{ki} = \det(s_{ij}) \\
&= I_3 + \frac{1}{3}I_1I_2 + \frac{2}{27}I_1^3 = I_3 - \frac{1}{3}I_1J_2 - \frac{1}{27}I_1^3 \\
&= \frac{1}{27}(2\sigma_1 - \sigma_2 - \sigma_3)(2\sigma_2 - \sigma_3 - \sigma_1)(2\sigma_3 - \sigma_1 - \sigma_2) \\
&= s_{xx}s_{yy}s_{zz} + 2s_{xy}s_{yz}s_{zx} - (s_{xx}s_{yz}^2 + s_{yy}s_{zx}^2 + s_{zz}s_{xy}^2) \\
&= s_1s_2s_3
\end{aligned}
\tag{701.13}
$$

The deviatoric stress state can therefore be represented by only two variables J_2 and J_3.

Combining hydrostatic and deviatoric stress, we can conclude that the stress state can be be represented by three variables I_1, J_2 and J_3. Using the three invariants (I_1, J_2, J_3) or its equivalents instead of the nine components of σ_{ij} is widely used in geomechanics.

The stress state may also be described in three dimensional space (p, q, θ_σ), defined as

$$p = -\frac{1}{3} I_1 \tag{701.14}$$

$$q = \sqrt{3J_2} \tag{701.15}$$

$$\theta_\sigma = \frac{1}{3} \arccos\left(\frac{3\sqrt{3}}{2} \frac{J_3}{\sqrt{J_2^3}}\right) \tag{701.16}$$

where $\theta_{\sigma_{ij}}$ is the stress Lode's angle $(0 \leq \theta_{\sigma_{ij}} \leq \pi/3)$. A stress state with $\theta_\sigma = 0$ corresponds to the meridian of conventional triaxial compression (CTC), while $\theta_\sigma = \pi/3$ to the meridian of conventional triaxial extension (CTE). The relationship between $(\sigma_1, \sigma_2, \sigma_3)$ and (p, q, θ_σ) is

$$\begin{pmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \end{pmatrix} = -p + \frac{2}{3} q \begin{pmatrix} \cos\theta_\sigma \\ \cos(\theta_\sigma - \frac{2}{3}\pi) \\ \cos(\theta_\sigma + \frac{2}{3}\pi) \end{pmatrix} \tag{701.17}$$

The line of the principal stress space diagonal is called hydrostatic axis. Any plane perpendicular to the hydrostatic axis is an deviatoric plane, or π plane. The Haigh-Westergaard three dimensional stress coordinate system $(\xi, \rho, \theta_\sigma)$ Chen and Han (1988a), is defined as

$$\xi = \frac{I_1}{\sqrt{3}} = -\sqrt{3} p \tag{701.18}$$

$$\rho = \sqrt{2J_2} = \sqrt{\frac{2}{3}} q \tag{701.19}$$

The Haigh-Westergaard invariants have physical meanings. ξ is the distance of the deviatoric plane to the origin of the Haigh-Westergaard coordinates, and ρ is the distance of a stress point to the hydrostatic line and represents the magnitude of the deviatoric stress. The projections of the axes σ_1, σ_2 and σ_3 on the deviatoric plane are assumed σ'_1, σ'_2 and σ'_3 respectively. (ρ, θ_σ) is the polar coordinate system in the deviatoric plane with the σ'_1 the polar axis and θ_σ the polar angle. The relationship between $(\sigma_1, \sigma_2, \sigma_3)$ and $(\xi, \rho, \theta_\sigma)$ is

$$\begin{pmatrix} \sigma_1 \\ \sigma_2 \\ \sigma_3 \end{pmatrix} = \frac{1}{\sqrt{3}} \xi + \sqrt{\frac{2}{3}} \rho \begin{pmatrix} \cos\theta_\sigma \\ \cos(\theta_\sigma - \frac{2}{3}\pi) \\ \cos(\theta_\sigma + \frac{2}{3}\pi) \end{pmatrix} \tag{701.20}$$

701.2.2 Strain

Point $P(x_i)$ and nearby point $Q(x_i + \mathrm{d}x_i)$ displace due to applied loading to new positions $P(x_i + U_i)$ and $Q(u_i + (\partial u_i/\partial x_j)\mathrm{d}x_j)$. We can define a displacement gradient tensor $u_{i,j}$ as

$$u_{i,j} = \frac{\partial u_i}{\partial x_j} \tag{701.21}$$

Matrix form of the displacement gradient can decomposed into the symmetric and antisymmetric parts

$$\begin{pmatrix} u_{1,1} & u_{1,2} & u_{1,3} \\ u_{2,1} & u_{2,2} & u_{2,3} \\ u_{3,1} & u_{3,2} & u_{3,3} \end{pmatrix} = \begin{pmatrix} u_{1,1} & \frac{1}{2}(u_{1,2}+u_{2,1}) & \frac{1}{2}(u_{1,3}+u_{3,1}) \\ \frac{1}{2}(u_{2,1}+u_{1,2}) & u_{2,2} & \frac{1}{2}(u_{2,3}+u_{3,2}) \\ \frac{1}{2}(u_{3,1}+u_{1,3}) & \frac{1}{2}(u_{3,2}+u_{2,3}) & u_{3,3} \end{pmatrix} + \begin{pmatrix} 0 & \frac{1}{2}(u_{1,2}-u_{2,1}) & \frac{1}{2}(u_{1,3}-u_{3,1}) \\ \frac{1}{2}(u_{2,1}-u_{1,2}) & 0 & \frac{1}{2}(u_{2,3}-u_{3,2}) \\ \frac{1}{2}(u_{3,1}-u_{1,3}) & \frac{1}{2}(u_{3,2}-u_{2,3}) & 0 \end{pmatrix} \tag{701.22}$$

or

$$u_{i,j} = \epsilon_{ij} + w_{ij} \tag{701.23}$$

where

$$\epsilon_{ij} = \frac{1}{2}\left(u_{i,j} + u_{j,i}\right) \tag{701.24}$$

$$w_{ij} = \frac{1}{2}\left(u_{i,j} - u_{j,i}\right) \tag{701.25}$$

The symmetric part of the deformation gradient tensor, ϵ_{ij}, is the small deformation strain tensor [1], while the antisymmetric part of the deformation gradient tensor, w_{ij}, is the rotation motion tensor. The matrix form of the strain ϵ_{ij} is

$$\boldsymbol{\epsilon} = \begin{pmatrix} \epsilon_{xx} & \epsilon_{xy} & \epsilon_{xz} \\ \epsilon_{yx} & \epsilon_{yy} & \epsilon_{yz} \\ \epsilon_{zx} & \epsilon_{zy} & \epsilon_{zz} \end{pmatrix} = \begin{pmatrix} \epsilon_x & \frac{1}{2}\gamma_{xy} & \frac{1}{2}\gamma_{xz} \\ \frac{1}{2}\gamma_{yx} & \epsilon_y & \frac{1}{2}\gamma_{yz} \\ \frac{1}{2}\gamma_{zx} & \frac{1}{2}\gamma_{zy} & \epsilon_z \end{pmatrix} \tag{701.26}$$

The engineering strain is usually expressed in the vector form

$$\boldsymbol{\epsilon} = \left\{\epsilon_x,\ \epsilon_y,\ \epsilon_z, \gamma_{xy},\ \gamma_{yz},\ \gamma_{zx}\right\}^T \tag{701.27}$$

Note that the engineering shear strain γ_{ij} is the double of the corresponding strain component ϵ_{ij}.

---

[1] Here the second and higher order derivative terms are neglected due to the small deformation assumption.

Similar to the stress tensor, the strain tensor also has three principle strains $\epsilon_i (\epsilon_1 \geq \epsilon_2 \geq \epsilon_3)$, and three strain invariants I_1', I_2', and I_3', defined as

$$\begin{aligned}
I_1' &= \epsilon_{ii} \\
&= \epsilon_v \\
&= \epsilon_{xx} + \epsilon_{yy} + \epsilon_{zz} \\
&= \epsilon_1 + \epsilon_2 + \epsilon_3 \qquad (701.28)
\end{aligned}$$

$$\begin{aligned}
I_2' &= \frac{1}{2}\epsilon_{ij}\epsilon_{ji} \\
&= -(\epsilon_{xx}\epsilon_{yy} + \epsilon_{yy}\epsilon_{zz} + \epsilon_{zz}\epsilon_{xx}) + (\epsilon_{xy}^2 + \epsilon_{yz}^2 + \epsilon_{zx}^2) \\
&= -(\epsilon_1\epsilon_2 + \epsilon_2\epsilon_3 + \epsilon_3\epsilon_1) \qquad (701.29)
\end{aligned}$$

$$\begin{aligned}
I_3' &= \frac{1}{3}\epsilon_{ij}\epsilon_{jk}\epsilon_{ki} = \det(\epsilon_{ij}) \\
&= \epsilon_{xx}\epsilon_{yy}\epsilon_{zz} + 2\epsilon_{xy}\epsilon_{yz}\epsilon_{zx} - (\epsilon_{xx}\epsilon_{yz}^2 + \epsilon_{yz}\epsilon_{zx}^2 + \epsilon_{zz}\epsilon_{xy}^2) \\
&= \epsilon_1\epsilon_2\epsilon_3 \qquad (701.30)
\end{aligned}$$

The first strain invariant is also called the volumetric strain ϵ_v.

The strain ϵ_{ij} can be decomposed into the hydrostatic strain $\epsilon_m\delta_{ij}$ and deviatoric strain e_{ij} through $\epsilon_{ij} = \epsilon_m\delta_{ij} + e_{ij}$ where:

$$\epsilon_m = \frac{1}{3}I_1', \quad e_{ij} = \epsilon_{ij} - \frac{1}{3}\epsilon_{kk}\delta_{ij} \tag{701.31}$$

Since both hydrostatic and deviatoric strains are strain tensors, they have their own strain invariants respectively. The three invariants of the hydrostatic strain are

$$I_1' = 3\epsilon_m = I_1', \quad I_2' = -3\epsilon_m^2 = -\frac{1}{3}(I_1')^2, \quad I_3' = \epsilon_m^3 = \frac{1}{27}(I_1')^3 \tag{701.32}$$

The hydrostatic strain state can therefore be represented by only one variable I_1'.

The three eigenvalues of the deviatoric strains e_{ij} are called principal deviatoric strains, with the order $e_1 \geq e_2 \geq e_3$. The three invariants of the deviatoric strain are

$$J_1' = e_{ii} = 0 \tag{701.33}$$

$$\begin{aligned}
J_2' &= \frac{1}{2}e_{ij}e_{ji} \\
&= \frac{1}{3}(I_1')^2 + I_2' \\
&= \frac{1}{6}[(\epsilon_1 - \epsilon_2)^2 + (\epsilon_2 - \epsilon_3)^2 + (\epsilon_3 - \epsilon_1)^2] \\
&= -(e_{xx}e_{yy} + e_{yy}e_{zz} + e_{zz}e_{xx}) + (e_{xy}^2 + e_{yz}^2 + e_{zx}^2) \\
&= \frac{1}{2}(e_1^2 + e_2^2 + e_3^2) = -(e_1e_2 + e_2e_3 + e_3e_1) \qquad (701.34)
\end{aligned}$$

$$\begin{aligned}
J'_3 &= \frac{1}{3}e_{ij}e_{jk}e_{ki} = \det(e_{ij}) \\
&= I'_3 + \frac{1}{3}I'_1I'_2 + \frac{2}{27}(I'_1)^3 = I_3 - \frac{1}{3}I'_1J'_2 - \frac{1}{27}(I'_1)^3 \\
&= \frac{1}{27}(2\epsilon_1 - \epsilon_2 - \epsilon_3)(2\epsilon_2 - \epsilon_3 - \epsilon_1)(2\epsilon_3 - \epsilon_1 - \epsilon_2) \\
&= e_{xx}e_{yy}e_{zz} + 2e_{xy}e_{yz}e_{zx} - (e_{xx}e^2_{yz} + e_{yy}s^2_{zx} + e_{zz}e^2_{xy}) \\
&= e_1e_2e_3 \qquad (701.35)
\end{aligned}$$

The deviatoric strain state can therefore be represented by only two variables J'_2 and J'_3.

Combining the hydrostatic and deviatoric strain, we can conclude that the strain state can be be represented by three variables I'_1, J'_2 and J'_3.

Strain state may also be represented with another three invariant $(\epsilon_p, \epsilon_q, \theta_\epsilon)$, defined as

$$\epsilon_p = -I'_1 = -\epsilon_v \qquad (701.36)$$

$$\epsilon_q = 2\sqrt{\frac{J'_2}{3}} \qquad (701.37)$$

$$\theta_\epsilon = \frac{1}{3}\arccos\left(\frac{3\sqrt{3}}{2}\frac{J'_3}{\sqrt{(J'_2)^3}}\right) \qquad (701.38)$$

where θ_ϵ is the strain Lode's angle and $0 \leq \theta_\epsilon \leq \pi/3$. The relationship between $(\epsilon_1, \epsilon_2, \epsilon_3)$ and $(\epsilon_p, \epsilon_q, \theta_\epsilon)$ is

$$\begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \epsilon_3 \end{pmatrix} = -\frac{1}{3}\epsilon_p + \sqrt{\frac{3}{2}}\epsilon_q \begin{pmatrix} \cos\theta_\epsilon \\ \cos(\theta_\epsilon - \frac{2}{3}\pi) \\ \cos(\theta_\epsilon + \frac{2}{3}\pi) \end{pmatrix} \qquad (701.39)$$

701.3 Derivatives of Stress Invariants

In this part of the Appendix, we shall derive some useful formulae, that are rarely found[2] in texts treating elasto–plastic problems in mechanics of solid continua.

First derivative of I_1 with respect to stress tensor σ_{ij}:

$$\frac{\partial I_1}{\partial \sigma_{ij}} = \frac{\partial \sigma_{kk}}{\partial \sigma_{ij}} = \delta_{ij}$$

First derivative of J_{2D} with respect to stress tensor σ_{ij}:

---

[2] if found at all.

$$
\begin{aligned}
\frac{\partial J_{2D}}{\partial \sigma_{ij}} = \frac{\partial(\frac{1}{2}s_{mn}s_{nm})}{\partial \sigma_{ij}} = \frac{1}{2}\frac{\partial s_{mn}}{\partial \sigma_{ij}}s_{nm} + \frac{1}{2}\frac{\partial s_{nm}}{\partial \sigma_{ij}}s_{mn} = \\
= \frac{\partial s_{nm}}{\partial \sigma_{ij}}s_{mn} = \frac{\partial(\sigma_{nm} - \frac{1}{3}\sigma_{kk}\delta_{nm})}{\partial \sigma_{ij}}s_{mn} = (\delta_{ni}\delta_{jm} - \frac{1}{3}\delta_{nm}\delta_{ki}\delta_{jk})s_{mn} = \\
= (\delta_{ni}\delta_{jm} - \frac{1}{3}\delta_{nm}\delta_{ij})s_{mn} = \delta_{ni}\delta_{jm}s_{nm} - \frac{1}{3}\delta_{nm}\delta_{ij}s_{mn} = s_{ij}{}^{\dagger}
\end{aligned}
$$

First derivative of J_{3D} with respect to stress tensor σ_{pq}:

$$
\begin{aligned}
\frac{\partial J_{3D}}{\partial \sigma_{pq}} = \frac{\partial(\frac{1}{3}s_{ij}s_{jk}s_{ki})}{\partial \sigma_{pq}} = \frac{1}{3}\frac{\partial s_{ij}}{\partial \sigma_{pq}}s_{jk}s_{ki} + \frac{1}{3}\frac{\partial s_{jk}}{\partial \sigma_{pq}}s_{ij}s_{ki} + \frac{1}{3}\frac{\partial s_{ki}}{\partial \sigma_{pq}}s_{ij}s_{jk} = \\
= \frac{\partial s_{ij}}{\partial \sigma_{pq}}s_{jk}s_{ki} = \frac{\partial(\sigma_{ij} - \frac{1}{3}\sigma_{kk}\delta_{ij})}{\partial \sigma_{pq}}s_{jk}s_{ki} = (\delta_{ip}\delta_{qj} - \frac{1}{3}\delta_{ij}\delta_{kp}\delta_{qk})s_{jk}s_{ki} = \\
= \delta_{ip}\delta_{qj}s_{jk}s_{ki} - \frac{1}{3}\delta_{ij}\delta_{kp}\delta_{qk}s_{jk}s_{ki} = s_{qk}s_{kp} - \frac{2}{3}\delta_{pq}J_{2D} = t_{pq}{}^{\ddagger}
\end{aligned}
$$

First derivative of s_{pq} with respect to stress tensor σ_{mn}, or second derivative of J_{2D} with respect to stress tensors σ_{pq} and σ_{mn}:

$$
\begin{aligned}
\frac{\partial s_{pq}}{\partial \sigma_{mn}} = \frac{\partial\left(\sigma_{pq} - \frac{1}{3}\delta_{pq}\sigma_{kk}\right)}{\partial \sigma_{mn}} = \frac{\partial\left(\left(\delta_{mp}\delta_{nq} - \frac{1}{3}\delta_{pq}\delta_{mn}\right)\sigma_{mn}\right)}{\partial \sigma_{mn}} = \\
= \left(\delta_{mp}\delta_{nq} - \frac{1}{3}\delta_{pq}\delta_{mn}\right) = p_{pqmn}
\end{aligned}
$$

Second derivative of J_{3D} with respect to stress tensors σ_{pq} and σ_{mn}:

$$
\begin{aligned}

Appendix 702

The nDarray Programming Tool

(1993-1995-1996-1999-)

702.1 Chapter Summary and Highlights

Material in this chapter is based on the following publications Jeremić (1993); Jeremić and Sture (1998).

This section describes a programming tool, nDarray, which is designed using an Object Oriented Paradigm (OOP) and implemented in the C++ programming language. Finite element equations, represented in terms of multidimensional tensors are easily manipulated and programmed. The usual matrix form of the finite element equations are traditionally coded in FORTRAN, which makes it difficult to build and maintain complex program systems. Multidimensional data systems and their implementation details are seldom transparent and thus not easily dealt with and usually avoided. On the other hand, OOP together with efficient programming in C++ allows building new concrete data types, namely tensors of any order, thus hiding the lower level implementation details. These concrete data types prove to be quite useful in implementing complicated tensorial formulae associated with the numerical solution of various elastic and elastoplastic problems in solid mechanics. They permit implementing complex nonlinear continuum mechanics theories in an orderly manner. Ease of use and the immediacy of the nDarray programming tool in constitutive driver programming and in building finite element classes will be shown.

702.2 Introduction

In implementing complex programming systems for finite element computations, the analyst is usually faced with the challenge of transforming complicated tensorial formulae to a matrix form. Considerable amount of time in solving problems by the finite element method is often devoted to the actual implementation process. If one decides to use FORTRAN, a number of finite element and numerical libraries are readily available. Although quick results can be produced in solving simpler problems, when implementing complex small deformation elastoplastic or large deformation elastic and elastoplastic algorithms, C++ provides clear benefits.

Some of the improvements C++ provides over C and FORTRAN are classes for encapsulating abstractions, the possibility of building user–defined concrete data types and operator overloading for expressing complex formulae in a natural way. In the following we shall show that the nDarray tool will allow analysts to be a step closer to the problem space and a step further away from the underlying machine.

As most analysts know, the intention (Stroustrup, 1994) behind C++ was not to replace C. Instead, C was extended with far more freedom given to the program designer and implementor. In C and FORTRAN, large applications become collections of programs and functions, order and the structure are left to the programmer. The C++ programming language embodies the OOP, which can be used to simplify and organize complex programs. One can build a hierarchy of derived classes and nest classes inside other classes. A concern in C and FORTRAN programming languages is handling data type conflicts and data which are being operated on or passed. The C++ programming language extends the definition of type to include abstract data types. With abstract data types, data can be encapsulated with the methods that operate on it. The C++ programming language offers structure and mechanisms to handle larger, more complex programming systems. Object Oriented technology, with function and operator overloading, inheritance and other features, provides means of attacking a problem in a natural way. Once basic classes are implemented, one can concentrate on the physics of a problem. By building further abstract data types one can describe the physics of a problem rather that spend time on the lower level programming issues. One should keep in mind the adage, credited to the original designer and implementor of C++ programming language, Bjarne Stroustrup: "C makes it easy to shoot yourself in the foot, C++ makes it harder, but when you do, it blows away your whole leg".

Rather than attempting here to give a summary of Object Oriented technology we will suggest useful references for readers who wish to explore the subject in greater depth (Booch, 1994). The current language definition is given in the *Working Paper for Draft Proposed International Standard for Information Systems–Programming Language C++* (ANS, 1995). Detailed description of language evolution and main design decisions are given by Stroustrup (1994). Useful sets of techniques, explanations and directions for designing and implementing robust C++ code are given in books (Coplien, 1992) (Eckel, 1989) and journal articles (Koenig, 1989 - 1993) (Various Authors, 1991-).

Increased interest in using Object Oriented techniques for finite element programming has resulted in a number (Donescu and Laursen, 1996) (Eyheramendy and Zimmermann, 1996) (Forde et al., 1990) (Miller, 1991) (Pidaparti and Hudli, 1993) (Scholz, 1992) (Zeglinski et al., 1994) of experimental developments and implementations. Programming techniques used in some of the papers are influenced by the FORTRAN programming style. Examples provided in some of the above mentioned papers are readable by C++ experts only. It appears that none of the authors have used Object Oriented techniques for complex elastoplasticity computations.

702.3 nDarray Programming Tool

702.3.1 Introduction to the nDarray Programming Tool

The nDarray programming tool is a set of classes written in the C++ programming language. The main purpose of the package is to facilitate algebraic manipulations with matrices, vectors and tensors that are often found in computer codes for solving engineering problems. The package is designed and implemented using the Object Oriented philosophy. Great care has been given to the problem of cross–platform and cross–compiler portability. Currently, the nDarray set of classes has been tested and running under the following C++ compilers:

- Sun CC on SunOS and Solaris platforms,
- IBM xlC on AIX RISC/6000 platforms,
- Borland C++ and Microsoft C++ on DOS/Windows platforms,
- CodeWarrior C++ on Power Macintosh platform,
- GNU g++ on SunOS, SOLARIS, LINUX, AIX, HPUX and AMIGA platforms.

702.3.2 Abstraction Levels

nDarray tool has the following simple class hierarchy:

```
nDarray_rep, nDarray
    matrix
        vector
    tensor
```

Indentation of class names implies the inheritance level. For example, class vector is derived from class matrix, which, in turn is derived from classes nDarray and nDarray_rep. The idea is to subdivide classes into levels of abstraction, and hide the implementation from end users. This means that the end user can use the nDarray tool on various levels.

- At the highest level of abstraction, one can use tensor, matrix and vector objects without knowing anything about the implementation and the inner workings. They are all designed and implemented as concrete data types. In spite of the very powerful code that can be built using Object Oriented technology, it would be unwise to expect proficiency in Object Oriented techniques and the C++ programming language from end users. It was our aim to provide power programming with multidimensional data types to users with basic knowledge of C.
- At a lower abstraction level, users can address the task of the actual implementation of operators and functions for vector, matrix and tensor classes. A number of improvements can be made, especially in optimizing some of the operators.
- The lowest level of abstraction is associated with nDarray and nDarray_rep classes. Arithmetic operators[1] are implemented at this level.

---

[1] Like addition and subtraction.

Next, classes are described from the base and down the inheritance tree. Later we focus our attention on nDarray usage examples. Our goal is to provide a useful programming tool, rather than to teach OOP or to show C++ implementation. For readers interested in actual implementation details, source code, examples and makefiles are available at `http://sokocalo.engr.ucdavis.edu/~jeremic`.

702.3.2.1 nDarray_rep class

The nDarray_rep class is a data holder and represents an n dimensional array object. A simple memory manager, implemented with the *reference counting idiom* (Coplien, 1992) is used. The memory manager uses rather inefficient built–in C memory allocation functions. Performance can be improved if one designs and implements specially tailored allocation functions for fast heap manipulations. Another possible improvement is in using memory resources other than heap memory. Sophisticated memory management introduced by the reference counting is best explained by Coplien (1992). The nDarray_rep class is not intended for stand–alone use. It is closely associated with the nDarray class.

The data structure of nDarray_rep introduces a minimal amount of information about a multidimensional array object. The actual data are stored as a one–dimensional array of double numbers. Rank, total number of elements, and array of dimensions are all that is needed to represent an multidimensional object. The data structure is allocated dynamically from the heap, and memory is reclaimed by the system after the object has gone out of scope.

702.3.2.2 nDarray class

The nDarray class together with the nDarray_rep class represents the abstract base for derived multidimensional data types: matrices, vectors and tensors. Objects derived from the nDarray class are generated dynamically by constructor functions at the first appearance of an object and are destroyed at the end of the block in which the object is referenced. The reference counting idiom provides for the object's life continuation after the end of the block where it was defined. To extend an object's life, a standard C++ compiler would by default call constructor functions, thus making the entire process of returning large objects from functions quite inefficient. By using reference counting idiom, destructor and constructor functions manipulate reference counter which results in a simple copying of a pointer to nDarray_rep object. By using this technique, copying of large objects is made very efficient.

Objects can be created from an array of values, or from a single scalar value, as shown in Table 702.1. Some of the frequently used multidimensional arrays are predefined and can be constructed by sending the proper flag to the constructor function. For example by sending the "`I`" flag one creates Kronecker delta δ_{ij} and by sending "e" flag, one creates a rank 3 Levi-Civita permutation tensor e_{ijk}. Functions and operators common to multidimensional data types are defined in the nDarray

constructor function	description
`nDarray(int rank_of_nD=1, double initval=0.0)`	default
`nDarray(int rank_of_nD, const int *pdim, double *val)`	from array
`nDarray(int rank_of_nD, const int *pdim, double initval)`	from scalar value
`nDarray(const char *flag, int rank_of_nD, const int *pdim)`	unit nDarrays
`nDarray(const nDarray & x)`	copy-initializer
`nDarray(int rank_of_nD, int rows, int cols, double *val)`	special for matrix
`nDarray(int rank_of_nD, int rows, int cols, double initval)`	special for matrix

Table 702.1: nDarray constructor functions.

class, as described in Table 702.2. These common operators and functions are inherited by derived classes. Occasionally, some of the functions will be redefined, overloaded in derived classes. In tensor multiplications we need additional information about indices. For example $C_{il} = (A_{ijk} + B_{ijk}) * D_{jkl} \overset{\text{coded}}{\longrightarrow}$ `C=(A("ijk")+B("ijk"))*D("jkl")`, the temporary in brackets will receive ijk indices, to be used for multiplication with D_{jkl}. It is interesting to note (Koenig, 1989 - 1993) that operator += is defined as a member and + is defined as an inline function in terms of += operator.

702.3.2.3 Matrix and Vector Classes

The matrix class is derived from the nDarray class through the public construct. It inherits common operators and functions from the base nDarray class, but it also adds its own set of functions and operators. Table (702.3) summarizes some of the more important additional functions and operators for the matrix class. The vector class defines vector objects and is derived and inherits most operators and data members from the matrix class. Some functions, like copy constructor, are overloaded in order to handle specifics of a vector object.

702.3.2.4 Tensor Class

The main goal of the tensor class development was to provide the implementing analyst with the ability to write the following equation directly into a computer program:

$$d\sigma_{mn} = -{}^{old}r_{ij} T^{-1}_{ijmn} - d\lambda\ E_{ijkl}\ {}^{n+1}m_{kl} T^{-1}_{ijmn}$$

as:

```
dsigma = -(r("ij")*Tinv("ijmn")) - dlambda*((E("ijkl")*dQods("kl"))*Tinv("ijmn"));
```

operator or function	left value	right value	description
`=`	nDarray	nDarray	nDarray assignment
`+`	nDarray	nDarray	nDarray addition
`+=`	nDarray	nDarray	nDarray addition
`-`		nDarray	unary minus
`-`	nDarray	nDarray	nDarray subtraction
`-=`	nDarray	nDarray	nDarray subtraction
`*`	double	nDarray	scalar multiplication (from left)
`*`	nDarray	double	scalar multiplication (from right)
`==`	nDarray	nDarray	nDarray comparison
`val(...)`	nDarray		reference to members of nDarray
`cval(...)`	nDarray		members of nDarray
`trace()`	nDarray		trace of square nDarray
`eigenvalues()`	nDarray		eigenvalues of rank 2 square nDarray
`eigenvectors()`	nDarray		eigenvectors of rank 2 square nDarray
`General_norm()`	nDarray		general p-th norm of nDarray
`nDsqrt()`	nDarray		square root of nDarray
`print(...)`	nDarray		generic print function

Table 702.2: Public functions and operators for nDarray class.

operator or function	left value	right value	description
`=`	matrix	matrix	matrix assignment
`*`	matrix	matrix	matrix multiplication
`transpose()`	matrix		matrix transposition
`determinant()`	matrix		determinant of a matrix
`inverse()`	matrix		matrix inversion

Table 702.3: Matrix class functions and operators (added on nDarray class definitions).

Instead of developing theory in terms of indicial notation, then converting everything to matrix notation and then implementing it, we were able to copy formulae directly from their indicial form to the C++ source code.

In addition to the definitions in the base nDarray class, the tensor class adds some specific functions and operators. Table 702.4 summarizes some of the main new functions and operators. The most significant addition is the tensor multiplication operator. With the help of a simple indicial parser, the multiplication operator contracts or expands indices and yields a resulting tensor of the correct rank. The resulting tensor receives proper indices, and can be used in further calculations on the same code statement.

operator or function	left value	right value	description
+	tensor	tensor	tensor addition
-	tensor	tensor	tensor subtraction
*	tensor	tensor	tensor multiplication
`transpose0110()`	tensor		$A_{ijkl} \rightarrow A_{ikjl}$
`transpose0101()`	tensor		$A_{ijkl} \rightarrow A_{ilkj}$
`transpose0111()`	tensor		$A_{ijkl} \rightarrow A_{iljk}$
`transpose1100()`	tensor		$A_{ijkl} \rightarrow A_{jikl}$
`transpose0011()`	tensor		$A_{ijkl} \rightarrow A_{ijlk}$
`transpose1001()`	tensor		$A_{ijkl} \rightarrow A_{ljki}$
`transpose11()`	tensor		$a_{ij} \rightarrow a_{ji}$
`symmetrize11()`	tensor		symmetrize second order tensor
`determinant()`	tensor		determinant of 2nd order tensor
`inverse()`	tensor		tensor inversion (2nd, 4th order)

Table 702.4: Additional and overloaded functions and operators for tensor class.

702.4 Finite Element Classes

702.4.1 Stress, Strain and Elastoplastic State Classes

The next step in our development was to use the nDarray tool classes for constitutive level computations. The simple extension was design and implementation of infinitesimal stress and strain tensor classes, namely stresstensor and straintensor. Both classes are quite similar, they inherit all the functions from the tensor class and we add some tools that are specific to them. Both stress and strain tensors are implemented as full second order 3×3 tensors. Symmetry of stress and strain tensor was not used to save storage space. Table 702.5 summarizes some of the main functions added on for the stresstensor class.

operator or function	description
`Iinvariant1()`	first stress invariant I1
`Iinvariant2()`	second stress invariant I2
`Iinvariant3()`	third stress invariant I3
`Jinvariant2()`	second deviatoric stress invariant J2
`Jinvariant3()`	third deviatoric stress invariant J3
`deviator()`	stress deviator
`principal()`	principal stresses on diagonal
`sigma_octahedral()`	octahedral mean stress
`tau_octahedral()`	octahedral shear stress
`xi()`	Haigh–Westergard coordinate ξ
`rho()`	Haigh–Westergard coordinate ρ
`p_hydrostatic()`	hydrostatic stress invariant
`q_deviatoric()`	deviatoric stress invariant
`theta()`	θ stress invariant (Lode's angle)

Table 702.5: Additional methods for stress tensor class.

Further on, we defined an elastoplastic state, which according to incremental theory of elastoplasticity with internal variables, is completely defined with the stress tensor and a set of internal variables. This definition led us to define an elastoplastic state termed class ep_state. Objects of type ep_state contain a stress tensor and a set of scalar or tensorial internal variables[2].

702.4.2 Material Model Classes

With all the previous developments, the design and implementation of various elastoplastic material models was not a difficult task. A generic class Material_Model defines techniques that form a framework for small deformation elastoplastic computations. Table 702.6 summarizes some of the main methods defined for the Material_Model class in terms of yield (F) and potential (Q) functions.

---

[2] Internal variables can be characterized as tensors of even order, where, for example, zero tensor is a scalar internal variable associated with isotropic hardening and second order tensors can be associated with kinematic hardening.

operator or function	description
`F`	F Yield function value
`dFods`	$\partial F / \partial \sigma_{ij}$
`dQods`	$\partial Q / \partial \sigma_{ij}$
`d2Qods2`	$\partial^2 Q / \partial \sigma_{ij} \partial \sigma_{kl}$
`dpoverds`	$\partial p / \partial \sigma_{ij}$
`dqoverds`	$\partial q / \partial \sigma_{ij}$
`dthetaoverds`	$\partial \theta / \partial \sigma_{ij}$
`d2poverds2`	$\partial^2 p / \partial \sigma_{ij} \partial \sigma_{kl}$
`d2qoverds2`	$\partial^2 q / \partial \sigma_{ij} \partial \sigma_{kl}$
`d2thetaoverds2`	$\partial^2 \theta / \partial \sigma_{ij} \partial \sigma_{kl}$
`ForwardPredictorEPState`	Explicit predictor elastoplastic state
`BackwardEulerEPState`	Implicit return elastoplastic state
`ForwardEulerEPState`	Explicit return elastoplastic state
`BackwardEulerCTensor`	Algorithmic tangent stiffness tensor
`ForwardEulerCTensor`	Continuum tangent stiffness tensor

Table 702.6: Some of the methods in material model class.

It is important to note that all the material model dependent functions are defined as virtual functions. Integration algorithms are designed and implemented using template algorithms, and each implemented material model appends its own yield and potential functions and appropriate derivatives. Implementation of additional material models requires coding of yield and potential functions and respective derivative functions.

702.4.3 Stiffness Matrix Class

Starting from the incremental equilibrium of the stationary body, the principle of virtual displacements and with the finite element approximation of the displacement field $u \approx \hat{u}_a = H_I \bar{u}_{Ia}$, the weak form of equilibrium can be expressed as (Zienkiewicz and Taylor, 1991a)

$$\bigcup_m \int_{V^m} H_{I,b}\, E_{abcd}\, H_{J,d}\, dV^m\, \bar{u}_{Jc} = \bigcup_m \int_{V^m} f_a\, H_I\, dV^m \quad \text{or} \quad (f_{Ia}(\bar{u}_{Jc}))_{int} = \lambda\, (f_{Ia})_{ext}$$

where E_{abcd} is the constitutive tangent stiffness tensor[3]. The element stiffness tensor is recognized as

$$k^e_{aIcJ} = \int_{V^m} H_{I,b} \; {}^{tan}E_{abcd} \; H_{J,d} \; dV^m$$

This generic form for the finite element stiffness tensor is easily programmed with the help of the nDarray tool. A simple implementation example is provided later. It should be noted that the element stiffness tensor in this case is a four–dimensional tensor. It is the task of the assembly function to collect proper terms for addition in a global stiffness matrix.

702.5 Examples

702.5.1 Tensor Examples

Some of the basic tensorial calculations with tensors are presented. Tensors have a default constructor that creates a first order tensor with one element initialized to 0.0:

```
tensor t1;
```

Tensors can be constructed and initialized from a given set of numbers:

```
static double t2values[] = {  1,2,3,
                              4,5,6,
                              7,8,9  };
tensor t2( 2, DefDim2, t2values); // order 2; 3x3 tensor (like matrix)
```

Here, `DefDim2`, `DefDim3` and `DefDim4` are arrays of dimensions for the second, third and fourth order tensor[4]. A fourth order tensor with 0.0 value assignment and dimension 3 in each order $(3 \times 3 \times 3 \times 3)$ is constructed in the following way:

```
tensor ZERO(4,DefDim4,0.0);
```

Tensors can be multiplied using indicial notation. The following example will do a tensorial multiplication of previously defined tensors `t2` and `t4` so that $tst1 = t2_{ij} t4_{ijkl} t4_{klpq} t2_{pq}$. Note that the memory is dynamically allocated to accept the proper tensor dimensions that will result from the multiplication[5]

```
tensor tst1 = t2("ij")*t4("ijkl")*t4("klpq")*t2("pq");
```

Inversion of tensors is possible. It is defined for 2 and 4 order tensors only. The fourth order tensor inversion is done by converting it to matrix, inverting that matrix and finally converting matrix back to tensor.

```
tensor t4inv_2 = t4.inverse();
```

---

[3] Which may be continuum or algorithmic (Jeremić and Sture, 1997) tangent stiffness tensor

[4] In this case dimensions are 3 in every order.

[5] In this case it will be zero dimensional tensor with one element.

There are two built–in tensor types, *Levi-Civita permutation tensor* e_{ijk} and *Kronecker delta tensor* δ_{ij}

```
tensor e("e",3,DefDim3);     // Levi-Civita permutation tensor
tensor I2("I", 2, DefDim2);  // Kronecker delta tensor
```

Trace and determinant functions for tensors are used as follows

```
double deltatrace = I2.trace();
double deltadet = I2.determinant();
```

Tensors can be compared to within a square root of *machine epsilon*[6] tolerance

```
tensor I2again = I2;
if ( I2again == I2 )
  printf("I2again == I2  TRUE (OK)");
else
  printf("I2again == I2  NOTTRUE");
```

702.5.2 Fourth Order Isotropic Tensors

Some of the fourth order tensors used in continuum mechanics are built quite readily. The most general representation of the fourth order isotropic tensor includes the following fourth order unit isotropic tensors[7]

```
tensor I_ijkl = I2("ij")*I2("kl");
```

The resulting tensor `I_ijkl` will have the correct indices, $I\_ijkl_{ijkl} = I2_{ij} I2_{kl}$. Note that `I_ijkl` is just a name for the tensor, and the `_ijkl` part reminds the implementor what that tensor is representing.

The real indices, $*_{ijkl}$ in this case, are stored in the tensor object, and can be used further or changed appropriately. The next tensor that is needed is a fourth order unit tensor obtained by transposing the previous one in the minor indices,

```
tensor I_ikjl = I_ijkl.transpose0110();
```

while the third tensor needed for representation of general isotropic tensor is constructed by using similar transpose function

```
tensor I_iljk = I_ijkl.transpose0111();
```

The inversion function can be checked for fourth order tensors:

---

[6] Machine epsilon ($macheps$) is defined as the smallest distinguishable positive number (in a given precision, i.e. float (32 bits), double (64 bits) or long double (80 bits), such that $1.0 + macheps > 1.0$ yields true on the given computer platform. For example, double precision arithmetics (64 bits), on the `Intel 80x86` platform yields `macheps=1.08E-19` while on the `SUN SPARCstation` and DEC platforms `macheps=2.22E-16`.

[7] Remember that `I2` was constructed as the Kronecker delta tensor δ_{ij}.

```
tensor I_ikjl_inv_2 = I_ikjl.inverse();
if ( I_ikjl == I_ikjl_inv_2 )
  printf(" I_ikjl == I_ikjl_inv_2 (OK) !");
else
  printf(" I_ikjl != I_ikjl_inv_2 !");
```

Creating a symmetric and skew symmetric unit fourth order tensors gets to be quite simple by using tensor addition and scalar multiplication

```
tensor I4s  = (1./2.)*(I_ikjl+I_iljk);
tensor I4sk = (1./2.)*(I_ikjl-I_iljk);
```

Another interesting example is a numerical check of the $e - \delta$ identity (Lubliner, 1990) ($e_{ijm}e_{klm} = \delta_{ik}\delta_{jl} - \delta_{il}\delta_{jk}$)

```
tensor id = e("ijm")*e("klm") - (I_ikjl - I_iljk);
if ( id == ZERO )
  printf(" e-delta identity HOLDS !! ");
```

702.5.3 Elastic Isotropic Stiffness and Compliance Tensors

The linear isotropic elasticity tensor E_{ijkl} can be built from Young's modulus E and Poisson's ratio ν

```
double Ey = 20000; // Young's modulus of elasticity
double nu = 0.2;   // Poisson's Ratio
tensor E = ((2.*Ey*nu)/(2.*(1.+nu)*(1-2.*nu)))*I_ijkl + (Ey/(1.+nu))*I4s;
```

Similarly, the compliance tensor is

```
tensor D = (-nu/Ey)*I_ijkl + ((1.0+nu)/Ey)*I4s;
```

One can multiply the two and check if the result is equal to the symmetric fourth order unit tensor

```
tensor test = E("ijkl")*D("klpq");
if ( test == I4s )
  printf(" test == I4s  TRUE  (OK up to sqrt(macheps)) ");
else
  printf(" test == I4s  NOTTRUE   ");
```

The linear isotropic elasticity and compliance tensors can be obtained in a different way, by using Lamé constants λ and μ

```
double lambda = nu * Ey / (1. + nu) / (1. - 2. * nu);
double mu = Ey / (2. * (1. + nu));
tensor E = lambda*I_ijkl + (2.*mu)*I4s;         // stiffness tensor
tensor D = (-nu/Ey)*I_ijkl  + (1./(2.*mu))*I4s; // compliance tensor
```

702.5.4 Second Derivative of θ Stress Invariant

As an extended example of nDarray tool usage, the implementation for the second derivative of the stress invariant θ (Lode angle) is presented. The derivative is used for implicit constitutive integration schemes applied to three invariant material models. The original equation reads:

$$
\begin{aligned}
\frac{\partial^2\theta}{\partial\sigma_{pq}\partial\sigma_{mn}} &= \\
&- \left(\frac{9}{2}\frac{\cos 3\theta}{q^4\sin(3\theta)} + \frac{27}{4}\frac{\cos 3\theta}{q^4\sin^3 3\theta}\right) s_{pq}\, s_{mn} + \frac{81}{4}\frac{1}{q^5\sin^3 3\theta}\, s_{pq}\, t_{mn} + \\
&+ \left(\frac{81}{4}\frac{1}{q^5\sin 3\theta} + \frac{81}{4}\frac{\cos^2 3\theta}{q^5\sin^3 3\theta}\right) t_{pq}\, s_{mn} - \frac{243}{4}\frac{\cos 3\theta}{q^6\sin^3 3\theta}\, t_{pq}\, t_{mn} + \\
&+ \frac{3}{2}\frac{\cos(3\theta)}{q^2\sin(3\theta)}\, p_{pqmn} - \frac{9}{2}\frac{1}{q^3\sin(3\theta)}\, w_{pqmn}
\end{aligned}
$$

where:

$$
q = \sqrt{\frac{3}{2}s_{ij}s_{ij}} \quad ; \quad \cos 3\theta = \frac{3\sqrt{3}}{2}\frac{\frac{1}{3}s_{ij}s_{jk}s_{ki}}{\sqrt{(\frac{1}{2}s_{ij}s_{ij})^3}} \quad ; \quad s_{ij} = \sigma_{ij} - \frac{1}{3}\sigma_{kk}\delta_{ij}
$$

$$
w_{pqmn} = s_{np}\delta_{qm} + s_{qm}\delta_{np} - \frac{2}{3}s_{qp}\delta_{nm} - \frac{2}{3}\delta_{pq}s_{mn} \quad ; \quad p_{pqmn} = \delta_{mp}\delta_{nq} - \frac{1}{3}\delta_{pq}\delta_{mn}
$$

and the implementation follows:

```
tensor Yield_Criteria::d2thetaoverds2(stresstensor & stress)
 {
  tensor ret( 4, DefDim4, 0.0);
  tensor I2("I", 2, DefDim2);
  tensor I_pqmn = I2("pq")*I2("mn");
  tensor I_pmqn = I_pqmn.transpose0110();
  double J2D = stress.Jinvariant2();
  tensor s = stress.deviator();
  tensor t = s("qk")*s("kp") - I2*(J2D*(2.0/3.0));
  double theta = stress.theta();
  double q_dev = stress.q_deviatoric();
//setting up some constants
  double c3t    = cos(3*theta);
  double s3t    = sin(3*theta);
  double s3t3   = s3t*s3t*s3t;
  double q3     = q_dev * q_dev * q_dev;
  double q4     = q3 * q_dev;
  double q5     = q4 * q_dev;
```

```
  double q6     = q5 * q_dev;
  double tempss = -(9.0/2.0)*(c3t)/(q4*s3t)-(27.0/4.0)*(c3t/(s3t3*q4));
  double tempst = +(81.0/4.0)*(1.0)/(s3t3*q5);
  double tempts = +(81.0/4.0)*(1.0/(s3t*q5))+(81.0/4.0)*(c3t*c3t)/(s3t3*q5);
  double temptt = -(243.0/4.0)*(c3t/(s3t3*q6));
  double tempp  = +(3.0/2.0)*(c3t/(s3t*q_dev*q_dev));
  double tempw  = -(9.0/2.0)*(1.0/(s3t*q3));
  tensor s_pq_d_mn = s("pq")*I2("mn");
  tensor s_pn_d_mq = s_pq_d_mn.transpose0101();
  tensor d_pq_s_mn = I2("pq")*s("mn");
  tensor d_pn_s_mq = d_pq_s_mn.transpose0101();
  tensor p = I_pmqn  - I_pqmn*(1.0/3.0);
  tensor w = s_pn_d_mq+d_pn_s_mq - s_pq_d_mn*(2.0/3.0)-d_pq_s_mn*(2.0/3.0);
// finally
  ret = (s("pq")*s("mn")*tempss + s("pq")*t("mn")*tempst +
         t("pq")*s("mn")*tempts + t("pq")*t("mn")*temptt +
         p*tempp + w*tempw );
   return ret;
 }
```

702.5.5 Application to Computations in Elastoplasticity

A useful application of the previously described classes is for elastoplastic computations. If the Newton iterative scheme is used at the global equilibrium level, then in order to preserve a quadratic rate, a consistent, algorithmic tangent stiffness (ATS) tensor should be used. For a general class of three–invariant, non–associated, hardening or softening material models, ATS is defined (Jeremić and Sture, 1997) as:

$$
{}^{cons}E^{ep}_{pqmn} = R_{pqmn} - \frac{R_{pqkl}\,{}^{n+1}H_{kl}\,{}^{n+1}n_{ij}R_{ijmn}}{{}^{n+1}n_{ot}R_{otpq}\;{}^{n+1}H_{pq} + {}^{n+1}\xi_*\;h_*}
$$

where

$$
m_{kl} = \frac{\partial Q}{\partial \sigma_{kl}} \quad ; \quad n_{kl} = \frac{\partial F}{\partial \sigma_{kl}} \quad ; \quad \xi_* = \frac{\partial F}{\partial q_*} \quad ; \quad T_{ijmn} = \delta_{im}\delta_{nj} + \Delta\lambda\; E_{ijkl}\,\frac{\partial m_{kl}}{\partial \sigma_{mn}}
$$

$$
H_{kl} = {}^{n+1}m_{kl} + \Delta\lambda \frac{\partial m_{kl}}{\partial q_*} h_* \quad ; \quad R_{mnkl} = \left({}^{n+1}T_{ijmn}\right)^{-1} E_{ijkl}
$$

A straightforward implementation of the above tensorial formula follows:

```
    double Ey = Criterion.E();
    double nu = Criterion.nu();
    tensor Eel = StiffnessTensorE(Ey,nu);
```

```
    tensor I2("I", 2, DefDim2);
    tensor I_ijkl = I2("ij")*I2("kl");
    tensor I_ikjl = I_ijkl.transpose0110();
    tensor m = Criterion.dQods(final_stress);
    tensor n = Criterion.dFods(final_stress);
    double lambda = current_lambda_get();
    tensor d2Qoverds2 = Criterion.d2Qods2(final_stress);
    tensor T = I_ikjl + Eel("ijkl")*d2Qoverds2("klmn")*lambda;
    tensor Tinv = T.inverse();
    tensor R = Tinv("ijmn")*Eel("ijkl");
    double h_  =  h(final_stress);
    double xi_ = xi(final_stress);
    double hardMod_ = h_ * xi_;
    tensor d2Qodqast2 = d2Qoverdqast2(final_stress);
    tensor H = m + d2Qodqast2 * lambda * h_;
//
    tensor upper = R("pqkl")*H("kl")*n("ij")*R("ijmn");
    double lower = (n("ot")*R("otpq"))*H("pq")).trace();
    lower = lower + hardMod_;
    tensor Ep = upper*(1./lower);
    tensor Eep =  R - Ep; // elastoplastic ATS constitutive tensor
```

This ATS tensor can be used further in building finite element stiffness tensors, as will be shown in our next example.

702.5.6 Stiffness Matrix Example

By applying a numerical integration technique to the stiffness matrix equation

$$k^e_{aIcJ} = \int_{V^m} H_{I,b}\, E_{abcd}\, H_{J,d}\, dV^m$$

individual contributions are summed into the element stiffness tensor. This process can be implemented on a integration point level by using the nDarray tool as

```
  K  =  K  +  H("Ib") * E("abcd") * H("Jd") * weight ;
```

It is interesting to note the lack of loops at this level of implementation. However, there exists a loop over integration points which contributes stiffness to the element tensor.

702.6 Performance Issues

In the course of developing the nDarray tool, execution speed was not a priority or issue that we tried to perfect. The benefit of being able to implement and test various numerical algorithms in a straightforward manner was the main concern. The efficiency of the nDarray tool when compared with FORTRAN or C was never assessed. In all honesty, some of the formulae implemented in C++ with the help of the nDarray tool would be difficult to implement in FORTRAN or C. The entire question of efficiency of the nDarray as compared to FORTRAN or C codes might thus remain unanswered for the time being.

The efficiency of C++ for numerical computations has been under consideration (Robison, 1996) for some time now. Poor efficiency and possible remedies for improving efficiency of C++ computations has been reported in literature (Robison, 1996) (Veldhuizen, 1995b) (Veldhuizen, 1996). Novel techniques, such as *Template Expressions* (Veldhuizen, 1995b) can be used to achieve and sometimes surpass the performance of hand–tuned FORTRAN or C codes.

702.7 Summary and Future Directions

A novel programming tool, named nDarray, has been presented which facilitates implementation of tensorial formulae. It was shown how OOP and efficient programming in C++ allows building of new concrete data types, in this case tensors of any order. In a number of examples these new data types were shown to be useful in implementing tensorial formulae associated with the numerical solution of various elastic and elastoplastic problems with the finite element method. The nDarray tool is been used in developing of the FEMtools tools library. The FEMtools tools library includes a set of finite elements, various solvers, solution procedures for non–linear finite element system of equations and other useful functions.

Appendix 703

Closed Form Gradients to the Plastic Potential Function

(1993-1994-)

703.1 Chapter Summary and Highlights

A complete derivation of gradients to the Potential and Yield function follows. The yield function F and potential function Q are functions of the stress tensor σ_{ij} and plastic internal variable tensor q_*. Only derivatives with respect to the stress tensor σ_{ij} are given here. It is assumed that any stress state can be represented with three stress invariants p, q and θ given in the following form:

$$p = -\frac{1}{3} I_1 \quad q = \sqrt{3 J_{2D}} \quad \cos 3\theta = \frac{3\sqrt{3}}{2} \frac{J_{3D}}{\sqrt{(J_{2D})^3}} \tag{703.1}$$

$$I_1 = \sigma_{kk} \quad J_{2D} = \frac{1}{2} s_{ij} s_{ij} \quad J_{3D} = \frac{1}{3} s_{ij} s_{jk} s_{ki} \quad s_{ij} = \sigma_{ij} - \frac{1}{3} \sigma_{kk} \delta_{ij} \tag{703.2}$$

and stresses are chosen as positive in tension. One can write the Potential Function in the following form:

$$Q = Q(p, q, \theta) \tag{703.3}$$

and the derivation follows. Hopefully the pace of derivation is rather slow, thus little explanation will be given until the end of the derivation. Chain rule of differentiation yields:

$$\frac{\partial Q}{\partial \sigma_{ij}} = \frac{\partial Q}{\partial p} \frac{\partial p}{\partial \sigma_{ij}} + \frac{\partial Q}{\partial q} \frac{\partial q}{\partial \sigma_{ij}} + \frac{\partial Q}{\partial \theta} \frac{\partial \theta}{\partial \sigma_{ij}} \tag{703.4}$$

and the intermediate derivatives are:

$$\frac{\partial p}{\partial \sigma_{ij}} = \frac{\partial(-\frac{1}{3}\sigma_{kk})}{\partial \sigma_{ij}} = -\frac{1}{3}\,\delta_{ij} \tag{703.5}$$

$$\frac{\partial q}{\partial \sigma_{ij}} = \frac{\partial \sqrt{3J_{2D}}}{\partial \sigma_{ij}} = \frac{\sqrt{3}}{2}\frac{1}{\sqrt{J_{2D}}}\frac{\partial J_{2D}}{\partial \sigma_{ij}} = \frac{\sqrt{3}}{2}\frac{1}{\sqrt{J_{2D}}}\,s_{ij} = \frac{3}{2}\frac{1}{q}s_{ij} \tag{703.6}$$

$$\frac{\partial \theta}{\partial \sigma_{ij}} = \tag{703.7}$$

$$= \quad \frac{1}{3}\frac{-1}{\sqrt{1-(\frac{3\sqrt{3}}{2}\frac{J_{3D}}{J_{2D}^{3/2}})^2}}\frac{3\sqrt{3}}{2}\left(\frac{\partial J_{3D}}{\partial \sigma_{ij}}\frac{1}{\sqrt{(J_{2D})^3}} - \frac{3}{2}J_{3D}\frac{\partial J_{2D}}{\partial \sigma_{ij}}\frac{1}{\sqrt{(J_{2D})^5}}\right) =$$

$$= \quad \frac{1}{3\sqrt{1-\left(\frac{3\sqrt{3}}{2}\frac{J_{3D}}{J_{2D}^{3/2}}\right)^2}}\frac{3\sqrt{3}}{2}\left(-t_{ij}\frac{1}{\sqrt{(J_{2D})^3}} + \frac{3}{2}J_{3D}s_{ij}\frac{1}{\sqrt{(J_{2D})^5}}\right) =$$

$$= \quad \frac{1}{\sin 3\theta}\frac{\sqrt{3}}{2}\left(\frac{3}{2}J_{3D}\frac{1}{\sqrt{(J_{2D})^5}}\;s_{ij} - \frac{1}{\sqrt{(J_{2D})^3}}\;t_{ij}\right) =$$

$$= \quad \frac{\sqrt{3}}{2}\frac{1}{\sin(3\theta)}\left(\frac{\sqrt{3}\cos(3\theta)}{q^2}\;s_{ij} - \frac{3\sqrt{3}}{q^3}\;t_{ij}\right) =$$

$$= \quad \frac{3}{2}\frac{\cos(3\theta)}{q^2\sin(3\theta)}s_{ij} - \frac{9}{2}\frac{1}{q^3\sin(3\theta)}t_{ij} \tag{703.8}$$

Second derivatives of the potential function Q using again the chain rule of differentiation are as follows:

$$
\begin{aligned}
&\frac{\partial^2 Q}{\partial \sigma_{pq} \partial \sigma_{mn}} = \frac{\partial \left(\frac{\partial Q}{\partial \sigma_{pq}} \right)}{\partial \sigma_{mn}} = \\
&\frac{\partial \left(\frac{\partial Q}{\partial p} \frac{\partial p}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial q} \frac{\partial q}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial \theta} \frac{\partial \theta}{\partial \sigma_{pq}} \right)}{\partial \sigma_{mn}} = \\
&\frac{\partial \left(\frac{\partial Q}{\partial p} \right)}{\partial \sigma_{mn}} \frac{\partial p}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial p} \frac{\partial^2 p}{\partial \sigma_{pq} \partial \sigma_{mn}} + \\
+ \quad &\frac{\partial \left(\frac{\partial Q}{\partial q} \right)}{\partial \sigma_{mn}} \frac{\partial q}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial q} \frac{\partial^2 q}{\partial \sigma_{pq} \partial \sigma_{mn}} + \\
+ \quad &\frac{\partial \left(\frac{\partial Q}{\partial \theta} \right)}{\partial \sigma_{mn}} \frac{\partial \theta}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial \theta} \frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}} = \\
&\left(\frac{\partial^2 Q}{\partial p^2} \frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial p \partial q} \frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial p \partial \theta} \frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial p}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial p} \frac{\partial^2 p}{\partial \sigma_{pq} \partial \sigma_{mn}} + \\
+ \quad &\left(\frac{\partial^2 Q}{\partial q \partial p} \frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial q^2} \frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial q \partial \theta} \frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial q}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial q} \frac{\partial^2 q}{\partial \sigma_{pq} \partial \sigma_{mn}} + \\
+ \quad &\left(\frac{\partial^2 Q}{\partial \theta \partial p} \frac{\partial p}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial \theta \partial q} \frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial^2 Q}{\partial \theta^2} \frac{\partial \theta}{\partial \sigma_{mn}} \right) \frac{\partial \theta}{\partial \sigma_{pq}} + \frac{\partial Q}{\partial \theta} \frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}}
\end{aligned}
$$

and the intermediate derivatives are as follows:

$$
\frac{\partial^2 p}{\partial \sigma_{pq} \partial \sigma_{mn}} = \frac{\partial^2 \left(-\frac{1}{3} \sigma_{kk} \right)}{\partial \sigma_{pq} \partial \sigma_{mn}} = \frac{\partial \left(-\frac{1}{3} \delta_{kp} \delta_{qk} \right)}{\partial \sigma_{mn}} = \emptyset
$$

$$
\begin{aligned}
\frac{\partial^2 q}{\partial \sigma_{pq} \partial \sigma_{mn}} &= \frac{\partial \left(\frac{\partial q}{\partial \sigma_{pq}} \right)}{\partial \sigma_{mn}} = \\
\frac{\partial \left(\frac{\sqrt{3}}{2} \frac{1}{\sqrt{J_{2D}}} s_{pq} \right)}{\partial \sigma_{mn}} = \frac{\sqrt{3}}{2} \frac{1}{\sqrt{J_{2D}}} \frac{\partial s_{pq}}{\partial \sigma_{mn}} + \frac{\sqrt{3}}{2} \frac{\partial \frac{1}{\sqrt{J_{2D}}}}{\partial \sigma_{mn}} s_{pq} &= \\
\frac{\sqrt{3}}{2} \frac{1}{\sqrt{J_{2D}}} \left(\delta_{pm} \delta_{nq} - \frac{1}{3} \delta_{pq} \delta_{km} \delta_{nk} \right) + \frac{\sqrt{3}}{2} \left(\frac{-1}{2} \left(\frac{1}{\left(\sqrt{J_{2D}} \right)^3} \right) s_{mn} \right) s_{pq} &= \\
\frac{\sqrt{3}}{2} \frac{1}{\sqrt{J_{2D}}} \left(\delta_{pm} \delta_{nq} - \frac{1}{3} \delta_{pq} \delta_{nm} \right) - \frac{\sqrt{3}}{4} \left(\frac{1}{\sqrt{J_{2D}}} \right)^3 s_{mn} s_{pq} &= \\
\frac{3}{2} \frac{1}{q} \left(\delta_{pm} \delta_{nq} - \frac{1}{3} \delta_{pq} \delta_{nm} \right) - \frac{9}{4} \frac{1}{q^3} \; s_{mn} s_{pq}
\end{aligned}
$$

Let us introduce a slightly different form for the equation $\frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}}$ in order to simplify writing:

$$\frac{\partial \theta}{\partial \sigma_{pq}} = \frac{3}{2}\frac{\cos(3\theta)}{q^2 \sin(3\theta)} s_{pq} - \frac{9}{2}\frac{1}{q^3 \sin(3\theta)} t_{pq} =$$

$$= AS\ s_{pq} + AT\ t_{pq}$$

where:

$$AS = \frac{3}{2}\frac{\cos(3\theta)}{q^2 \sin(3\theta)}$$

$$AT = -\frac{9}{2}\frac{1}{q^3 \sin(3\theta)}$$

Now the problem will be separated in two smaller problems, namely:

$$\frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}} = \frac{\partial \frac{\partial \theta}{\partial \sigma_{pq}}}{\partial \sigma_{mn}} =$$

$$\frac{\partial \left(\frac{3}{2}\frac{\cos(3\theta)}{q^2 \sin(3\theta)} s_{pq} - \frac{9}{2}\frac{1}{q^3 \sin(3\theta)} t_{pq} \right)}{\partial \sigma_{mn}} =$$

$$\frac{\partial \left(AS\ s_{pq} + AT\ t_{pq} \right)}{\partial \sigma_{mn}} =$$

$$\frac{\partial \left(AS\ s_{pq} \right)}{\partial \sigma_{mn}} + \frac{\partial \left(AT\ t_{pq} \right)}{\partial \sigma_{mn}}$$

Now let us take a look at $\frac{\partial (AS\ s_{pq})}{\partial \sigma_{mn}}$. Since:

$$
\begin{aligned}
&\frac{\partial \left(AS \; s_{pq} \right)}{\partial \sigma_{mn}} = \\
&\frac{\partial AS}{\partial \sigma_{mn}} \; s_{pq} + AS \; \frac{\partial s_{pq}}{\partial \sigma_{mn}} = \\
&\left(\frac{\partial AS}{\partial q} \frac{\partial q}{\partial \sigma_{mn}} + \frac{\partial AS}{\partial \theta} \frac{\partial \theta}{\partial \sigma_{mn}} \right) \; s_{pq} + AS \; \frac{\partial s_{pq}}{\partial \sigma_{mn}} = \\
&\Bigg(\frac{-3. \; \cot(3\,\theta)}{q^3} \; \frac{3}{2} \frac{1}{q} \; s_{mn} \; + \\
&+ \frac{-4.5 \csc(3\,\theta)^2}{q^2} \left(\frac{3}{2} \frac{\cos{(3\theta)}}{q^2 \sin{(3\theta)}} s_{mn} - \frac{9}{2} \frac{1}{q^3 \sin{(3\theta)}} t_{mn} \right) \Bigg) \; s_{pq} \; + \\
&\frac{3}{2} \frac{\cos{(3\theta)}}{q^2 \sin{(3\theta)}} \; p_{pqmn} = \\
&-\frac{9}{2} \frac{\cos 3\theta}{q^4 \sin{(3\theta)}} \; s_{pq} \; s_{mn} - \frac{27}{4} \frac{\cos 3\theta}{q^4 \sin^3 3\theta} \; s_{pq} \; s_{mn} + \frac{81}{4} \frac{1}{q^5 \sin^3 3\theta} \; s_{pq} \; t_{mn} \; + \\
&\frac{3}{2} \frac{\cos{(3\theta)}}{q^2 \sin{(3\theta)}} \; p_{pqmn} = \\
&-\left(\frac{9}{2} \frac{\cos 3\theta}{q^4 \sin{(3\theta)}} + \frac{27}{4} \frac{\cos 3\theta}{q^4 \sin^3 3\theta} \right) \; s_{pq} \; s_{mn} + \frac{81}{4} \frac{1}{q^5 \sin^3 3\theta} \; s_{pq} \; t_{mn} \; + \\
&\frac{3}{2} \frac{\cos{(3\theta)}}{q^2 \sin{(3\theta)}} \; p_{pqmn}
\end{aligned}
$$

where:

$$
p_{pqmn} = \frac{\partial s_{pq}}{\partial \sigma_{mn}} = \left(\delta_{mp} \delta_{nq} - \frac{1}{3} \delta_{pq} \delta_{mn} \right)
$$

is the projection tensor and:

$$
\frac{\partial AS}{\partial q} = \frac{-3. \; \cot(3\,\theta)}{q^3}
$$

$$
\frac{\partial AS}{\partial \theta} = \frac{-4.5 \csc(3\,\theta)^2}{q^2}
$$

The second member is $\frac{\partial (AT \; t_{pq})}{\partial \sigma_{mn}}$:

$$
\begin{aligned}
&\frac{\partial\left(AT\ t_{pq}\right)}{\partial\sigma_{mn}} = \\
&\frac{\partial AT}{\partial\sigma_{mn}}\ t_{pq} + AT\ \frac{\partial t_{pq}}{\partial\sigma_{mn}} = \\
&\left(\frac{\partial AT}{\partial q}\frac{\partial q}{\partial\sigma_{mn}} + \frac{\partial AT}{\partial\theta}\frac{\partial\theta}{\partial\sigma_{mn}}\right)\ t_{pq} + AT\ \frac{\partial t_{pq}}{\partial\sigma_{mn}} =
\end{aligned}
$$

$$
\begin{aligned}
&\left(\frac{13.5\ \csc(3\,\theta)}{q^4}\frac{3}{2}\frac{1}{q}\ s_{mn}+\right.\\
&\left.+\ \frac{13.5\ \cot(3\,\theta)\ \csc(3\,\theta)}{q^3}\left(\frac{3}{2}\frac{\cos(3\theta)}{q^2\sin(3\theta)}s_{mn} - \frac{9}{2}\frac{1}{q^3\sin(3\theta)}t_{mn}\right)\right)\ t_{pq} + \\
&+ - \frac{9}{2}\frac{1}{q^3\sin(3\theta)}\ w_{pqmn} =
\end{aligned}
$$

$$
\begin{aligned}
&\frac{81}{4}\frac{1}{q^5\sin 3\theta}\ t_{pq}\ s_{mn} + \frac{81}{4}\frac{\cos^2 3\theta}{q^5\sin^3 3\theta}\ t_{pq}\ s_{mn} - \frac{243}{4}\frac{\cos 3\theta}{q^6\sin^3 3\theta}\ t_{pq}\ t_{mn} - \\
&-\frac{9}{2}\frac{1}{q^3\sin(3\theta)}\ w_{pqmn} =
\end{aligned}
$$

$$
\begin{aligned}
&\left(\frac{81}{4}\frac{1}{q^5\sin 3\theta} + \frac{81}{4}\frac{\cos^2 3\theta}{q^5\sin^3 3\theta}\right)\ t_{pq}\ s_{mn} - \frac{243}{4}\frac{\cos 3\theta}{q^6\sin^3 3\theta}\ t_{pq}\ t_{mn} - \\
&-\frac{9}{2}\frac{1}{q^3\sin(3\theta)}\ w_{pqmn}
\end{aligned}
$$

where:

$$w_{pqmn} = \frac{\partial t_{pq}}{\partial \sigma_{mn}} = s_{np}\delta_{qm} + s_{qm}\delta_{np} - \frac{2}{3} s_{qp}\delta_{nm} - \frac{2}{3}\delta_{pq}s_{mn}$$

$$\frac{\partial AT}{\partial q} = \frac{13.5\ \csc(3\,\theta)}{q^4}$$

$$\frac{\partial AT}{\partial \theta} = \frac{13.5\ \cot(3\,\theta)\ \csc(3\,\theta)}{q^3}$$

Then finally by collecting terms back again we have:

$$\begin{aligned}
\frac{\partial^2 \theta}{\partial \sigma_{pq} \partial \sigma_{mn}} &= \\
\frac{\partial \left(AS\ s_{pq}\right)}{\partial \sigma_{mn}} + \frac{\partial \left(AT\ t_{pq}\right)}{\partial \sigma_{mn}} &= \\
-\left(\frac{9}{2}\frac{\cos 3\theta}{q^4 \sin(3\theta)} + \frac{27}{4}\frac{\cos 3\theta}{q^4 \sin^3 3\theta}\right)\ s_{pq}\ s_{mn} + \frac{81}{4}\frac{1}{q^5 \sin^3 3\theta}\ s_{pq}\ t_{mn} &+ \\
+\left(\frac{81}{4}\frac{1}{q^5 \sin 3\theta} + \frac{81}{4}\frac{\cos^2 3\theta}{q^5 \sin^3 3\theta}\right)\ t_{pq}\ s_{mn} - \frac{243}{4}\frac{\cos 3\theta}{q^6 \sin^3 3\theta}\ t_{pq}\ t_{mn} &+ \\
+\frac{3}{2}\frac{\cos(3\theta)}{q^2 \sin(3\theta)}\ p_{pqmn} - \frac{9}{2}\frac{1}{q^3 \sin(3\theta)}\ w_{pqmn}
\end{aligned}$$

Hyperelasticity, Detailed Derivations

(1995-1996-)

704.1 Chapter Summary and Highlights

704.2 Simo–Serrin's Formula

In order to derive the analytical gradient of the fourth order tensor

$$\mathcal{M}_{IJKL} = \frac{\partial M_{IJ}}{\partial C_{KL}} \tag{704.1}$$

we shall proceed by using the third equation in (106.86).

$$\begin{aligned}
\frac{\partial M_{IJ}}{\partial C_{KL}} &= \frac{1}{D_{(A)}} \left(I_{IKJL} - \frac{\partial I_1}{\partial \, C_{KL}} \delta_{IJ} + 2\lambda_{(A)} \, \frac{\partial \lambda_{(A)}}{\partial C_{KL}} \, \delta_{IJ} + \right. \\
&\left. + \frac{\partial I_3}{\partial C_{KL}} \, \lambda_{(A)}^{-2} \, (C^{-1})_{IJ} - 2\lambda_{(A)}^{-3} \, \frac{\partial \lambda_{(A)}}{\partial C_{KL}} \, I_3 \, (C^{-1})_{IJ} + \frac{\partial (C^{-1})_{IJ}}{\partial C_{KL}} \, \lambda_{(A)}^{-2} \, I_3 \right) - \\
&- \frac{1}{D_{(A)}^2} \, \frac{\partial D_{(A)}}{\partial C_{KL}} \left(C_{IJ} - \left(I_1 - \lambda_{(A)}^2 \right) \delta_{IJ} + I_3 \, \lambda_{(A)}^{-2} \, (C^{-1})_{IJ} \right)
\end{aligned} \tag{704.2}$$

where it was used that

$$\frac{\partial C_{IJ}}{\partial C_{KL}} = I_{IKJL} \tag{704.3}$$

Derivatives $\partial \lambda_{(A)} / \partial C_{KL}$ can be found by starting from equation for C_{IJ} (106.63) and differentiating it

$$dC_{IJ} = 2\lambda_A d\lambda_{(A)} \, \left(N_I^{(A)} N_J^{(A)} \right)_A + \lambda_A^2 \, \left(dN_I^{(A)} \, N_J^{(A)} \right)_A + \lambda_A^2 \, \left(N_I^{(A)} \, dN_J^{(A)} \right)_A \tag{704.4}$$

By premultiplying previous equation with $N_J^{(A)}$ and post-multiplying with $N_I^{(A)}$, and by noting that

$$N_I^{(A)} \, dN_I^{(A)} \equiv 0 \qquad ; \qquad \| N_I^{(A)} \| \equiv 1 \tag{704.5}$$

we get

$$N_J^{(A)} \, dC_{IJ} \, N_I^{(A)} = 2\lambda_A d\lambda_{(A)} \tag{704.6}$$

or

$$dC_{IJ} N_I^{(A)} \, N_J^{(A)} = dC_{IJ} \lambda_{(A)} \, M_{IJ}^{(A)} = 2\lambda_A d\lambda_{(A)} \quad \Rightarrow \quad \frac{\partial \lambda_A}{\partial C_{KL}} = \frac{1}{2} \, \lambda_{(A)} \, (M_{KL}^{(A)})_A \tag{704.7}$$

It can be proved[1] that

$$\frac{\partial I_1}{\partial \, C_{KL}} = \delta_{IJ} \quad ; \quad \frac{\partial I_2}{\partial \, C_{KL}} = I_1 \, \delta_{KL} - C_{KL} \quad ; \quad \frac{\partial I_3}{\partial \, C_{KL}} = I_3 \, (C^{-1})_{KL} \tag{704.8}$$

and since $I_3 = J^2$

$$\frac{\partial J}{\partial \, C_{KL}} = \frac{1}{2} \, J \, (C^{-1})_{KL} \tag{704.9}$$

---

[1] See Marsden and Hughes (1983)

With this in mind, equation (704.2) can be rewritten as:

$$\begin{aligned}
\frac{\partial M_{IJ}}{\partial C_{KL}} \; = \; & \frac{1}{D_{(A)}} \left(I_{IKJL} - \delta_{KL}\, \delta_{IJ} + 2\lambda_{(A)}^{2}\, \frac{1}{2}\, M_{KL}^{(A)}\, \delta_{IJ} + \right. \\
& + I_3\, \lambda_{(A)}^{-2}\, (C^{-1})_{IJ}\, (C^{-1})_{KL} - \lambda_{(A)}^{-2}\, I_3\, (C^{-1})_{IJ}\, M_{KL}^{(A)} + \\
& \left. + \frac{1}{2} \left((C^{-1})_{IK} (C^{-1})_{JL} + (C^{-1})_{IL} (C^{-1})_{JK} \right)\, \lambda_{(A)}^{-2}\, I_3 \right) - \\
& - \frac{1}{D_{(A)}}\, \frac{\partial D_{(A)}}{\partial C_{KL}} M_{IJ}
\end{aligned} \tag{704.10}$$

where the definition of M_{IJ} from equation (106.86) was used and also:

$$\frac{\partial (C^{-1})_{IJ}}{\partial C_{KL}} = -\frac{1}{2} \left((C^{-1})_{IK} (C^{-1})_{JL} + (C^{-1})_{IL} (C^{-1})_{JK} \right) = I_{IJKL}^{(C^{-1})} \tag{704.11}$$

Relation (704.11) can be obtained if one starts from the identity:

$$C_{IJ}\, (C^{-1})_{JK} = \delta_{IK} \tag{704.12}$$

which after differentiation reads:

$$\begin{aligned}
dC_{IJ}\, (C^{-1})_{JK} + C_{IJ}\, d(C^{-1})_{JK} = 0 \Rightarrow \\
\Rightarrow d(C^{-1})_{JK} = -(C^{-1})_{JM}\, dC_{MN}\, (C^{-1})_{NK} = \\
= -\frac{1}{2} \left((C^{-1})_{JM}\, (C^{-1})_{KN} + (C^{-1})_{JN}\, (C^{-1})_{KM} \right)\, dC_{MN} \Rightarrow \\
\Rightarrow \frac{\partial (C^{-1})_{JK}}{\partial C_{MN}} = -\frac{1}{2} \left((C^{-1})_{JM} (C^{-1})_{KN} + (C^{-1})_{JN} (C^{-1})_{KM} \right)
\end{aligned} \tag{704.13}$$

The derivative of $D_{(A)}$, that was defined in equation (106.77)as

$$D_{(A)} = 2\lambda_{(A)}^{4} - I_1 \lambda_{(A)}^{2} + I_3 \lambda_{(A)}^{-2} \tag{704.14}$$

is given by:

$$\begin{aligned}
\frac{\partial D_{(A)}}{\partial C_{KL}} &= 8\lambda_{(A)}^{3}\frac{\partial \lambda_{(A)}}{\partial C_{KL}} - \frac{\partial I_1}{\partial C_{KL}}\ \lambda_{(A)}^{2} - 2\lambda_{(A)} I_1\ \frac{\partial \lambda_{(A)}}{\partial C_{KL}} + \frac{\partial I_3}{\partial C_{KL}}\ \lambda_{(A)}^{-2} - 2\lambda_{(A)}^{-3} I_3\ \frac{\partial \lambda_{(A)}}{\partial C_{KL}} \\
&= 4\lambda_{(A)}^{4}\ M_{KL}^{(A)} - \delta_{KL}\ \lambda_{(A)}^{2} - \lambda_{(A)}^{2} I_1\ M_{KL}^{(A)} + I_3 (C^{-1})_{KL}\ \lambda_{(A)}^{-2} - \lambda_{(A)}^{-2} I_3\ M_{KL}^{(A)} \\
&= \left(4\lambda_{(A)}^{4} - \lambda_{(A)}^{2} I_1 - \lambda_{(A)}^{-2} I_3\right) M_{KL}^{(A)} - \delta_{KL}\ \lambda_{(A)}^{2} + I_3 (C^{-1})_{KL}\ \lambda_{(A)}^{-2} \\
&= D'_{(A)}\ M_{KL}^{(A)} - \delta_{KL}\ \lambda_{(A)}^{2} + I_3 (C^{-1})_{KL}\ \lambda_{(A)}^{-2}
\end{aligned} \tag{704.15}$$

where $D'_{(A)} = 4\lambda_{(A)}^{4} - \lambda_{(A)}^{2} I_1 - \lambda_{(A)}^{-2} I_3$. With the previous derivations, equation (704.10) can be written in expanded form as:

$$\begin{aligned}
\frac{\partial M_{IJ}}{\partial C_{KL}} = &\frac{1}{D_{(A)}} \Bigg(I_{IKJL} - \delta_{KL}\ \delta_{IJ} + 2\lambda_{(A)}^{2}\ \frac{1}{2}\ M_{KL}^{(A)}\ \delta_{IJ} + \\
&+ I_3\ \lambda_{(A)}^{-2}\ (C^{-1})_{IJ}\ (C^{-1})_{KL} - \lambda_{(A)}^{-2}\ I_3\ (C^{-1})_{IJ}\ M_{KL}^{(A)}\ + \\
&+ \frac{1}{2}\left((C^{-1})_{IK}(C^{-1})_{JL} + (C^{-1})_{IL}(C^{-1})_{JK}\right)\ \lambda_{(A)}^{-2}\ I_3\ - \\
&- \left(D'_{(A)}\ M_{KL}^{(A)} - \delta_{KL}\ \lambda_{(A)}^{2} + I_3 (C^{-1})_{KL}\ \lambda_{(A)}^{-2}\right) M_{IJ} \Bigg)
\end{aligned} \tag{704.16}$$

If one collects similar terms, equation (704.16), also known as *Simo–Serrin's formula* can be written in the final form as:

$$\begin{aligned}
\frac{\partial M_{IJ}}{\partial C_{KL}} = &\ \mathcal{M}_{IJKL} = \\
&\frac{1}{D_{(A)}}\Bigg(I_{IKJL} - \delta_{KL}\ \delta_{IJ} + \lambda_{(A)}^{2}\left(\delta_{IJ}\ M_{KL}^{(A)} + M_{IJ}^{(A)}\ \delta_{KL}\right) + \\
&+ I_3\ \lambda_{(A)}^{-2}\left((C^{-1})_{IJ}\ (C^{-1})_{KL} + \frac{1}{2}\left((C^{-1})_{IK}(C^{-1})_{JL} + (C^{-1})_{IL}(C^{-1})_{JK}\right)\right) - \\
&- \lambda_{(A)}^{-2}\ I_3\ \left((C^{-1})_{IJ}\ M_{KL}^{(A)} + M_{IJ}^{(A)}\ (C^{-1})_{KL}\right) - D'_{(A)}\ M_{IJ}^{(A)}\ M_{KL}^{(A)}\Bigg)
\end{aligned} \tag{704.17}$$

704.3 Derivation of $\partial^{2vol}W/(\partial C_{IJ}\ \partial C_{KL})$

The volumetric part $\partial^{2vol}W/(\partial C_{IJ}\ \partial C_{KL})$ can be derived by starting from the equation (106.96):

$$
\begin{aligned}
&\frac{\partial^{2\,vol}W}{\partial C_{IJ}\;\partial C_{KL}} = \\
&\frac{\partial\left(\frac{1}{2}\,\frac{\partial^{vol}W}{\partial J}\;J\;(C^{-1})_{IJ}\right)}{\partial C_{KL}} = \\
&\frac{1}{2}\,\frac{\partial\left(\frac{\partial^{vol}W}{\partial J}\right)}{\partial C_{KL}}\;J\;(C^{-1})_{IJ} + \frac{1}{2}\,\frac{\partial^{vol}W}{\partial J}\,\frac{\partial\,(J)}{\partial C_{KL}}\;(C^{-1})_{IJ} + \frac{1}{2}\,\frac{\partial^{vol}W}{\partial J}\;J\;\frac{\partial\left((C^{-1})_{IJ}\right)}{\partial C_{KL}} \\
&= \\
&\frac{1}{2}\,\frac{\partial^2\,\left({}^{vol}W\right)}{\partial J\;\partial J}\,\frac{\partial J}{\partial C_{KL}}J\;(C^{-1})_{IJ} + \frac{1}{2}\,\frac{\partial\;{}^{vol}W}{\partial J}\;\frac{1}{2}\;J\;(C^{-1})_{KL}\;(C^{-1})_{IJ} + \frac{1}{2}\,\frac{\partial^{vol}W}{\partial J}\;J\;I^{(C^{-1})}_{IJKL} \\
&= \\
&\frac{1}{4}\;J^2\;\frac{\partial^2\;{}^{vol}W}{\partial J\;\partial J}\;(C^{-1})_{KL}(C^{-1})_{IJ} + \frac{1}{4}\;J\frac{\partial^{vol}W}{\partial J}\;(C^{-1})_{KL}\;(C^{-1})_{IJ} + \frac{1}{2}\;J\;\frac{\partial^{vol}W}{\partial J}\;I^{(C^{-1})}_{IJKL} \\
&= \\
&\frac{1}{4}\left(J^2\;\frac{\partial^2\;{}^{vol}W}{\partial J\;\partial J} + J\frac{\partial^{vol}W}{\partial J}\right)(C^{-1})_{KL}\;(C^{-1})_{IJ} + \frac{1}{2}\;J\;\frac{\partial^{vol}W}{\partial J}\;I^{(C^{-1})}_{IJKL}
\end{aligned}
\tag{704.18}
$$

where equations (704.11) and (704.9) were used.

704.4 Derivation of $\partial^{2iso}W/(\partial C_{IJ}\;\partial C_{KL})$

The isochoric part $\partial^{2iso}W/(\partial C_{IJ}\;\partial C_{KL})$ can be derived by starting from equation (106.97)

$$
\begin{aligned}
\frac{\partial^{2\,iso}W(\lambda_{(A)})}{\partial C_{IJ}\partial C_{KL}} &= \\
\frac{1}{2}\,\frac{\partial\left(w_A\;(M^{(A)}_{IJ})_A\right)}{\partial C_{KL}} &= \\
\frac{1}{2}\,\frac{\partial w_A}{\partial C_{KL}}\;(M^{(A)}_{IJ})_A + \frac{1}{2}\;w_A\;\frac{\partial (M^{(A)}_{IJ})_A}{\partial C_{KL}} &= \\
\frac{1}{2}\,\frac{\partial w_A}{\partial \lambda_B}\frac{\partial \lambda_B}{\partial C_{KL}}\;(M^{(A)}_{IJ})_A + \frac{1}{2}\;w_A\;(\mathcal{M}^{(A)}_{IJKL})_A &= \\
\frac{1}{2}\,\frac{\partial w_A}{\partial \lambda_B}\frac{1}{2}\;\lambda_{(B)}\;(M^{(B)}_{KL})_B(M^{(A)}_{IJ})_A + \frac{1}{2}\;w_A\;(\mathcal{M}^{(A)}_{IJKL})_A &= \\
\frac{1}{4}\;Y_{AB}\;(M^{(B)}_{KL})_B\;(M^{(A)}_{IJ})_A + \frac{1}{2}\;w_A\;(\mathcal{M}^{(A)}_{IJKL})_A &
\end{aligned}
\tag{704.19}
$$

where equation (704.7) was used and tensor Y_{AB} is defined as:

$$
Y_{AB} = \frac{\partial w_A}{\partial \lambda_B}\;\lambda_{(B)}
\tag{704.20}
$$

704.5 Derivation of w_A

$$
w_A = \frac{\partial^{iso}W}{\partial \lambda_{(A)}}\;\lambda_A \;=\; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_B}\;\frac{\partial \tilde{\lambda}_B}{\partial \lambda_{(A)}}\;\lambda_A
\tag{704.21}
$$

where $\tilde{\lambda}_B$ is the isochoric part of the stretch defined as

$$
\tilde{\lambda}_B = J^{-\frac{1}{3}}\;\lambda_B
\tag{704.22}
$$

From the definition of $\tilde{\lambda}_B$ in equation (704.22) it follows

$$
\frac{\partial \tilde{\lambda}_B}{\partial \lambda_{(A)}} \;=\; \frac{\partial J^{-\frac{1}{3}}}{\partial \lambda_{(A)}}\;\lambda_B + J^{-\frac{1}{3}}\;\frac{\partial \lambda_B}{\partial \lambda_{(A)}} \;= -\frac{1}{3}\;J^{-\frac{1}{3}}\;\lambda^{-1}_{(A)}\;\lambda_B + J^{-\frac{1}{3}}\;\delta_{B(A)}
\tag{704.23}
$$

since

$$
\frac{\partial J^{-\frac{1}{3}}}{\partial \lambda_{(A)}} = -\frac{1}{3}\;J^{-\frac{4}{3}}\;\;\frac{\partial \lambda_1\lambda_2\lambda_3}{\partial \lambda_{(A)}} = -\frac{1}{3}\;J^{-\frac{4}{3}}\;\;J\;\lambda^{-1}_{(A)} = -\frac{1}{3}\;J^{-\frac{1}{3}}\;\lambda^{-1}_{(A)}
\tag{704.24}
$$

then

$$
\begin{aligned}
w_A \;&=\; -\frac{1}{3}\;J^{-\frac{1}{3}}\;\frac{\partial^{iso}W}{\partial \tilde{\lambda}_B}\;\lambda^{-1}_{(A)}\;\lambda_B\;\lambda_{(A)} + J^{-\frac{1}{3}}\;\frac{\partial^{iso}W}{\partial \tilde{\lambda}_B}\;\delta_{B(A)}\;\lambda_{(A)} \\
&=\; -\frac{1}{3}\;\frac{\partial^{iso}W}{\partial \tilde{\lambda}_B}\;\tilde{\lambda}_B \;+\; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}}\;\tilde{\lambda}_{(A)}
\end{aligned}
\tag{704.25}
$$

704.6 Derivation of Y_{AB}

By starting from equation 704.20

$$Y_{AB} = \frac{\partial w_A}{\partial \lambda_B} \; \lambda_{(B)} \tag{704.26}$$

and by using equation 704.25

$$w_A = -\frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_C} \; \tilde{\lambda}_C \; + \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \tilde{\lambda}_{(A)} \tag{704.27}$$

we can write:

$$Y_{AB} = \frac{\partial w_A}{\partial \tilde{\lambda}_D} \; \frac{\partial \tilde{\lambda}_D}{\partial \lambda_B} \; \lambda_{(B)} \tag{704.28}$$

By first considering $\partial w_A / \partial \tilde{\lambda}_D$ we get:

$$\begin{aligned}
\frac{\partial w_A}{\partial \tilde{\lambda}_D} \; &= \; \frac{\partial \left(-\frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_C} \; \tilde{\lambda}_C \; + \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \tilde{\lambda}_{(A)} \right)}{\partial \tilde{\lambda}_D} \\
&= \; -\frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C - \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_C} \; \frac{\partial \tilde{\lambda}_C}{\partial \tilde{\lambda}_D} + \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} + \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \frac{\partial \tilde{\lambda}_{(A)}}{\partial \tilde{\lambda}_D} \\
&= \; -\frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C - \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_C} \; \delta_{CD} + \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} + \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \delta_{(A)D} \\
&= \; -\frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C - \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_D} \; + \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} + \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \delta_{(A)D}
\end{aligned} \tag{704.29}$$

Next, from equation 704.23, we have that

$$\frac{\partial \tilde{\lambda}_D}{\partial \lambda_{(B)}} = -\frac{1}{3} \; J^{-\frac{1}{3}} \; \lambda_{(B)}^{-1} \; \lambda_D + J^{-\frac{1}{3}} \; \delta_{D(B)} \tag{704.30}$$

and by multiplying the result for $\partial w_A / \partial \tilde{\lambda}_D$ from equation 704.29 and the result for $\partial \tilde{\lambda}_D / \partial \lambda_{(B)}$ from equation 704.30 we obtain:

$$\begin{aligned}
\frac{\partial w_A}{\partial \tilde{\lambda}_D} \; \frac{\partial \tilde{\lambda}_D}{\partial \lambda_{(B)}} = \; & + \; \frac{1}{9} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C \; J^{-\frac{1}{3}} \; \lambda_{(B)}^{-1} \; \lambda_D \; - \; \frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C J^{-\frac{1}{3}} \; \delta_{D(B)} \\
& + \; \frac{1}{9} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_D} \; J^{-\frac{1}{3}} \; \lambda_{(B)}^{-1} \; \lambda_D \; - \; \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_D} \; J^{-\frac{1}{3}} \; \delta_{D(B)} \\
& - \; \frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} J^{-\frac{1}{3}} \; \lambda_{(B)}^{-1} \; \lambda_D \; + \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} J^{-\frac{1}{3}} \; \delta_{D(B)} \\
& - \; \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \delta_{(A)D} J^{-\frac{1}{3}} \; \lambda_{(B)}^{-1} \; \lambda_D \; + \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \delta_{(A)D} J^{-\frac{1}{3}} \; \delta_{D(B)} \\
\\
= \; & + \; \frac{1}{9} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \; \tilde{\lambda}_C \; \lambda_{(B)}^{-1} \; \tilde{\lambda}_D \; - \; \frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_{(B)}} \; \tilde{\lambda}_C \; J^{-\frac{1}{3}} \\
& + \; \frac{1}{9} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_D} \; \lambda_{(B)}^{-1} \; \tilde{\lambda}_D \; - \; \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(B)}} \; J^{-\frac{1}{3}} \\
& - \; \frac{1}{3} \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \; \tilde{\lambda}_{(A)} \lambda_{(B)}^{-1} \; \tilde{\lambda}_D \; + \; \frac{\partial^{2\,iso}W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_{(B)}} \; \tilde{\lambda}_{(A)} \; J^{-\frac{1}{3}} \\
& - \; \frac{1}{3} \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \lambda_{(B)}^{-1} \; \tilde{\lambda}_{(A)} \; + \; \frac{\partial^{iso}W}{\partial \tilde{\lambda}_{(A)}} \; \delta_{(A)(B)} \; J^{-\frac{1}{3}}
\end{aligned} \tag{704.31}$$

where equation 704.22 was used. The final form for Y_{AB} is obtained by multiplying equation 704.31 with $\tilde{\lambda}_{(B)}$ to obtain:

$$
\begin{aligned}
Y_{AB} = \quad & \frac{\partial w_A}{\partial \tilde{\lambda}_D} \frac{\partial \tilde{\lambda}_D}{\partial \lambda_B} \lambda_{(B)} = \\
+ \quad & \frac{1}{9} \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \tilde{\lambda}_C \, \lambda^{-1}_{(B)} \, \tilde{\lambda}_D \, \lambda_{(B)} \quad - \quad \frac{1}{3} \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_C \, \tilde{\lambda}_{(B)} \\
+ \quad & \frac{1}{9} \frac{\partial^{iso} W}{\partial \tilde{\lambda}_D} \lambda^{-1}_{(B)} \, \tilde{\lambda}_D \, \lambda_{(B)} \quad - \quad \frac{1}{3} \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_{(B)} \\
- \quad & \frac{1}{3} \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \tilde{\lambda}_{(A)} \lambda^{-1}_{(B)} \, \tilde{\lambda}_D \, \lambda_{(B)} \quad + \quad \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_{(A)} \, \tilde{\lambda}_{(B)} \\
- \quad & \frac{1}{3} \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(A)}} \, \lambda^{-1}_{(B)} \, \tilde{\lambda}_{(A)} \, \lambda_{(B)} \quad + \quad \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(A)}} \delta_{(A)(B)} \, \tilde{\lambda}_{(B)}
\end{aligned}
\tag{704.32}
$$

By recognizing that $\lambda^{-1}_{(B)} \lambda_{(B)} \equiv 1$ and after rearranging elements, we can finally write the equation for Y_{AB} as:

$$
\begin{aligned}
Y_{AB} = \quad & \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(A)}} \delta_{(A)(B)} \, \tilde{\lambda}_{(B)} + \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_{(A)} \, \tilde{\lambda}_{(B)} \\
- \quad & \frac{1}{3} \left(\frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_C \, \tilde{\lambda}_{(B)} + \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(B)}} \tilde{\lambda}_{(B)} + \frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_{(A)} \partial \tilde{\lambda}_D} \tilde{\lambda}_{(A)} \tilde{\lambda}_D + \frac{\partial^{iso} W}{\partial \tilde{\lambda}_{(A)}} \tilde{\lambda}_{(A)} \right) \\
+ \quad & \frac{1}{9} \left(\frac{\partial^{2\,iso} W}{\partial \tilde{\lambda}_C \partial \tilde{\lambda}_D} \tilde{\lambda}_C \, \tilde{\lambda}_D + \frac{\partial^{iso} W}{\partial \tilde{\lambda}_D} \tilde{\lambda}_D \right)
\end{aligned}
\tag{704.33}
$$

Appendix 705

Body and Surface Wave Analytic Solutions

(2005-2001-2010-2011-2018-2019-2021-)

(In collaboration with Dr. Nima Tafazzoli, Mr. Chang-Gyun Jeong, and Dr. Hexiang Wang)

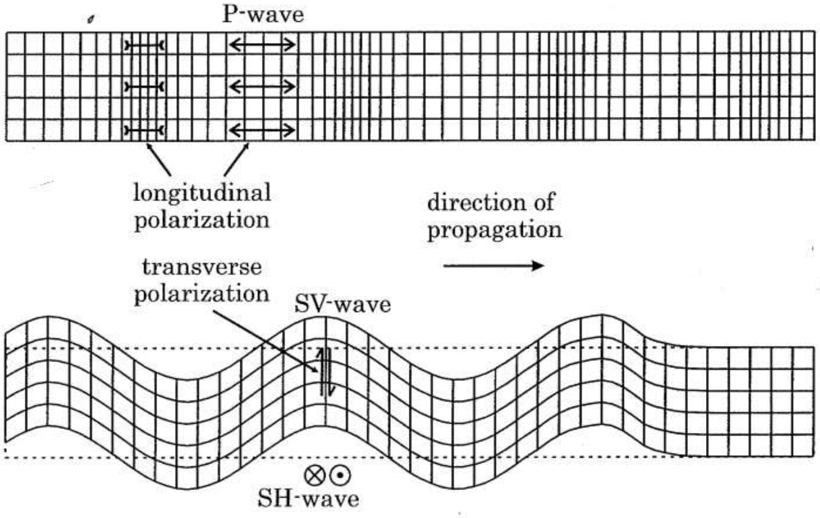

Figure 705.1: Motion due to plane pressure waves (P-wave) and shear waves (S-wave) (Semblat and Pecker, 2009)

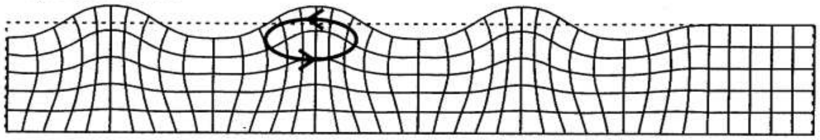

Figure 705.2: Particle movement due to surface Rayleigh waves near free surface (Semblat and Pecker, 2009)

705.1 3D Seismic Wave Field: Analytic Solution

In this chapter, wave field generation methods using analytic solution, and frequency wavenumber integration method are introduced. Theoretical background and examples are presented for each method.

705.1.1 Analytic solution

Seismic waves can be categorized as body waves and surface waves. The seismic body waves are traveling through the interior of the earth whereas the surface waves are traveling through the surface of the earth.

There are two different body waves, such as the pressure wave (also called as P wave, Figure 705.1 top) and the shear waves (also called as S wave, Figure 705.1 bottom). The shear waves which have the same velocity V_S can be polarized along its plane location to the direction of propagation (vertical plane - SV and horizontal plane - SH, Figure 705.1 bottom).

Surface waves are mainly categorized as Rayliegh waves (Rayleigh, 1885) and Love waves (Love,

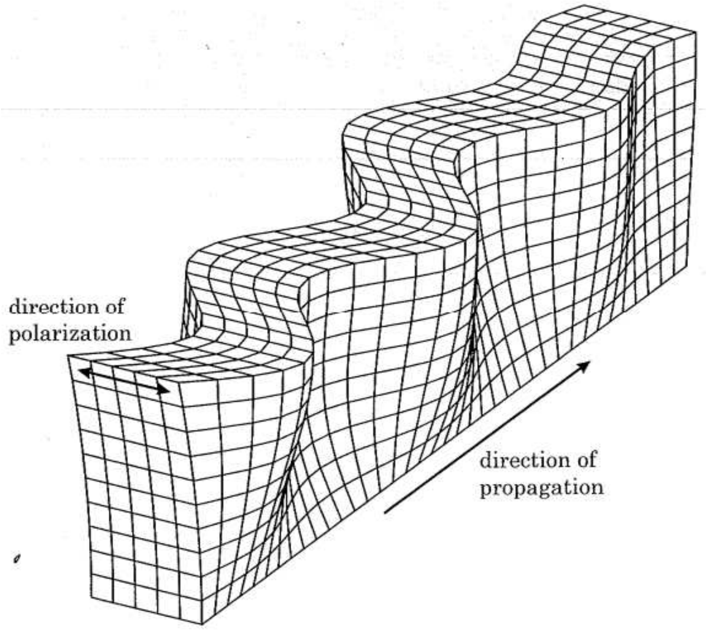

Figure 705.3: Displacements due to surface Love waves (Semblat and Pecker, 2009)

1911). The Rayleigh waves induce elliptical ground movement near the surface (Figure 705.2) whereas the Love waves induce shearing movement (Figure 705.3).

Following sections introduce full three dimensional exact-solution and its examples for plane body and surface waves in homogeneous media. The chapter does not include full derivation of equations since it's beyond the scope. Instead, final equations for body and surface waves are presented.

The original works for those problems are done by Green (1848), Knott (1899), and Wiechert and Zoeppritz (1907). The notations and equations hereafter are mainly based on Semblat and Pecker (2009) and Aki and Richard's work (Aki and Richards, 2002).

705.1.1.1 Wave equations for body waves

Hereafter, the reflection and refraction coefficients are indicated by using its wave component symbols. An acute and grave accents are adapted to explain the direction of propagation. The acute accent indicates an upcoming wave, and the grave accent indicates a down-going wave (e.g. $\acute{P}$, $\grave{P}$). For example, if the upcoming incident wave type is P and down-going reflected wave type is S, then reflected wave will be indicated as $\acute{P}\grave{S}$.

Reflected and transmitted waves arising from incident SH wave In the case of SH incident wave on the interface between two half-spaces, reflected wave is SH wave (Figure 705.4). The vector displacements

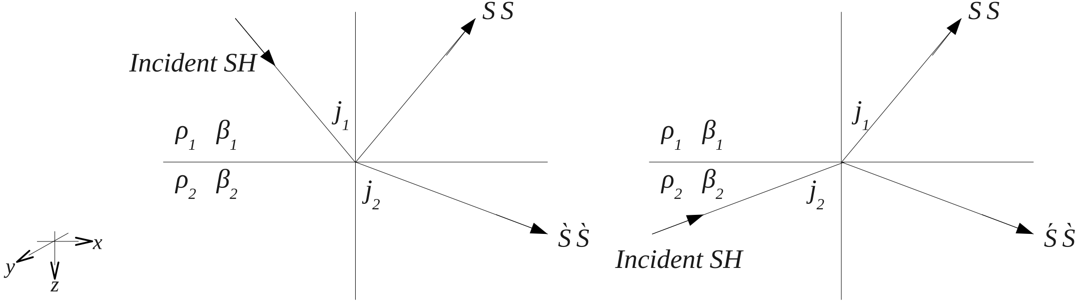

Figure 705.4: Schematic cartoon to show all possible coefficients of reflection and transmission with SH incident wave

for the downgoing and upgoing incident SH waves can be calculated as below equation (705.1) and (705.2), respectively (Aki and Richards, 2002).

$$
\begin{aligned}
\text{(Downgoing SH)} &= S(0, S, 0) exp \left[i\omega \left(px + \frac{\cos j_1}{\beta_1} z - t \right) \right] \\
\text{(Upgoing SH)} &= S(0, S, 0) \grave{S}\acute{S} exp \left[i\omega \left(px - \frac{\cos j_1}{\beta_1} z - t \right) \right] \\
\text{(Downgoing SH)} &= S(0, S, 0) \grave{S}\grave{S} exp \left[i\omega \left(px + \frac{\cos j_2}{\beta_2} z - t \right) \right]
\end{aligned}
\tag{705.1}
$$

$$
\begin{aligned}
\text{(Upgoing SH)} &= S(0, S, 0) exp \left[i\omega \left(px - \frac{\cos j_2}{\beta_2} z - t \right) \right] \\
\text{(Upgoing SH)} &= S(0, S, 0) \acute{S}\acute{S} exp \left[i\omega \left(px - \frac{\cos j_1}{\beta_1} z - t \right) \right] \\
\text{(downgoing SH)} &= S(0, S, 0) \acute{S}\grave{S} exp \left[i\omega \left(px + \frac{\cos j_2}{\beta_2} z - t \right) \right]
\end{aligned}
\tag{705.2}
$$

where,

$$
\begin{aligned}
\grave{S}\acute{S} &= \frac{\rho_1 \beta_1 \cos j_1 - \rho_2 \beta_2 \cos j_2}{\Delta} \\
\acute{S}\acute{S} &= \frac{2 \rho_2 \beta_2 \cos j_2}{\Delta} \\
\grave{S}\grave{S} &= \frac{2 \rho_1 \beta_1 \cos j_1}{\Delta} \\
\acute{S}\grave{S} &= -\grave{S}\acute{S} \\
\Delta &= \rho_1 \beta_1 \cos j_1 + \rho_2 \beta_2 \cos j_2
\end{aligned}
\tag{705.3}
$$

where α is the P wave velocity, β is the S wave velocity, ρ is the density, $p = (\sin i)/\alpha = (\sin j)/\beta$ is the ray parameter, and S is the amplitude of the incident wave.

Figure 705.4 shows all possible reflection and transmission coefficients with incident SH waves. Equation (705.4) is a ‘scattering matrix’ which includes every possible reflection and transmission coefficients

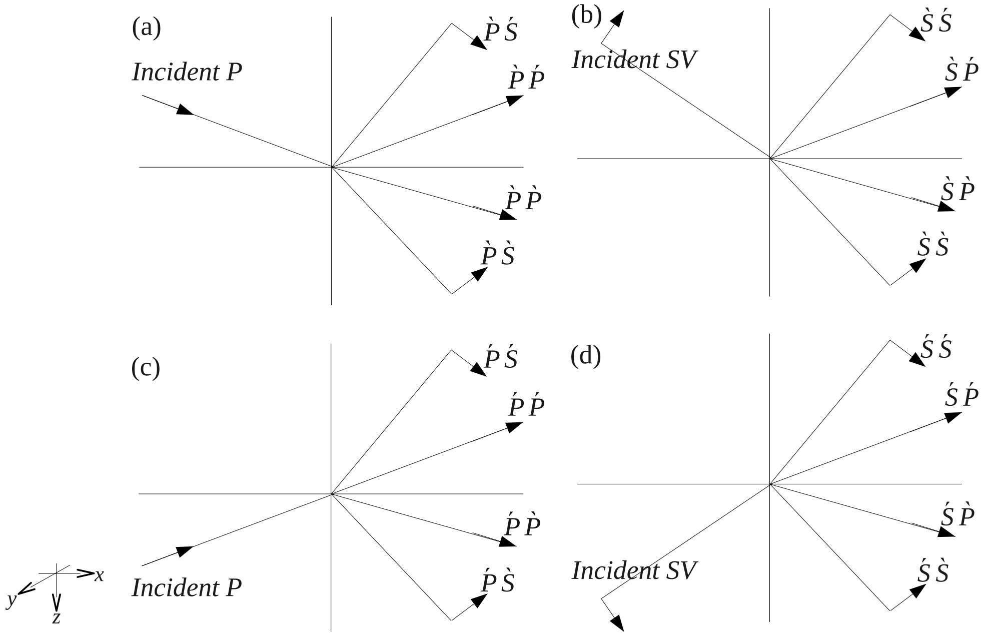

Figure 705.5: Schematic cartoon to show all possible coefficients of reflection and transmission with P/SV incident wave

for the problem. The matrix components have one to one relation with Figure 705.4.

$$\begin{pmatrix} \grave{S}\acute{S} & \acute{S}\acute{S} \\ \grave{S}\acute{S} & \acute{S}\grave{S} \end{pmatrix} \tag{705.4}$$

Reflected and transmitted waves arising from incident P/SV wave The displacements generated by the downgoing incident P/SV and upgoing incident P/SV waves can be calculated as below equation (705.5), (705.6), (705.7), and (705.8), respectively (Figure 705.5) (Aki and Richards, 2002).

$$\begin{aligned}
\text{(Downgoing P)} &= S(\sin i_1, 0, \cos i_1) exp\left[i\omega\left(px + \frac{\cos i_1}{\alpha_1}z - t\right)\right] \\
\text{(Upgoing P)} &= S(\sin i_1, 0, -\cos i_1)\grave{P}\acute{P} exp\left[i\omega\left(px - \frac{\cos i_1}{\alpha_1}z - t\right)\right] \\
\text{(Upgoing SV)} &= S(\cos j_1, 0, \sin j_1)\grave{P}\acute{S} exp\left[i\omega\left(px - \frac{\cos j_1}{\beta_1}z - t\right)\right] \\
\text{(Downgoing P)} &= S(\sin i_2, 0, \cos i_2)\grave{P}\grave{P} exp\left[i\omega\left(px + \frac{\cos i_2}{\alpha_2}z - t\right)\right] \\
\text{(Downgoing SV)} &= S(\cos j_2, 0, -\sin j_2)\grave{P}\grave{S} exp\left[i\omega\left(px + \frac{\cos j_2}{\beta_2}z - t\right)\right]
\end{aligned} \tag{705.5}$$

$$
\begin{aligned}

\grave{P}\acute{P} & \grave{S}\acute{P} & \acute{P}\acute{P} & \acute{S}\acute{P} \\
\grave{P}\acute{S} & \grave{S}\acute{S} & \acute{P}\acute{S} & \acute{S}\acute{S} \\
\grave{P}\grave{P} & \grave{S}\grave{P} & \acute{P}\grave{P} & \acute{S}\grave{P} \\
\grave{P}\grave{S} & \grave{S}\grave{S} & \acute{P}\grave{S} & \acute{S}\grave{S}
\end{pmatrix}
\tag{705.13}
$$

705.1.1.2 Wave equations for surface waves

Surface wave with incident SH wave – Love wave The displacements of surface wave due to the incident SH wave can be obtained by solving wave equations under free-surface condition (zero traction on surface). Below equation (705.14) shows the time history displacement with incident SH wave

(Semblat and Pecker, 2009).

$$
\begin{aligned}
u_y^i &= A_{SH} exp\left[\frac{i\omega}{V_S}\left(x\sin\theta_i^{SH} + z\cos\theta_i^{SH} - V_S t\right)\right] \\
u_y^R &= R_{SH} exp\left[\frac{i\omega}{V_S}\left(x\sin\theta_R^{SH} - z\cos\theta_R^{SH} - V_S t\right)\right] \\
u_y &= u_y^i + u_y^R = 2A_{SH}\cos\left(\frac{\omega z\cos\theta_i^{SH}}{V_S}\right) exp\left[\frac{i\omega}{V_S}\left(x\sin\theta_i - V_S t\right)\right]
\end{aligned}
\tag{705.14}
$$

As shown in equation (705.14) displacements of waves induced by incident SH waves can be calculated by summing incident and reflected waves on the ground surface. The particle movement of a Love wave is a perpendicular to the propagation plane.

Surface wave with incident P/SV wave – Rayleigh wave. Equation (705.15) shows the displacements of surface wave due to the incident P/SV waves (Semblat and Pecker, 2009).

$$
\begin{aligned}
u_x &= \frac{i\omega}{V_R} A\left(e^{az} - \frac{2ab}{b^2 + \omega^2/V_R^2} e^{bz}\right) exp\left[\frac{i\omega}{V_R}\left(x - V_R t\right)\right] \\
u_z &= aA\left(e^{az} - \frac{2\omega^2/V_R^2}{b^2 + \omega^2/V_R^2} e^{bz}\right) exp\left[\frac{i\omega}{V_R}\left(x - V_R t\right)\right]
\end{aligned}
\tag{705.15}
$$

where, $a^2 = \frac{\omega^2}{V_R^2} - \frac{\omega^2}{V_P^2}$, and $b^2 = \frac{\omega^2}{V_R^2} - \frac{\omega^2}{V_S^2}$.

Imaginary term on u_x shows that the components has a 90° phase shift from u_z. The particle movement of the wave is ellipses in x, z plane.

705.5 Wave Potential Formulation – Domain Reduction Method

Methodology presented here is from Wang et al. (2021).

Presented is a methodology developed to investigate influence of inclined body and surface seismic wave on linear or nonlinear earthquake soil structure interaction (ESSI) behavior of soil-structure systems. Methodology is based on Wave Potential Formulation (WPF) (Thomson, 1950; Haskell, 1953) as well as Domain Reduction Method (DRM) (Bielak et al., 2003a).

Presented WPF-DRM methodology consists of three main steps:

1. Analytic development of free field ground motions for a layered half space, excited by an incident, inclined plane wave. Development of this seismic wave field is relying on wave potential formulation in frequency-wave number domain. Time domain spatially varying ground motions are then synthesized through inverse Fourier transformation.
2. Development of the Effective Earthquake Forces, from DRM formulation, is then performed using free field seismic motions developed in the previous step.
3. Earthquake Soil Structure Interaction (ESSI) analysis of the soil-structure system is then performed using effective earthquake forces that are applied to a single layer of finite elements surrounding soil-structure system, so called DRM layer. The only waves that are radiated from the soil-structure system and exit the DRM layer are due to oscillations of the structure. These outgoing waves are absorbed by damping layers.

Sections ?? and ?? below provide details of Wave Potential Formulation and Domain Reduction Method, respectively.

Appendix 706

Body and Surface Wave Numerical Modeling

(2010-2012-2018-2019-2021-)

(In collaboration with Dr. Nima Tafazzoli, Mr. Chang-Gyun Jeong and Dr. Hexiang Wang)

706.1 Integral equations

Second method to generate wave fields is frequency-wavenumber integration method. The fk package is a frequency-wavenumber integration (Haskell, 1964; Wang and Herrmann, 1980) code developed by Zhu and Rivera (2002). The fk code package can be downloaded from `http://www.eas.slu.edu/People/LZhu`. In this section, using fk code package, wave propagation is simulated. The main modules of the fk code package and its function are shown as followings.

1. fk – compute Green's functions
2. syn – compute synthetic seismogram
3. fk.pl – PERL script to simplify the use of fk

First of all, Green's function is computed by fk with ground model properties (model layer dimension, shear and P wave velocity, density, Q and so on) and source, station (receiver) properties (source depth, epicentral distance, wave propagation direction, and receiver depth and so on). Then, Using syn with calculated Green's function, seismograph is synthesized with given variables such as magnitude, fault strike/dip/rake, and station azimuth. Synthesized seismograph (by syn) are stored as binary / Seismic Analysis Code (SAC) form (Goldstein and Snoke, 2005). Thus, in addition to fk package, Python code to run fk package iteratively, convert results from binary to ASCII text, and make plot is developed (plot.py). All necessary variables to run fk and syn can be adjusted in plot.py. Variables are explained in next sections and can also be found in source codes (fk.f, syn,c, fk.pl, and plot.py)

706.1.1 fk3.0 package

In this section, fk3.0 package is briefly introduced. All source code can be downloaded from `http://www.eas.slu.edu/People/LZhu`.

706.1.1.1 fk and 'sample_input'

Program fk can be run by using input text file or using PERL wrapper fk.pl as shown in next section. Example input file 'sample_input' is used to run fk. 'sample_input' is included in fk package. Total layer number, source layer number, source type, and receiver layer number are defined in the first row of input file. Layer properties are defined from second to fourth row (layer thickness / Vp / Vs / density / Qp / Qs values are defined from the first column to sixth column, respectively). Then, sigma, number of sampling points, sampling interval, tapering factor, high / low pass filter frequencies, slowness limit, epicentral distances are defined. In example, variables can be set as following.

Line1: 3 2 2 1 0

3 – total number of layers

2 – source is located at the top of 2nd layer

2 – double coupled source (0: explosion, 1: single coupled)

1 – receiver is located at the top of 1st layer

0 – consider both up and down going wave (1: down going wave, -1: up going wave)

Line2: 10.0000 6.3000 3.5000 2.7860 1000.00 500.00

10.0 – depth (km)

6.3 – Vp (km/s)

3.5 – Vs (km/s)

2.7860 – density (g/cm^3)

1000 – Qp

500 – Qs

Line3: 25.0000 6.3000 3.5000 2.7860 1000.00 500.00

ref. Line2

Line4: 0.0000 8.1000 4.7000 3.3620 1600.00 800.00

ref. Line2

Line5: 2 512 0.2 0.5 25 2 1 1

2 – sigma in 1/trace length, the small imaginary frequency (2 – 3)

512 – number of points in the time domain

0.2 – time step (sec, dt)

0.5 – tapering factor to suppress high frequencies

25 – number of points to be saved before t0

2 – smooth factor to increase the sampling rate

1 1 – high pass filter (wc1, wc2)

Line6: 0. 1 0.3 15

0. 1 – minimum and maximum slowness, to sepcify the window for the wavenumber integration (pmin, pmax)

0.3 – wavenumber sampling interval

15 – the maximum wavenumber at zero frequency

Line7: 1

1 – number of distance ranges

Line8: 200.00 20.00 200.grn.

200.00 – distance (km)

20.00 – t0

200.grn. – output file name

706.1.1.2 fk.pl

fk also can be run by PERL wrapper. Using the PERL wrapper fk.pl is strongly recommended by Zhu (README file of fk package). Since most of variables those are introduced on prior section are set to default values and also can be adjusted on the command line, it is much easier to use fk.pl than run fk.

706.1.1.3 syn

Using syn with calculated Green's function, seismogram is computed. Direction of fault (strike / dip / rake) and recording station (azimuth), magnitude have to be defined to run syn.

706.1.1.4 plot.py

As mentioned above, output seismogram is in SAC form (binary). PERL script plot.py is coded to convert binary to ASCII, run fk / syn repetitively, perform Fourier transform, and plot figures. Necessary options to run fk and syn can be adjusted in plot.py.

706.1.2 3D seismic wave field generation using integral equation

Using fk package, 3D seismic wave field is generated. Analysis for the most common fault mechanism (strike-slip, dip-slip, and normal fault) are presented. A real earthquake example (Northridge) is also given toward the end of the section.

706.1.2.1 Case 1: strike-slip fault / single layer ground

The first example is strike slip fault case. Model is as shown in Figure 706.1. Ground, fault, and wave properties are shown as below.

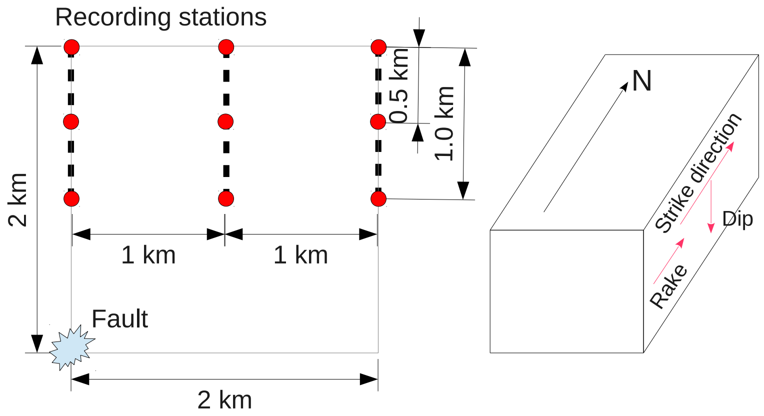

Figure 706.1: Ground and fault model used for analysis, results are captured on circles

- Ground properties
  - $V_S = 1$ km/s
  - $V_P/V_S = 1.73$
  - Poisson's ratio = 0.25
  - Density = 1.32 g/cm^3
  - Shear modulus = 1.32 GPa
  - Elastic modulus = 3.31 GPa
- Fault properties
  - Moment magnitude = 3.5
  - Strike = 0°
  - Dip = 90°
  - Rake = 0°
  - Double - coupled source
  - Triangular source time function
- Wave properties
  - dt = 0.1 s (Max available freq. = 5 Hz, Nyquist freq.)

As indicated above, single layer ground (Vs = 1 km/s) is modeled. Fault is located at 2 km depth, 2 km away from the recording points (stations). Double coupled fault source is assumed and triangular source time function is used (Aki and Richards, 2002). Nine recording points are set as recording stations (Figure 706.1). Direction of the fault is aligned parallel to the north (strike = 0°) and recording station azimuth is set to 0°, 45°, and 90°.

Figure 706.2 – 706.10 show analyses results for the example. Legends on figures mean 'component (epicentral distance, receiver depth)'. EW, NS, and UD components mean East - West, North - South, and Up - Down, respectively (those terms are used for all seismograms, hereafter).

Only EW components are predicted on the stations at 0° azimuth (Figure 706.2 – 706.4) and NS components are showed up on the station at 90° azimuth (Figure 706.8 – 706.10). On the station at 45° azimuth, all components (EW, NS, and UD) are observed.

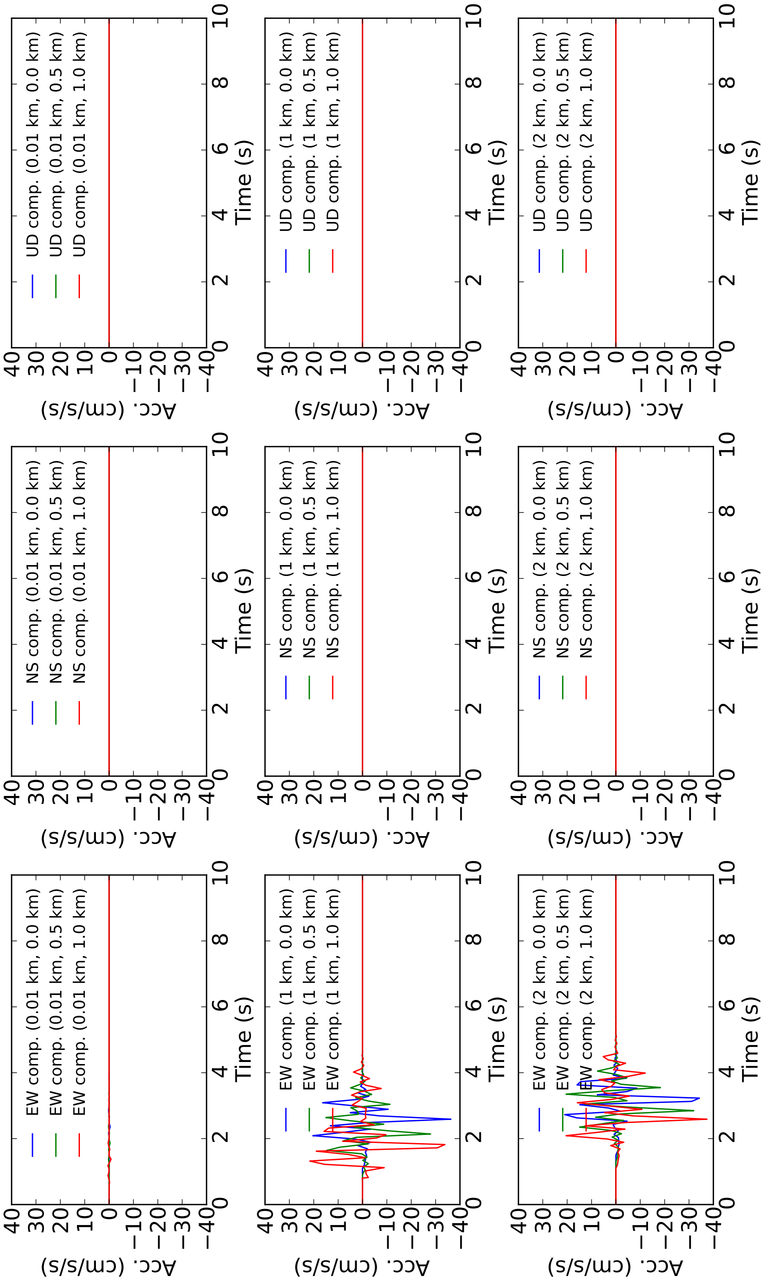

Figure 706.2: Calculated time history acceleration, station azimuth $= 0^{\circ}$

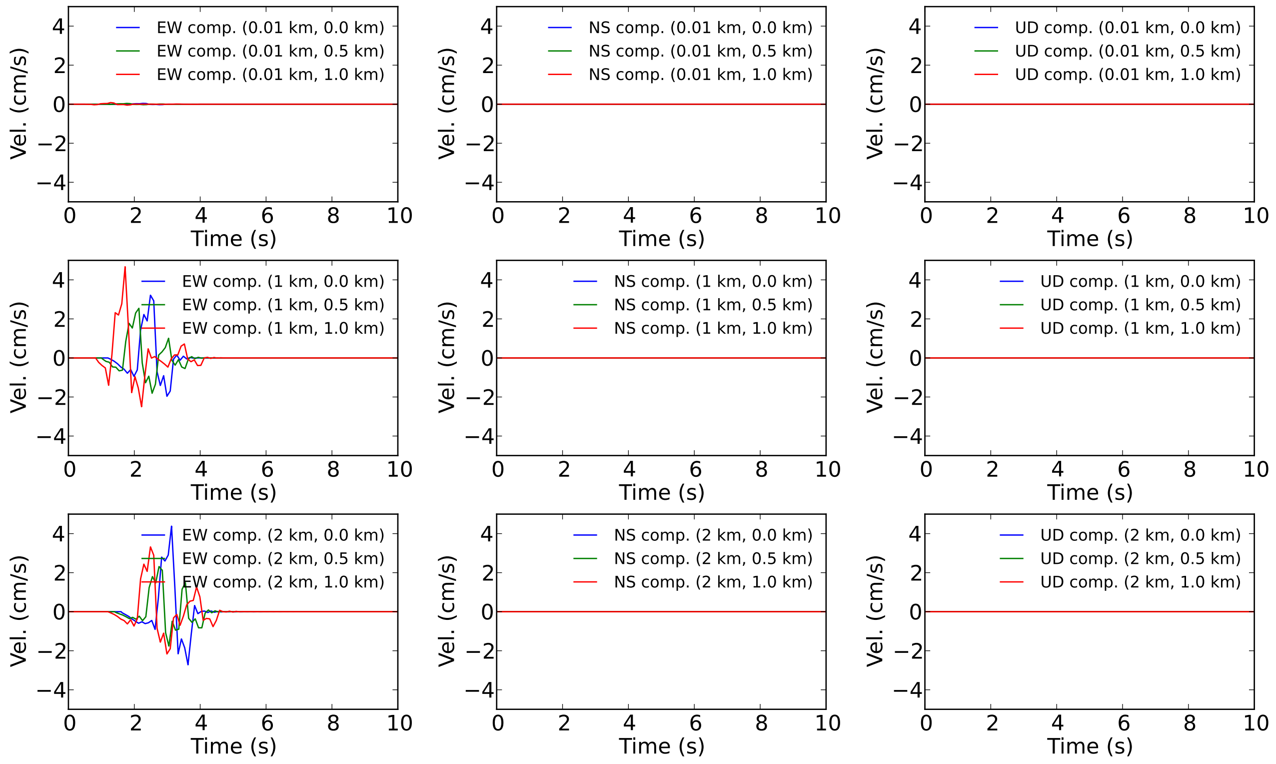

Figure 706.3: Calculated time history velocity, station azimuth $= 0^{\circ}$

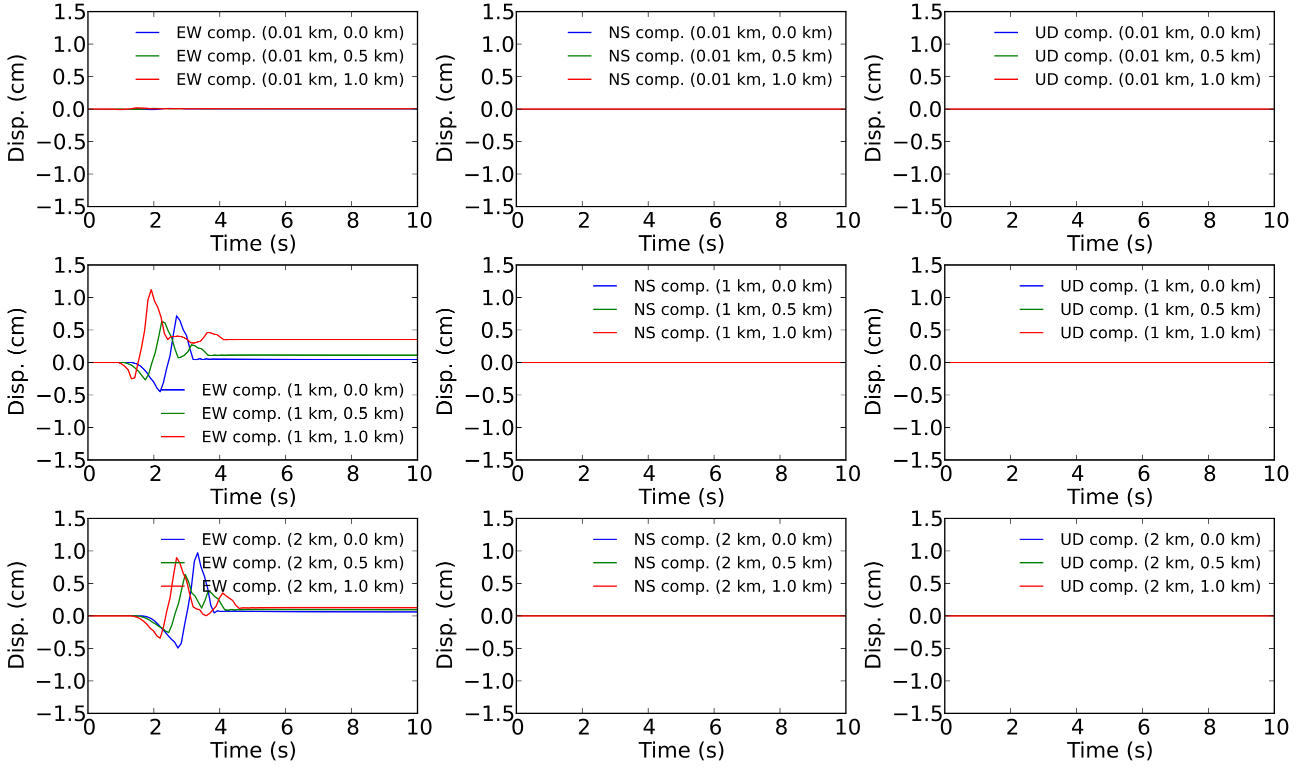

Figure 706.4: Calculated time history displacement, station azimuth $= 0^\circ$

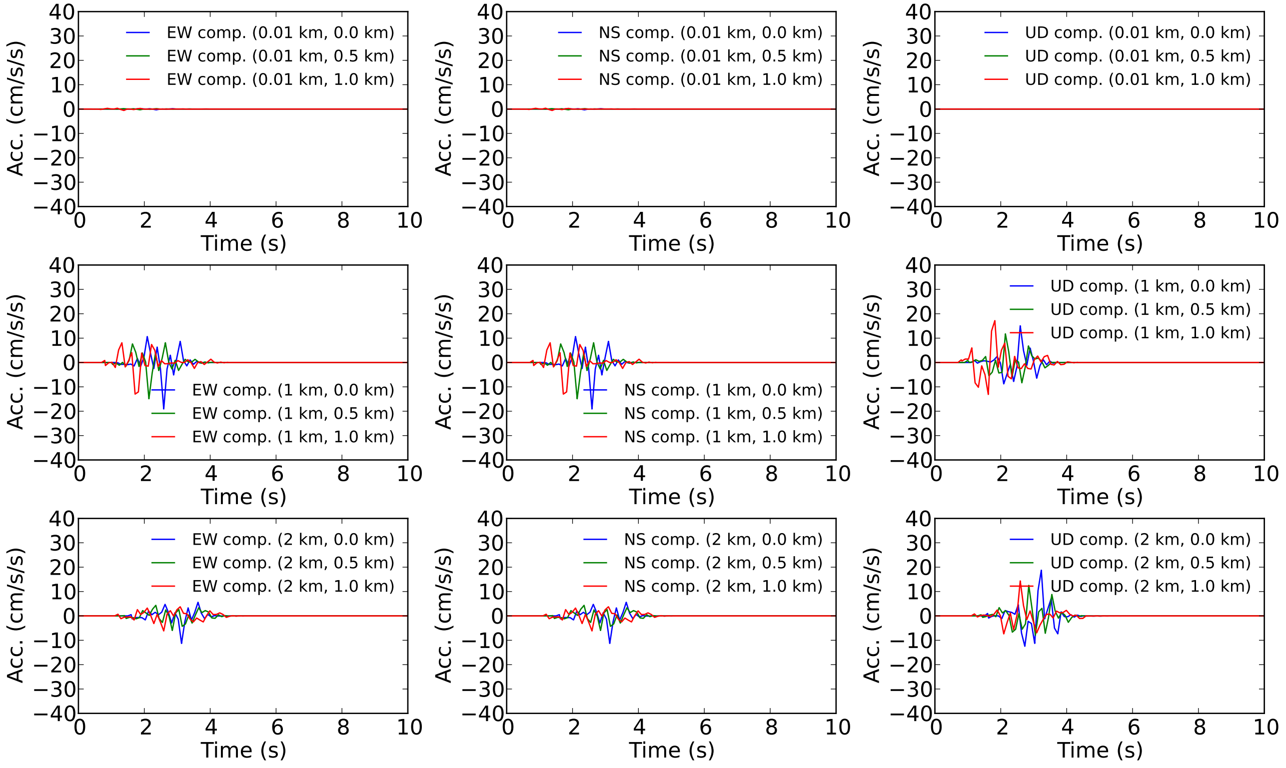

Figure 706.5: Calculated time history acceleration, station azimuth $= 45^{\circ}$

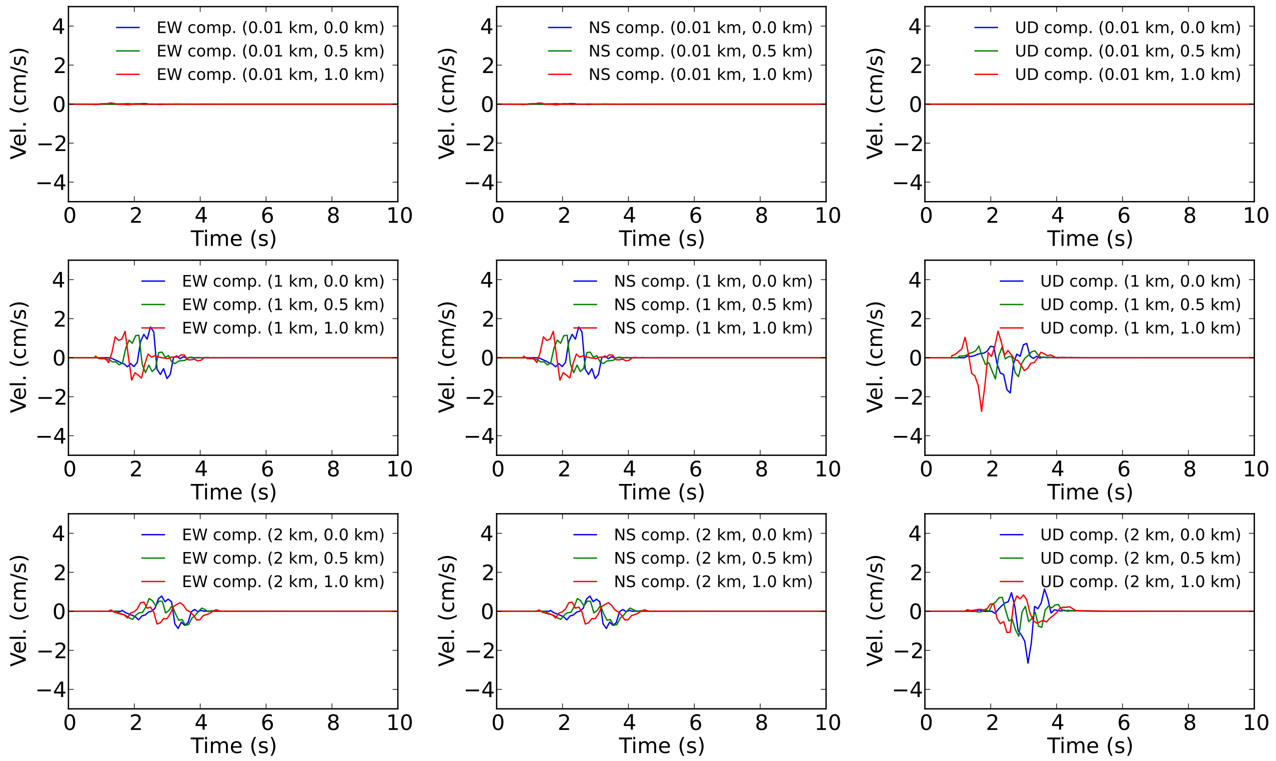

Figure 706.6: Calculated time history velocity, station azimuth = 45°

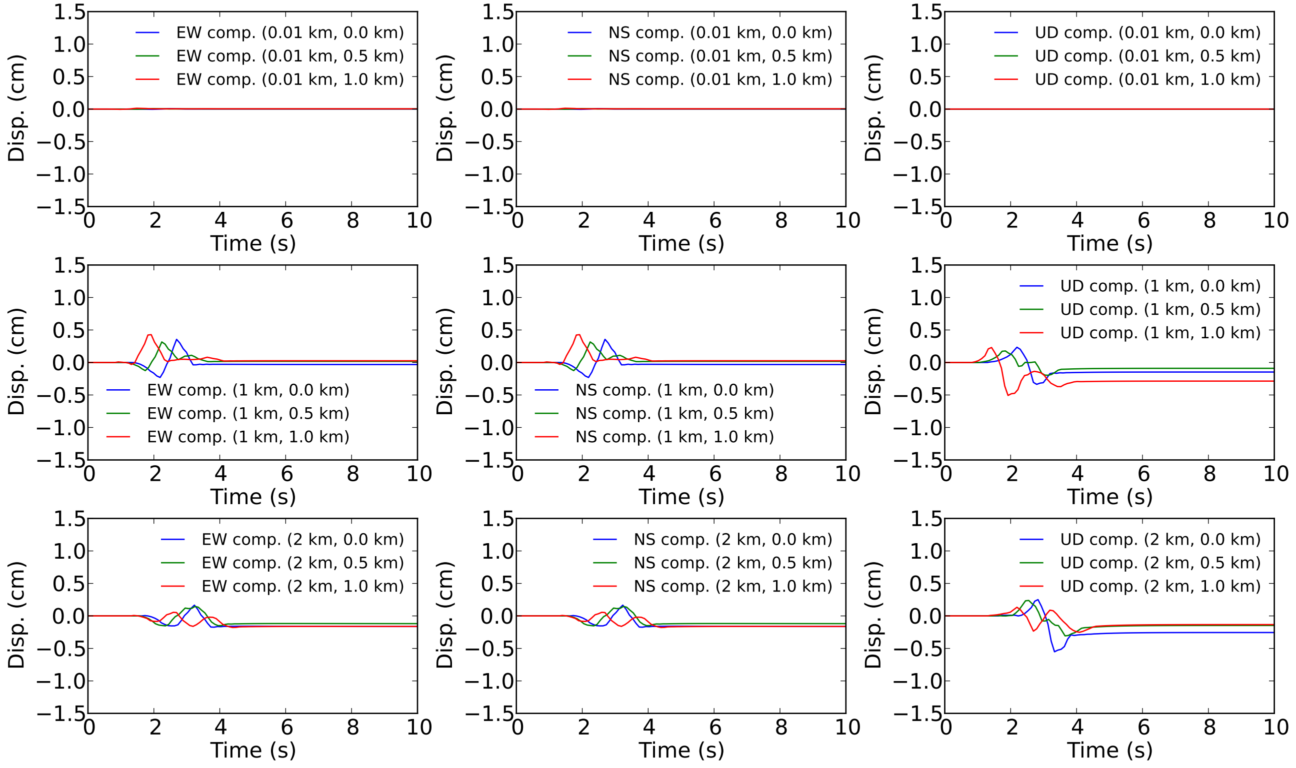

Figure 706.7: Calculated time history displacement, station azimuth = 45°

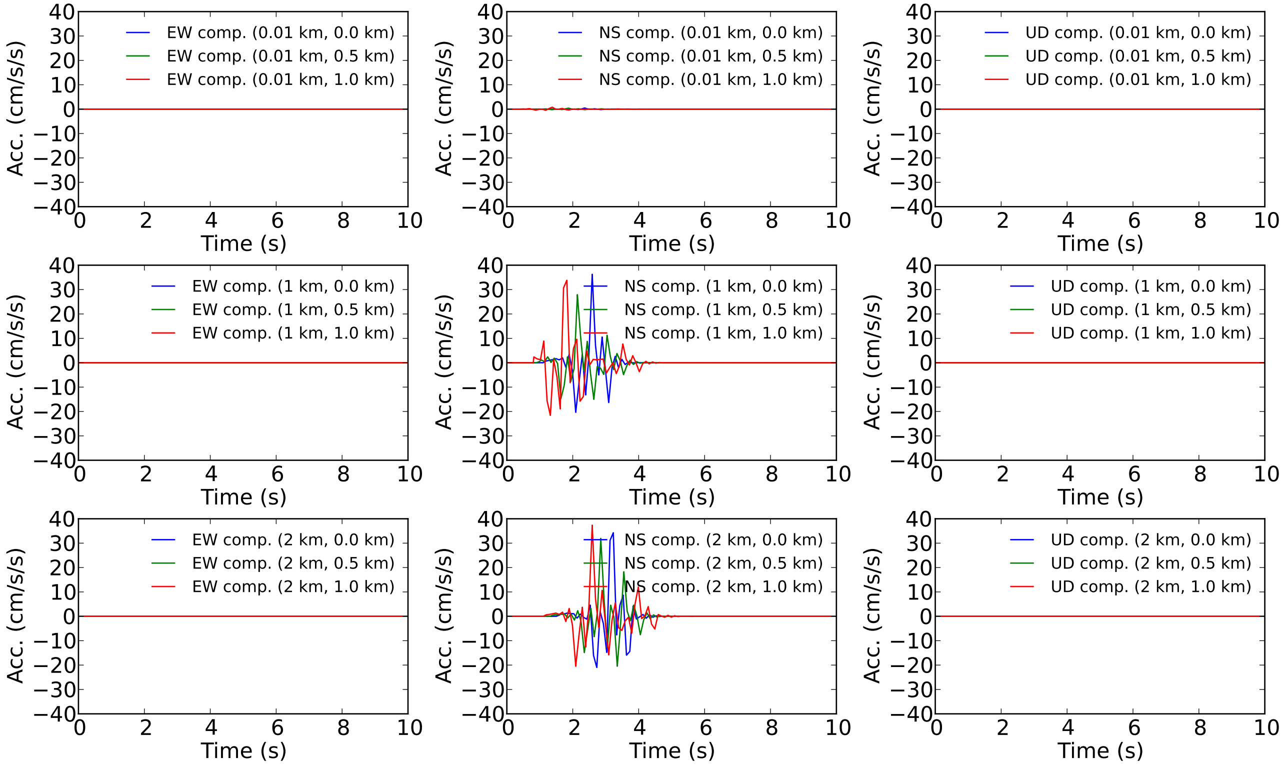

Figure 706.8: Calculated time history acceleration, station azimuth = 90°

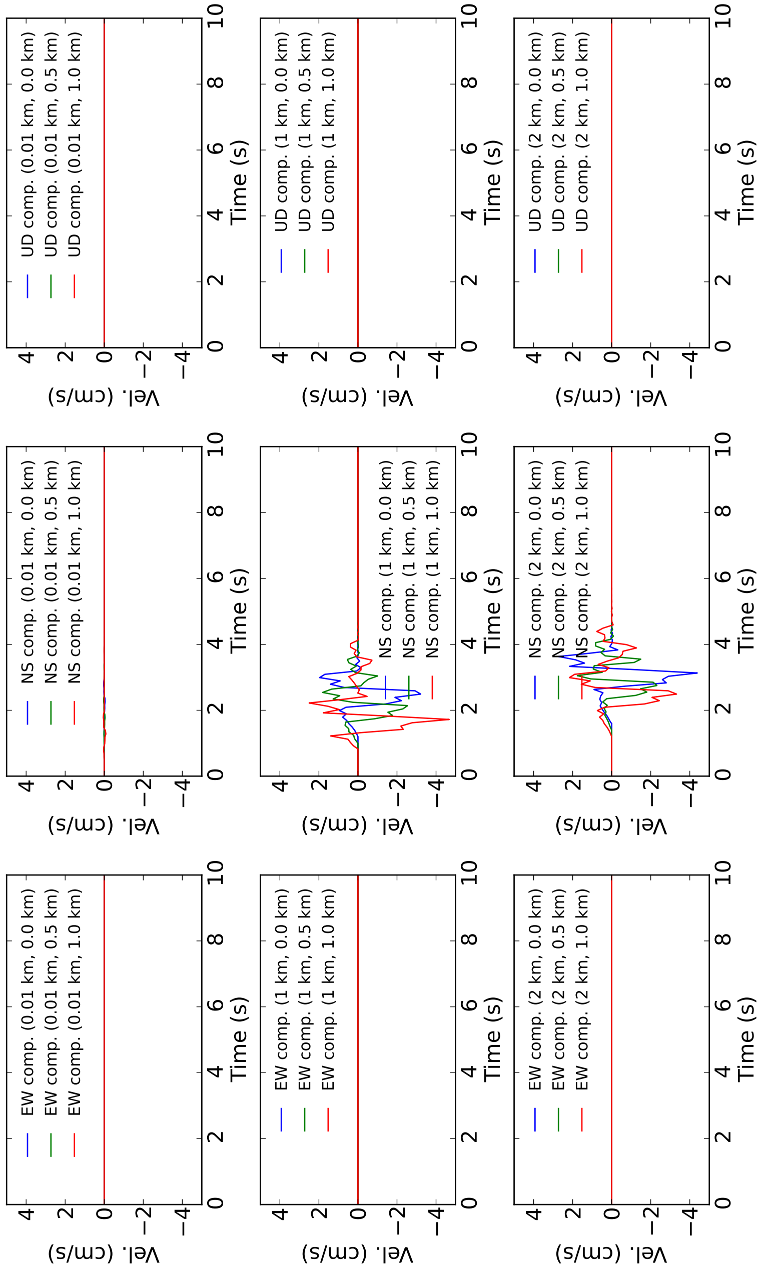

Figure 706.9: Calculated time history velocity, station azimuth = 90°

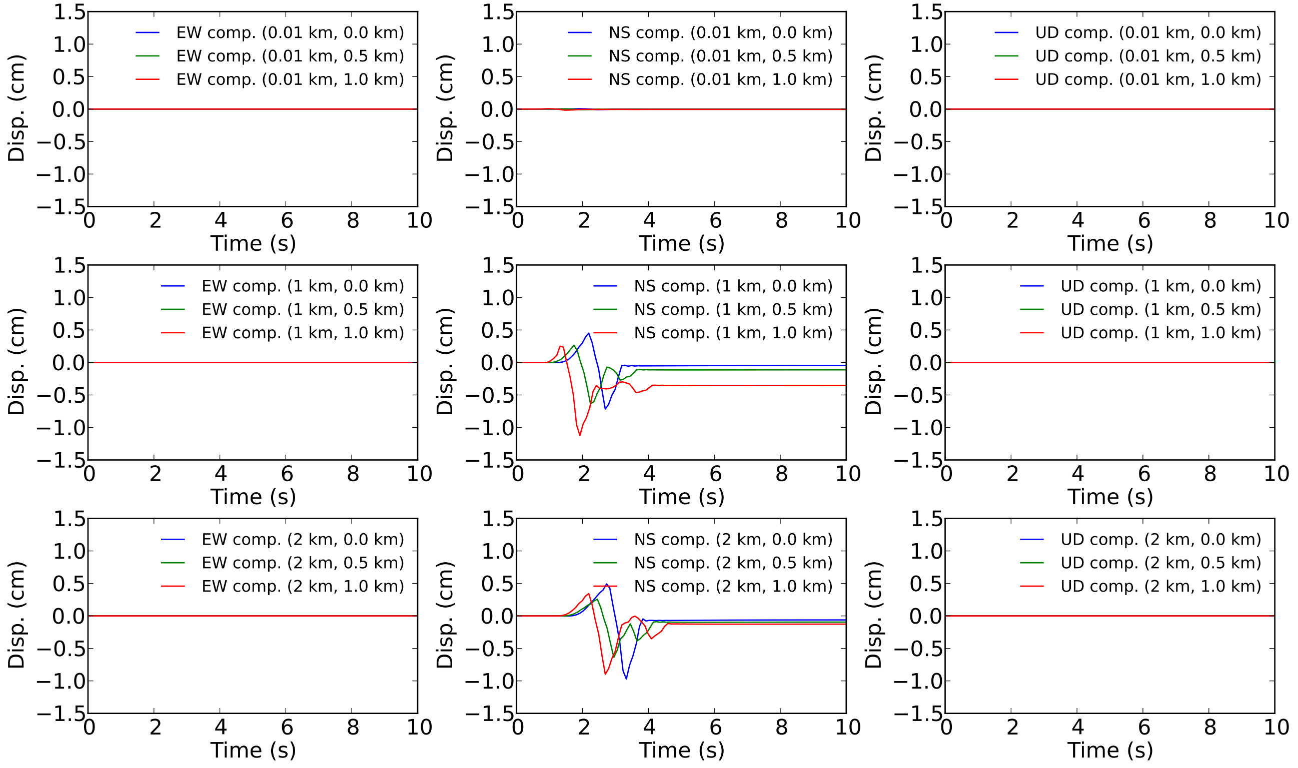

Figure 706.10: Calculated time history displacement, station azimuth = 90°

706.1.2.2 Case 2: dip-slip fault / single layer ground

Similar fault is tested for vertical (dip) slip (rake = 90°) fault case. Figure 706.11 shows model used for the analysis. Ground, fault, and wave properties are shown as below.

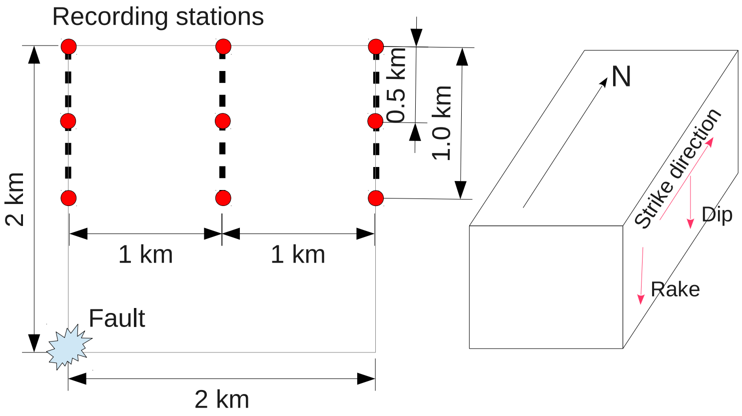

Figure 706.11: Ground and fault model used for analysis, results are captured on circles

- Ground properties
  - V_S = 1 km/s
  - V_P/V_S = 1.73
  - Poisson's ratio = 0.25
  - Density = 1.32 g/cm^3
  - Shear modulus = 1.32 GPa
  - Elastic modulus = 3.31 GPa
- Fault properties
  - Moment magnitude = 3.5
  - Strike = 0°
  - Dip = 90°
  - Rake = 90°
  - Double - coupled source
  - Triangular source time function
- Wave properties

- dt = 0.1 s (Max available freq. = 5 Hz, Nyquist freq.)

Similar to the strike slip example, single layer ground (Vs = 1 km/s) is modeled. Fault is located at 2 km depth, 2 km away from the recording stations. Double coupled fault source is assumed and triangular source time function is used (Aki and Richards, 2002). Nine recording points are set as recording stations (Figure 706.11). Direction of the fault is aligned parallel to the north (strike = 0°) and rake is 90°. Station azimuth is set to 0°, 45°, and 90°.

Figure 706.12 – 706.20 show analyses results for this example. Since it's dip slip case, permanent deformation on UD components are observed (Figure 706.17 and 706.20).

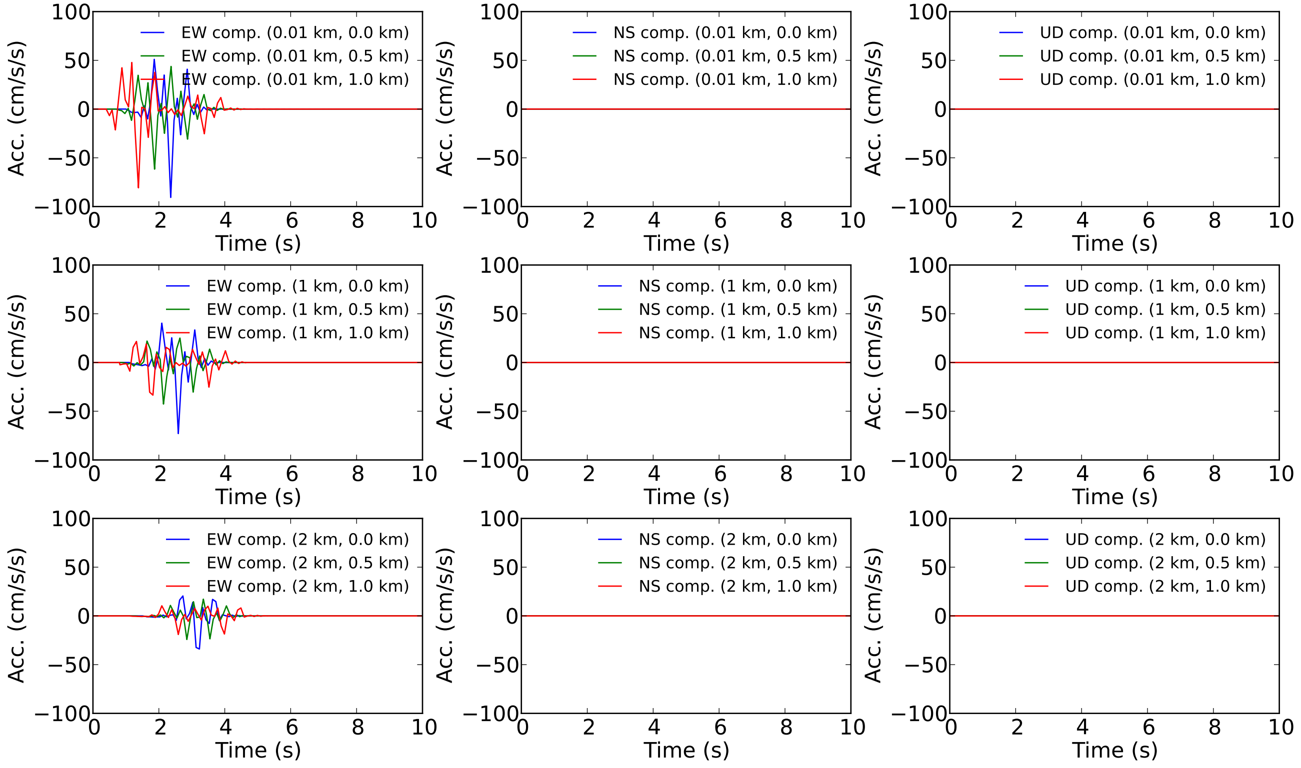

Figure 706.12: Calculated time history acceleration, station azimuth $= 0^\circ$

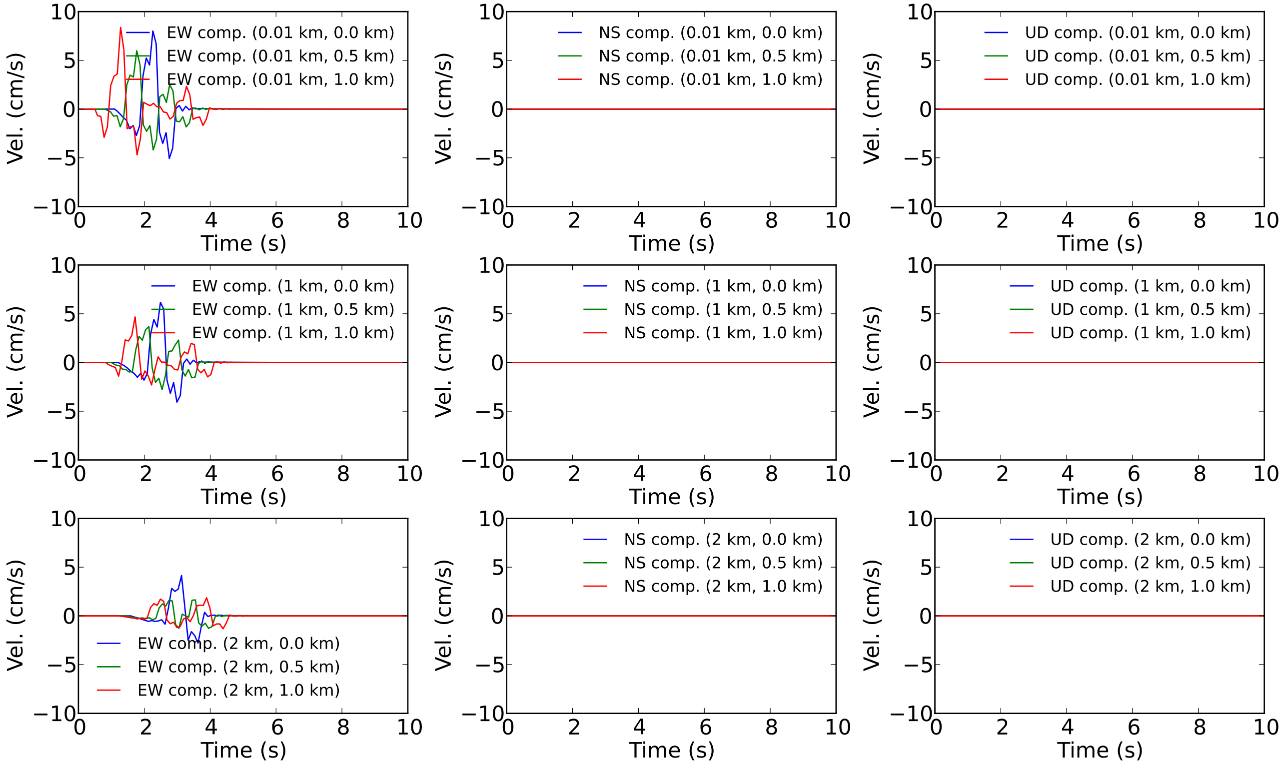

Figure 706.13: Calculated time history velocity, station azimuth $= 0^\circ$

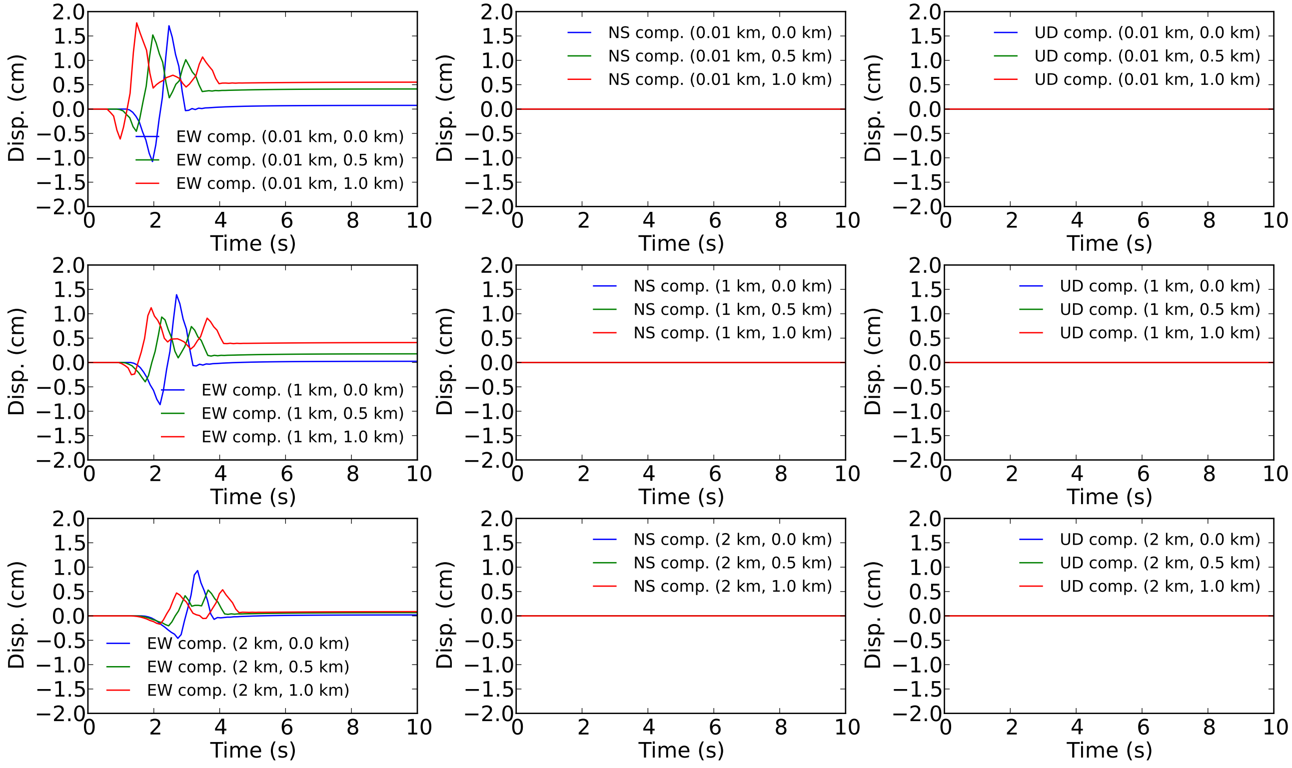

Figure 706.14: Calculated time history displacement, station azimuth = 0°

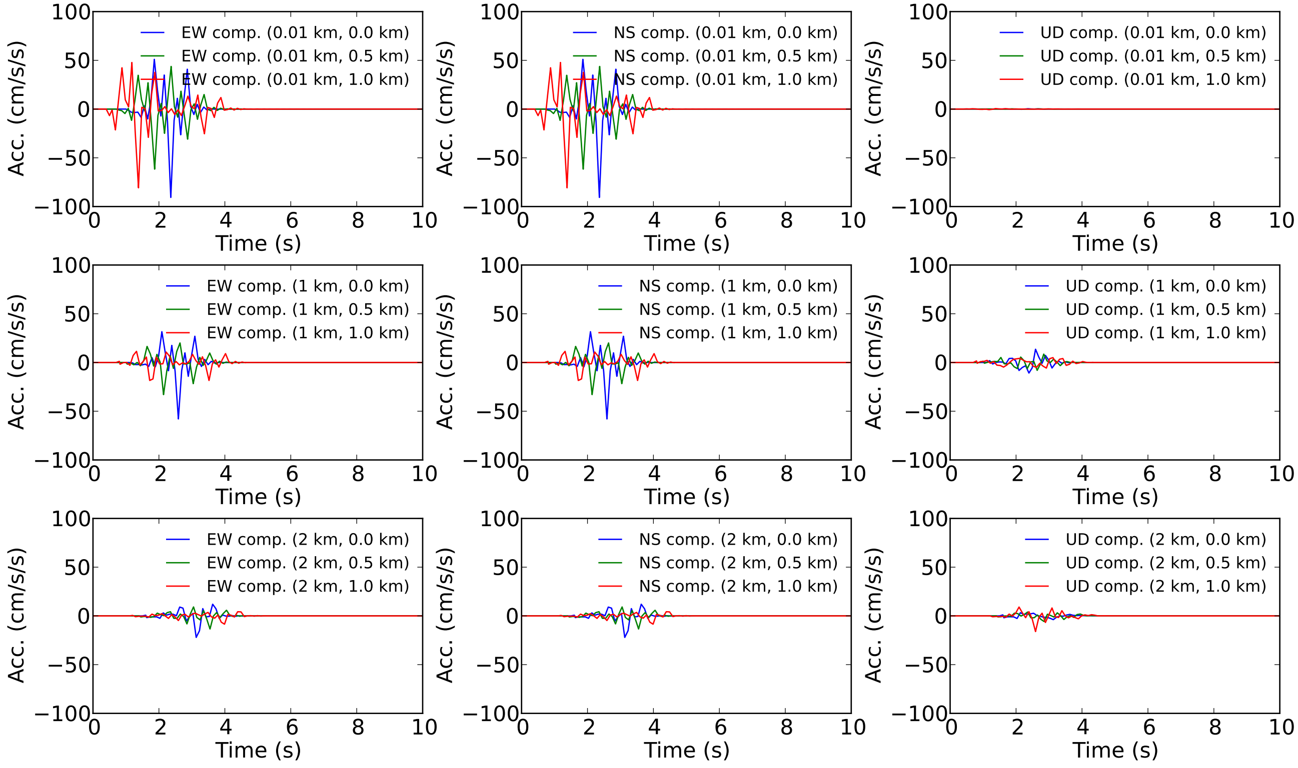

Figure 706.15: Calculated time history acceleration, station azimuth = 45°

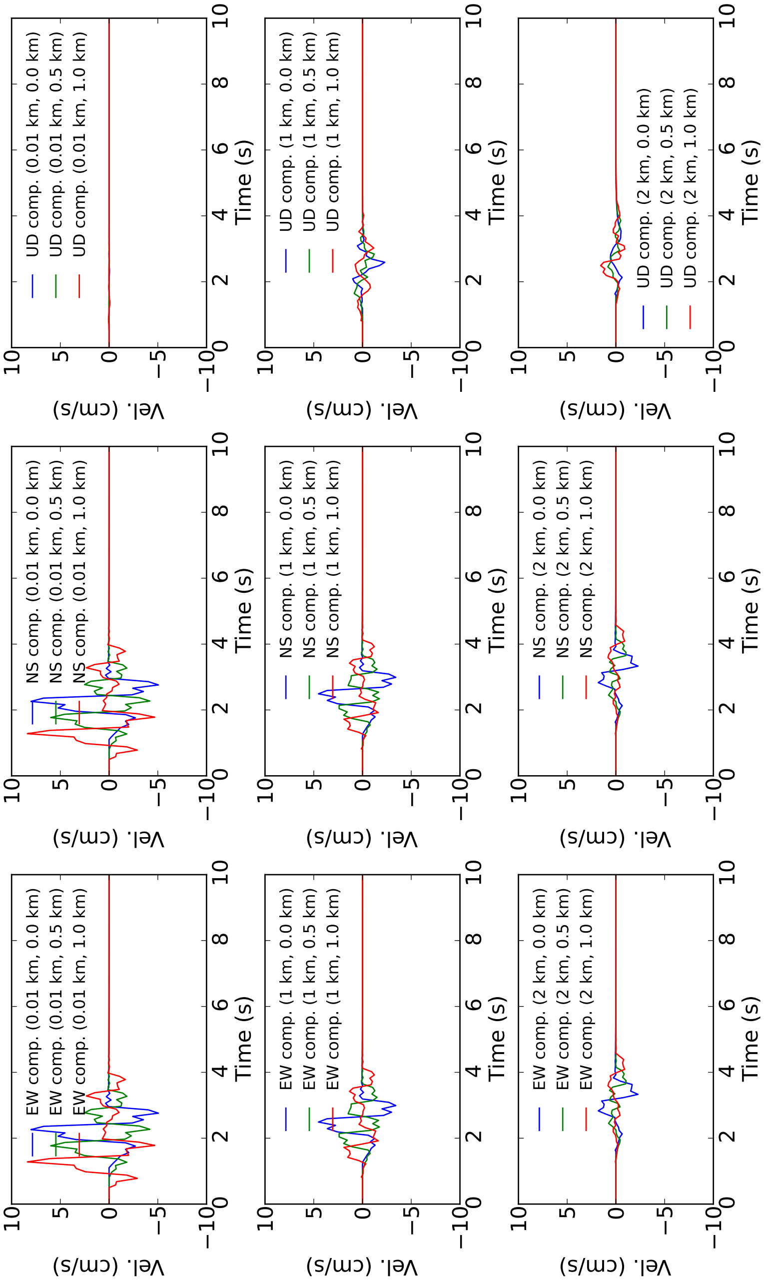

Figure 706.16: Calculated time history velocity, station azimuth $= 45^\circ$

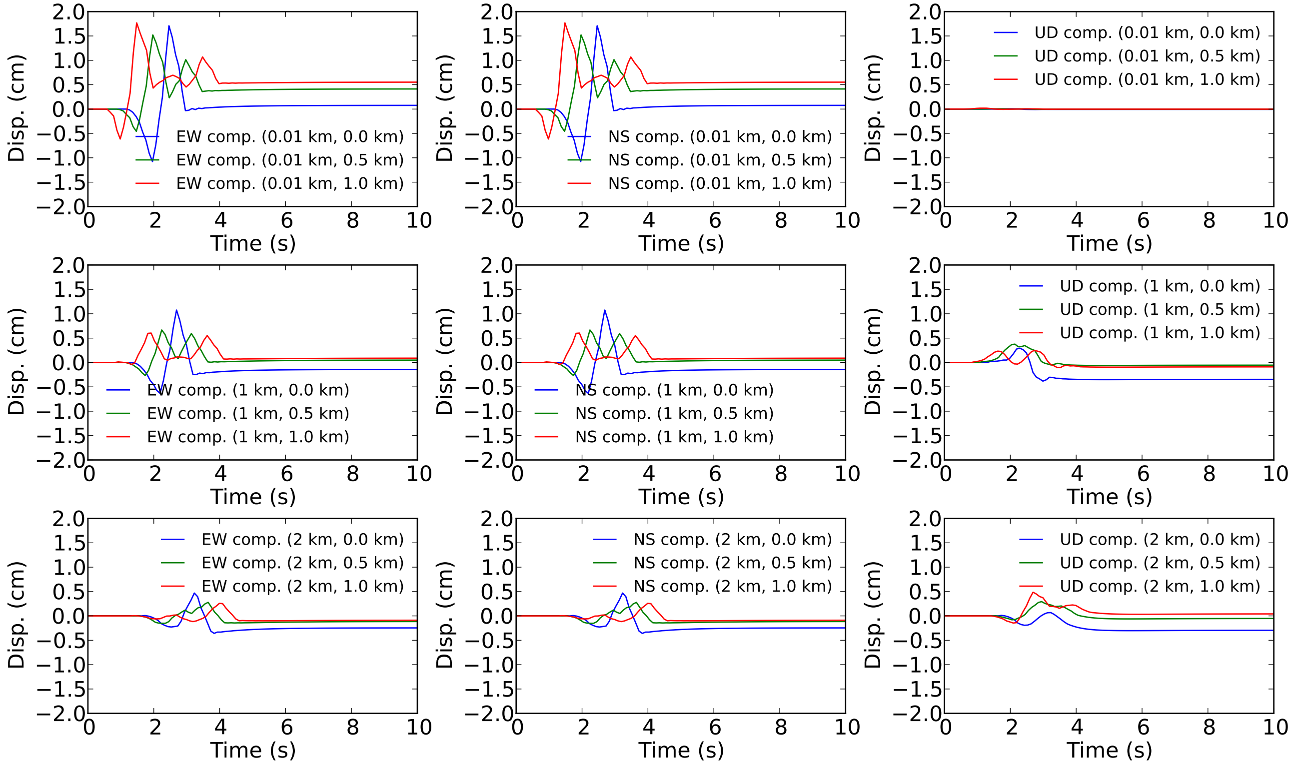

Figure 706.17: Calculated time history displacement, station azimuth = 45°

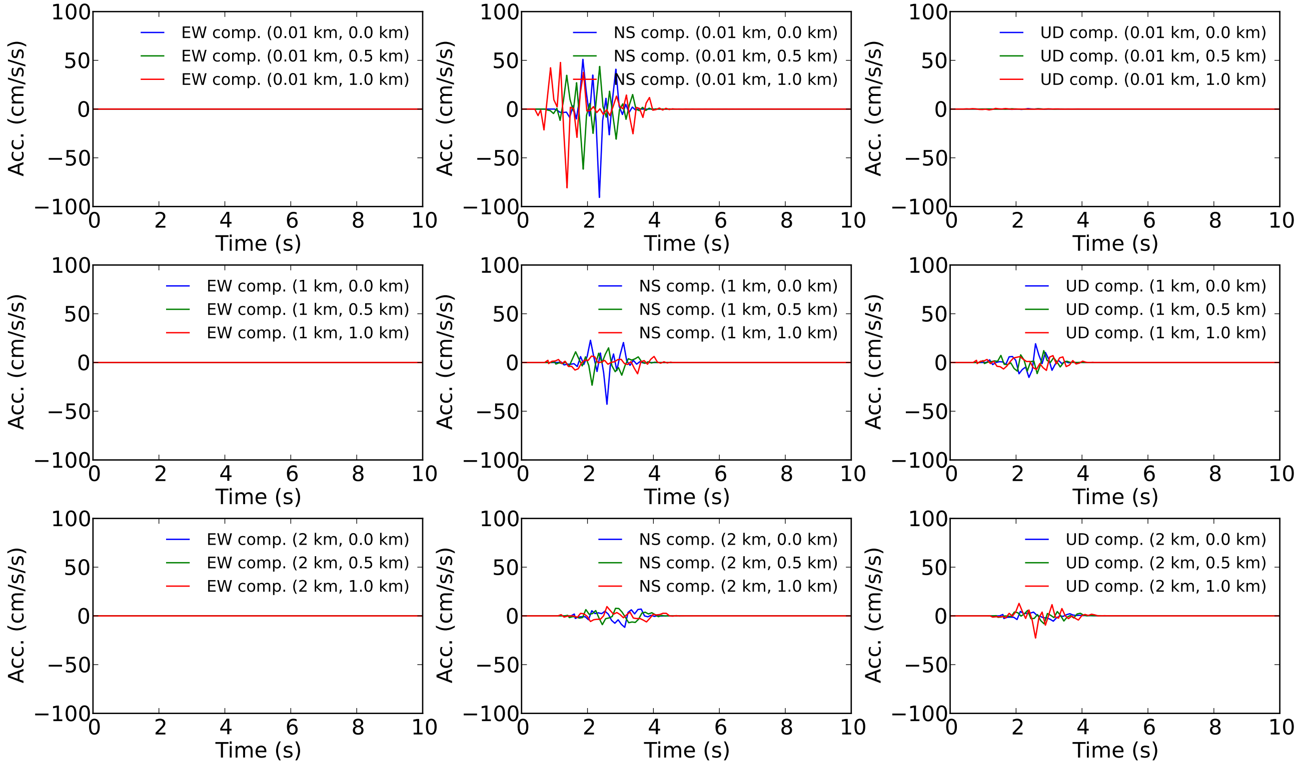

Figure 706.18: Calculated time history acceleration, station azimuth $= 90^{\circ}$

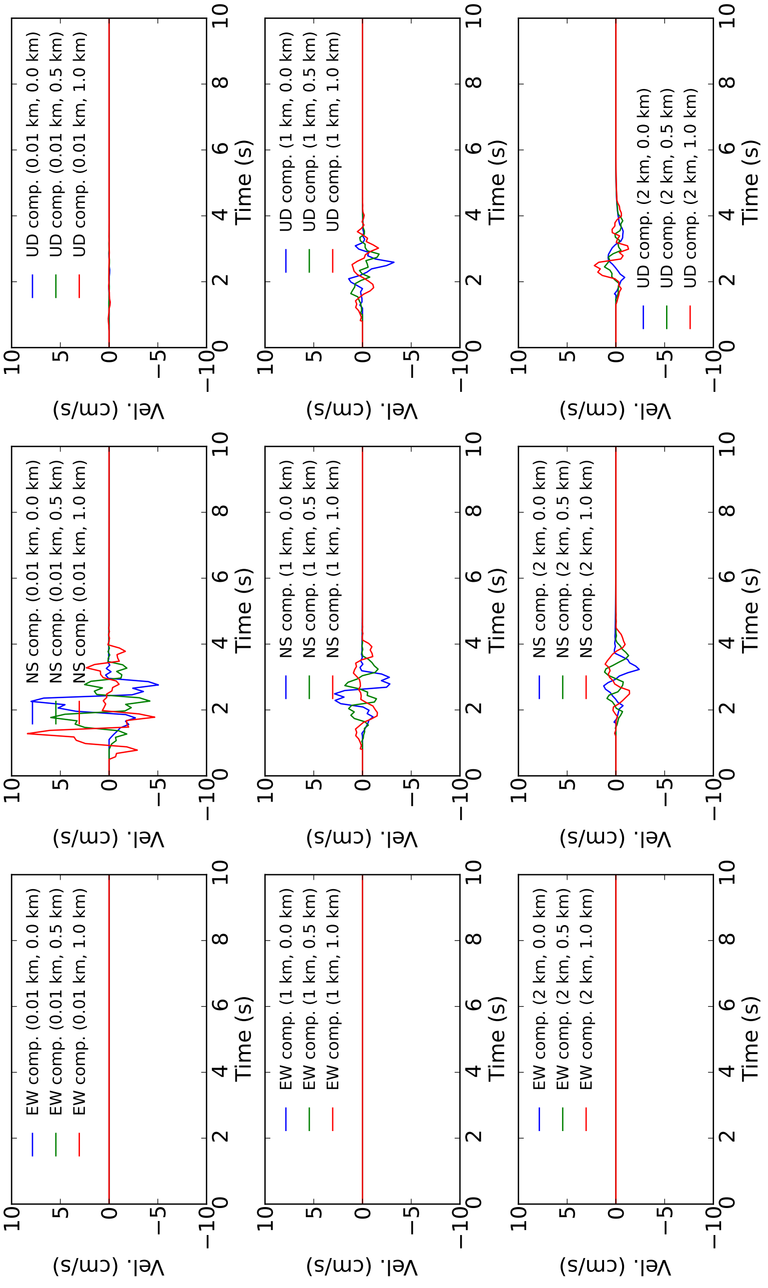

Figure 706.19: Calculated time history velocity, station azimuth = 90°

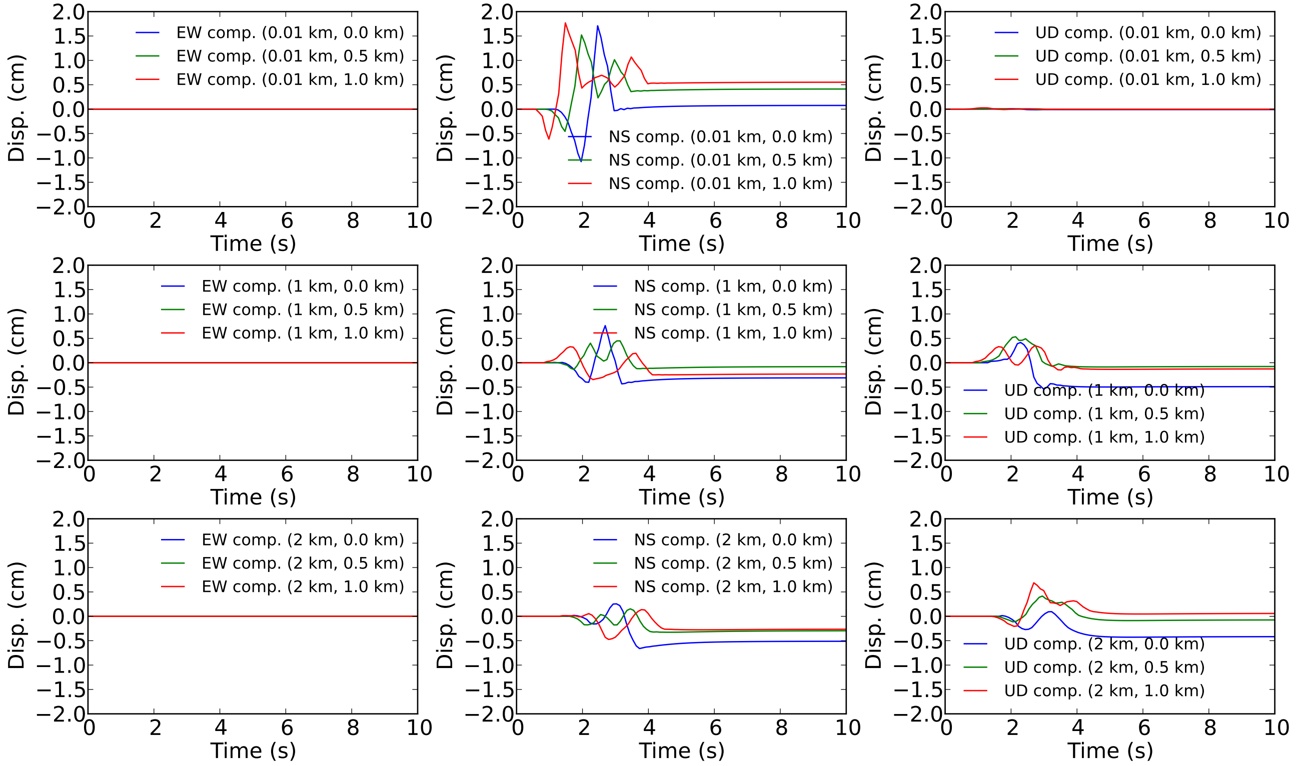

Figure 706.20: Calculated time history displacement, station azimuth $= 90^\circ$

706.1.2.3 Case 3: normal fault / single layer ground

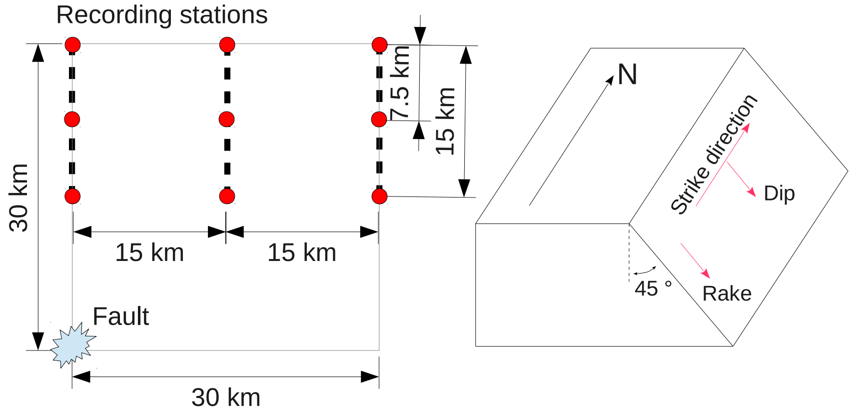

Figure 706.21: Ground and fault model used for analysis, results are captured on circles

Normal fault is tested. Figure 706.21 shows model used for the analysis. Wave is propagated through the single layer ground (Vs = 1 km/s). Properties are shown as below.

- Ground properties
  - V_S = 1 km/s
  - V_P/V_S = 1.73
  - Poisson's ratio = 0.25
  - Density = 1.32 g/cm^3
  - Shear modulus = 1.32 GPa
  - Elastic modulus = 3.31 GPa
- Fault properties
  - Moment magnitude = 5.0
  - Strike = 0°
  - Dip = 45°
  - Rake = 90°
  - Double - coupled source
  - Triangular source time function
- Wave properties

  - dt = 0.1 s (Max available freq. = 5 Hz, Nyquist freq.)

In this example, the distance between the fault and the station is increased and magnitude is changed also (Mw = 5.0). Fault is located at 30 km depth, 30 km away from the recording stations (Figure 706.21). Double coupled fault source is assumed and triangular source time function is used (Aki and Richards, 2002). Recording points are similar as prior examples (total 9 stations). Azimuth of recording station is set to 0°, 45°, and 90°.

Figure 706.22 – 706.30 show analyses results. Since the distance between fault and station is increased to 30 km and waves are propagated through the ground with relatively low shear wave velocity, arrival of propagating and reflecting waves can be observed easily (the first arrival of P wave followed by S wave). Permanent displacements by the fault movement are observed as desired at all stations (0°, 45°, and 90°).

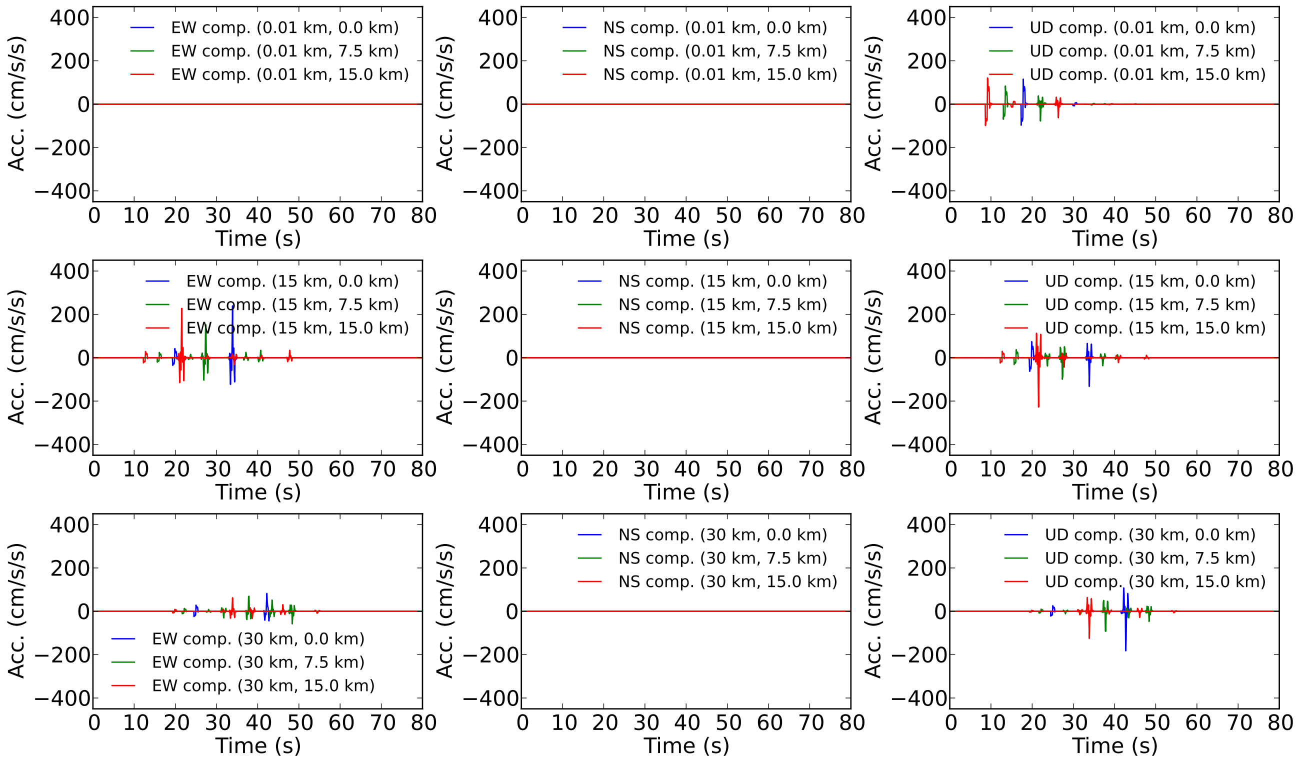

Figure 706.22: Calculated time history acceleration, station azimuth $= 0^\circ$

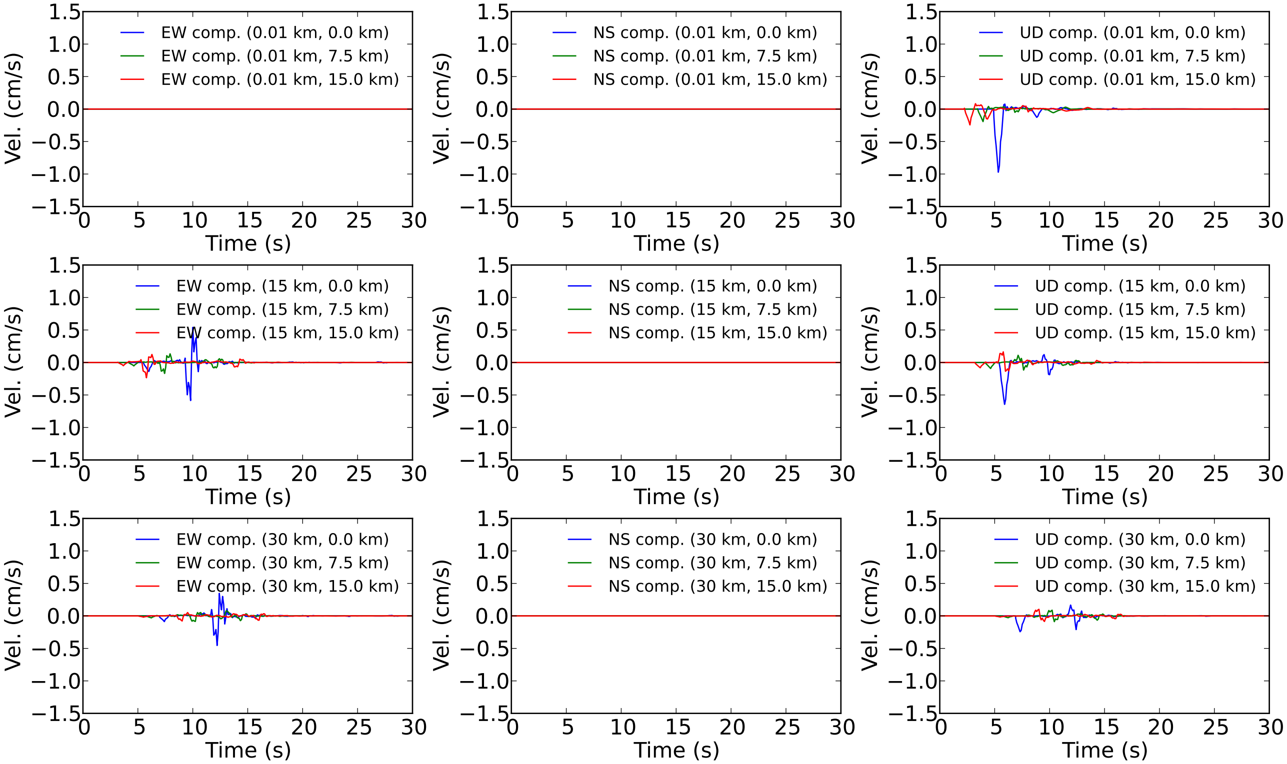

Figure 706.23: Calculated time history velocity, station azimuth $= 0^{\circ}$

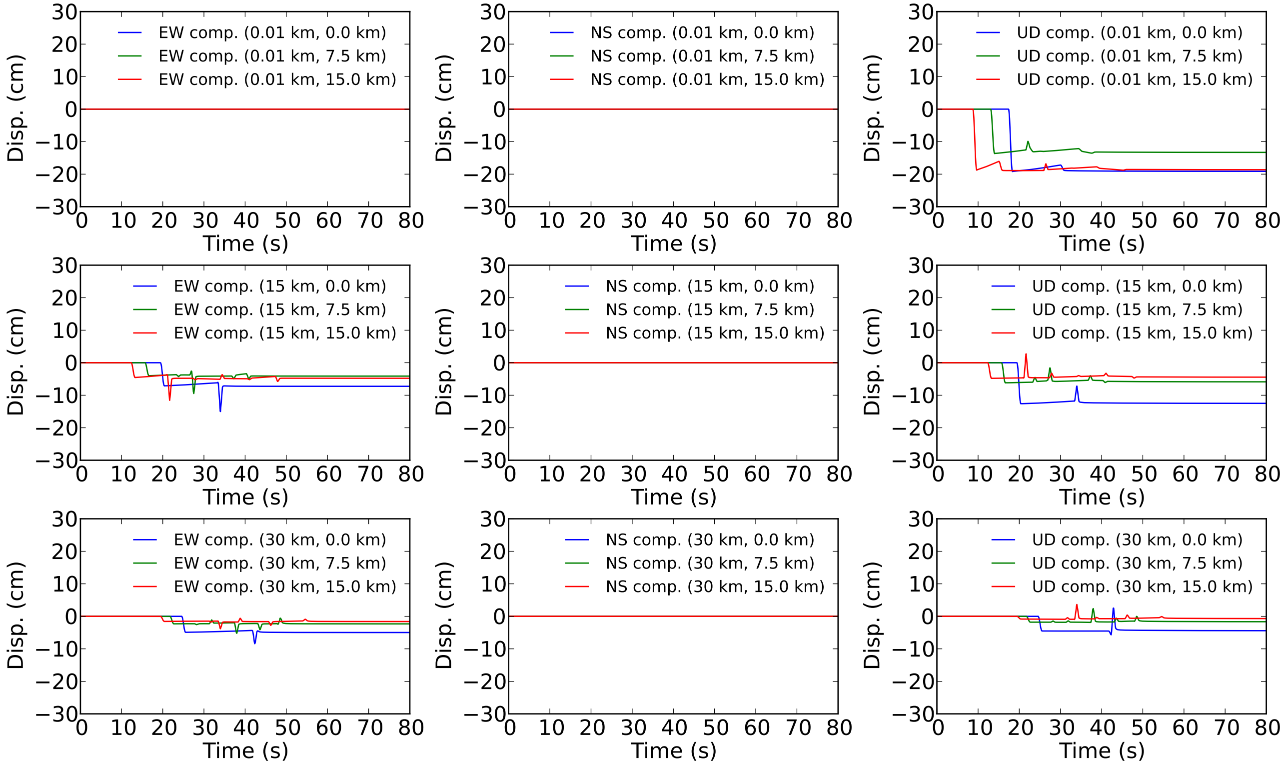

Figure 706.24: Calculated time history displacement, station azimuth $= 0^\circ$

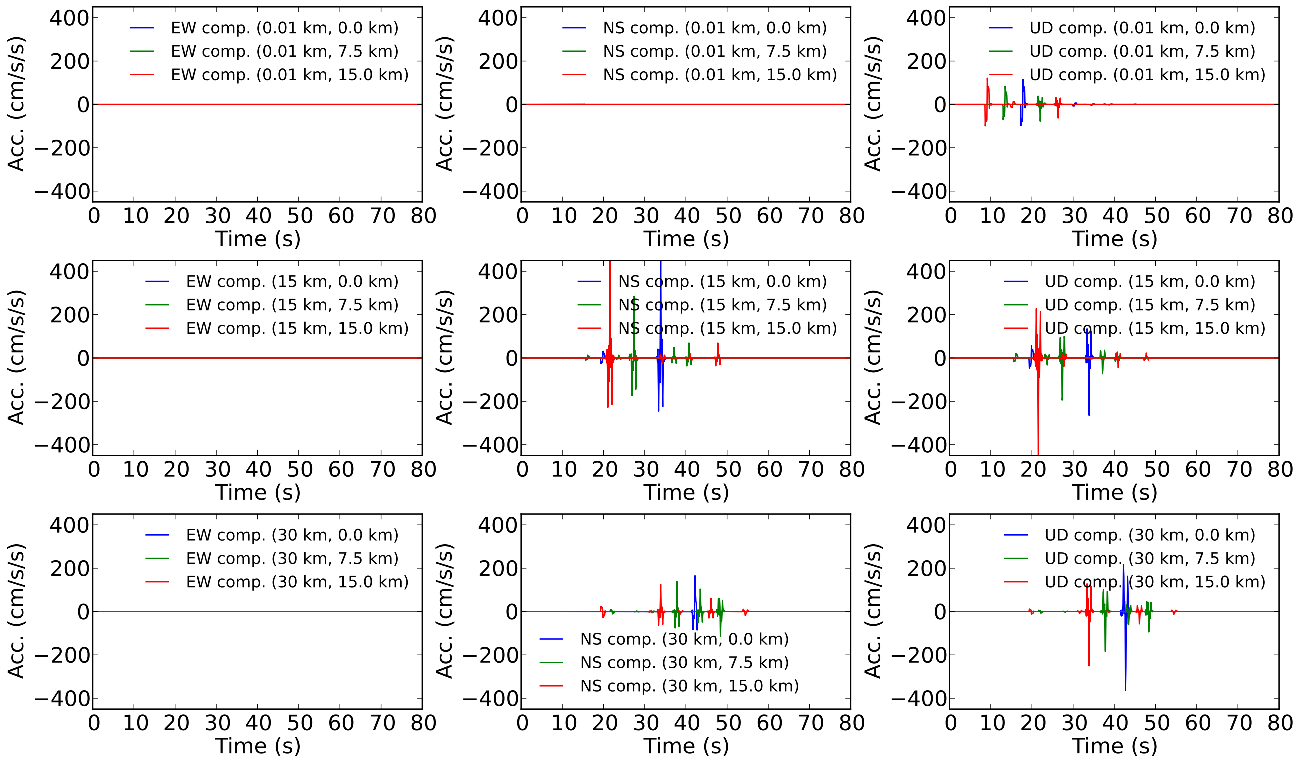

Figure 706.28: Calculated time history acceleration, station azimuth $= 90^{\circ}$

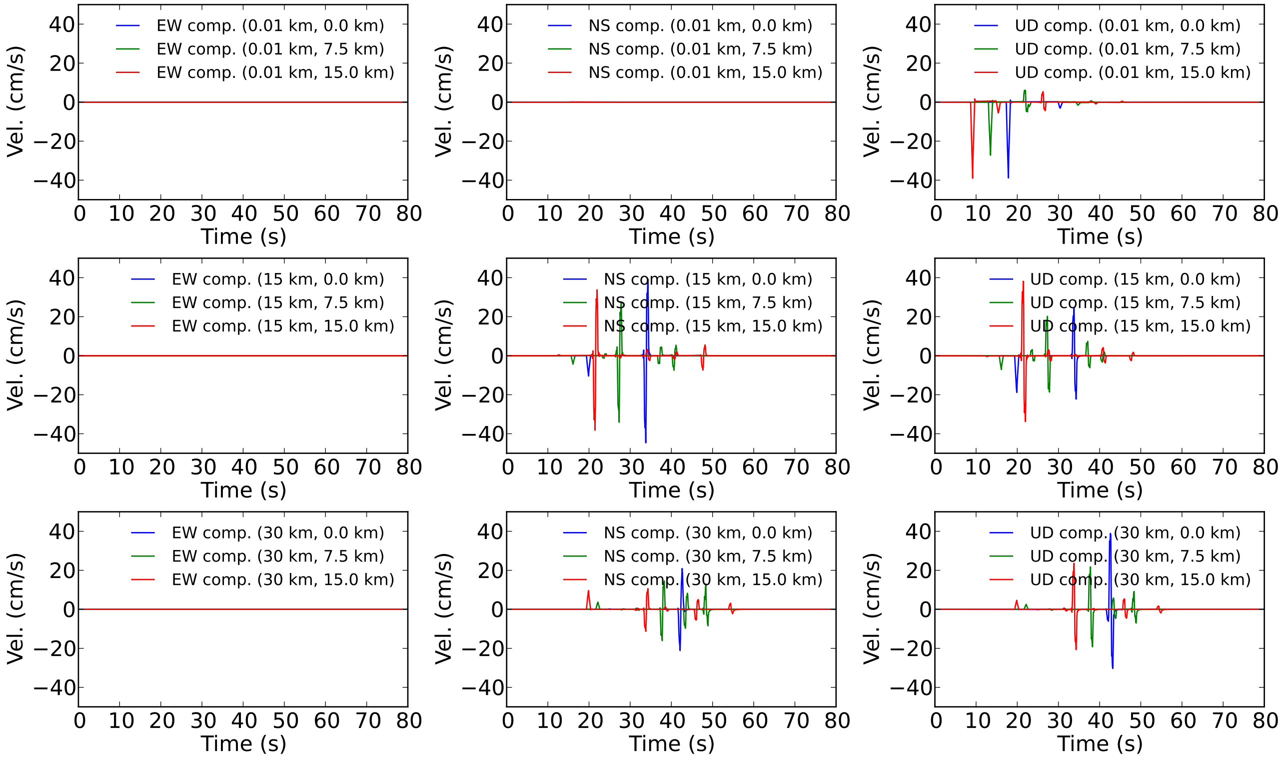

Figure 706.29: Calculated time history velocity, station azimuth = 90°

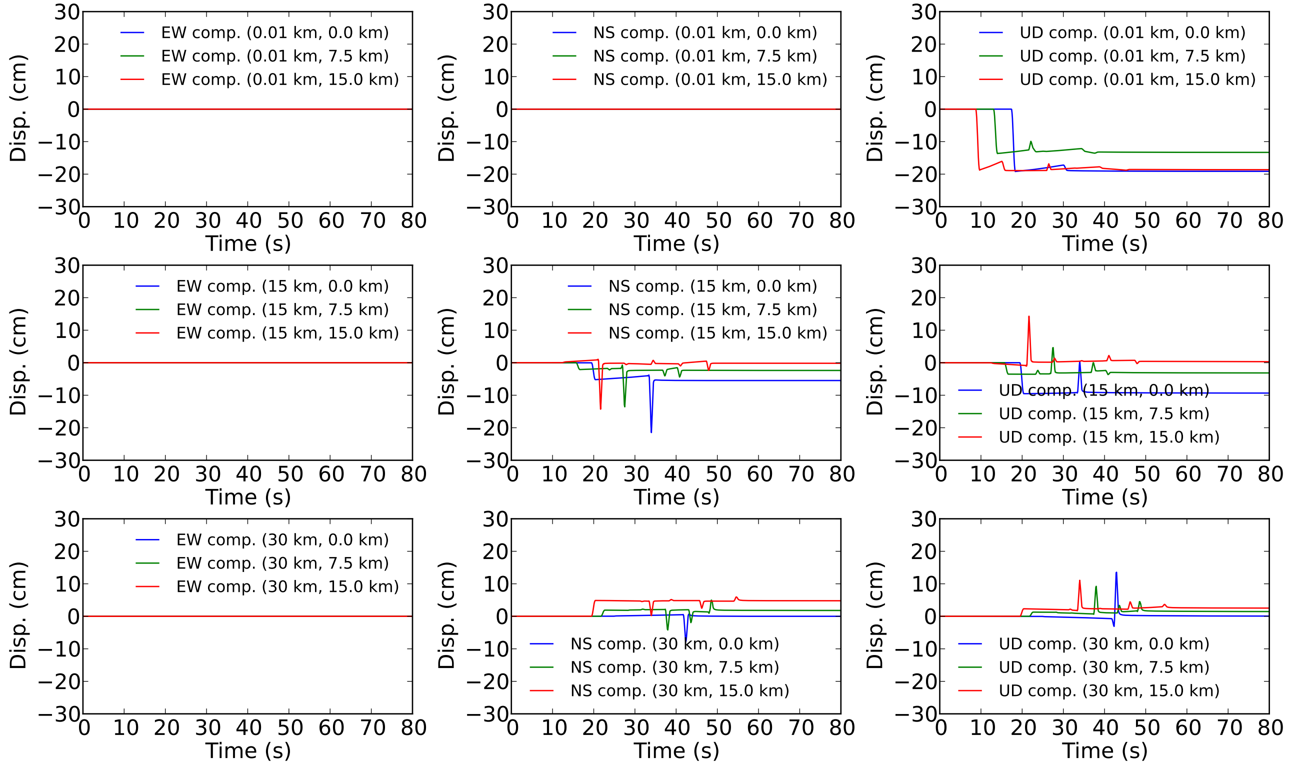

Figure 706.30: Calculated time history displacement, station azimuth = 90°

706.1.2.4 Case 4: normal fault / layered ground

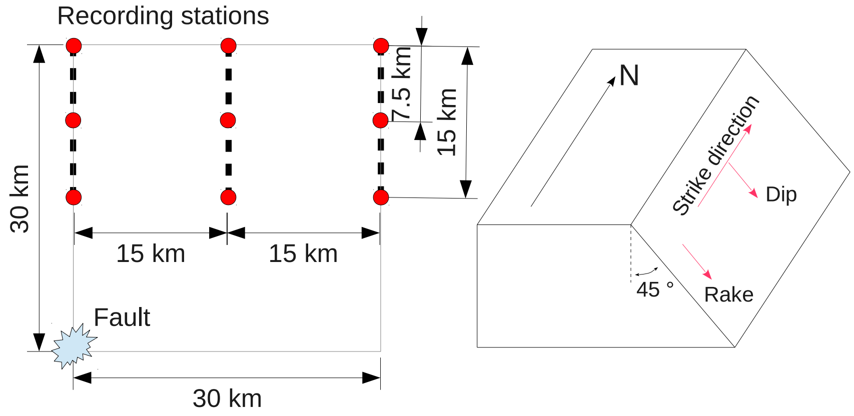

Figure 706.31: Ground and fault model used for analysis, results are captured on circles

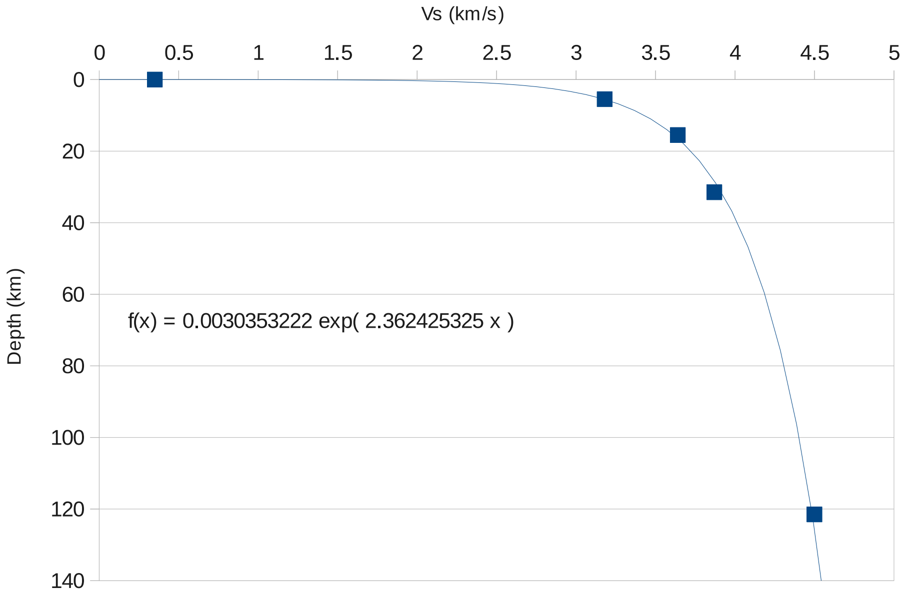

Figure 706.32: Vs profile, square points are hk model; blue line is trend line based on hk model

Normal fault within layered ground is modeled. Model is as shown Figure 706.31 and 706.32. Properties are shown below.

- Ground properties: see Figure 706.32 and Table 706.1
- Fault properties

  - Moment magnitude = 5.0
  - Strike = 0°
  - Dip = 45°
  - Rake = 90°
  - Double - coupled source
  - Triangular source time function

- Wave properties
  - dt = 0.1 s (Max available freq. = 5 Hz, Nyquist freq.)

Fault is located at depth of 30 km, 30 km away from the recording point (station) at surface. Double coupled fault source is assumed and triangular source time function is used (Aki and Richards, 2002). Recording points are similar as prior examples (total 9 stations). The 1D standard southern California model (Hadley and Kanamori (1977), hk model hereafter) is used for ground layering. As shown in Figure 706.32, hk model is interpolated and divided to define ground layer (Table 706.1).

Results are shown on Figure 706.33 – 706.35. Since wave is propagated through the layered ground, compared to prior examples, more realistic waves are observed.

Table 706.1: Ground properties for the example

Depth (km)	Thickness (km)	VS (km/s)	VP/VS	QB	VP (km/s)	Poisson's R	Density (g/cm3)	G (GPa)	E (GPa)

706.1.2.5 Case 5: Northridge earthquake / layered ground

In this example, Northridge earthquakes are simulated. Northridge earthquake has occurred on January, 1994 with a moment magnitude of 6.7. Properties are shown as below and partly adapted from Hisada (2008) and Wald et al. (1996).

- Ground properties: see Table 706.2
- Fault properties
  - Moment magnitude = 6.7
  - Strike = 122°
  - Dip = 40°
  - Rake = 140°
  - Double - coupled source
  - Triangular source time function
- Wave properties
  - dt = 0.05 s (Max available freq. = 10 Hz, Nyquist freq.)

Source depth is set as 25 km and epicentral distance from the fault to the station is set as 30 km. Station is located on the ground surface. As shown in Table 706.2, ground is divided into 9 layers (Hisada, 2008).

Figure 706.42 shows analyses results. Computed results are compared with measured one. Measured records are obtained from cosmos virtual data center `http://db.cosmos-eq.org/`. As shown in Figure 706.42, predicted seismogram agrees well with measured ones considering the fk package assumes a single point source and simplified ground.pdf.

Table 706.2: Ground properties for the example

Depth (km)	Thickness (km)	VS (km/s)	VP/VS	QB	VP (km/s)	Poisson's R	Density (g/cm3)	G (GPa)	E (GPa)

Appendix 707

Real-ESSI Illustrative Examples

(2015-2016-2017-2018-2019-2021-)

(In collaboration with Dr. Yuan Feng, Prof. José Abell, Prof. Sumeet Kumar Sinha, Prof. Han Yang and Dr. Hexiang Wang)

This chapter presents a number of illustrative examples. The main aim is simple: present Real-ESSI Simulator features (available elements, algorithms, domain specific language (DSL), &c.) through a number of simple examples. It is noted that all presented elements and algorithms work in sequential and parallel mode. However, presented examples are very small, and parallel mode will not bring any benefits.

707.1 Elastic Beam Element Under Static Loading

This is a simple beam example under static loading in three directions. The diagram below shows the loading in one bending direction.

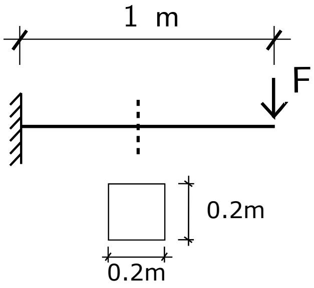

Figure 707.1: The cantilever model

ESSI model fei/DSL file:

```
model name "beam_1element" ;
// define the node coordinates
add node # 1 at ( 0.0*m , 0.0*m, 0.0*m) with 6 dofs;
add node # 2 at ( 1.0*m , 0.0*m, 0.0*m) with 6 dofs;
// Geometry: width and height. Help the beam definition.
b=0.2*m;
h=0.2*m;
I=b*h^3/12.0;
// define the beam element
add element # 1 type beam_elastic with nodes (1,2)
  cross_section = b*h
  elastic_modulus = 1e9*N/m^2
  shear_modulus = 5e8*N/m^2
  torsion_Jx = 0.33*b*h^3
  bending_Iy = I
  bending_Iz = I
  mass_density = 0*kg/m^3
  xz_plane_vector = ( 1, 0, 1)
  joint_1_offset = (0*m, 0*m, 0*m)
  joint_2_offset = (0*m, 0*m, 0*m);
// add boundary condition
fix node # 1 dofs all;
// axial loading
new loading stage "axial";
add load # 1 to node # 2 type linear Fx = 1*N;
define load factor increment 1;
define algorithm With_no_convergence_check ;
define solver ProfileSPD;
simulate 1 steps using static algorithm;
```

```
// bending in one direction
new loading stage "bending1";
remove load # 1;
add load # 2 to node # 2 type linear Fy = 1*N;
define load factor increment 1;
define algorithm With_no_convergence_check ;
define solver ProfileSPD;
simulate 1 steps using static algorithm;
// bending in the other direction
new loading stage "bending2";
remove load # 2;
add load # 3 to node # 2 type linear Fz = 1*N;
define load factor increment 1;
define algorithm With_no_convergence_check ;
define solver ProfileSPD;
simulate 1 steps using static algorithm;

bye;
```

707.9 Elastic Beam Element for a Simple Frame Structure

Problem Description

- Dimensions: hidth=$6m$, height=$6m$, force=$100N$
- Element dimensions: length=6m, cross section width=1m, cross section height=1m, mass density $\rho = 0.0\mathrm{kN/m}^3$, Young's modulus $E = 1E8$ Pa, Poisson's ratio $\nu = 0.0$.

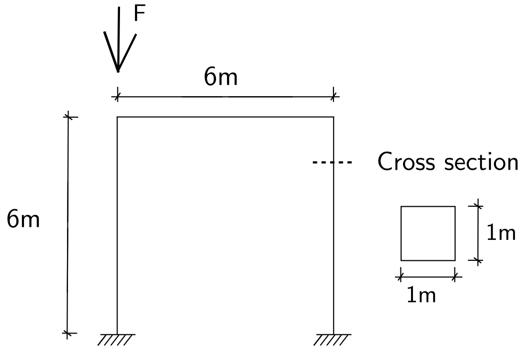

Figure 707.33: Elastic frame with beam_elastic elements.

707.15 One Dimensional DRM Model

Problem description:

A simple 1D DRM model is shown in Fig.(707.44). The "DRM element", "Exterior node" and "Boundary node" are required to be designated in the DRM HDF5 input. The format and script for the HDF5 input is available in DSL/input manual.

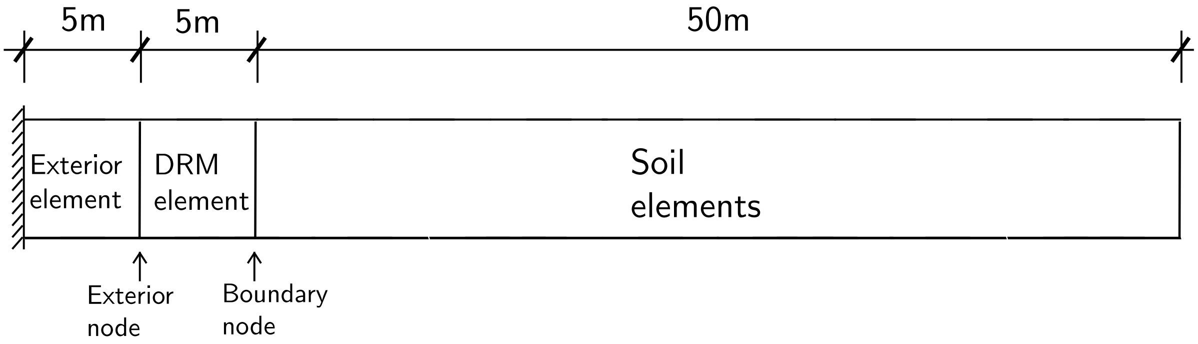

Figure 707.44: 1D DRM model.

Numerical model:

ESSI model fei/DSL file:

```
model name "DRM" ;

//Material for soil
add material # 1 type linear_elastic_isotropic_3d_LT
  mass_density = 2000*kg/m^3

Long 1D DRM model 1000:1

To show the wave propagation explicitly, a long 1D model (1000:1) similar to the 1D DRM model above was made in this section.

The model description is same to Fig.(707.44) except this model use far more soil elements.

The general view is shown in Fig.(707.46) below.

There is still now outgoing waves at the exterior layers, which is shown in Fig(707.47).

The ESSI model fei/DSL files for this example can be downloaded here.

The results can also be seen in this animation.

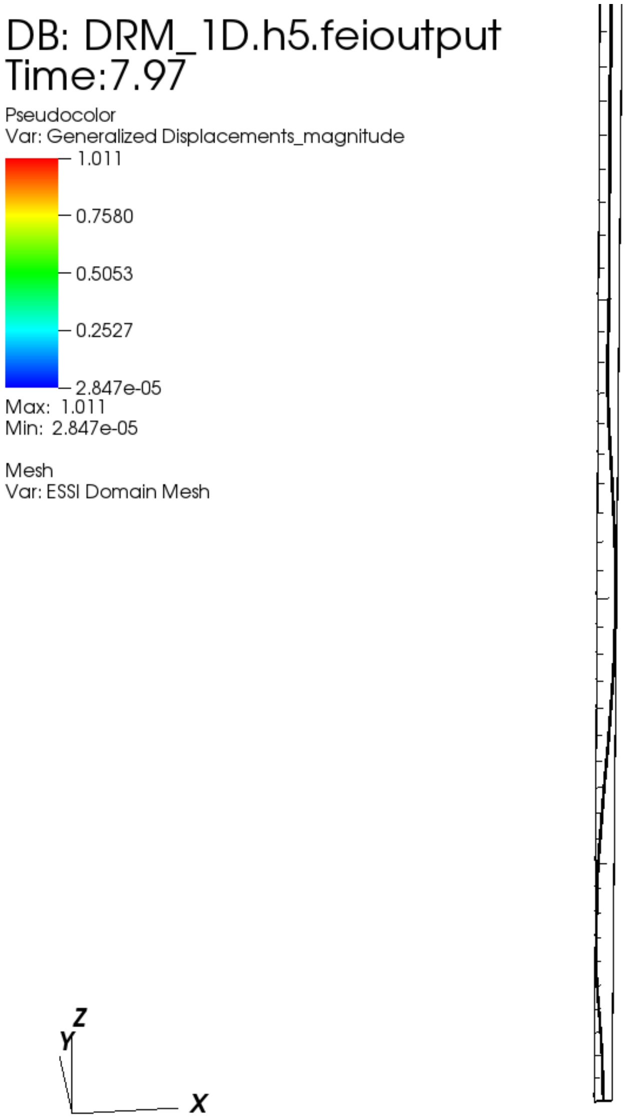

Figure 707.46: Long 1D DRM model

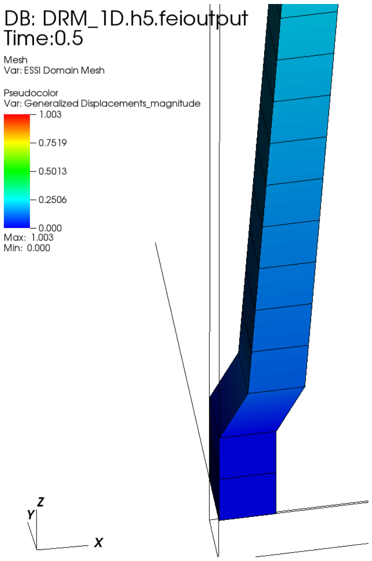

Figure 707.47: Long 1D DRM model: exterior layer

707.16 Three Dimensional DRM Model

Problem description:

As shown in Fig.(707.48), the DRM layer is used to add the earthquake motion.

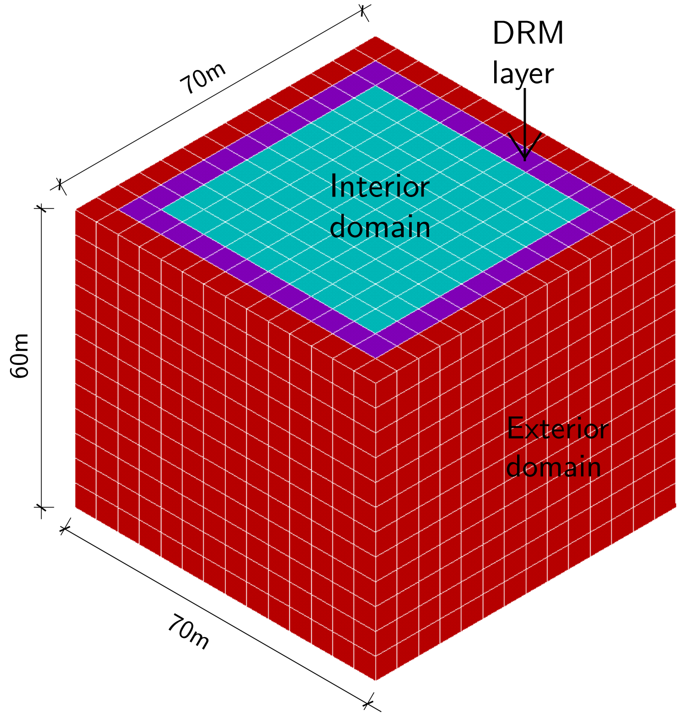

Figure 707.48: The diagram for 3D Domain Reduction Method example.

707.17 ShearBeam Element, Pisano Material

Problem description:

In the element type "ShearBeamLT", only one Gauss point exists. ShearBeamLT element was used here to test the Pisanó material model.

Vertical force F_z was used to apply confinement to the element. Then, cyclic force F_x is used to load. point.

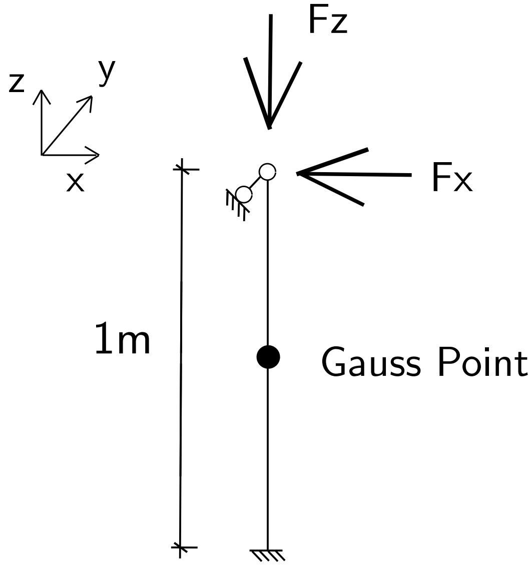

Figure 707.50: ShearBeam element.

Results

Resulting stress-strain relationship is shown in Fig.(707.51).

707.18 8NodeBrickLT Element, Drucker-Prager Material, Armstrong-Frederick Rotational Kinematic Hardening

Problem description:

This example is used to test the materials properties, such as G/Gmax against strains. The element type is 8NodeBrickLT. And there are two stages of loading. The first loading stage is confinement and the second loading stage is shearing.

The boundary condition is specially designed such that each Gauss point has the same stress state.

Results

Resulting stress-strain relationship is shown in Fig.(707.52).

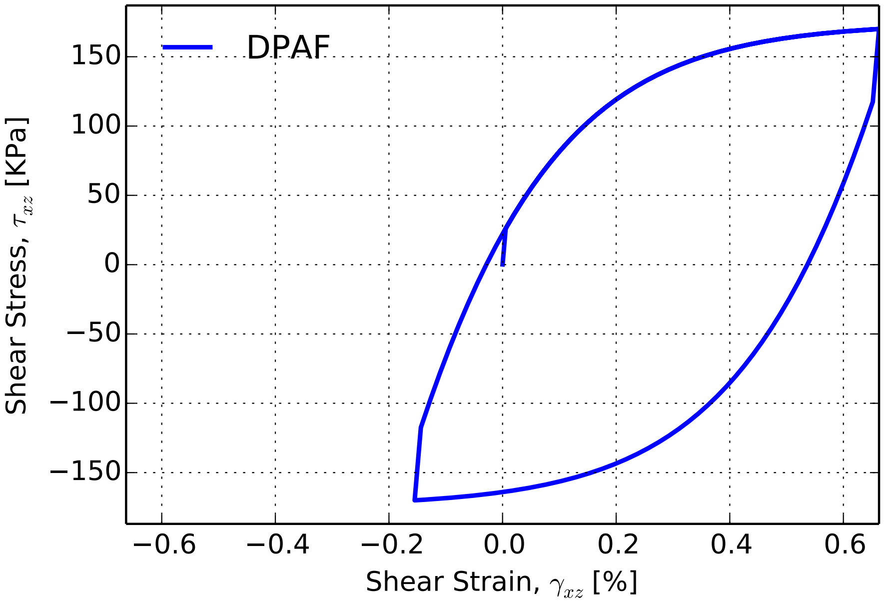

Figure 707.52: Shear stress-strain response.

707.24 Multi-yield-surface von-Mises for G/Gmax plot

Problem description:

This model illustates the G/Gmax input to multi-yield-surface von-Mises material. This example is based on one Gauss-point with multi-yield-surface von-Mises material. The G/Gmax is converted to material modelingn parameters (yield-surface size and hardening parameter) inside the DSL.

ESSI model fei/DSL file:

```
model name "GGmax";
add material # 1 type vonMisesMultipleYieldSurfaceGoverGmax
  mass_density = 0.0*kg/m^3
  initial_shear_modulus = 3E8 * Pa
  poisson_ratio = 0.0
  total_number_of_shear_modulus = 9
  GoverGmax =
  "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
  ShearStrainGamma =
  "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01"
  ;

incr_size = 0.000001 ;
max_strain= 0.005 ;
num_of_increm = max_strain/incr_size -1 ;
simulate constitutive testing strain control pure shear use material # 1
  confinement_strain = 0.0
  strain_increment_size = incr_size
  maximum_strain = max_strain
  number_of_increment = num_of_increm;
bye;
```

Computed G/Gmax curve exactly matches the one used for input at control points.

The difference in G/Gmax between control points can be reduced by using more than just 9 control points as in this example.

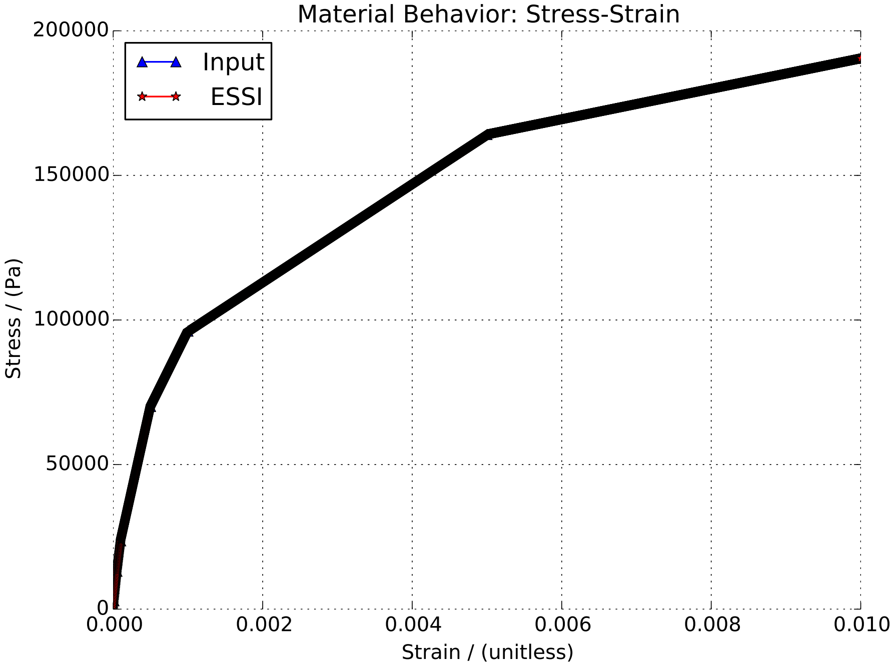

Figure 707.65: Stress-Strain Relationship

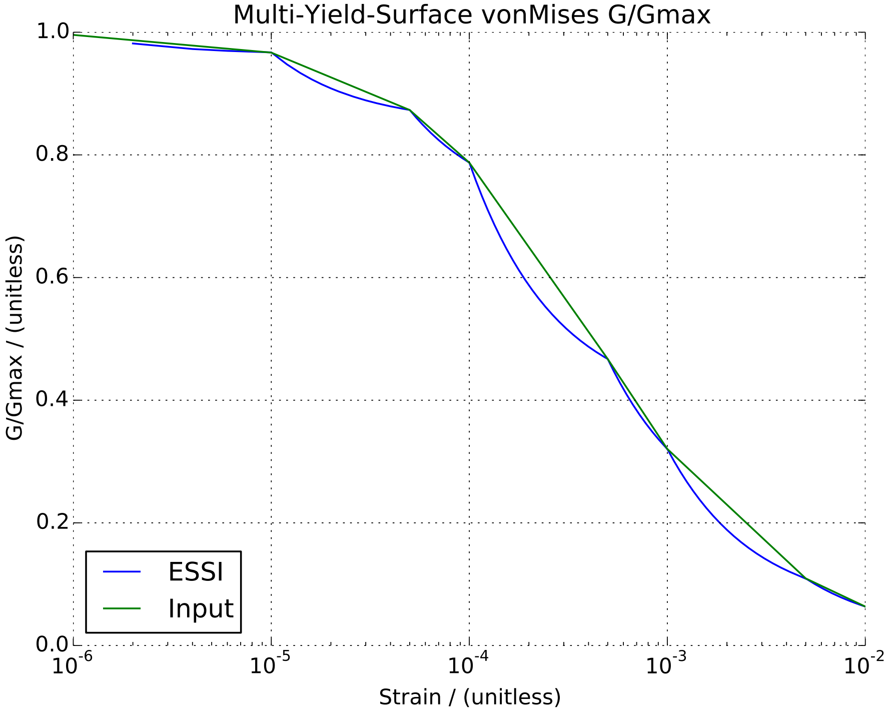

Figure 707.66: The G/Gmax results.

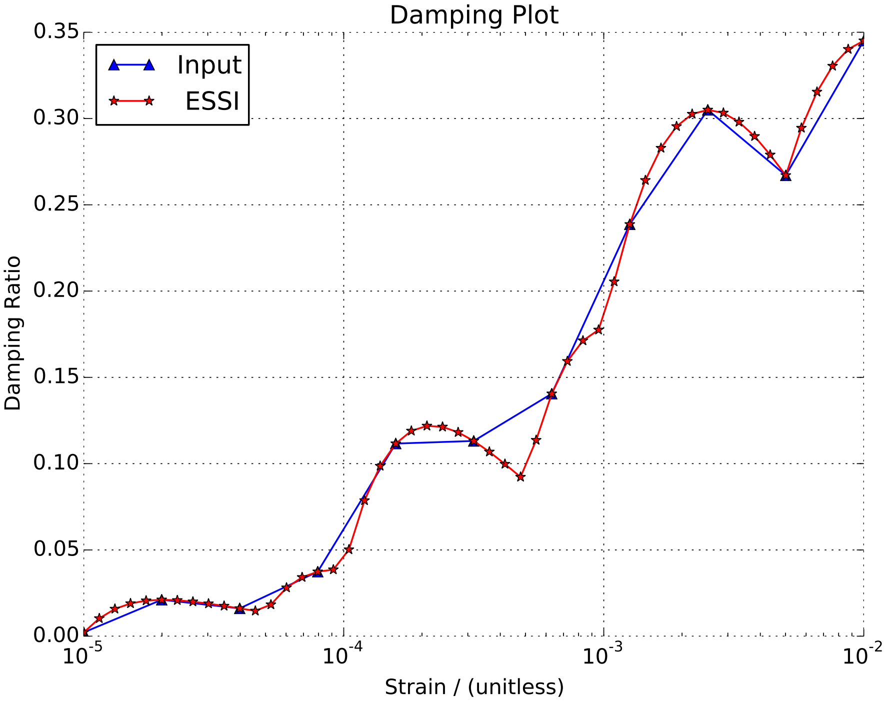

Figure 707.67: Damping Ratio Plot

707.25 Multi-yield-surface Drucker-Prager for G/Gmax plot

Problem description:

This model illustrates the G/Gmax input to multi-yield-surface Drucker-Prager material. Purely deviatoric plastic flow is used in this material, which means that the parameter dilation_scale is set to zero. If user wants to model change of volume (dilation or compression) for this material, then G/Gmax curve need to be iterated upon manually by changing yield surface size directly, which is done using different DruckerPragerMultipleYieldSurface command. This example is based on one Gauss-point which use multi-yield-surface Drucker-Prager material. The G/Gmax is converted to the yield-surface size and hardening parameter inside the DSL.

ESSI model fei/DSL file:

```
model name "GGmax";
add material # 1 type DruckerPragerMultipleYieldSurfaceGoverGmax
  mass_density = 0.0*kg/m^3
  initial_shear_modulus = 3E8 * Pa
  poisson_ratio = 0.0
  initial_confining_stress = 1E5 * Pa
  reference_pressure = 1E5 * Pa
  pressure_exponential_n = 0.5
  cohesion = 0. * Pa
  dilation_angle_eta =1.0
  dilation_scale = 0.0
  total_number_of_shear_modulus = 9
  GoverGmax =
  "1,0.995,0.966,0.873,0.787,0.467,0.320,0.109,0.063"
  ShearStrainGamma =
  "0,1E-6,1E-5,5E-5,1E-4, 0.0005, 0.001, 0.005, 0.01"
  ;

incr_size = 0.000001 ;
max_strain= 0.005 ;
num_of_increm = max_strain/incr_size -1 ;
simulate constitutive testing strain control pure shear use material # 1
  confinement_strain = 0.0
  strain_increment_size = incr_size
  maximum_strain = max_strain
  number_of_increment = num_of_increm;
bye;
```

Inside the DSL, the yield surface radius is calculated as $\sqrt{3}\sigma_y$, where σ_y is the yield stress of the corresponding yield surface. Then, the radius is divided by the confinement to obtain the slope (opening angle).

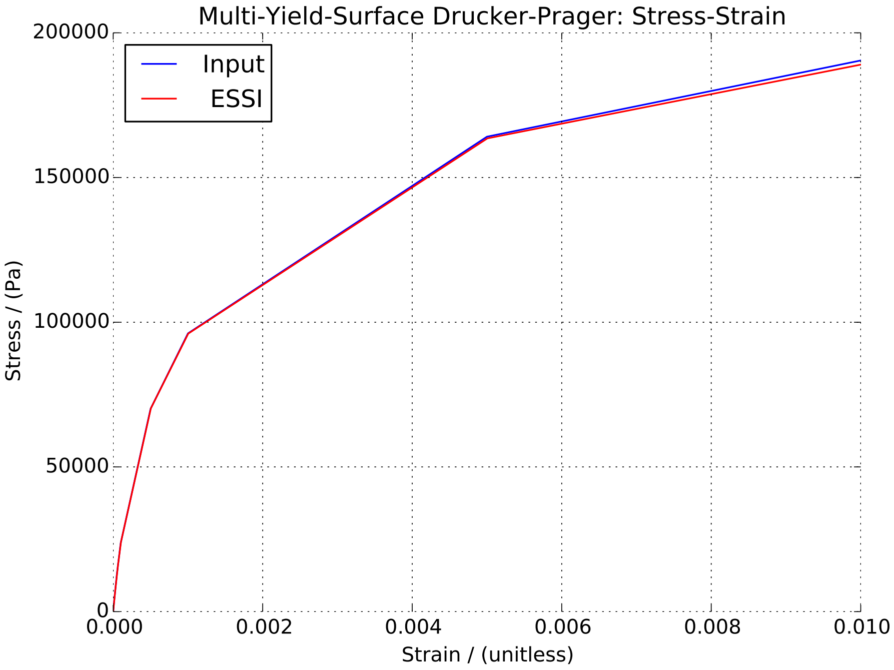

Figure 707.68: Nested-Yield-Surface Drucker-Prager Stress-Strain Relationship

The hardening parameter is calculated as

$$\frac{1}{H_i'} = \frac{1}{H_i} - \frac{1}{2G} \tag{707.1}$$

where H_i' is the current hardening parameter corresponding to yield surface i. H_i is the current tangent shear modulus to surface i, namely, $H_i = 2(\frac{\tau_{i+1}-\tau_i}{\gamma_{i+1}-\gamma_i})$. And G is the initial shear modulus.

Appendix 708

Brief History of the Real-ESSI Simulator Development

(1986-)

This section briefly describes history of the development of the Finite Element Interpreted, FEI, that is currently represented by the Real-ESSI Simulator system. Developments are presented chronologically, with very brief description of capabilities, and with references to further reading and documents with more information.

1986-1988: Development of the `FRAME_and_GRID` program, in 2D, using BASIC programming language, on SHARP 1500, CASIO 1000 (48KB RAM) and ZX Spectrum (128KB RAM), by Boris Jeremić, undergraduate student at the University of Belgrade.

1988-1989: Development of the Earthquake Soil Structure Interaction (ESSI) Program in time domain for axisymmetric solids with general 3D loads, using higher modes of response in circumferential direction, expanded in Fourier series, so that any general 3D loading and deformation can be modeled, earthquake shaking applied through "heavy" rock at the bottom of the model, using FORTRAN programming language, on PC-DOS, x286+287, 640KB+384KB RAM, by Boris Jeremić, undergraduate student at the University of Belgrade, as part of his Diploma Thesis (Jeremić, 1989).

1989-1992: Development of the Finite Element Interpreter (FEI), a general purpose static and dynamic, elastic and elastic-plastic finite element program for solids (3D), rudimentary parser for a simple Domain Specific Language (DSL), using C Programming language, on PC-DOS, x286+287, 640KB+384KB RAM, by Boris Jeremić, a staff engineer at (a) Energoprojekt-Hidroinžinjering Company in Belgrade, Yugoslavia, at (b) Bekhme Dam Project site in Iraq, and at (c) Gasser&Scepan Design Bureau in Baar, Switzerland.

1992-1997: Development of the program FEM, featuring small and large deformation (large strain, large displacements/rotations), elasto-plasticity, solids (bricks with 8, 20 and 27 nodes), solution advancement control (hyperspherical/arc length control), using C++ Programming language, on Sun-SparcStation 5, Solaris, 256MB RAM, and on PC-DOS x386, x486 and on PC-Linux-TurboRedHat, by Boris Jeremić, a graduate student at the University of Colorado at Boulder, as part of his Master Thesis (Jeremić, 1994) and PhD Dissertation (Jeremić, 1997).

1997-2000: Continued development of the program FEM, addition of dynamics from ESSI, structural elements from `FRAME_and_GRID`, Parallel version, MPI based, linking with FEI, using C++ Programming language, on PC-Linux, and PC-Linux cluster: NorthCountry, 4 nodes + master, 100based T network, by Professor Boris Jeremić, at Clarkson University and at the University of California at Davis.

2000-2006: Developments continued with introduction of all the previous and new developments from FEM into G3 Framework, later renamed OpenSEES. at PEER, using C++ Programming language, on PC-Linux, by Professor Boris Jeremić and co-workers at the University of California at Davis, CA, USA, see Final Report Presentation.

2006-Present: Development of the Real-ESSI Simulator System (aka Real-ESSI, MS-ESSI, NRC-ESSI), using C++, FORTRAN, FEI-DSL, Python Programming languages, on PC-Linux, by Professor Boris Jeremić and co-workers at UCD. For details see main Real-ESSI Simulator web site or/and real-essi.us or/and real-essi.info (they all point to the same URL),

Appendix 709

Computer Programs for ESSI Analysis

(2019-)

This section lists a number of available computer programs, commercial, Open Source, Public Domain and Open Use, that can be used and are used for performing Earthquake Soil-Structure Interaction (ESSI) analysis. Focus is on presenting information about programs without much critical assessment of programs capabilities for ESSI analysis.

709.1 Overview of Available ESSI Analysis Programs

This section is based in part on material from Pecker et al. (2022).

709.1.1 Program Distribution Methods

Briefly described here are method for distribution of programs, in source code form or in executable form

- Commercial programs (CP): Distributed, sold, made available by commercial companies. It is very important to note that these companies need to earn funds to support company, staff, etc. Commercial programs usually have features and capabilities that are defined by a commercial license. Commercial license content is usually controlled and written by company lawyers. Commercial programs usually guaranty good accuracy of examples provided in the manual. These example usually show good, nice comparison or results with some, carefully chosen analytic solution. Publicly available, accessible Verification and Validation (V&V) for commercial programs is usually not available. One of the reasons for this, as privately noted by one of principal engineers from one of big software companies, is that verification will document level of error for approximate, numerical methods, however these errors are small, for elements, algorithms. These errors of implemented numerical approximation methods are not deemed good for business. It is reasonable to assume that commercial programs do have a significant V&V effort and documentation...
- Open Source programs (OSP): Distributed online by developers, covered by one of the open source licenses (OSL): (a) General Public License (GPL), (b) Lesser General Public License (LGPL), (c) Creative Commons (CC)) The OSL guarantees that software source code and derivative source code will be always available through similar OSL. The OSL does not even attempt to provide any quality assurance for the quality of program due to legal reasons, liability. The quality assurance (QA) for a given program, is usually a separate effort. It is noted that QA for OSL programs is almost impossible, as anyone can obtain a source code for a program, make changes to program sources, that can possibly destroy any previous QA and V&V effort and present results as using the same program...

- Restricted Source programs (RSP): Distributed to select developers, users, using a restricted version of an open source license. The difference is that developers and program owners can restrict source code distribution, mostly due to intellectual property reasons. A version of OSL is used, usually a revised version of CC license. Quality Assurance with restricted source programs is easier, as the main developer, program owner, quality assurance maintainer controls program sources distribution and can, therefor, main control of the QA process.
- Open Use programs (OUS): Distributed are executable versions of the program. The program owner can place limitations on use of the program. The quality assurance (QA) is controlled by the program owner, distributor. The QA, if it exists, is easily mainteined.
- Public Domain programs (PDP): Distributed are source code and/or executable without any restrictions for any future use. Original developer and owner of the program releases all the rights to the program sources and executables for any future use.

709.1.2 Available Programs

Provided is an incomplete list of programs that can be used and are used for ESSI analysis, or part of the ESSI analysis. These programs are available using one of the distribution methods as noted in previous section 709.1.1 on page 3080.

- Commercial Programs:
  - ABAQUS (`http://www.3ds.com`)
  - ADINA (`http://www.adina.com`)
  - ANSYS (`http://www.ansys.com/`)
  - CLASSI ()
  - GT STRUDL (`https://hexagonppm.com/offerings/products/gt-strudl`)
  - LS-DYNA (`http://www.lstc.com`)
  - NASTRAN (`http://www.mscsoftware.com`)
  - RIGID ()
  - SAP2000 (`https://www.csiamerica.com`)
  - SASSI 2010 (`http://sassi2000.net`)
  - ACS SASSI (`http://www.ghiocel-tech.com`)

  - SMACS ()
  - STARDYNE (`ftp://ftp.cray.com`)
  - SOFISTIK (`http://www.sofistik.com`)
  - PLAXIS (`http://www.plaxis.nl/`)
  - FLAC (`http://www.itascacg.com`)
  - DYNAFLOW (`https://blogs.princeton.edu/prevost/dynaflow/`)
  - Zsoil (`http://www.zsoil.com`)
  - Real-ESSI (`http://real-essi.us/`, `http://essi-consultants.com`)

- Open Source programs, Restricted Source programs, and Open Use programs:
  - FEAP (`http://www.ce.berkeley.edu`)
  - DEEPSOIL (`http://deepsoil.cee.illinois.edu/`)
  - SIMQKE1 (`http://nisee.berkeley.edu/`)
  - OpenSees (`http://opensees.berkeley.edu/`)
  - Code_ASTER (`http://www.code_astair.org`)
  - Real-ESSI (`http://real-essi.us/`)

- Public Domain programs:
  - SHAKE91 (`http://nisee.berkeley.edu/`)
  - EERA and NEERA (`http://www.ce.memphis.edu/`)
  - DESRA-2 ()
  - SUMDES ()
  - D-MOD ()
  - TESS ()
  - OpenSees (`http://opensees.berkeley.edu/`)

Appendix 710

Work Organization

(1989-)

This section describes in some detail work organization related to the development of FEI modeling and computational system.

710.1 Communication

Tablets, smart phones, laptops and computers, using `https://zoom.us/` as it works on linux and all other OSs.

710.2 Writing (Notes, Code, &c.) Version Control

710.2.1 Source Code

Memory Leaks Memory leaks are best discovered by running Valgrind (`http://valgrind.org/`). There are a number of tools that can be used with Valgrind. Mentioned are some of the most important ones, with example commands[1]

use of `tcsh` is assumed, with a time stamp (used in commands below) set as: `` set TIMESTAMP = `date +%h_%d_%Y_%Hh_%Mm_%Ss__%A` ``

-
  ```
  (time valgrind --tool=cachegrind $argv[1] >! $argv[1].cachegrind.$TIMESTAMP.out)>&! ↩
  $argv[1].cachegrind.$TIMESTAMP.err
  ```

-
  ```
  (time valgrind --tool=callgrind $argv[1] >! $argv[1].callgrind.$TIMESTAMP.out)>&! ↩
  $argv[1].callgrind.$TIMESTAMP.err
  ```

-
  ```
  (time valgrind --tool=massif $argv[1] >! $argv[1].massif.$TIMESTAMP.out)>&! ↩
  $argv[1].massif.$TIMESTAMP.err
  ```

-
  ```
  (time valgrind --tool=memcheck --leak-check=full --show-reachable=yes --freelist-vol=10000
  $argv[1] >! $argv[1].memcheck.$TIMESTAMP.out)>&! $argv[1].memcheck.$TIMESTAMP.err
  ```

-
  ```
  valgrind -v --leak-check=yes --show-reachable=yes --num-callers=32 --trace-malloc=yes ↩
  --error-limit=no --tool=massif $argv[1]
  ```

---

[1] Examples use synthax from few years ago, so should be proper synthax should be verified using excellent Valgrind documentation.

710.2.2 Verification of Real-ESSI

The aim is to run the verification procedure for Real-ESSI as automatically as possible. The verification of Real-ESSI is based on the verification of C++ libraries by https://www.boost.org/.

The verification is divided into 3 parts:

1. verification of `essi.sequential`, run by calling bash script

   ```
   ESSI_VERIFICATION_run_all_verification_SEQUENTIAL.sh
   ```

2. verification of `essi.parallel`, run by calling bash script

   ```
   ESSI_VERIFICATION_run_all_verification_PARALLEL.sh
   ```

3. check of the code stability, run by calling bash script

   `ESSI_VERIFICATION_run_CODE_STABILITY.sh`.

710.2.2.1 Update of the verification procedure from 2019

The following was done in `.../oofep/Rad_na_cml04/GLOBAL_RELEASE/Real-ESSI-Examples`.

1. In `*.fei` files, variable `Gamma` was replaced by `GammaParam` because `Gamma` is a keyword. The following was used

   ```
   grep -rl --include \*.fei ’Gamma’ * | xargs -i@ sed -i ’s/Gamma/GammaParam/g’ @
   ```

   and then

   ```
   grep -rl --include $\backslash$*.fei 'ShearStrainGammaParam' * $\vert$ xargs ↩
   -i@ sed -i 's/ShearStrainGammaParam/ShearStrainGamma/g' @
   ```

2. `Beta` was replaced by `BetaParam` using

   ```
   grep -rl --include \*.fei ’Beta’ * | xargs -i@ sed -i ’s/Beta/BetaParam/g’ @
   ```

3. 2TO3 converter was used to convert the `*.py` files from PYTHON2 to PYTHON3 using

   ```
   cd .../oofep/Rad_na_cml04/GLOBAL_RELEASE/Real-ESSI-Examples/
   ```

   and then

   ```
   2to3 -w .
   ```

   Before that, 2TO3 was installed as follows

   ```
   sudo apt install 2to3
   sudo apt install python3-lib2to3
   sudo apt install python3-toolz
   ```

4. During the evaluation of dynamic examples in `../Real-ESSI-Examples/dynamic_test`, warning:

   ```
   DeprecationWarning: Please use ‘fftfreq‘ from the ‘scipy.fftpack‘ namespace,
   the ‘scipy.fftpack.helper‘ namespace is deprecated.
   ```

   was returned, so in `../Real-ESSI-Examples/dynamic_test`, the following was done:

   ```
   grep -rl --include \*.py 'scipy.fftpack.helper' * | xargs -i@ sed -i 's/scipy.fftpack.helper/scipy.fftpack/g'
   @
   ```

5. During the evaluation of dynamic examples in `../Real-ESSI-Examples/dynamic_test`, an error was returned:

   ```
   xi, fs, Ys = measure_damping(f[0:N/2], abs(D[0:N/2]))
   TypeError: slice indices must be integers or None or have an __index__ method Solution
   ```

   so in `../Real-ESSI-Examples/dynamic_test`, the following was done:

   ```
   grep -rl --include \*.py 'N/2]' * | xargs -i@ sed -i 's#N/2]#N//2]#g' @
   ```

6. During the evaluation of dynamic examples in `../Real-ESSI-Examples/dynamic_test`, an error was returned:

   ```
   runall.sh: line 28: cd: */: No such file or directory
   ```

   Examples in all subfolders are evaluated by `runall.sh`. The error pertains to the folder __pycache__. I added `__pycache__.fei` (with just `bye;` inside), in folder __pycache__.

7. `ESSI_VERIFICATION_run_all_verification_SEQUENTIAL.sh` and `ESSI_VERIFICATION_run_all_verification_PARALLEL.sh` were modified.

710.2.3 Lecture Notes

Maintain lecture notes using git on https://github.com/.

Checking all http links in lecture notes using script `ESSI_check_URLs_in_lecture_notes.sh` in bin.

710.2.4 Bibliography

Bibliography List.

Papers of interest are organized in bibtex files (managed through *git* version control.

A list of those paper is compiled and available at:

http://sokocalo.engr.ucdavis.edu/~jeremic/research/Jeremic_et_al_bibliography_mechanics.pdf

http://sokocalo.engr.ucdavis.edu/~jeremic/research/Jeremic_et_al_bibliography_computers.pdf

http://sokocalo.engr.ucdavis.edu/~jeremic/research/Jeremic_et_al_bibliography_education.pdf

Bibliography Repository.

Most listed papers are available at: http://sokocalo.engr.ucdavis.edu/~jeremic/PAPERSlocalREPO/. This site is only accessible to members of the Computational Mechanics group at University of California at Davis, and few other collaborating entities.

710.3 Backup

710.4 Calendar

710.5 Useful Programs and Scripts

710.5.1 Backup Scripts

710.5.2 Domain Reduction Method Processing Programs and Scripts

DRM Node Extraction for fk.

fk Output Processing for DRM.

710.5.3 Pre Processing Programs and Scripts

710.5.4 Post Processing Programs and Scripts

710.5.5 Parallel Computer Architecture

http://www.open-mpi.org/projects/hwloc/

Appendix 711

Collected Bibliography

Compilation of all collected bibliography, over years, not necessarily cited in this book.
