## ABSTRACT

Presented is a study on energy dissipation in dynamic inelastic systems due to material inelasticity, viscous damping, and algorithmic damping. Formulation for plastic dissipation is based on thermodynamics, with consideration of plastic free energy. Computation of viscous energy dissipation of the Rayleigh type is developed and discussed. Energy dissipation due to algorithmic damping is discussed as well, and compared with previous two, physical energy dissipation mechanisms. Energy dissipation due to all three dissipation mechanisms are illustrated and discussed in relation to single element tests and dynamic wave propagation problems.

## INTRODUCTION

Numerical simulation of inelastic dynamic solid systems has three mechanisms of energy dissipation:

- Material inelasticity, hysteretic damping,
- Viscous coupling between solid and fluid (external or internal),
- Algorithmic, numerical damping.

23 The first two energy dissipation mechanisms have physical interpretations, while the last mechanism  
24 is primarily due to numerical integration of dynamic equations of motion.

25 Energy dissipation from inelasticity and viscous effects is physically correct if properly mod-  
26 eled and calibrated. Energy dissipation can also be used to improve performance and optimize  
27 engineering design. Proper modeling of different energy dissipation mechanics provides insight  
28 into realistic response of engineering solids. Substituting one mechanism of energy dissipation  
29 with another one might not provide proper insight into realistic response of engineering solids.

30 The mechanical energy that irreversibly transforms into heat in inelastic materials is defined as  
31 the energy dissipation due to material inelasticity, or simply referred to as plastic energy dissipation.  
32 This energy dissipation mechanism is dominant for any significant static or dynamic loading, that  
33 leads to yielding and material damage. Plastic energy dissipation is displacement proportional  
34 ([Argyris and Mlejnek 1991](#)).

35 The proper modeling of plastic energy dissipation in inelastic solids was presented earlier ([Yang](#)  
36 [et al. 2018b](#)). The difference between plastic energy dissipation and plastic work, which was first  
37 described by [Farren and Taylor \(1925\)](#), was addressed with focus on the accurate computation of  
38 plastic free energy and plastic dissipation in different inelastic material models. Plastic energy  
39 dissipation modeling and experiments are discussed in a number of recent papers ([Mason et al.](#)  
40 [1994](#); [Collins and Houlsby 1997](#); [Rittel 2000](#); [Rittel and Rabin 2000](#); [Rosakis et al. 2000](#); [Collins](#)  
41 [and Kelly 2002](#); [Feigenbaum and Dafalias 2007](#); [Veveakis et al. 2012](#)).

42 The dissipative interaction between solid and viscous fluid, internal in pores of porous solid,  
43 or external to solids and structures, can also dissipate significant amount of mechanical energy.  
44 This type of dissipation is referred to as viscous energy dissipation or viscous damping. Viscous  
45 energy dissipation is velocity proportional ([Argyris and Mlejnek 1991](#)). Modeling of viscous  
46 damping without explicitly taking into account interacting solid/structure and fluid is usually done  
47 using Caughey damping ([Caughey 1960](#)). Special case of Caughey damping is Rayleigh damping,  
48 where damping matrix is obtained by a linear combination of the mass and stiffness matrices. It  
49 was pointed out by [Hall \(2006\)](#) that the damping forces obtained from Rayleigh damping can be

50 unrealistically high. This makes the analysis result nonconservative, and require careful calibration  
51 of damping parameters.

52 Sometimes high level of Rayleigh damping is used to mimic inelastic material behavior. In  
53 other words, material nonlinear/inelastic behavior is modeled using linear elastic material and  
54 non-physical, high level of Rayleigh damping. It will be shown that energy dissipation using  
55 plastic dissipation and Rayleigh viscous damping lead to differences in response, particularly when  
56 significant material nonlinear/inelastic behavior is present.

57 Algorithmic damping, or numerical damping, is introduced into the system during time inte-  
58 gration of equations of motion, by most commonly used time marching algorithms, for example  
59 the Newmark family algorithms ([Newmark 1959](#); [Hilber et al. 1977](#); [Chung and Hulbert 1993](#)).  
60 These time integration methods can be made energy conserving with proper choice of integration  
61 parameters, for example by choosing  $\gamma = 0.500$  and  $\beta = 0.250$  for Newmark algorithm.

62 However, recent studies have shown that the Newmark family of algorithm might lose its energy  
63 conserving properties in some cases, for example, geometric nonlinear problems, impact/contact  
64 problems, and large time step simulations ([Krenk 2006](#); [Krenk 2014](#)). Efforts have been made to  
65 develop various types of energy conserving time integration algorithms ([Simo and Wong 1991](#);  
66 [Bathe 2007](#); [Gonzalez 2000](#); [Krenk 2014](#)). In this study, the classic Newmark time integration  
67 algorithm is used, and no energy conserving issue mentioned earlier is observed in any of the  
68 presented cases. System energy conservation is in fact maintained in all cases when the Newmark  
69 parameter  $\gamma = 0.500$  and  $\beta = 0.250$ . For any choice of  $\gamma > 0.500$ , Newmark family algorithms  
70 will dissipate, or produce energy in the elastic or inelastic system ([Argyris and Mlejnek 1991](#);  
71 [Hughes 1987](#)). This algorithmic energy dissipation or production can have significant effect on  
72 results of modeling and simulation of a dynamic system.

73 It is noted that energy dissipation due to plastic dissipation and/or viscous damping and/or  
74 algorithmic damping is inherent to loading of solids and structures. Plastic dissipation is always  
75 present for yielding material, and is calculated on the constitutive level for any type of loading,  
76 monotonic or cyclic, static or transient. Viscous damping is present for transient loading only,

77 monotonic or cyclic, and is calculated on a single finite element level. Algorithmic damping is  
78 present for transient loading only, monotonic or cyclic, and can be calculated for a single finite  
79 element or finite element system level. Presented framework allows for detailed energy dissipation  
80 calculations for all of the above mechanisms.

81 The next section presents the theoretical formulations used to compute energy dissipation due  
82 to material inelasticity, Rayleigh damping, and algorithmic damping. Next, a number of numerical  
83 examples are used to illustrate the differences in displacement and energy responses when different  
84 energy dissipation mechanisms are used. Paper is concluded with a number of suggestions on the  
85 choices of energy dissipation mechanisms for dynamic modeling of inelastic solids.

## 86 **ENERGY DISSIPATION MECHANISMS**

### 87 **Plastic Energy Dissipation**

88 Energy dissipation due to material inelasticity is a phenomenon that can be observed in most  
89 structural and geotechnical materials during deformation. Plastic energy dissipation can be used to  
90 estimate material damage. According to the second law of thermodynamics, the energy dissipation  
91 of a system should always increase or remain constant as deformation occurs. Ability to follow  
92 energy dissipation, a scalar, during static and dynamic deformation can provide useful information  
93 about the performance of solids and structures, and can be used to improve design and/or retrofit.

94 Unfortunately, there exists a misconception where plastic work is used as a measure of plastic  
95 energy dissipation. This misconception originates from ignoring plastic free energy, which together  
96 with plastic dissipation makes up plastic work. Plastic free energy can make up a significant  
97 portion of plastic work, which renders energy dissipation results incorrect. The correct modeling  
98 of plastic energy dissipation follows the principles of thermodynamics, which ensures energy  
99 balance and nonnegative incremental energy dissipation. Based on the formulations derived from  
100 thermodynamics, a framework for computing plastic energy dissipation was established by [Yang  
101 et al. \(2018b\)](#), which is applied to the numerical examples presented in this paper.

102 Following the first and second laws of thermodynamics, the equation for plastic energy dissi-

103 pation in decoupled material models was presented by [Yang et al. \(2018b\)](#):

$$104 \quad \Phi = \sigma_{ij} \dot{\epsilon}_{ij} - \sigma_{ij} \dot{\epsilon}_{ij}^{el} - \rho \dot{\psi}_{pl} \geq 0 \quad (1)$$

105 where  $\Phi$  is the rate of plastic energy dissipation per unit volume,  $\sigma_{ij}$  is the stress tensor,  $\epsilon_{ij}$  is the  
106 strain tensor,  $\epsilon_{ij}^{el}$  is the elastic part of the strain tensor,  $\rho$  is the mass density of the material,  $\psi_{pl}$   
107 is the plastic free energy per unit volume. All stresses are defined as the effective stresses. Sign  
108 convention for the stress is consistent with the standard definition in mechanics of materials, i.e.  
109 positive in tension. Note that Equation 1 holds under the assumption of isothermal process, which  
110 is a reasonable assumption for analysis of most civil engineering problems ([Collins and Houlsby](#)  
111 [1997](#)).

112 For most inelastic material models, the stress  $\sigma_{ij}$ , total strain  $\epsilon_{ij}$  and elastic strain  $\epsilon_{ij}^{el}$  are parts  
113 of the standard output for the material response. A challenge is to evaluate plastic free energy  $\psi_{pl}$ ,  
114 that is not defined explicitly, if at all, for many classic material models. The physical interpretation  
115 of plastic free energy is related to the state of the material's micro-structure. Physical interpretation  
116 of plastic free energy was discussed and illustrated in earlier publications ([Besseling and Van](#)  
117 [Der Giessen 1994](#); [Collins and Kelly 2002](#); [Yang et al. 2018b](#); [Yang et al. 2018a](#)).

118 For pressure-independent inelastic material models (e.g. von Mises plasticity) with isotropic  
119 and/or kinematic hardening, the plastic free energy can be calculated from

$$120 \quad \psi_{pl} = \psi_{pl}^{iso} + \psi_{pl}^{kin} = \frac{1}{2\rho\kappa_1} k^2 + \frac{1}{2\rho a_1} \alpha_{ij} \alpha_{ij} \quad (2)$$

121 where the plastic free energy  $\psi_{pl}$  is decomposed into two parts that are related to isotropic hardening  
122  $\psi_{pl}^{iso}$  and kinematic hardening  $\psi_{pl}^{kin}$ . Here scalar  $k$  is the size of the yield surface and tensor  $\alpha_{ij}$  is  
123 the back stress tensor representing the center of the yield surface, while  $\kappa$  and  $a_1$  are nonnegative  
124 material constants.

## Rayleigh Damping

To compute the energy dissipation due to viscous damping, we start with the general form of the equation of motion:

$$M_{ij}\ddot{u}_j(t) + C_{ij}\dot{u}_j(t) + K_{ij}^{elpl}(t)u_j(t) = f_i(t) \quad (3)$$

where  $u_j(t)$  is the vector of generalized displacements,  $M_{ij}$  is the mass matrix,  $C_{ij}$  is the damping matrix,  $K_{ij}^{elpl}(t)$  is the inelastic stiffness matrix that generally evolves with time,  $f_i(t)$  is the external load vector. For linear viscous damping of the Rayleigh type, the damping matrix is expressed as

$$C_{ij} = a_M M_{ij} + a_K K_{ij}^{el} \quad (4)$$

where  $a_M$  and  $a_K$  are damping constants with units of  $s^{-1}$  and  $s$ , respectively. The stiffness matrix used to construct the damping matrix is usually the initial tangent stiffness matrix, which is also the elastic stiffness  $K_{ij}^{el}$  for inelastic materials. Equation 4 indicates that the damping matrix  $C_{ij}$  is constant through the entire simulation.

The expression used to compute the damping constants for a desired damping ratio  $\xi$  in a specified frequency range from  $\hat{\omega}$  to  $R\hat{\omega}$  was given by Hall (2006) as

$$a_M = 2\xi\hat{\omega} \frac{2R}{1 + R + 2\sqrt{R}} \quad , \quad a_K = 2\xi \frac{1}{\hat{\omega}} \frac{2}{1 + R + 2\sqrt{R}} \quad (5)$$

It can be seen in Equation 4 that there are mass-proportional and stiffness-proportional parts in Rayleigh damping. The combination of mass-proportional and stiffness-proportional damping can provide a desired control over modal damping ratios. However, as pointed out by Hall (2006), classic Rayleigh damping must be used with appropriate damping coefficients, which should give a near-constant value of damping for all modes with frequencies that are of interest. For the modes outside the prescribed frequency range, the damping ratios are unrealistically high.

The incremental form of energy balance for a dynamic system with viscous damping can be

147 expressed as

$$148 \quad \Delta W_{Input} = \Delta E_K + \Delta D_V + \Delta W_M \quad (6)$$

149 The left hand side of Equation 6 is the increment of external input work

$$150 \quad \Delta W_{Input} = f_i \Delta u_i \quad (7)$$

151 The three terms on the right hand side of Equation 6 are the increment of kinetic energy  $\Delta E_K$ , the  
152 increment of viscous energy dissipation  $\Delta D_V$ , and the increment of material work of the system  
153  $\Delta W_M$

$$\Delta E_K = M_{ij} \ddot{u}_j \Delta u_i$$

$$154 \quad \Delta D_V = C_{ij} \dot{u}_j \Delta u_i \quad (8)$$

$$\Delta W_M = K_{ij}^{elpl} u_j \Delta u_i = \Delta E_S + \Delta E_P + \Delta D_P$$

155 Note that the term of material work  $W_M$  can be separated into an elastic part and a plastic part.  
156 These two components are known as the elastic strain energy  $E_S$  and the plastic work of the system,  
157 respectively. Then, as mentioned in the previous section, plastic work can be further decomposed  
158 into plastic free energy  $E_P$  and plastic energy dissipation  $D_P$ .

### 159 **Algorithmic Energy Dissipation**

160 Newmark time integration method (Newmark 1959) is used for all cases in this study. The  
161 forward displacements  ${}^{n+1}u_i$  and velocities  ${}^{n+1}\dot{u}_i$  are expressed in terms of their current values and  
162 the forward and current values of the acceleration

$$163 \quad \begin{aligned} {}^{n+1}\dot{u}_i &= {}^n\dot{u}_i + (1 - \gamma)h {}^n\ddot{u}_i + \gamma h {}^{n+1}\ddot{u}_i \\ {}^{n+1}u_i &= {}^nu_i + h {}^n\dot{u}_i + \left(\frac{1}{2} - \beta\right)h^2 {}^n\ddot{u}_i + \beta h^2 {}^{n+1}\ddot{u}_i \end{aligned} \quad (9)$$

164 where  $\Delta t$  is the length of each time step,  $\gamma$  and  $\beta$  are the Newmark integration parameters that  
165 controls the amount of algorithmic damping in the system.

166 Krenk (2006) gave the incremental form of the energy balance equation 6 over increment  $t_n$  to

167  $t_{n+1}$ , for Newmark algorithm

$$\begin{aligned}
& \left[ \frac{1}{2} M_{ij}^* \dot{u}_i \dot{u}_j + \frac{1}{2} K_{ij} u_i u_j + \left( \beta - \frac{1}{2} \gamma \right) \frac{1}{2} h^2 M_{ij}^* \ddot{u}_i \ddot{u}_j \right] \Big|_{t_n}^{t_{n+1}} = \\
& + \Delta u_i \left[ \frac{1}{2} (f_i^{n+1} + f_i^n) + \left( \gamma - \frac{1}{2} \right) \Delta f_i \right] \\
& - \left( \gamma - \frac{1}{2} \right) \left[ K_{ij} \Delta u_i \Delta u_j + \left( \beta - \frac{1}{2} \gamma \right) h^2 M_{ij}^* \Delta \ddot{u}_i \Delta \ddot{u}_j \right] \\
& - \frac{1}{2} h \left[ h^{-2} C_{ij} \Delta u_i \Delta u_j + \frac{1}{4} C_{ij} (\dot{u}_i^{n+1} + \dot{u}_i^n) (\dot{u}_j^{n+1} + \dot{u}_j^n) \right] \\
& + \frac{1}{2} \left( \beta - \frac{1}{2} \gamma \right)^2 h^3 C_{ij} \Delta \ddot{u}_i \Delta \ddot{u}_j
\end{aligned} \tag{10}$$

169 where the equivalent mass matrix  $M_{ij}^*$  is defined as

$$M_{ij}^* = M_{ij} + \left( \gamma - \frac{1}{2} \right) h C_{ij} \tag{11}$$

171 Rearranging Equation 10 gives the explicit expression for the amount of algorithmic energy  
172 dissipation over an increment

$$\begin{aligned}
& [E_K + D_V + W_M - W_{Input}]_{t_n}^{t_{n+1}} = \\
& + \left( \gamma - \frac{1}{2} \right) \Delta f_i \Delta u_i + \frac{1}{2} \left( \beta - \frac{1}{2} \gamma \right)^2 h^3 C_{ij} \Delta \ddot{u}_i \Delta \ddot{u}_j \\
& - \left( \gamma - \frac{1}{2} \right) \left[ K_{ij} \Delta u_i \Delta u_j + \left( \beta - \frac{1}{2} \gamma \right) h^2 M_{ij}^* \Delta \ddot{u}_i \Delta \ddot{u}_j \right] \\
& - \left[ \frac{1}{2} \left( \gamma - \frac{1}{2} \right) h C_{ij} \dot{u}_i \dot{u}_j + \left( \beta - \frac{1}{2} \gamma \right) \frac{1}{2} h^2 M_{ij}^* \ddot{u}_i \ddot{u}_j \right] \Big|_{t_n}^{t_{n+1}}
\end{aligned} \tag{12}$$

174 When  $\gamma = 0.500$  and  $\beta = 0.250$ , all the terms on the right hand side of Equation 12 vanish, thus no  
175 algorithmic energy dissipation exists. For other values of  $\gamma$  and  $\beta$ , algorithmic energy dissipation,  
176 or even energy production, is observed in the system.

## 177 NUMERICAL EXAMPLES

178 Numerical simulations presented in this paper are performed using the MS ESSI Simulator

179 system (Jeremić et al. 2018), and all the examples presented here are available at [http://ms-essi.](http://ms-essi.info/)  
180 [info/](http://ms-essi.info/). Energy dissipation due to material inelasticity and Rayleigh damping is investigated through  
181 a series of single-element tests with different material parameters and loading conditions. Then,  
182 elastic and inelastic materials are used in a stack of solid brick elements model to further illustrate  
183 energy dissipation in wave propagation problems. Finally, cases with plastic energy dissipation,  
184 Rayleigh damping, and algorithmic damping are analyzed to demonstrate the importance of energy  
185 dissipation mechanisms in dynamic finite element modeling.

186 The inelastic material model used in this study is associated von Mises plasticity with nonlinear  
187 Armstrong-Frederick kinematic hardening. The yield function of von Mises plasticity is

$$188 \quad f = \sqrt{(s_{ij} - \alpha_{ij})(s_{ij} - \alpha_{ij})} - \sqrt{\frac{2}{3}}k \quad (13)$$

189 The general expression for Armstrong-Frederick kinematic hardening rule is

$$190 \quad d\alpha_{ij} = \frac{2}{3}h_a d\epsilon_{ij}^{pl} - \sqrt{\frac{2}{3}}c_r d\lambda \alpha_{ij} \quad (14)$$

191 where  $d\lambda$  is a nonnegative scalar plastic multiplier and  $h_a$  and  $c_r$  are nonnegative material hardening  
192 constants. The parameter  $h_a$  controls the initial stiffness of the material after yielding, while ratio  
193  $h_a/c_r$  controls the limit of stress magnitude, or shear strength.

194 For all dynamic problems analyzed, Newmark integration algorithm is used. In most cases with  
195 elasticity and inelasticity and Rayleigh damping, the numerical integration parameters are chosen  
196 in a way so that no algorithmic damping exists in the system, i.e. Newmark parameters  $\gamma = 0.500$   
197 and  $\beta = 0.250$ . Only for the last example, algorithmic damping was used, by choosing Newmark  
198 parameters  $\gamma > 0.500$  and  $\beta = 0.250(\gamma + 0.500)^2$ .

199 External loads are applied incrementally using load- or displacement-control scheme. Non-  
200 linear system of equations is solved using Newton-Raphson algorithm with line searching to help  
201 convergence. Standard 8-node-brick elements are used in all examples.

## Single Element Tests

Energy dissipation in single 8-node-brick element is studied in this section. The individual and combined effects of material inelasticity and Rayleigh damping are investigated through a series of numerical examples.

The single element model, with boundary conditions and loads, is shown in Fig.1. During the shearing stage, the bottom of the element is fixed and imposed motion is applied on the top. The main reason for using displacement-control scheme is to eliminate any resonance effects that might occur during faster dynamic tests, if load-control is used. The time increment  $\Delta t$  for the Newmark algorithm is set to  $\Delta t = 0.01s$ .

### *Elastic Material without Rayleigh Damping*

The first example uses linear elastic material with no Rayleigh damping. No energy dissipation in any form is expected in this case. The equivalence between external work and mechanical energy stored in the system (energy balance) in single-element model is verified through this example.

The material properties used for this case are summarized in Table 1.

Fig.2 shows the displacement, stress-strain, and energy responses of the case using linear elastic material without Rayleigh damping. The stress-strain response indicates that the material is linear elastic, which is expected. Only kinetic energy and strain energy appear in this example since there is no energy dissipation. Notice that the kinetic energy is not zero at the beginning because of the initial velocity that comes with the sine-wave imposed motion.

The comparison between external work, which is computed using the imposed displacement time series and nodal force response, and total mechanical energy stored in the system, calculated at each Gauss point, shows that energy balance is achieved. Note that the frequency of oscillation of energy curves, shown in Fig.2(c)(d), is twice of that of the displacement time series, Fig.2(a). This is expected for linear elastic systems under displacement control loading.

### *Inelastic Material without Rayleigh Damping*

The next example focuses on the energy dissipation due to material inelasticity only. A more systematic study of plastic energy dissipation in solids can be found in [Yang et al. \(2018b\)](#), where the

229 energy dissipation behavior of various inelastic material models was investigated. In this section, a  
 230 material model defined with von Mises yield function and Armstrong-Frederick nonlinear kinematic  
 231 hardening is used. No Rayleigh damping is added to any model in this section.

232 Table 2 summarizes material parameters for these studies. Three materials with the same  
 233 shear strength, controlled by ratio  $h_a/c_r$ , but different post-yield stiffness,  $h_a$ , are modeled. These  
 234 three materials are used in single element examples and wave propagation problems. They will  
 235 be referred to as soft, medium, and hard inelastic materials in the remaining parts of this paper.  
 236 Fig.3 shows the stress-strain response and energy computation results for the cases using inelastic  
 237 material and no Rayleigh damping.

238 According to Fig.3, by keeping shear strength constant and increase post-yield stiffness, the  
 239 amount of plastic energy dissipation increases. This is consistent with the stress-strain response  
 240 which shows that the degree of plastification increases as the parameter  $h_a$  increases. It is also  
 241 noted that changes in strain energy during cyclic shearing, is very small, due to a small elastic  
 242 region of the material model.

### 243 *Elastic Material with Rayleigh Damping*

244 The next example focuses on the energy dissipation due to viscous damping. Viscous damping  
 245 is modeled using Rayleigh damping. Linear elastic material is used in all cases in this section so  
 246 that energy dissipation can only be caused by Rayleigh damping.

247 Energy dissipation by Rayleigh damping can be analyzed using equations presented in section 2.  
 248 By substituting the expression of Rayleigh damping matrix (Equation 4 and 5) into the term of  
 249 viscous energy dissipation in Equation 8, one obtains

$$250 \quad \Delta D_V = C_{ij} \dot{u}_j \Delta u_i = \frac{4\xi}{1 + R + 2\sqrt{R}} \left( \hat{\omega} R M_{ij} + \frac{K_{ij}^{el}}{\hat{\omega}} \right) \dot{u}_j \Delta u_i \quad (15)$$

251 Table 3 shows the parameters used in this section. The effect of damping ratio  $\xi$  to the amount of  
 252 viscous energy dissipation is investigated. Typical values of damping ratio  $\xi$  for soils and structures  
 253 are selected. The lower limit of damping range  $\hat{\omega}$  can be computed from the model's fundamental

254 frequency  $\omega_1$ . It is common practice to set  $\hat{\omega} = (2/3)\omega_1 = (4\pi)/(3T_1)$  due to nonlinear response of  
255 the system (Hall 2006). In order to cover the frequency range from  $(2/3)\omega_1$  to  $3\omega_1$ , a second-mode  
256 frequency of a linear shear beam, the parameter  $R$  should be set to 4.5. For the examples in this  
257 section,  $R$  is chosen to be slightly larger,  $R = 5.0$ , to cover a larger range.

258 The energy computation results are shown in Fig.4. It can be observed that the viscous energy  
259 dissipation increases as the damping ratio increases. The values indicate a linear relationship  
260 between the viscous energy dissipation and damping ratio, that is consistent with Equation 15. All  
261 other forms of energy are the same in these cases.

### 262 *Inelastic Material with Rayleigh Damping*

263 In the previous examples, the separate effects of material inelasticity and Rayleigh damping  
264 have been studied. In this example, both energy dissipation mechanisms, inelasticity and Rayleigh  
265 damping, are used. In particular, it will be shown that the relative amount of energy dissipation  
266 due to these two mechanisms is very sensitive to the choice of material and damping parameters.

267 Fig.5 shows the stress-strain response and energy computation results for the three cases using  
268 inelastic material model with Rayleigh damping. As can be observed, energy dissipation results are  
269 very different in these three cases. Plastic energy dissipation can be much larger or much smaller or  
270 very similar to the viscous energy dissipation, depending on the choices of simulation parameters.  
271 More discussion on the combined effect of plastic energy dissipation and Rayleigh damping is  
272 shown in section 3 where a wave propagation problem is studied.

### 273 **Wave Propagation**

274 The numerical examples for a single-element present a fundamental understanding of the energy  
275 behavior for a fully controlled system, with fixed and prescribed displacements. In this section, the  
276 energy dissipation due to material inelasticity and viscous damping in a wave propagation problem  
277 is investigated. Compared to the single-element cases where energy transformation happens in one  
278 element, the wave propagation problem can illustrate the evolution of energy storage and dissipation  
279 in time and space.

280 It is important to select appropriate grid-spacing and time-step size to ensure numerical stability

281 and accuracy. A detailed study on the discretization effects in the finite element simulation of  
282 seismic waves in elastic and inelastic media was conducted by [Watanabe et al. \(2017\)](#). According  
283 to [Jeremić et al. \(2009\)](#), the suitable maximum grid spacing  $\Delta x$  for shear wave propagation for a  
284 model using eight-node-brick finite elements can be determined by considering shear wave velocity  
285  $V_s$ , and the highest frequency of the input signal  $f_{max}$ :

$$286 \quad \Delta x \leq \frac{V_s}{10f_{max}} \quad (16)$$

287 The time-step size  $\Delta t$  in wave propagation problem is usually chosen on the basis that a given  
288 wave front does not reach two consecutive nodes at the same time. The following condition,  
289 given by [Watanabe et al. \(2017\)](#), is used to ensure numerical stability when using Newmark time  
290 integration algorithm:

$$291 \quad \Delta t \leq \frac{\Delta x}{V_s} \quad (17)$$

292 The model used in this section is a stack of 8-node-brick elements, as shown in Fig.6. It is  
293 noted that for inelastic material models, where shear stiffness is reduced due to inelasticity, as is  
294 the case here, Equation 16 should still hold. This means that the element size has to be small  
295 enough so that the model is capable of propagating waves through inelastic material. However,  
296 there is a limit of how small the mesh size can become, and what frequencies can be accurately  
297 propagated. For a given example, assuming reduction of shear stiffness, shear wave velocity, from  
298  $V_s = 400\text{m/s}$  (elastic) to  $V_s = 40\text{m/s}$  (inelastic). Then, based on Equation 16, the length of each  
299 element is chosen to be  $\Delta x = 1\text{m}$ . Meanwhile, according to Equation 17, the time increment  $\Delta t$  for  
300 the Newmark algorithm is set to  $\Delta t = 0.001\text{s}$ .

301 Model features a total of 4000 eight-node-brick elements, with boundary conditions that allow  
302 only shear waves to propagate. The left 3900 elements are used to model a layer of material that is  
303 assumed to remain elastic during wave propagation. The material model properties of the elastic  
304 layer was given in Table 1. The right 100 elements represent a layer that can be elastic or inelastic.  
305 In some examples, this layer remains elastic, in order to investigate the effect of Rayleigh damping.

306 In other examples, this layer is inelastic, and dissipates energy through material inelasticity and/or  
 307 Rayleigh damping.

308 An Ormsby wavelet (Ryan 1994), with peak value controlled by  $A$  and frequency contents  
 309 starting from  $f_1$  to  $f_4$ , with a constant amplitude from  $f_2$  to  $f_3$ , is imposed to the fixed end of the  
 310 model. The function of Ormsby wavelet is

$$311 \quad f(t) = A \left[ \left( \frac{\pi f_4^2}{f_4 - f_3} \text{sinc}(\pi f_4(t - t_s))^2 - \frac{\pi f_3^2}{f_4 - f_3} \text{sinc}(\pi f_3(t - t_s))^2 \right) \right. \\
 312 \quad \left. - \left( \frac{\pi f_2^2}{f_2 - f_1} \text{sinc}(\pi f_2(t - t_s))^2 - \frac{\pi f_1^2}{f_2 - f_1} \text{sinc}(\pi f_1(t - t_s))^2 \right) \right] \quad (18)$$

312 where  $t_s$  is the time when maximum amplitude is occurring, and sine cardinal is defined as  
 313  $\text{sinc}(x) = \sin(x)/x$ . Please note that from Equation 18, peak value  $f^{peak}$  is defined at  $t = t_s$  as

$$314 \quad f^{peak} = A\pi (f_4 + f_3 - f_2 - f_1) \quad (19)$$

315 Fig.7 shows the imposed displacement, in time domain and frequency domain, created using  
 316 Ormsby wavelet with  $A = 0.01\text{m}\cdot\text{s}$ ,  $f_1 = 1.0\text{Hz}$ ,  $f_2 = 2.0\text{Hz}$ ,  $f_3 = 4.0\text{Hz}$ , and  $f_4 = 5.0\text{Hz}$ .

### 317 *Elastic Material without Rayleigh Damping*

318 In the first case, material parameters for elastic material are used for the entire model. This  
 319 simple setup illustrates the energy transformation process as shear waves propagate and reflect  
 320 within a uniform media.

321 Fig.8 shows the displacement response at the free end of the model in time and frequency  
 322 domain, as well as the energy and stress-strain results, for the case of wave propagation within an  
 323 uniform media. As expected, the displacement at the free end is twice in magnitude and same in  
 324 frequency contents. The stress-strain response of the material is a straight line since linear elastic  
 325 material is used in this case.

326 Because of the absence of energy dissipation mechanism, the total mechanical energy remains  
 327 constant after the wave is input into the system. The transformation between kinetic energy and

328 strain energy is observed when the shear wave hits the free end of the model and gets reflected  
329 back. During the wave propagation process, before and after the reflection, the amounts of kinetic  
330 energy and strain energy are exactly the same, which is expected in a wave propagation problem.

### 331 *Elastic and Inelastic Material without Rayleigh Damping*

332 In this section, the energy dissipation due to material inelasticity during wave propagation is  
333 investigated. The inelastic material model uses von Mises yield function in combination with  
334 Armstrong-Frederick kinematic hardening. Soft, medium, and hard inelastic materials, shown in  
335 Table 2 on page 26, are used to investigate the influence of post-yield stiffness on plastic dissipation.

336 Fig.9, 10, and 11 show the displacement response at the free end of the model in time and  
337 frequency domain, as well as the stress-strain and energy results, for the cases with material  
338 inelasticity and no Rayleigh damping. Peak displacement response at the free end of the model is  
339 larger when the inelastic material is stiffer after yield. Due to the use of inelastic material, permanent  
340 deformation is observed in the displacement time series. This leads to the low frequency contents  
341 in the displacement spectrum.

342 According to the energy plots, more energy is dissipated due to material inelasticity when the  
343 inelastic material has a larger post-yield stiffness. This observation is consistent with the findings  
344 from single element examples (section 3) that harder inelastic material has more plastic dissipation.  
345 When the inelastic layer is much softer than the elastic layer, the majority of the incoming wave is  
346 reflected back at the material interface instead of entering the inelastic layer. As a result, energy  
347 dissipation and displacement response are less significant in the case of a softer inelastic material.

### 348 *Elastic Material with Rayleigh Damping*

349 The next section focuses on the effect of Rayleigh damping in wave propagation problems.  
350 Linear elastic material, shown in Table 1, is used in order to only have viscous dissipation mech-  
351 anism. Due to the use of Rayleigh damping, it is expected to observe viscous energy dissipation  
352 and displacement reduction throughout the model. Parametric study on the damping coefficient  $\xi$   
353 is performed. The damping parameters used in this section are summarized in Table 4.

354 Fig.12, 13, and 14 show the displacement response in time and frequency domain, as well as

355 the energy results, when different values of damping ratio  $\xi$  are used. As expected, the amount  
356 of surface displacement reduction and energy dissipation increases when larger  $\xi$  is used. Despite  
357 changes in the peak value, the frequency contents of the displacement response at the free end  
358 remain the same as those of the input motion.

359 For structural materials like steel and concrete, the Rayleigh damping ratio is usually chosen  
360 to be between 0.02 to 0.05. As seen in Fig.13, about half of the input energy is dissipated due  
361 to Rayleigh damping when  $\xi$  is 0.05. It is noted that sometimes large Rayleigh damping ratio are  
362 used, as high as 0.20. These high Rayleigh damping ratios lead to a significant amount of energy  
363 dissipation through viscous energy dissipation mechanism. Such high level of energy dissipation  
364 may not be physical and will lead to underestimation of the system response.

#### 365 *Comparison between Plastic Dissipation and Viscous Damping*

366 As previously noted, sometimes Rayleigh damping of the system is set to a high level to  
367 mimic inelastic material behavior. By comparing the example using soft inelastic material without  
368 Rayleigh damping, shown in Fig.9, with the one using linear elastic material and Rayleigh damp-  
369 ing  $\xi = 0.05$ , shown in Fig.13, it appears that the amounts of energy dissipation are similar in  
370 these two examples. However, this correspondence is very sensitive to material properties, damp-  
371 ing parameters, loading conditions and frequency of loading. In this section, the two examples  
372 with different energy dissipation mechanisms are reanalyzed using an input motion with different  
373 frequency content,  $f_1 = 0.5\text{Hz}$ ,  $f_2 = 1.0\text{Hz}$ ,  $f_3 = 3.0\text{Hz}$ , and  $f_4 = 3.5\text{Hz}$ , as shown in Fig.15.

374 Fig.16 shows the displacement responses and energy computation results for the two examples  
375 using different energy dissipation mechanisms. The first case uses soft inelastic material, shown in  
376 Table 2 on page 26, with no Rayleigh damping, while the second case uses linear elastic material with  
377 Rayleigh damping  $\xi = 0.05$ . From Fig.16, it can be seen that the amounts of energy dissipation are  
378 very different in these two cases with the new input motion. Thus, material inelasticity and viscous  
379 damping may give equal, similar amounts of energy dissipation for a specific set of simulation  
380 parameters and loading conditions, but this similarity will not hold if the model is subject to  
381 a different loading. In other words, plastic dissipation and viscous energy dissipation are not

interchangeable energy dissipation mechanisms, and should always be considered independently. Moreover, viscous damping assumes that each node of the finite element model is connected to a viscous damper, while in reality for civil engineering solids and structures most energy is not dissipated in the form of linear viscous damping (Ostadan et al. 2004; Hall 2006).

It should also be pointed out that the response, especially in the frequency domain, are very different when comparing the examples using inelastic material with the ones using only Rayleigh damping. Permanent deformation and change of stiffness, which can only be modeled with inelastic materials, are not observed in the cases using linear elastic material with Rayleigh damping. For the cases using inelastic materials, the displacement response contains frequencies that are both higher and lower than those of the input motion. For practical engineering designs, if only elastic material is used in numerical simulations, these important high frequency motions and permanent deformations could be missed completely.

#### *Combined Effects of Plastic Dissipation and Viscous Damping*

In this section, the combined effect of energy dissipation through material inelasticity and Rayleigh damping is presented. Three cases with different combinations of inelastic materials (Table 2) and damping coefficients ( $\xi = 0.02, 0.04, \text{ or } 0.10$ ) are simulated and analyzed. Fig. 17, 18, and 19 show the displacement, stress-strain, and energy results of these three cases with both material inelasticity and Rayleigh damping. Permanent deformation and low frequency response at the free end is observed. Note that the high frequency content of motions is significantly reduced because of the Rayleigh damping in the system.

Depending on the choices of simulation parameters, it is shown that the amount of energy dissipation due to material inelasticity can be larger, smaller, or comparable to that caused by Rayleigh damping. For problems where significant solid-fluid interaction is expected, e.g. underground structure in saturated soil, the viscous damping of the soil structure interaction (SSI) system is likely to have significant contribution to energy dissipation. For other problems with little solid-fluid interaction, but large material damage, e.g. aboveground structure suffering large seismic loading, more energy is likely to be dissipated due to material inelasticity. Thus it is

409 important to model not only the correct amount of energy dissipation of a system but the proper  
410 energy dissipation mechanisms as well. The system response can be very different, as shown, when  
411 different combinations of energy dissipation mechanisms are used.

### 412 *Influence of Algorithmic Damping*

413 Algorithmic damping was excluded in all previously presented examples by setting the Newmark  
414 parameter to  $\gamma = 0.500$  and  $\beta = 0.250$  (Hughes 1987). In practice, Newmark parameters  $\gamma$  and  $\beta$   
415 are usually set to  $\gamma > 0.500$  and  $\beta = 0.250(\gamma + 0.500)^2$  in order to introduce algorithmic damping  
416 into the system. To illustrate the influence of Newmark parameters  $\gamma$  and  $\beta$  on energy dissipation,  
417 two sets of examples with algorithmic damping are analyzed.

418 Fig.20 and 21 show the displacement, stress-strain, and energy results of two cases where linear  
419 elastic material and no Rayleigh damping is used, which means that only algorithmic damping  
420 dissipates system energy. There is a noticeable amount of algorithmic damping when the Newmark  
421 parameters are increased to  $\gamma = 0.505$  and  $\beta = 0.253$ . As Newmark parameters are increased  
422 to  $\gamma = 0.700$  and  $\beta = 0.360$ , it is observed that the algorithmic damping in the system becomes  
423 unrealistically high. More importantly, most of the mechanical energy propagated by the wave is  
424 numerically dissipated even before the wave reaches the free end of the column.

### 425 *Combined Effects of Plastic Dissipation, Viscous Damping, and Algorithmic Damping*

426 For realistic modeling and simulation, usually all three energy dissipation mechanisms are  
427 used. Fig.22, 23, and 24 show the displacement, stress-strain, and energy results of the three  
428 cases where plastic dissipation, Rayleigh damping, and algorithmic damping are all present. The  
429 medium inelastic material defined in Table 2 and Rayleigh damping coefficient  $\xi = 0.04$  are used  
430 for all three cases. It is observed that for a relatively small Newmark parameters  $\gamma = 0.505$  and  
431  $\beta = 0.253$ , the amount of energy dissipation due to algorithmic damping is comparable but less than  
432 energy dissipation caused by material inelasticity and viscous damping. As Newmark parameter  
433  $\gamma$  increases to  $\gamma = 0.510$  and  $\beta = 0.253$ , algorithmic damping becomes the comparable energy  
434 dissipation mechanism in the system. Then, when Newmark parameter  $\gamma$  increases even higher  
435 to  $\gamma = 0.550$  and  $\beta = 0.276$ , the motions in the system are almost completely damped out by

436 algorithmic damping, and material inelasticity and viscous damping do not play any significant  
437 role.

438 As noted by [Argyris and Mlejnek \(1991\)](#), high frequencies can be introduced into finite element  
439 models, during discretization process. It is thus important to be able to try to damp those unrealistic  
440 higher frequencies by applying a reasonable amount of algorithmic damping. It is noted that  
441 introduction of algorithmic damping has to be done carefully, as in some cases, as shown here,  
442 algorithmic damping can surpass all other physical forms of energy dissipation. It is thus suggested  
443 that a sensitivity study should be conducted for dynamic finite element models, so that influence of  
444 algorithmic damping on results is better understood.

## 445 **CONCLUSIONS**

446 Presented was a study on energy dissipation due to material inelasticity, Rayleigh damping, and  
447 algorithmic damping for dynamic loading of solids. The importance of proper modeling of energy  
448 dissipation due to inelastic material behavior, due to Rayleigh damping, and due to algorithmic  
449 damping in dynamic nonlinear systems was investigated and discussed. The differences in system  
450 response with these three energy dissipation mechanisms were illustrated through a series of  
451 numerical examples.

452 Thermomechanics formulation that correctly computes plastic energy dissipation in inelastic  
453 materials was presented. The important role of plastic free energy was emphasized. In addition,  
454 Rayleigh damping and corresponding viscous energy dissipation formulation was presented as well.  
455 Use of significant, potentially unrealistic Rayleigh damping was illustrated and discussed. This  
456 high Rayleigh damping might lead to unrealistically high energy dissipation and underestimation  
457 of the system response. Considering both plastic energy dissipation and viscous damping of the  
458 Rayleigh type, the rate form of energy balance for a dynamic system was obtained.

459 Presented analysis approach was illustrated using several numerical examples with energy  
460 dissipation due to material inelasticity, and/or Rayleigh damping, and/or algorithmic damping.  
461 Permanent deformation was observed in the cases using inelastic material (as expected), leading to  
462 the low frequency contents in the displacement response at the ground surface. Rayleigh damping

463 can significantly reduce high frequency motions, which might have important implications in  
464 evaluating the safety of structures, systems and components.

465 The influence of algorithmic damping was illustrated and discussed as well. Algorithmic  
466 damping mainly reduces higher frequency motions, and it exists throughout simulation process.  
467 Unrealistically high values of algorithmic damping can be obtained, and sensitivity studies are  
468 needed for proper choice of algorithmic damping parameters.

469 Although the amounts of dissipated energy were comparable in some cases, the observed system  
470 responses were very different when different energy dissipation mechanisms were used. All three  
471 energy dissipation mechanisms, material inelasticity, viscous damping, and algorithmic damping,  
472 model fundamentally different physical or mathematical phenomena in finite element simulation.  
473 Therefore, it is important to use appropriate energy dissipation mechanisms by following proper  
474 physics and mathematics, allowing analysts to gain confidence in obtained results, and use those  
475 results for design, assessment and retrofits.

2	Energy computation of single brick element modeled using linear elastic material and no Rayleigh damping: (a) Displacement time series; (b) Stress-strain response; (c) Energy results; (d) External work. . . . .	33
3	Energy computation for a single brick element modeled using inelastic material and no Rayleigh damping: (a) Soft material; (b) Medium material; (c) Hard material. . . . .	34
4	Energy computation of single brick element modeled using elastic material with Rayleigh damping: (a) $\xi = 0.02$ ; (b) $\xi = 0.05$ ; (c) $\xi = 0.10$ ; (d) $\xi = 0.20$ . . . . .	35
5	Energy computation of single brick element modeled using inelastic material with Rayleigh damping: (a) Soft material, $\xi = 0.1$ ; (b) Medium material, $\xi = 0.06$ ; (c) Hard material, $\xi = 0.02$ . . . . .	36
6	Numerical model of the wave propagation problem used in this paper. . . . .	37
7	Imposed displacement of the wave propagation problem created using Ormsby wavelet with $A = 0.01\text{m}\cdot\text{s}$ , $f_1 = 1.0\text{Hz}$ , $f_2 = 2.0\text{Hz}$ , $f_3 = 4.0\text{Hz}$ , and $f_4 = 5.0\text{Hz}$ : (a) Time series; (b) Frequency domain. . . . .	38
8	Energy computation of wave propagation within an uniform elastic media: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response. . . . .	39
9	Energy computation of wave propagation using soft inelastic material and no Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response. . . . .	40
10	Energy computation of wave propagation using medium inelastic material and no Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response. . . . .	41

581	11	Energy computation of wave propagation using hard inelastic material and no	
582		Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c)	
583		Energy results; (d) Stress-strain response. . . . .	42
584	12	Energy computation of wave propagation using linear elastic material and Rayleigh	
585		damping ( $\xi = 0.02$ ): (a) Displacement time series; (b) Displacement spectrum; (c)	
586		Energy results; (d) Stress-strain response. . . . .	43
587	13	Energy computation of wave propagation using linear elastic material and Rayleigh	
588		damping ( $\xi = 0.05$ ): (a) Displacement time series; (b) Displacement spectrum; (c)	
589		Energy results; (d) Stress-strain response. . . . .	44
590	14	Energy computation of wave propagation using linear elastic material and Rayleigh	
591		damping ( $\xi = 0.10$ ): (a) Displacement time series; (b) Displacement spectrum; (c)	
592		Energy results; (d) Stress-strain response. . . . .	45
593	15	Imposed displacement of the wave propagation problem created using Ormsby	
594		wavelet with $A = 0.01\text{m}\cdot\text{s}$ , $f_1 = 0.5\text{Hz}$ , $f_2 = 1.0\text{Hz}$ , $f_3 = 3.0\text{Hz}$ , and $f_4 = 3.5\text{Hz}$ :	
595		(a) Time series; (b) Frequency domain. . . . .	46
596	16	Energy computation of wave propagation using a different input motion: (a) Soft in-	
597		elastic material without Rayleigh damping; (b) Linear elastic material with Rayleigh	
598		damping $\xi = 0.05$ . . . . .	47
599	17	Energy computation of wave propagation using soft inelastic material and Rayleigh	
600		damping with $\xi = 0.01$ : (a) Displacement time series; (b) Displacement spectrum;	
601		(c) Energy results; (d) Stress-strain response. . . . .	48
602	18	Energy computation of wave propagation using medium inelastic material model	
603		and Rayleigh damping with $\xi = 0.04$ : (a) Displacement time series; (b) Displace-	
604		ment spectrum; (c) Energy results; (d) Stress-strain response. . . . .	49
605	19	Energy computation of wave propagation using hard inelastic material model and	
606		Rayleigh damping with $\xi = 0.10$ : (a) Displacement time series; (b) Displacement	
607		spectrum; (c) Energy results; (d) Stress-strain response. . . . .	50

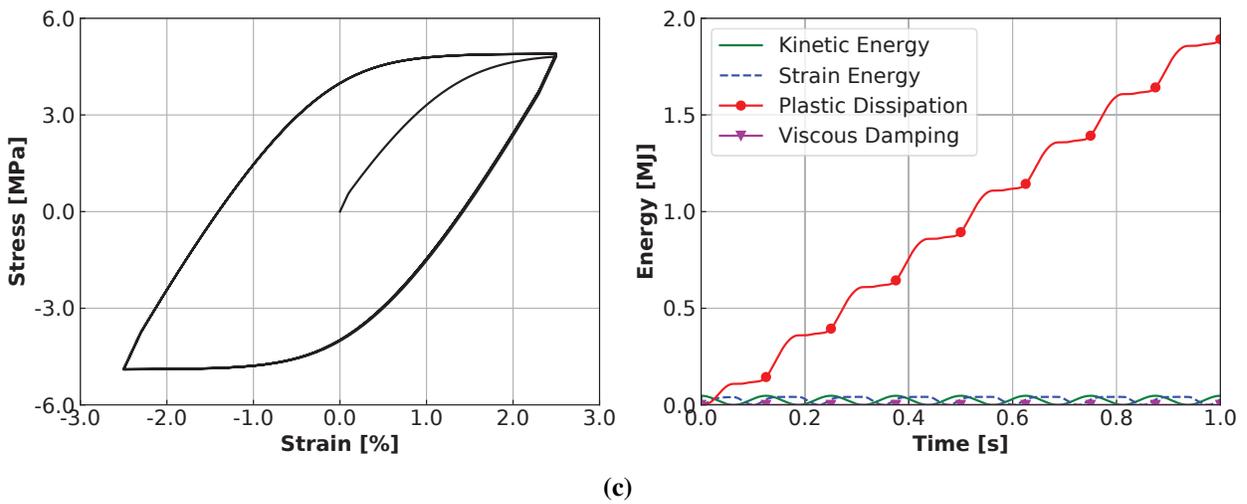

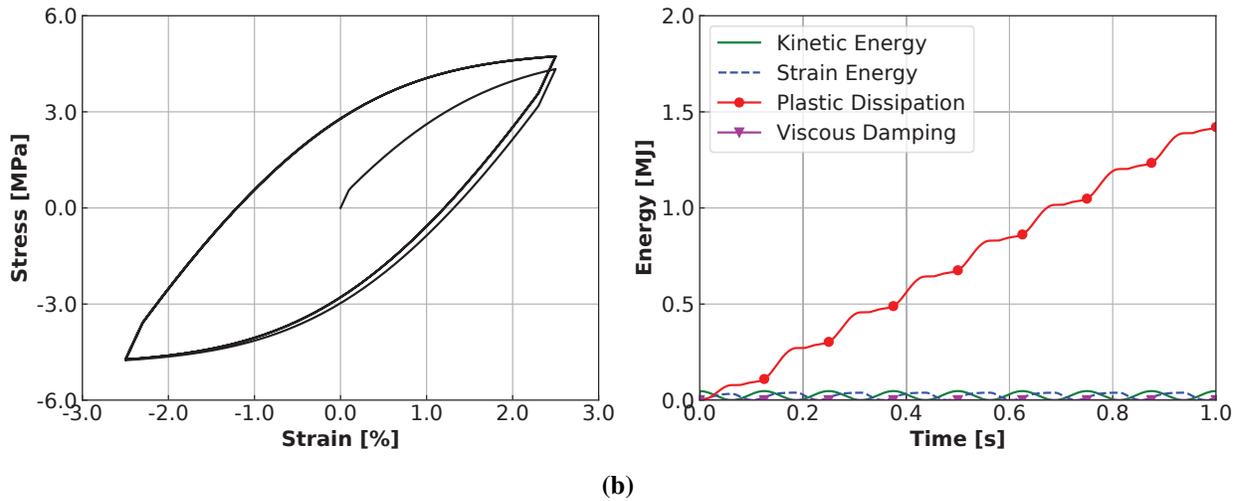

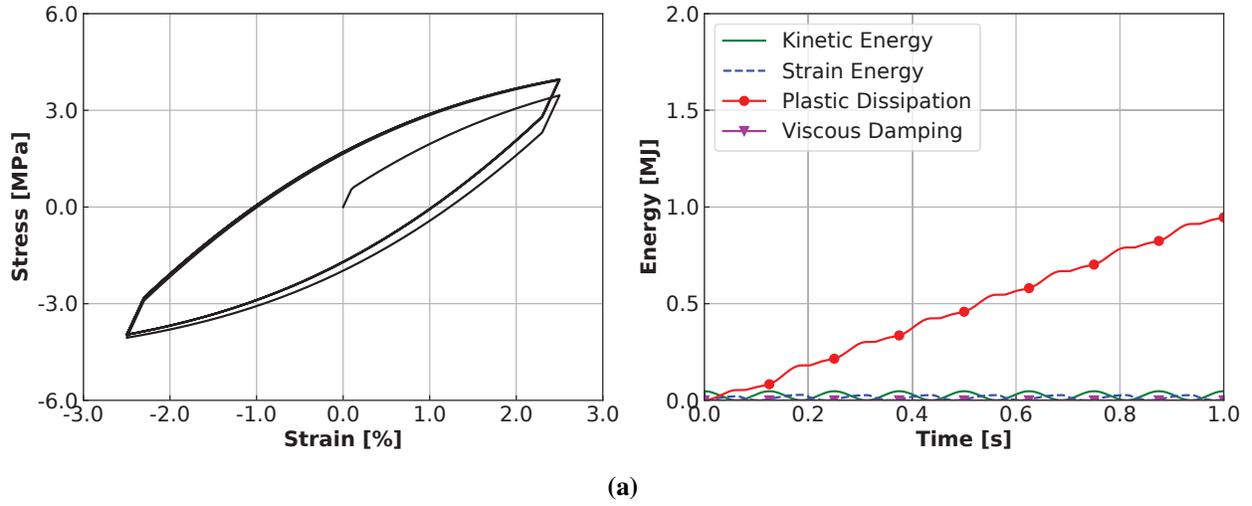

608	20	Energy computation of wave propagation using linear elastic material and algo-	
609		rithmic damping ( $\gamma = 0.505$ , $\beta = 0.253$ ): (a) Displacement time series; (b)	
610		Displacement spectrum; (c) Energy results; (d) Stress-strain response. . . . .	51
611	21	Energy computation of wave propagation using linear elastic material model and	
612		algorithmic damping ( $\gamma = 0.700$ , $\beta = 0.360$ ): (a) Displacement time series; (b)	
613		Displacement spectrum; (c) Energy results; (d) Stress-strain response. . . . .	52
614	22	Energy computation of wave propagation using medium inelastic material model,	
615		Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.505$ , $\beta = 0.253$ ):	
616		(a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d)	
617		Stress-strain response. . . . .	53
618	23	Energy computation of wave propagation using medium inelastic material model,	
619		Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.510$ , $\beta = 0.255$ ):	
620		(a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d)	
621		Stress-strain response. . . . .	54
622	24	Energy computation of wave propagation using medium inelastic material model,	
623		Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.550$ , $\beta = 0.276$ ):	
624		(a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d)	
625		Stress-strain response. . . . .	55

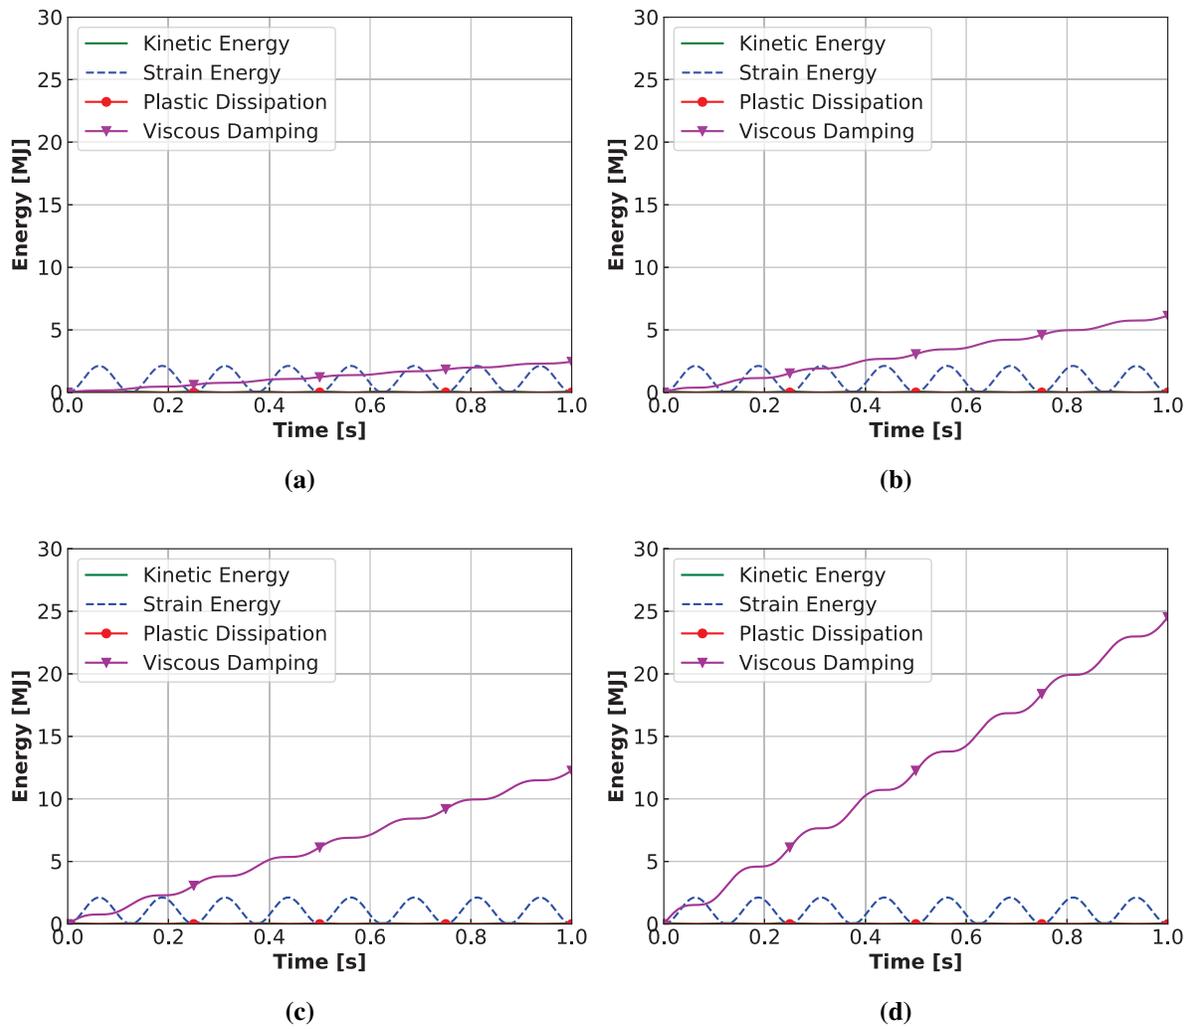

**Fig. 1.** Single element model under shear loading.

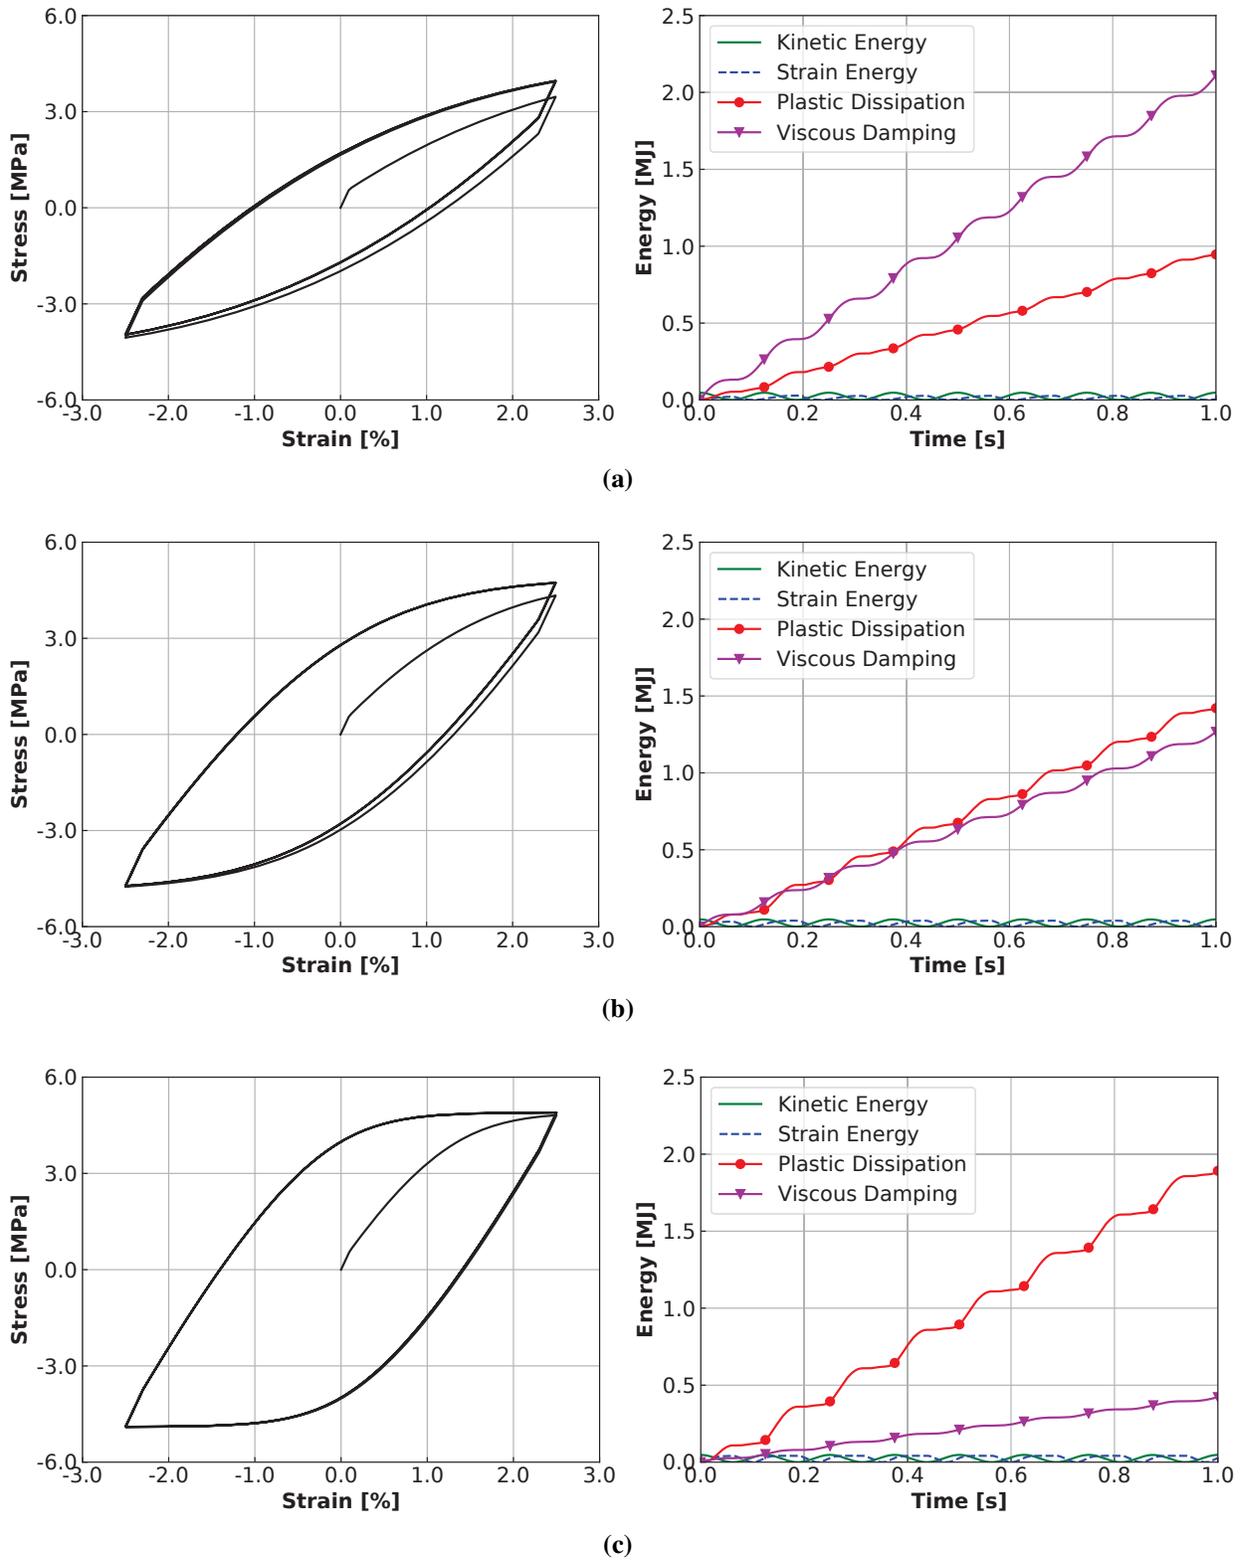

**Fig. 2.** Energy computation of single brick element modeled using linear elastic material and no Rayleigh damping: (a) Displacement time series; (b) Stress-strain response; (c) Energy results; (d) External work.

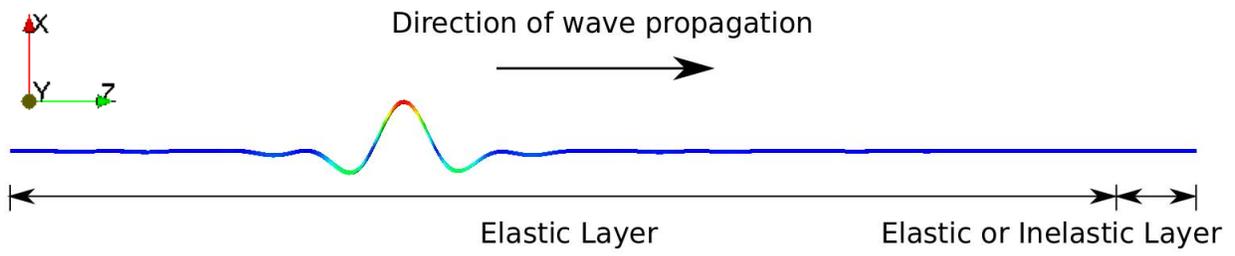

**Fig. 3.** Energy computation for a single brick element modeled using inelastic material and no Rayleigh damping: (a) Soft material; (b) Medium material; (c) Hard material.

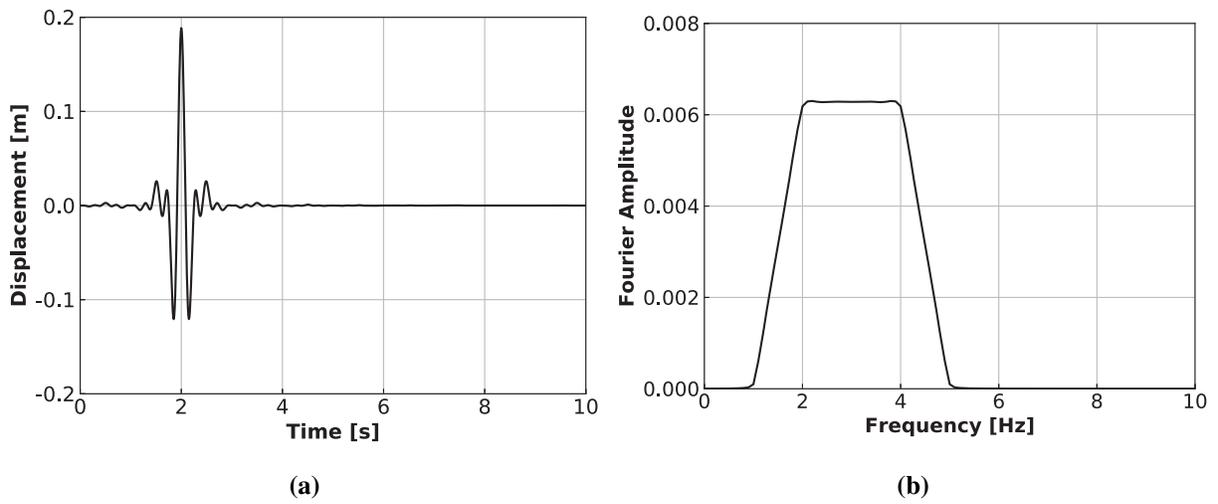

**Fig. 4.** Energy computation of single brick element modeled using elastic material with Rayleigh damping: (a)  $\xi = 0.02$ ; (b)  $\xi = 0.05$ ; (c)  $\xi = 0.10$ ; (d)  $\xi = 0.20$ .

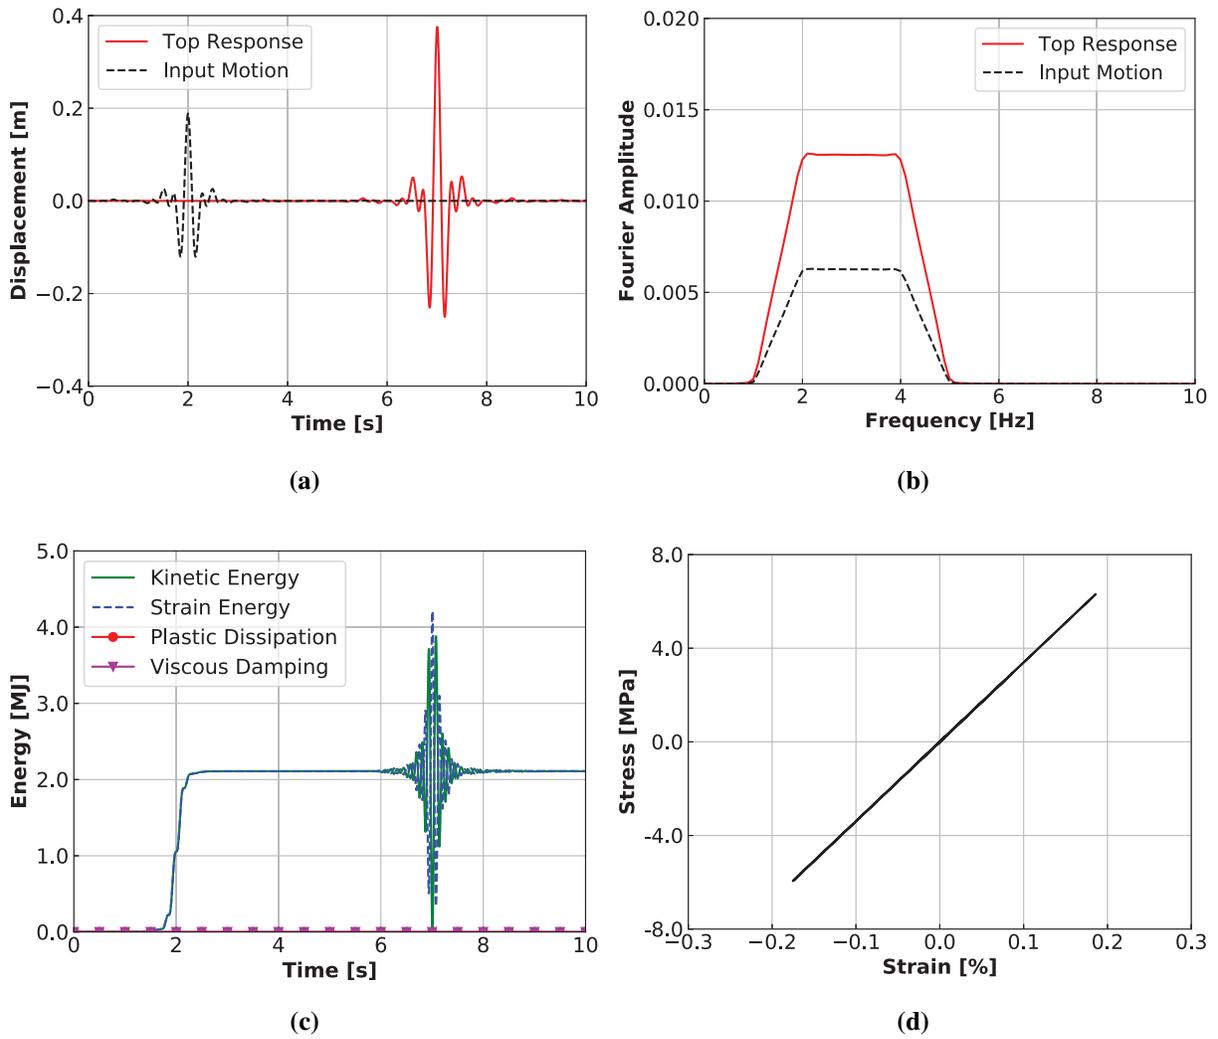

**Fig. 5.** Energy computation of single brick element modeled using inelastic material with Rayleigh damping: (a) Soft material,  $\xi = 0.1$ ; (b) Medium material,  $\xi = 0.06$ ; (c) Hard material,  $\xi = 0.02$ .

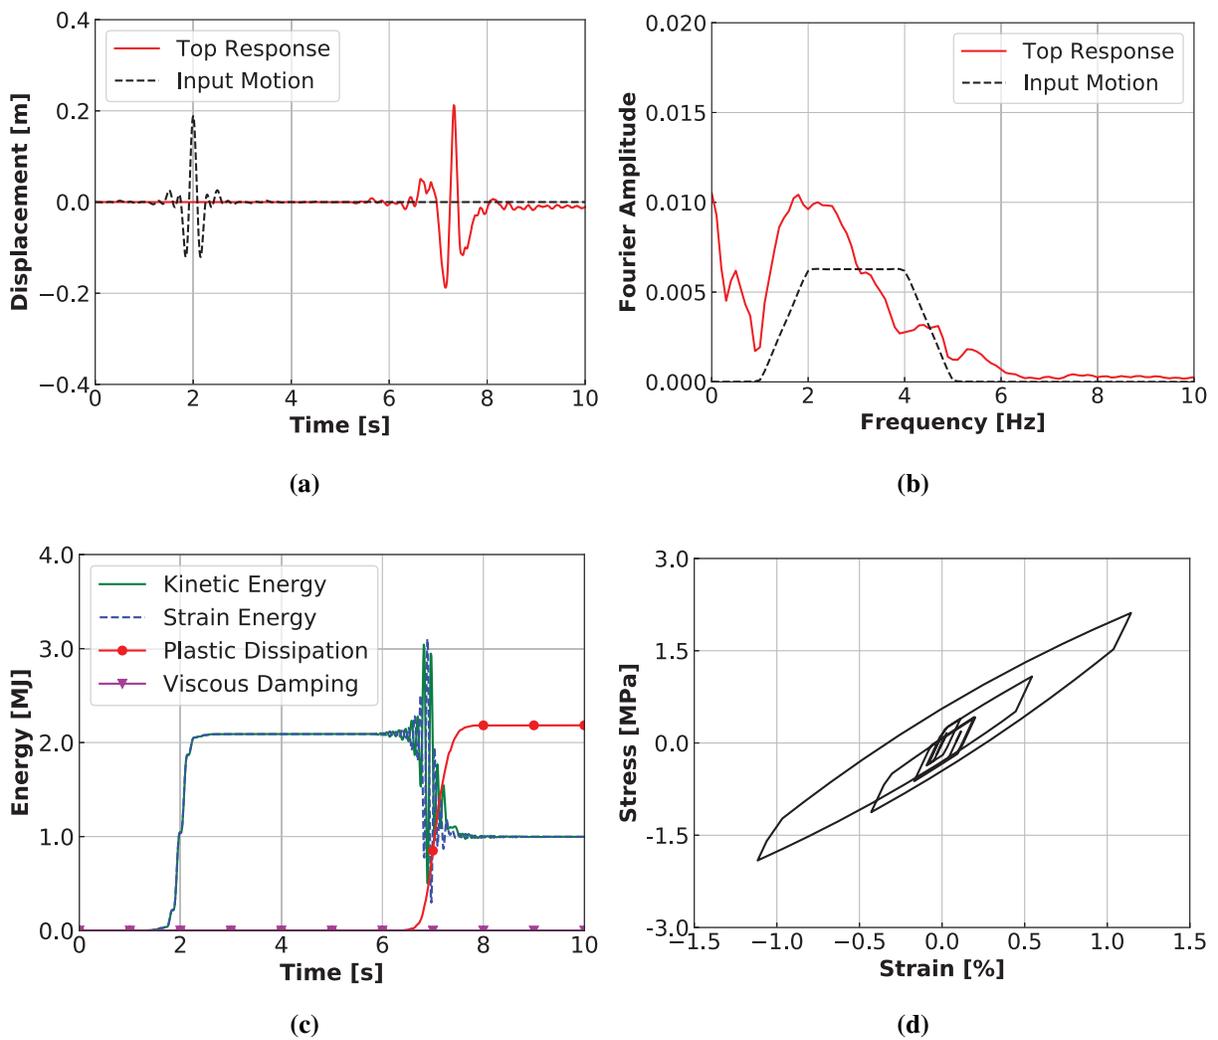

**Fig. 6.** Numerical model of the wave propagation problem used in this paper.

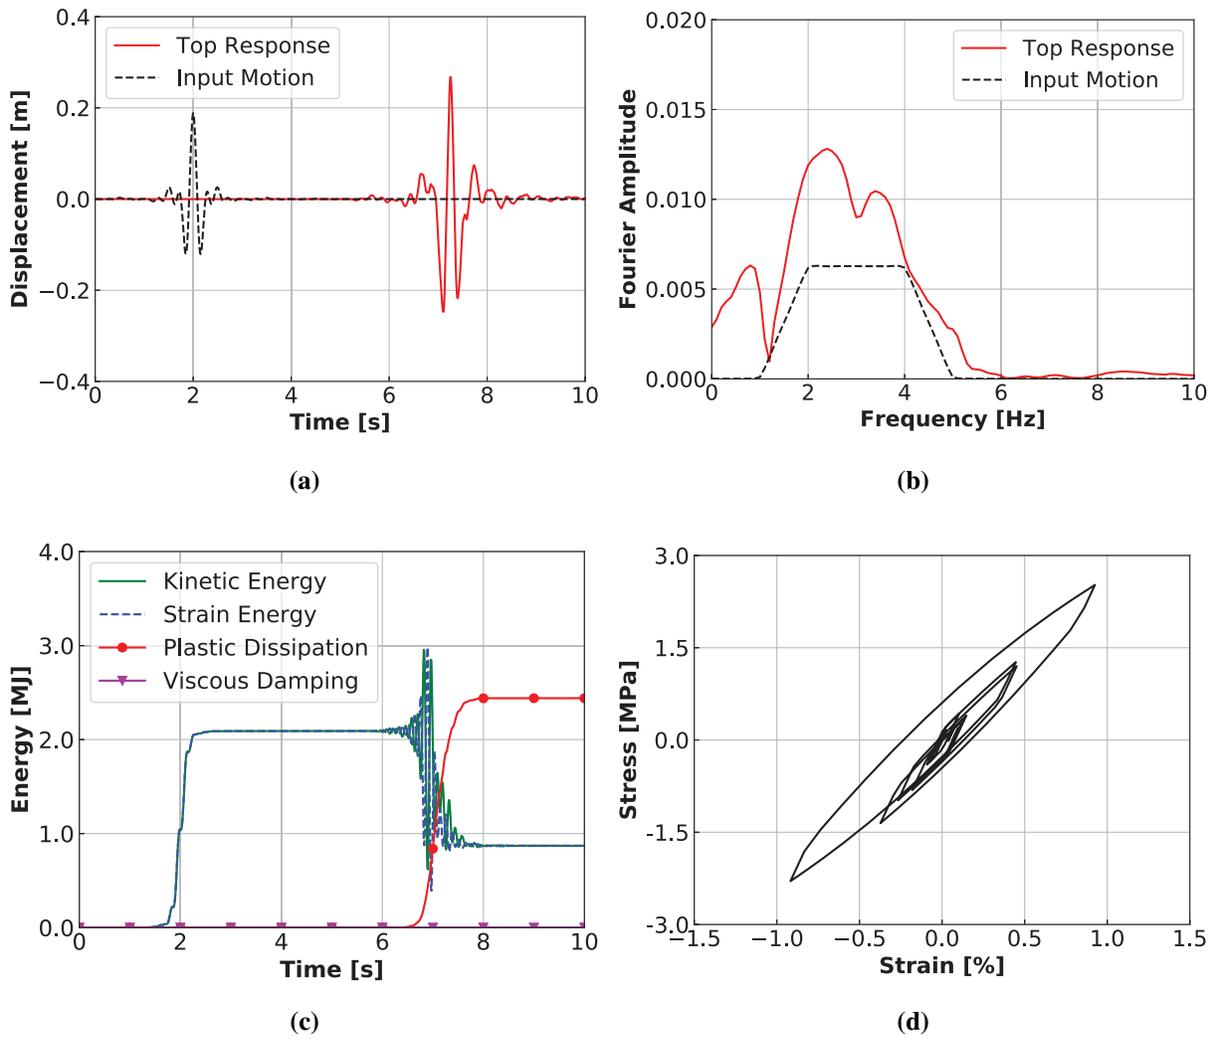

**Fig. 7.** Imposed displacement of the wave propagation problem created using Ormsby wavelet with  $A = 0.01\text{m}\cdot\text{s}$ ,  $f_1 = 1.0\text{Hz}$ ,  $f_2 = 2.0\text{Hz}$ ,  $f_3 = 4.0\text{Hz}$ , and  $f_4 = 5.0\text{Hz}$ : (a) Time series; (b) Frequency domain.

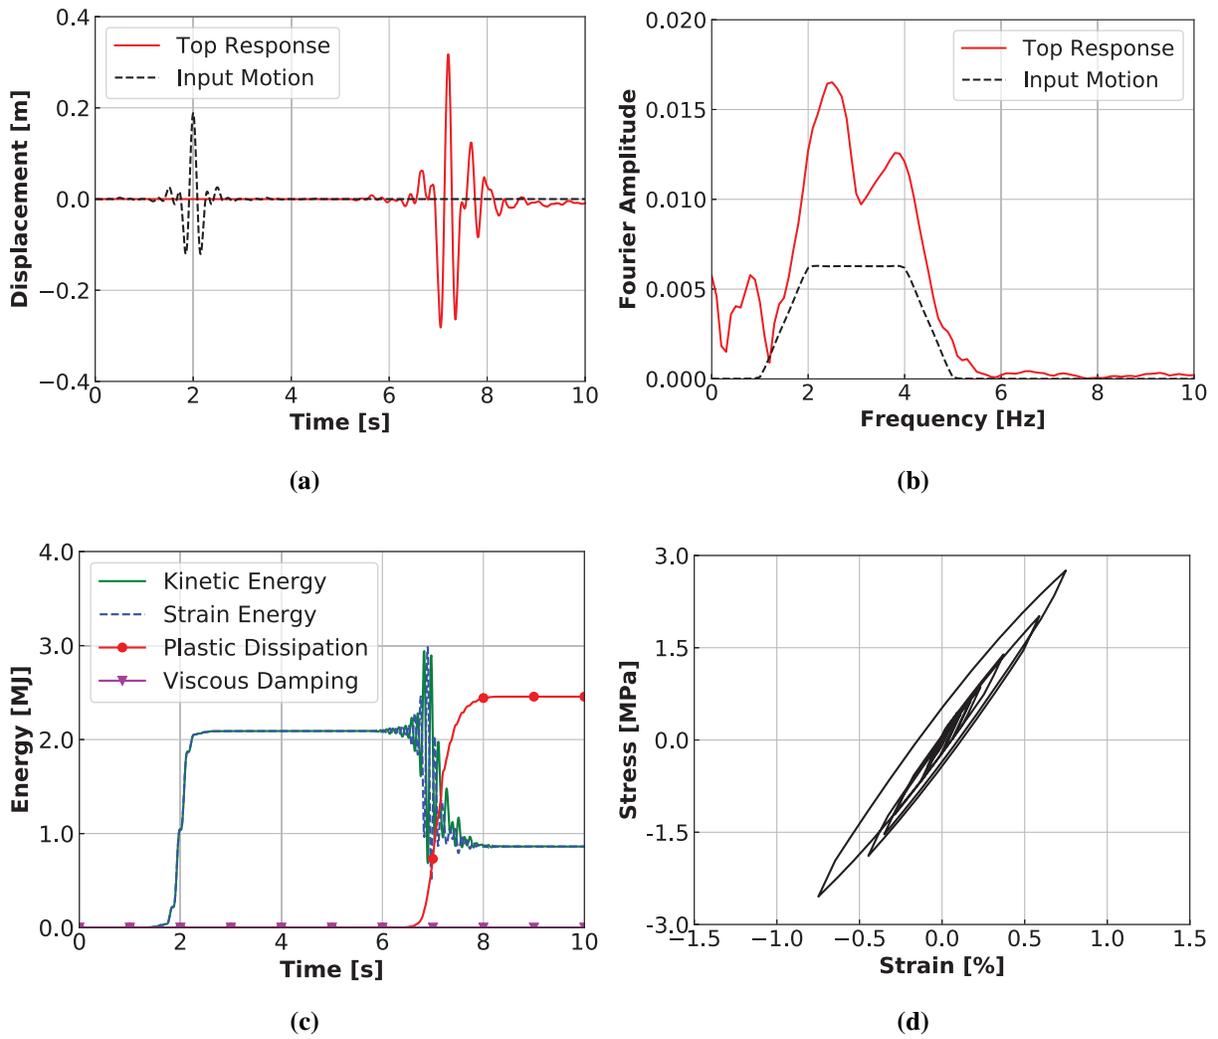

**Fig. 8.** Energy computation of wave propagation within an uniform elastic media: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

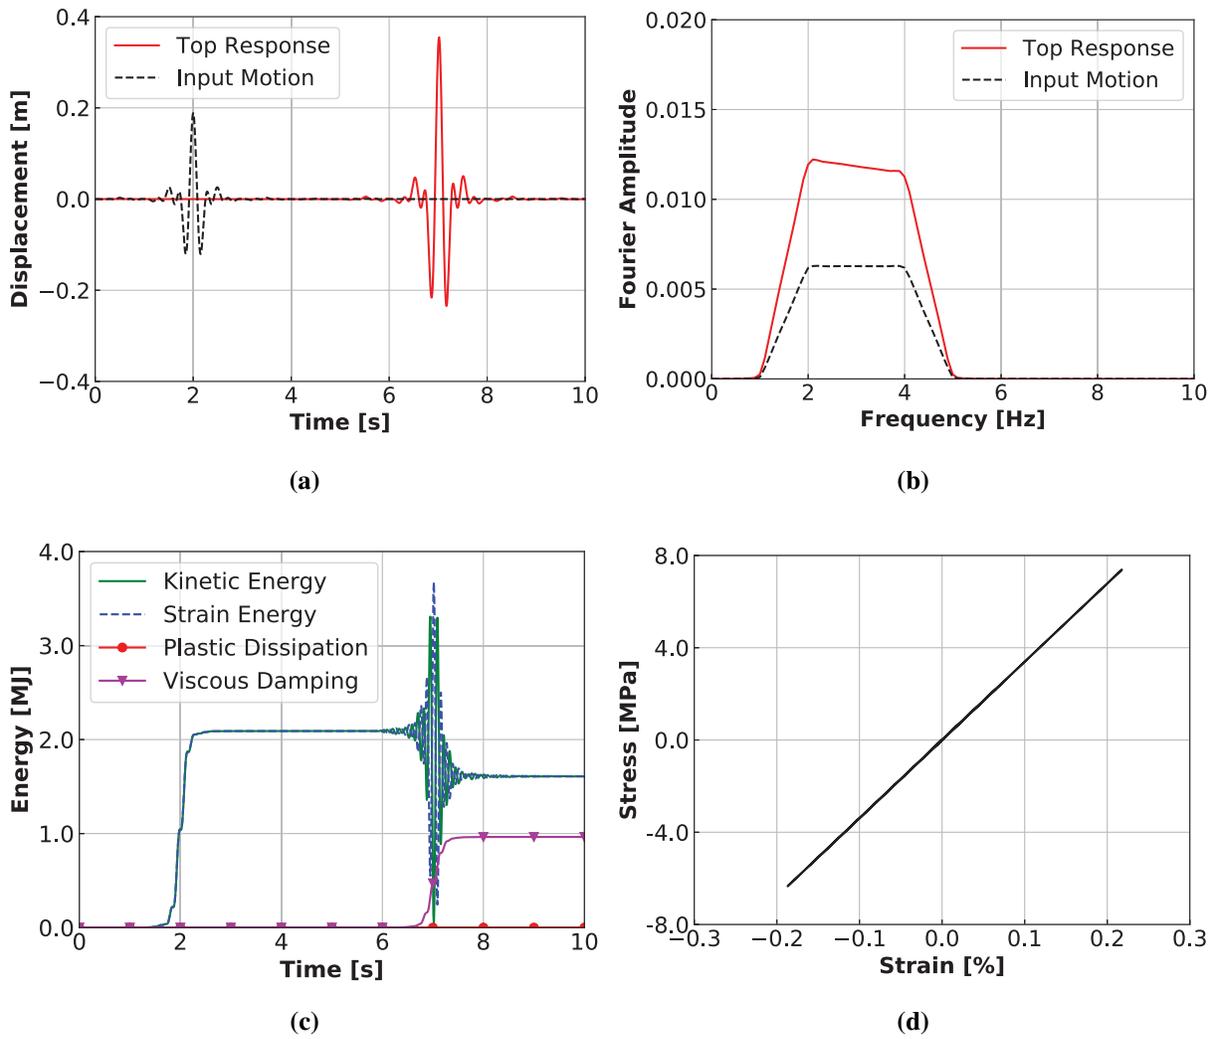

**Fig. 9.** Energy computation of wave propagation using soft inelastic material and no Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

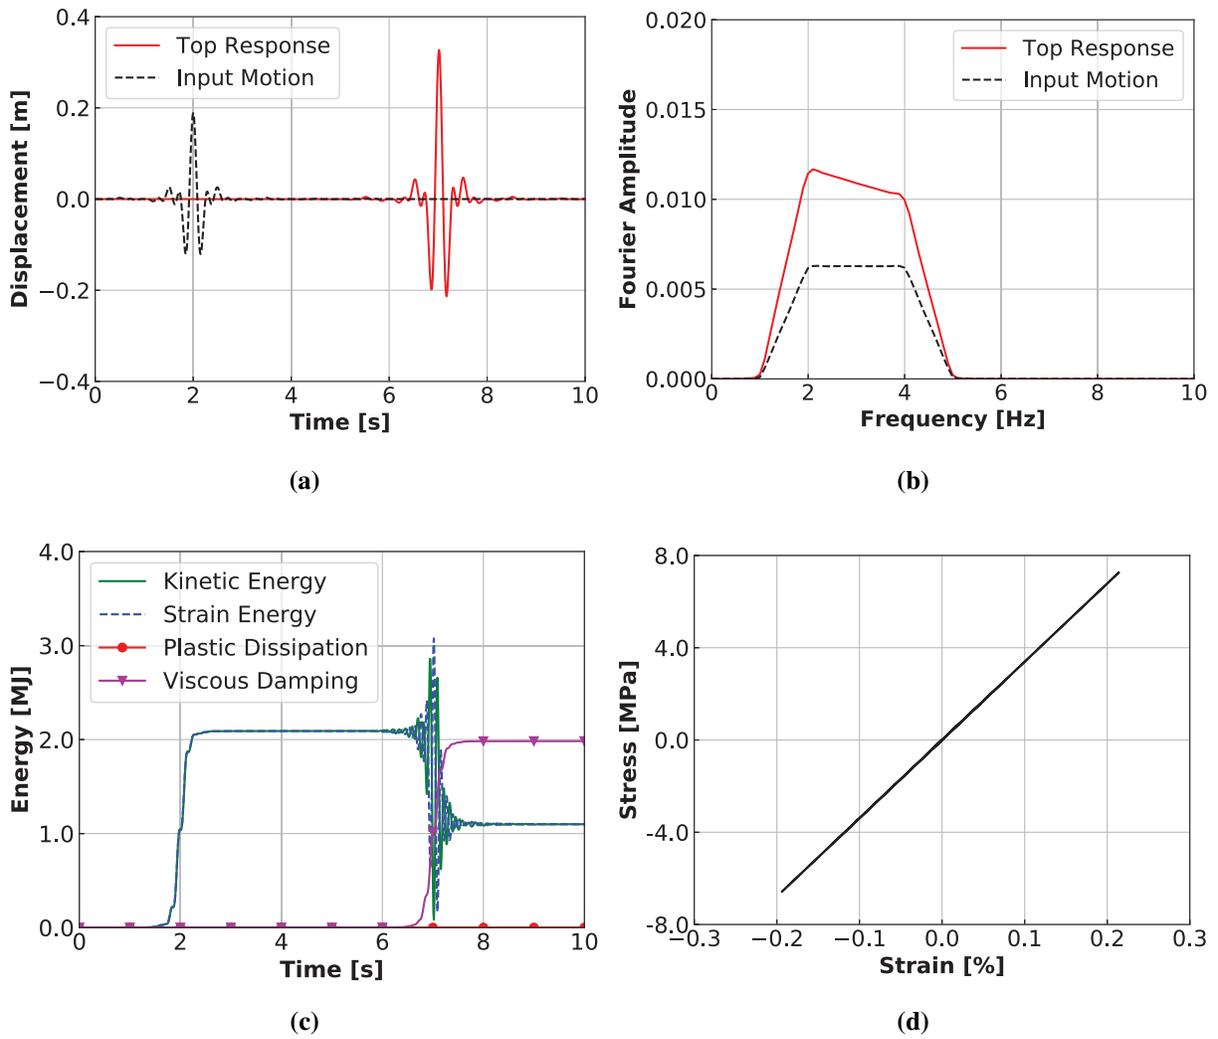

**Fig. 10.** Energy computation of wave propagation using medium inelastic material and no Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

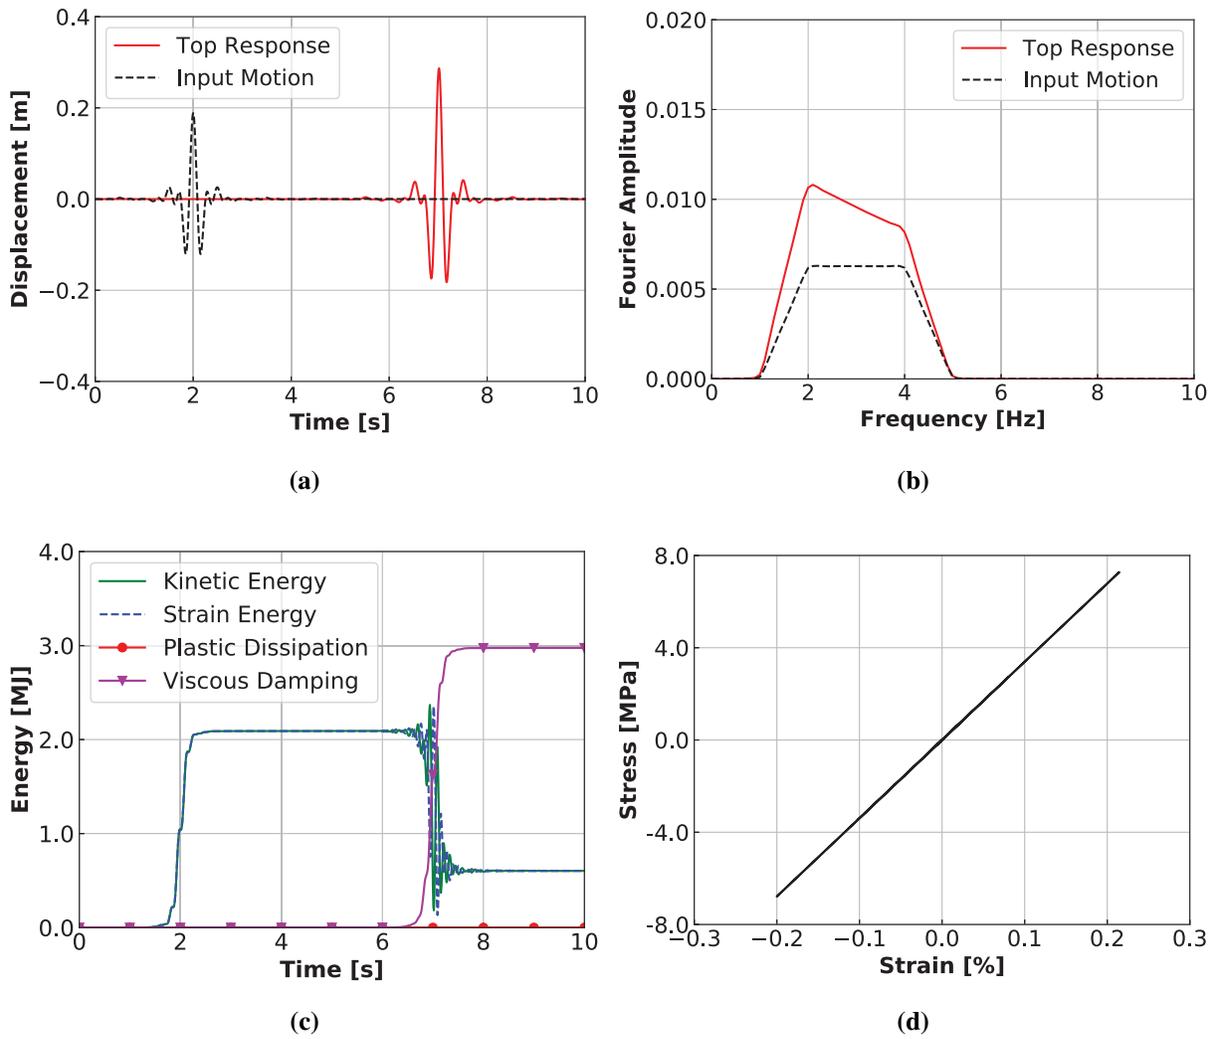

**Fig. 11.** Energy computation of wave propagation using hard inelastic material and no Rayleigh damping: (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

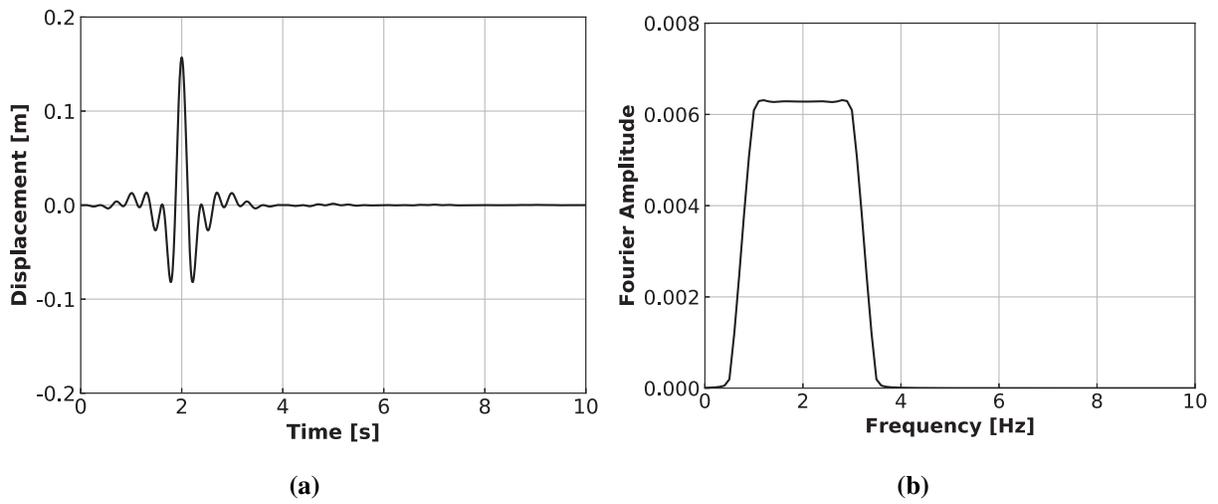

**Fig. 12.** Energy computation of wave propagation using linear elastic material and Rayleigh damping ( $\xi = 0.02$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

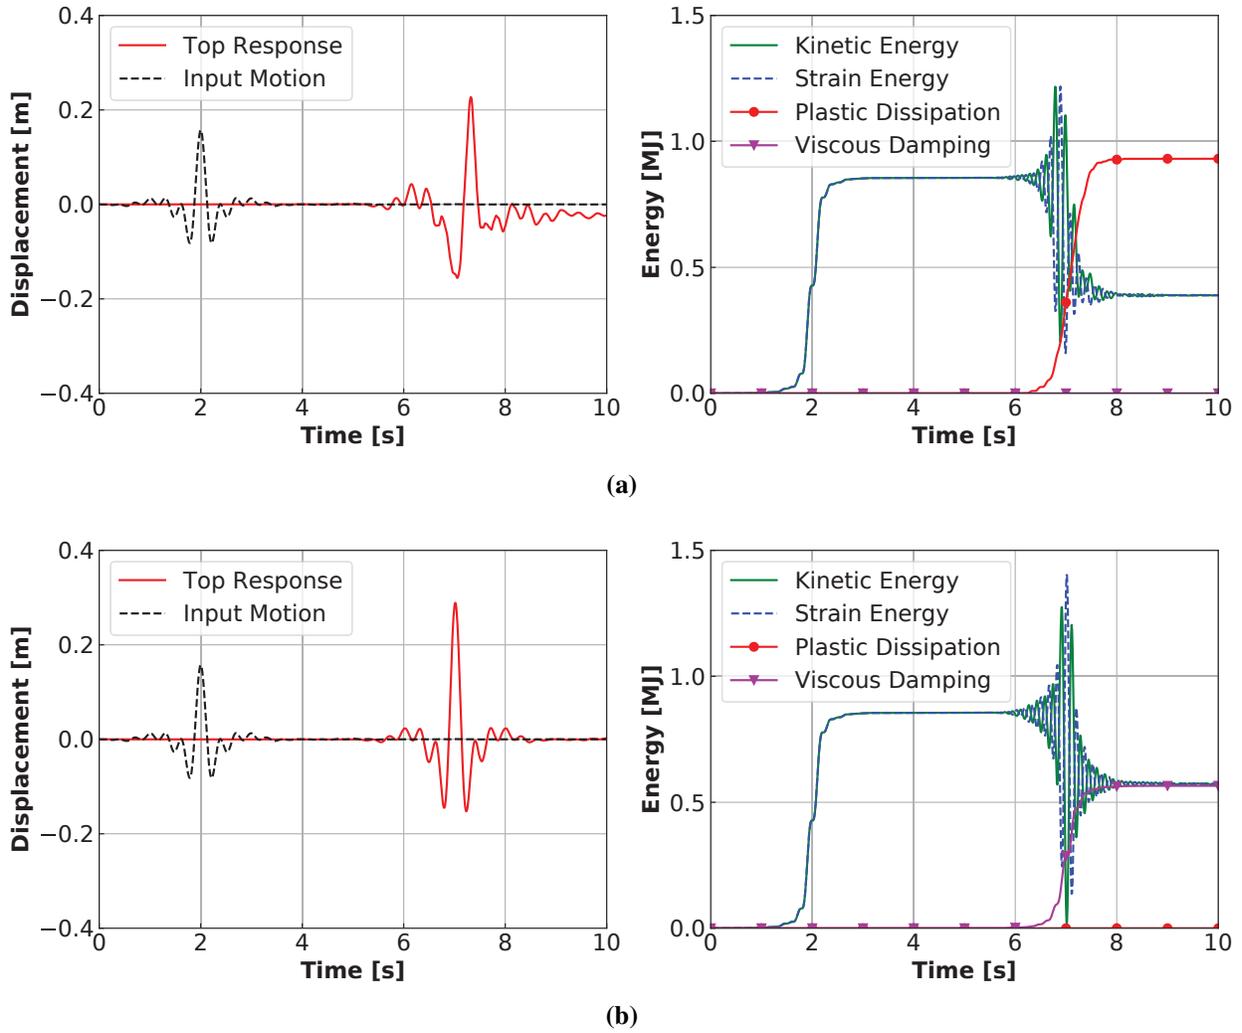

**Fig. 13.** Energy computation of wave propagation using linear elastic material and Rayleigh damping ( $\xi = 0.05$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

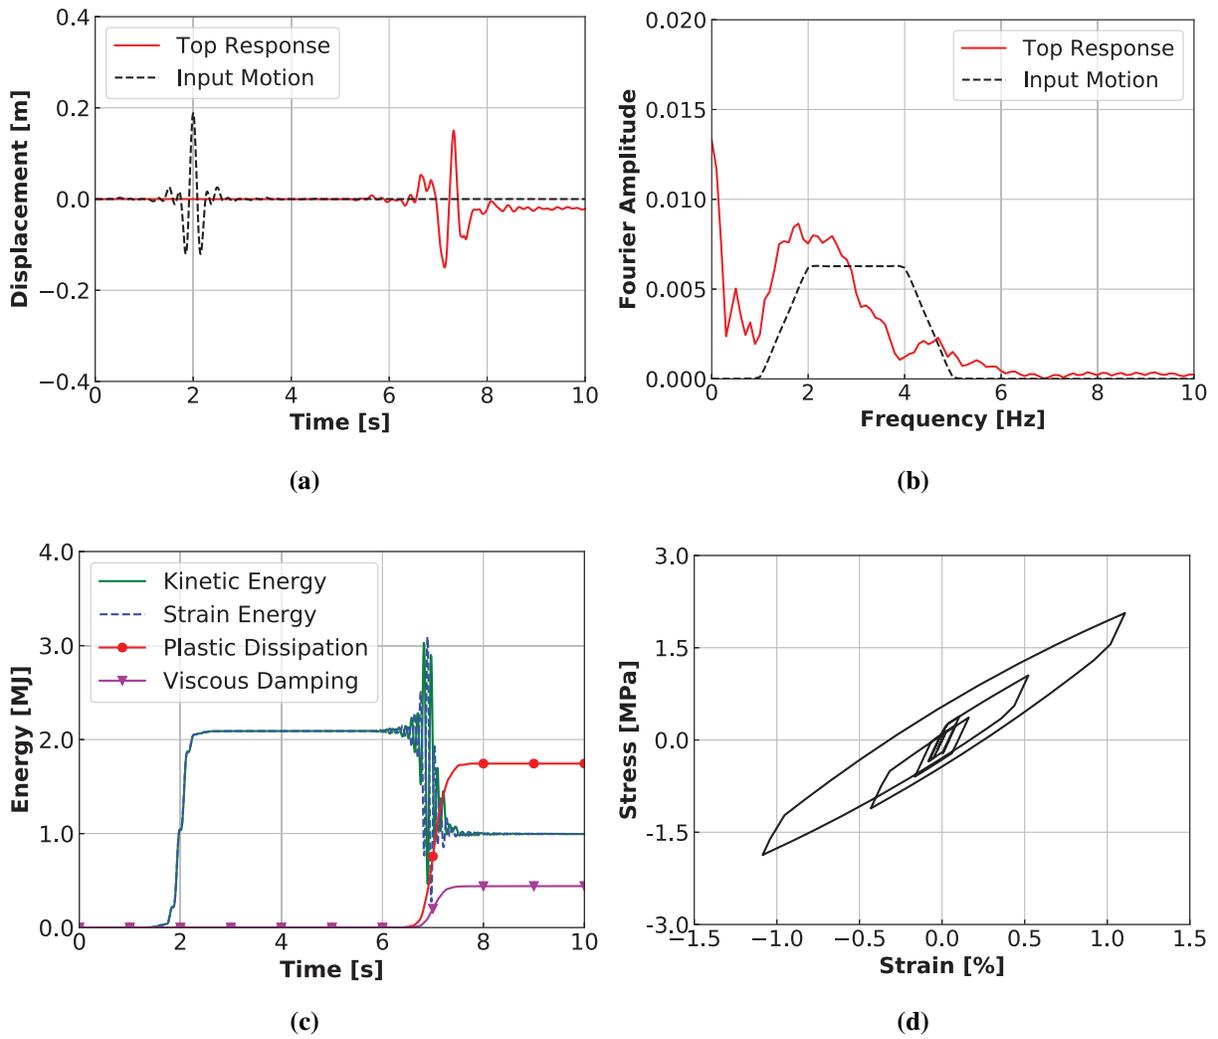

**Fig. 14.** Energy computation of wave propagation using linear elastic material and Rayleigh damping ( $\xi = 0.10$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

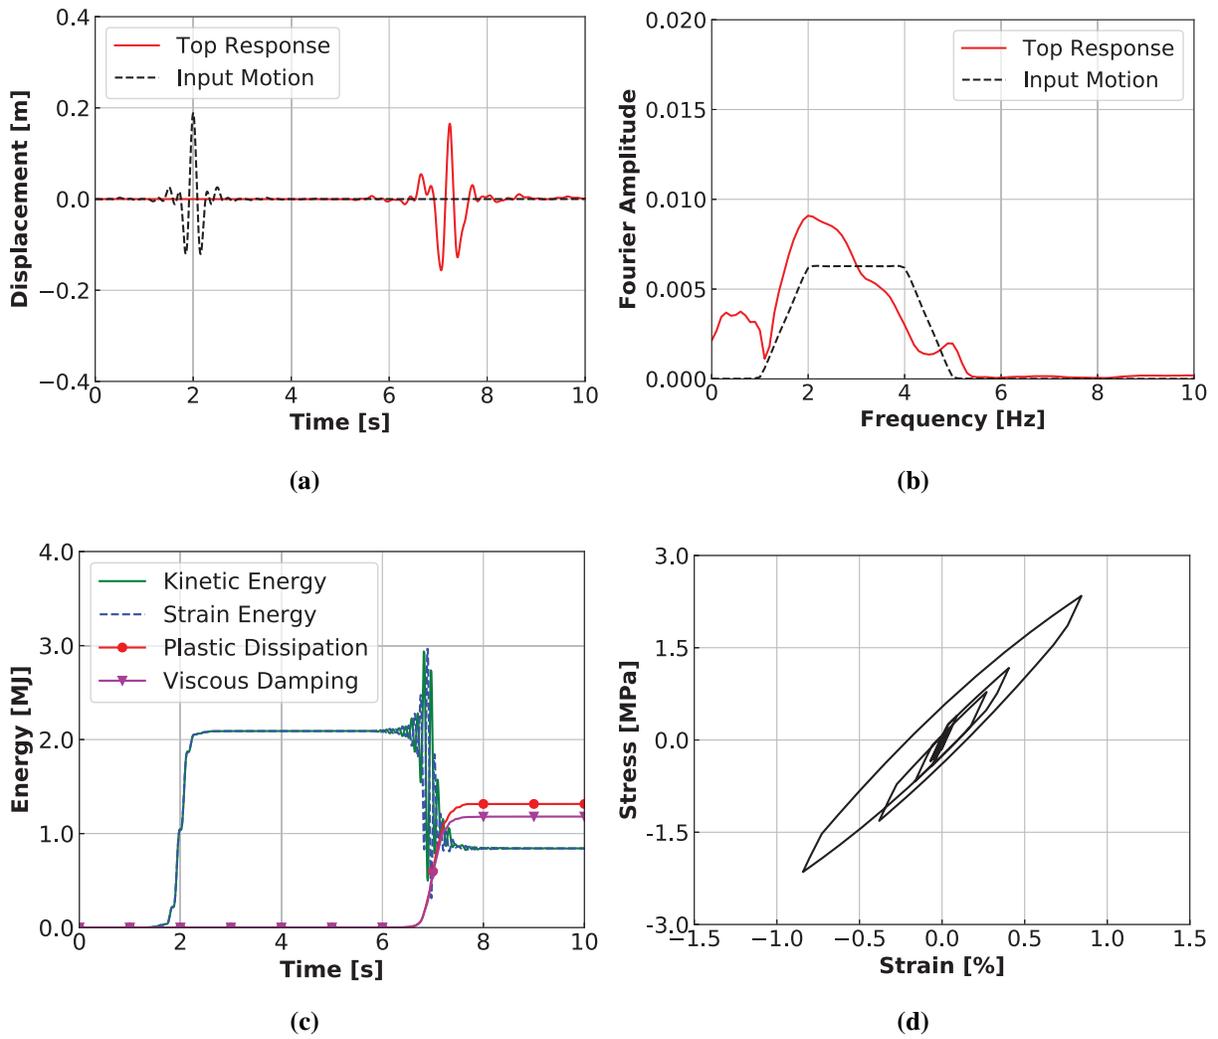

**Fig. 15.** Imposed displacement of the wave propagation problem created using Ormsby wavelet with  $A = 0.01\text{m}\cdot\text{s}$ ,  $f_1 = 0.5\text{Hz}$ ,  $f_2 = 1.0\text{Hz}$ ,  $f_3 = 3.0\text{Hz}$ , and  $f_4 = 3.5\text{Hz}$ : (a) Time series; (b) Frequency domain.

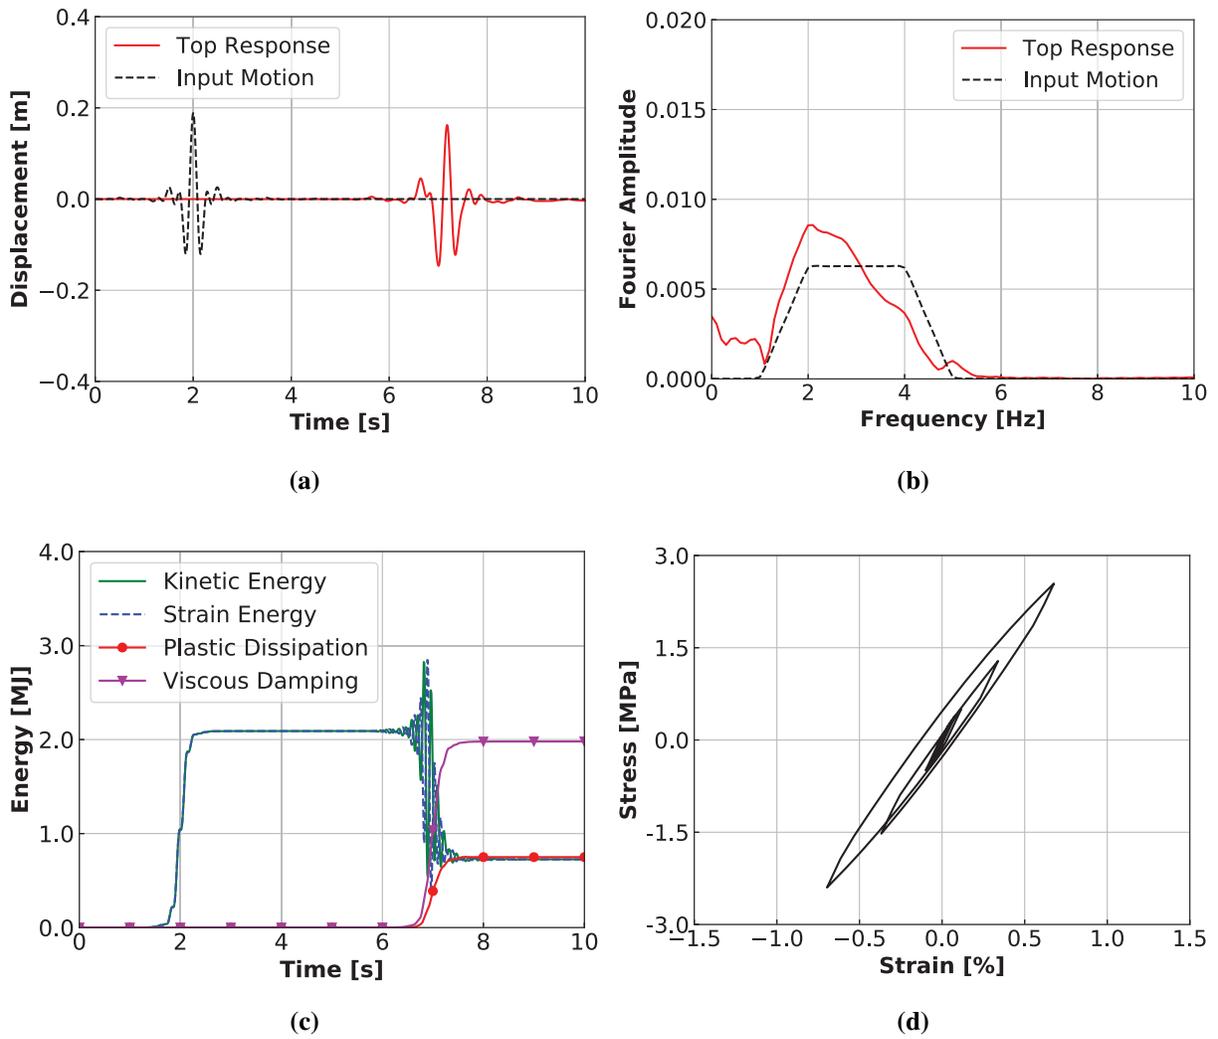

**Fig. 16.** Energy computation of wave propagation using a different input motion: (a) Soft inelastic material without Rayleigh damping; (b) Linear elastic material with Rayleigh damping  $\xi = 0.05$ .

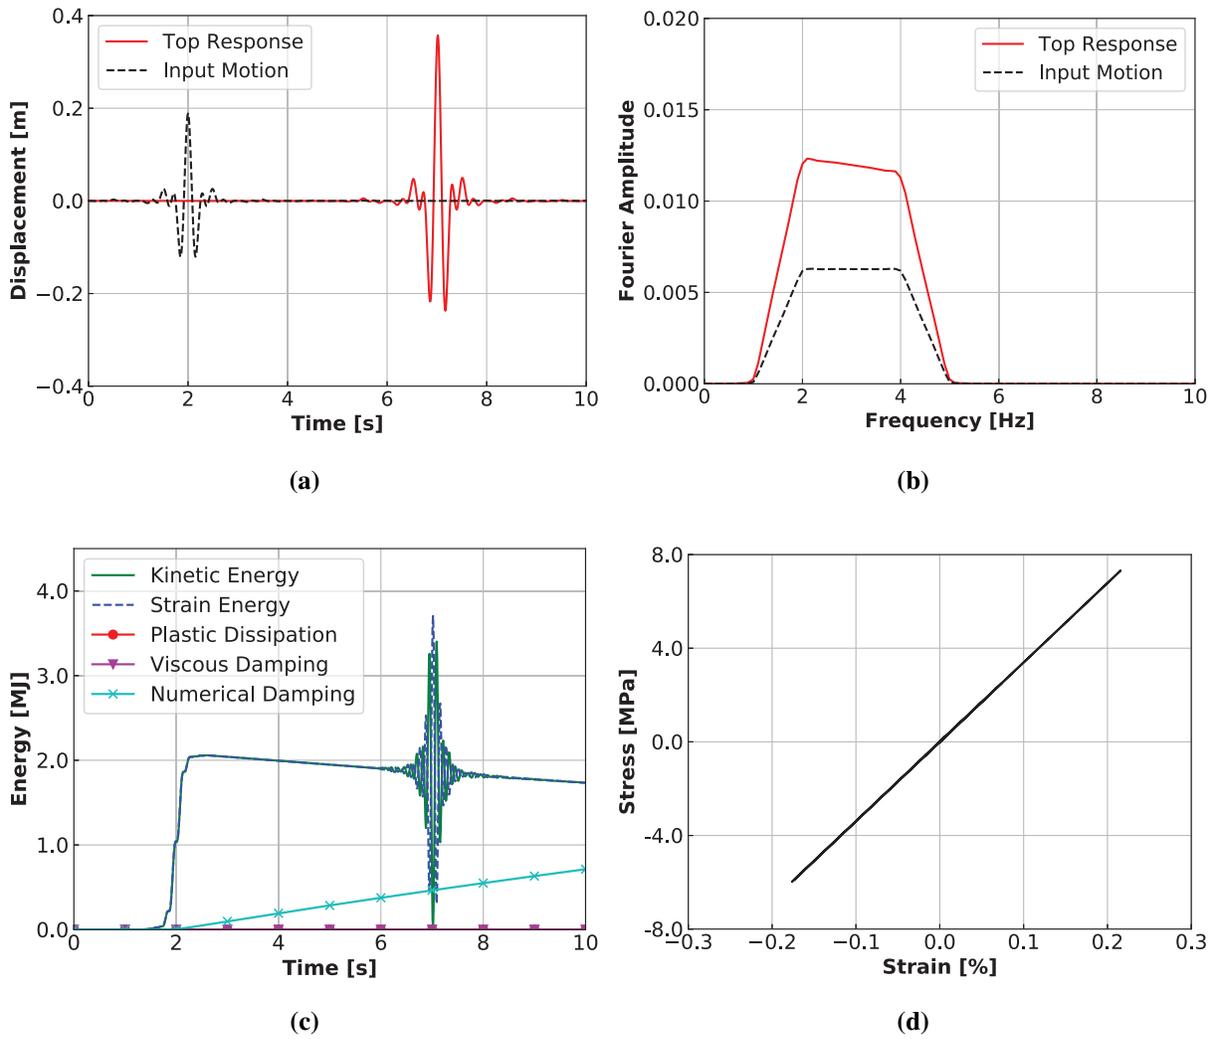

**Fig. 17.** Energy computation of wave propagation using soft inelastic material and Rayleigh damping with  $\xi = 0.01$ : (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

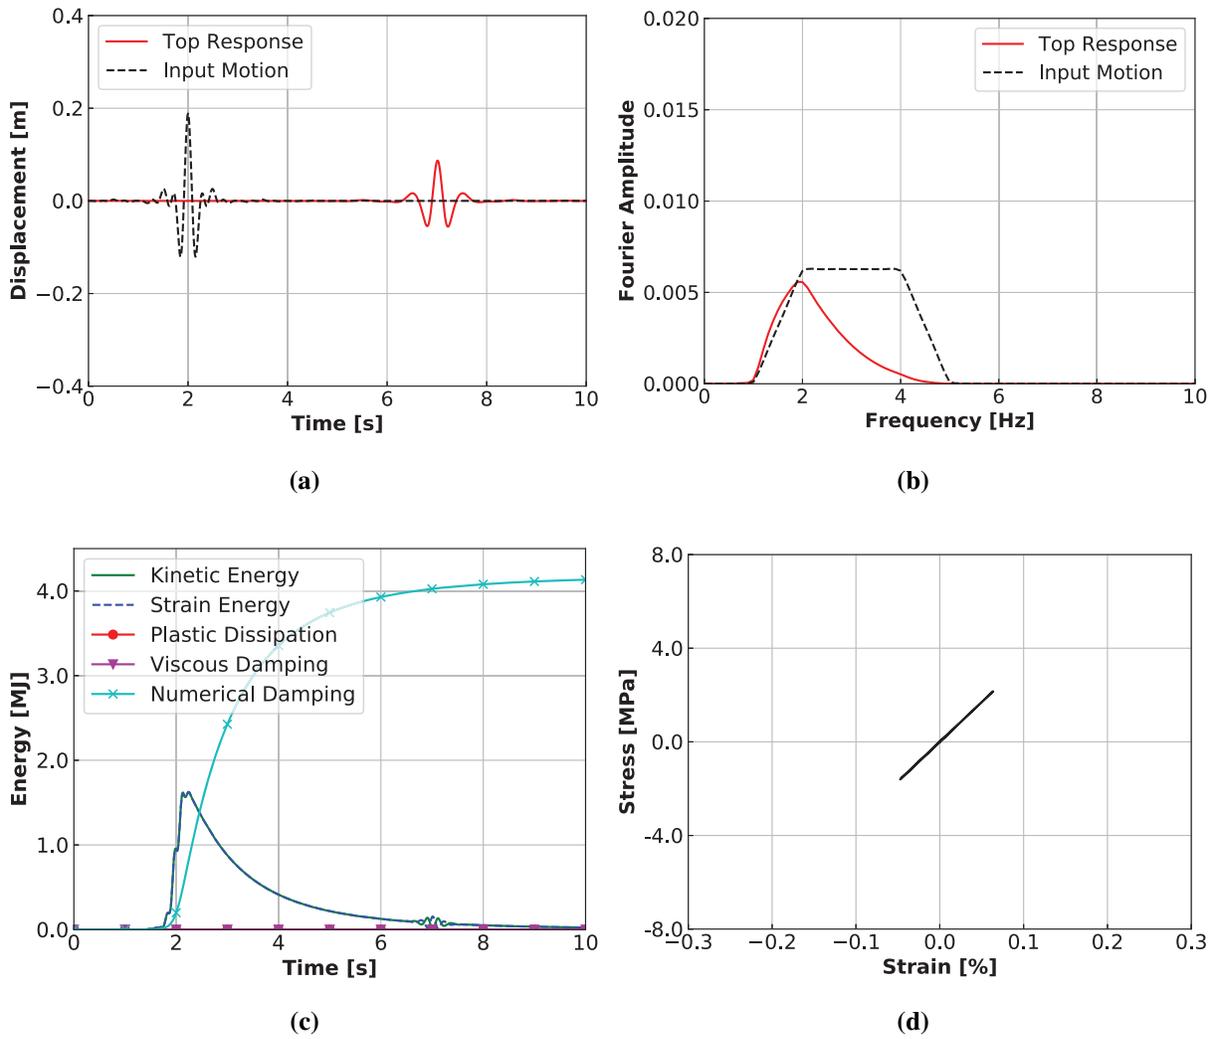

**Fig. 18.** Energy computation of wave propagation using medium inelastic material model and Rayleigh damping with  $\xi = 0.04$ : (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

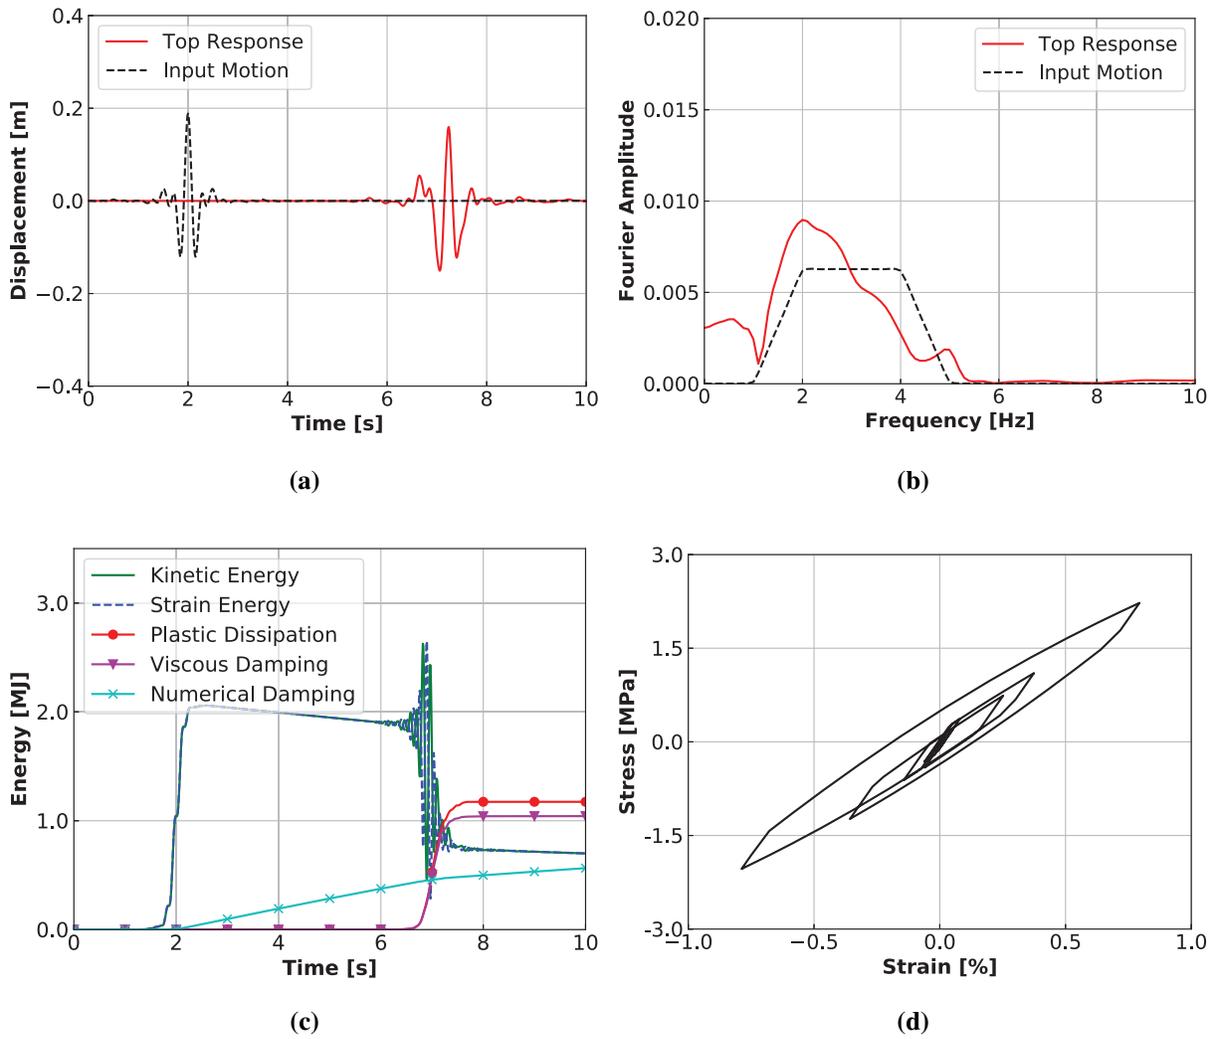

**Fig. 19.** Energy computation of wave propagation using hard inelastic material model and Rayleigh damping with  $\xi = 0.10$ : (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

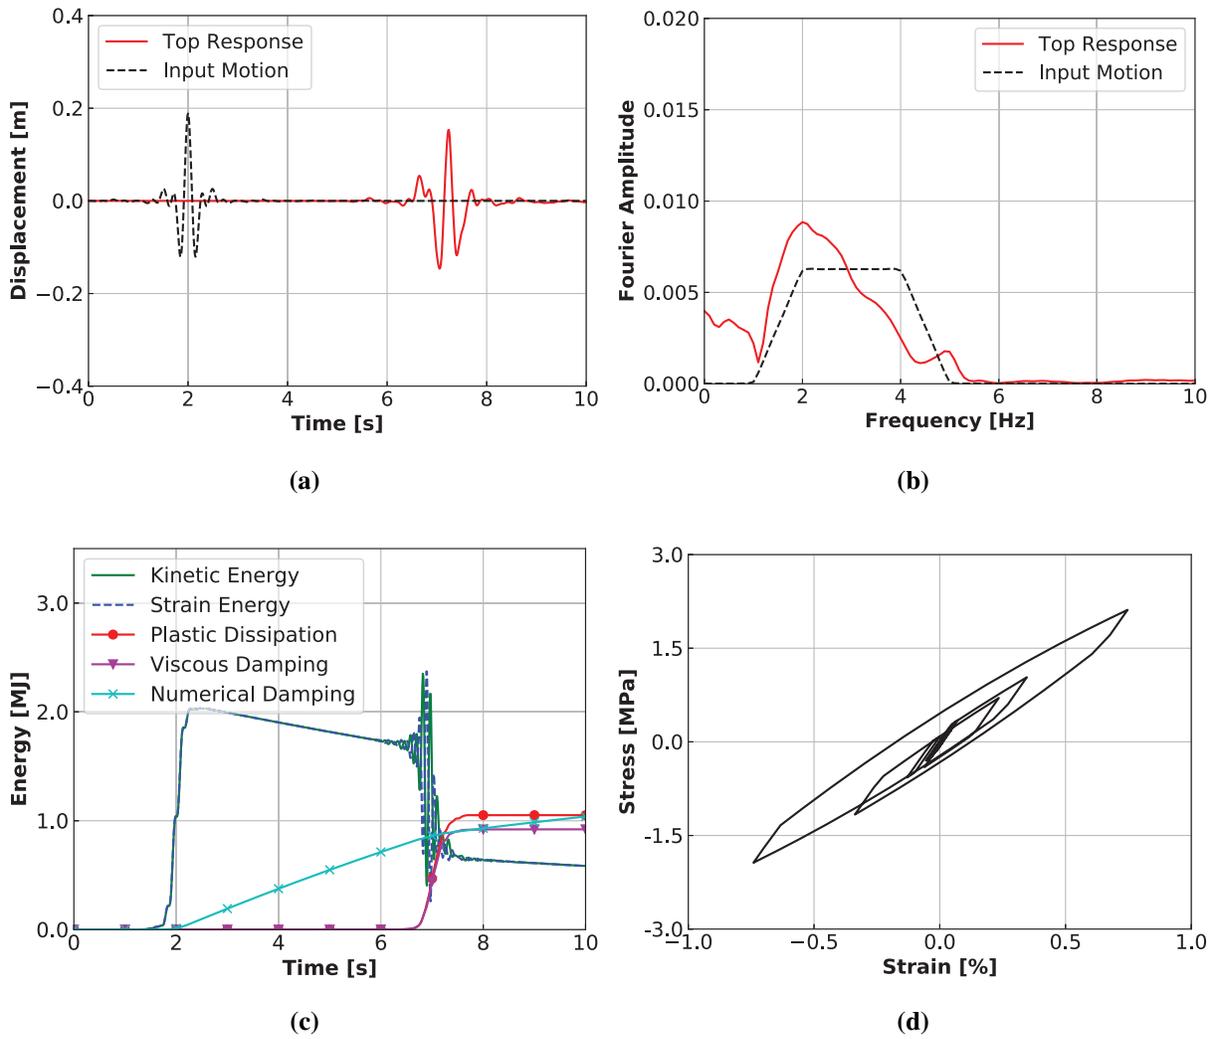

**Fig. 20.** Energy computation of wave propagation using linear elastic material and algorithmic damping ( $\gamma = 0.505$ ,  $\beta = 0.253$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

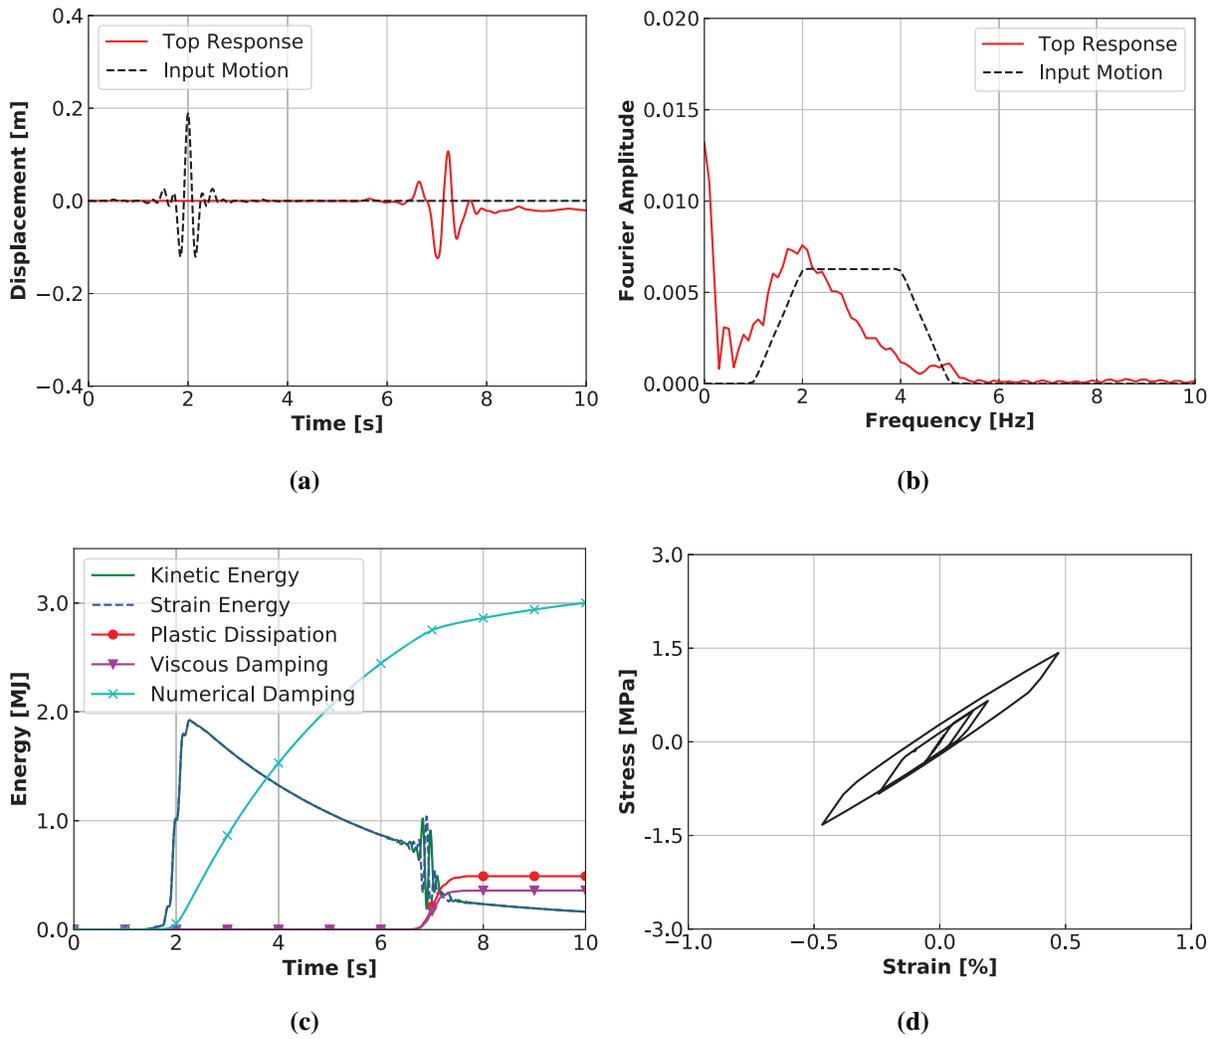

**Fig. 21.** Energy computation of wave propagation using linear elastic material model and algorithmic damping ( $\gamma = 0.700$ ,  $\beta = 0.360$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

**Fig. 22.** Energy computation of wave propagation using medium inelastic material model, Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.505$ ,  $\beta = 0.253$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

**Fig. 23.** Energy computation of wave propagation using medium inelastic material model, Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.510$ ,  $\beta = 0.255$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.

**Fig. 24.** Energy computation of wave propagation using medium inelastic material model, Rayleigh damping ( $\xi = 0.04$ ), and algorithmic damping ( $\gamma = 0.550$ ,  $\beta = 0.276$ ): (a) Displacement time series; (b) Displacement spectrum; (c) Energy results; (d) Stress-strain response.
